
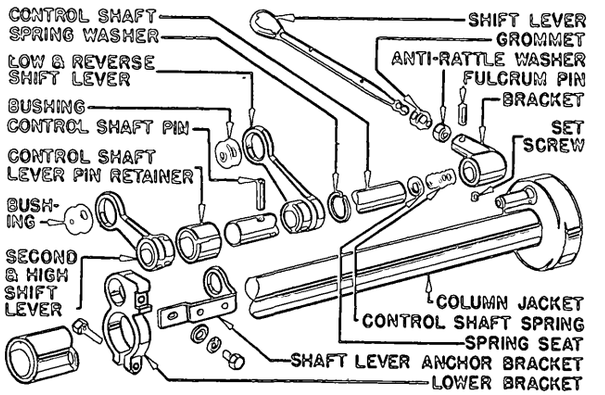
Gearshift Lever Removal—Remove control tube upper bracket clamp bolt (use Phillips type screwdriver), remove upper bracket and fulcrum bracket ring. Use Allen wrench (1941-42), or conventional wrench (1946-47) to remove the control lever fulcrum, withdraw control lever & anti-rattle washer. Remove selector cable anchor (at lower end of steering column unit), push end of pushrod up for access to control lever upper end. Assemble in same manner applying small amount of viscous chassis grease to bracket before installing.

NOTE—On 1946-47 cars, shift lever mounting bracket screws are self-locking, dowel type. Point of screw enters hole in jacket tube to positively anchor the bracket.

Steering Column Unit—Remove front seat cushion, accelerator pedal, floor mat, transmission opening cover, horn button and steering wheel. Disconnect control rod at steering column end, remove selector cable anchor bracket bolt, remove cable anchor and jacket tube bracket cap, pull jacket tube and control tube off steering column tube. Remove control tube upper bracket clamp bolt (Phillips type screw-driver), bracket, and bracket ring. Remove gearshift lever (see above). Remove fulcrum bracket setscrew, mark control tube and fulcrum bracket (to insure reassembly in same relative positions), press tube out of bracket. To remove lower bracket, remove clamp bolt and slide bracket off. Reassemble in same manner being careful to line up marks on control tube and fulcrum bracket. Adjust control rod and selector cable as directed above.



Transmission Case Shifter Mechanism—Refer t Hudson Transmission article for servicing data.

1953-54 HUDSON JET

Hudson Jet, All Models (1953-54)

DESCRIPTION: Remote control with steering column mounted gearshift lever of a design different than other Hudson Models.

ADJUSTMENT: Place gearshift lever in neutral, loosen both trunnion nuts on each shift rod at levers on lower end of steering column so that rods are free. Make certain that each gearshift lever (on transmission) is in neutral position by feel of plunger engaging notches in shifter shaft sectors. Tighten both trunnion nuts on each shift rod against trunnion, being careful not to change position of rods or shift levers. *CAUTION*—Place gearshift lever in each position and make certain that pin does not bottom in groove of either lever in any shift position. If pin bottoms, adjust anchor bracket as necessary.

HUDSON JET TRANSMISSION CONTROL

REMOVAL OF CONTROL SHAFT & LEVERS: Disconnect low & reverse and second & high shifter rods at control shaft levers by removing cotter pins and flat washers. Remove control arm fulcrum pin in gear shift lever at top of column. Remove shift lever grommet, silencer, and take out shift lever. Loosen the Allen screw at control shaft lower bracket attaching Handi-shift control shaft to steering column jacket tube and slide bracket and levers down on tube approximately 2¼" to clear control shaft pilot at steering column jacket tube housing. Remove screw, lockwasher and plain washer attaching control shaft lever anchor bracket to control shaft lower bracket. While holding control shaft remove second & high shift lever, control shaft drive pin retainer, drive pin, low & reverse shift lever, spring washer, and control shaft lever anchor bracket from lower end of control shaft. Control shaft and fulcrum bracket can now be removed by pulling control shaft away from jacket tube. CAUTION—Do not lose the pilot compression spring and flat washer when removing control tube assembly.

INSTALLATION OF CONTROL SHAFT & LEVERS: Install spring and washer into fulcrum bracket and install fulcrum and shift control shaft over pilot. Install control lever silencer, control lever grommet. Insert control lever through grommet, silencer, fulcrum bracket and in socket of pivot. Insert lock pin, using care not to damage fulcrum bracket. Place spring washer, low & reverse lever on control shaft.

1948-EARLY 1952 HUDSON HANDI-SHIFT (USED WITH OWN MAKE TRANSMISSION)

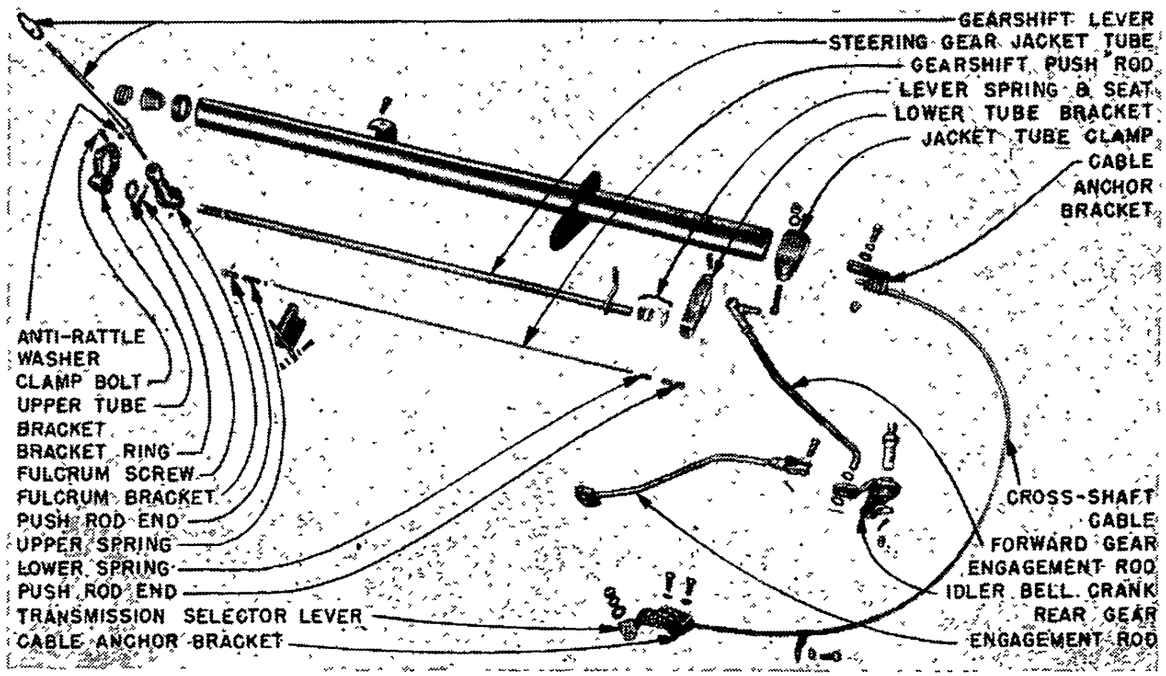
6 & 8, All Models (1948-52)—See Note

►**Transmission Control Note**—Used with Hudson Own Make transmission. See "Late 1952-53 Hudson Handi-Shift" for models with Warner Transmissions.

►**DRIVE-MASTER CAUTION:** Handy-shift control used on Drive-master cars but should be adjusted in conjunction with other Drive-master units. *See "Hudson Drive-Master" data in this section.*

DESCRIPTION: Remote control with steering column mounted gearshift lever. Design is same as used on previous Hudson models except for new gear engagement linkage as follows:

Gear Engagement Rods & Lever—New idler lever or bellcrank is pivoted on stud on steering gear mounting flange with forward rod extending from bellcrank to control tube on steering column, and rear rod extending from bellcrank to shift lever on transmission case. Linkage is adjusted by means of an adjusting clevis on the bellcrank end of the rear rod.



ADJUSTMENT: Check and adjust linkage in order as follows (Selector cable should only require adjustment if hard shifting, particularly in Second Gear, has been noted):

Gearshift Lever Position—Lever should be in crosswise (horizontal) position in neutral. If lever position not correct, remove clevis pin and adjust clevis on forward end of rear control rod at bellcrank on steering gear.

Gear Engagement Rod—Disconnect rear control rod at bellcrank on steering gear by removing clevis pin. Place gearshift lever in neutral position (see above). Make certain that the shift lever on side of transmission is in neutral (can be determined by feel), loosen locknut and adjust clevis on forward end of rear rod until clevis pin can just be inserted in clevis and bellcrank without disturbing position of gearshift lever or transmission shift lever.

Selector Cable (Cross-shift)—Move gearshift lever to extreme upper (Low-Reverse) position in neutral and block or hold lever in this position while adjusting. Loosen cable casing anchor bracket capscrew on steering column, pull anchor bracket up (screw hole slotted to permit this adjustment) until all slack removed from casing and shifter shaft inner lever on transmission case is fully over in the "Low-Reverse" position. Tighten anchor bracket capscrew and see that anchor has clearance at top bottom of travel.

►*CAUTION*—Make certain that shift selector lever on transmission case (to which selector cable attached) is tight on its shaft and that bracket is tight on transmission case.

1948-EARLY 1952 HUDSON HANDI-SHIFT TRANS. CONTROL (USED WITH OWN MAKE TRANSMISSI N)

REMOVAL & INSTALLATION OF CONTROL UNITS: Gearshift pushrod (cross-shift selector cable rod) can be removed separately, or entire steering column gearshift unit can be removed as follows:

Gearshift Pushrod Removal: Remove steering wheel. Take out clamp bolt and remove control tube upper bracket and fulcrum bracket ring. Remove fulcrum screw from gearshift lever, remove lever and anti-rattle spring washer. Disconnect cross-shift cable at lower end of steering column unit by removing hairpin clip. Remove anchor bracket capscrew, pull pushrod down far enough to remove key attaching pushrod to pushrod upper end fitting, remove this end fitting, use a wire hook to remove compression spring and seat at upper end of pushrod. Pushrod can then be withdrawn from control tube.

Installation—Coat pushrod end fittings with viscous chassis lubricant when installing them in control tube, assemble parts by reversing removal instructions.

Gearshift Assembly Removal: Remove horn ring and steering wheel. Lift carpet around steering column, remove metal and rubber dustcovers at floor opening. Remove setscrew from gearshift lever fulcrum bracket and clamp bolt from control tube upper bracket. Remove retainer plate and steering jacket tube clamp at instrument panel. Disconnect cross-shift cable from pushrod at lower end of control tube by taking out hairpin clip. Free cable anchor bracket by taking out capscrew. Disconnect gear engagement rod (forward rod) at lever on lower end of control tube. Remove compression spring and spring seat washer from lower end of control tube. Control tube assembly can then be removed.

►**Steering Gear Jacket Tube Removal Note**—This tube can be removed as a unit with gearshift control tube attached by loosening steering gear housing mounting bolts to allow steering gear to drop sufficiently for clearance. Then loosen jacket tube clamp at steering gear housing, lift jacket tube by swinging the lever up and to the right and out through opening at floor cover. When installing jacket tube, reverse this procedure.

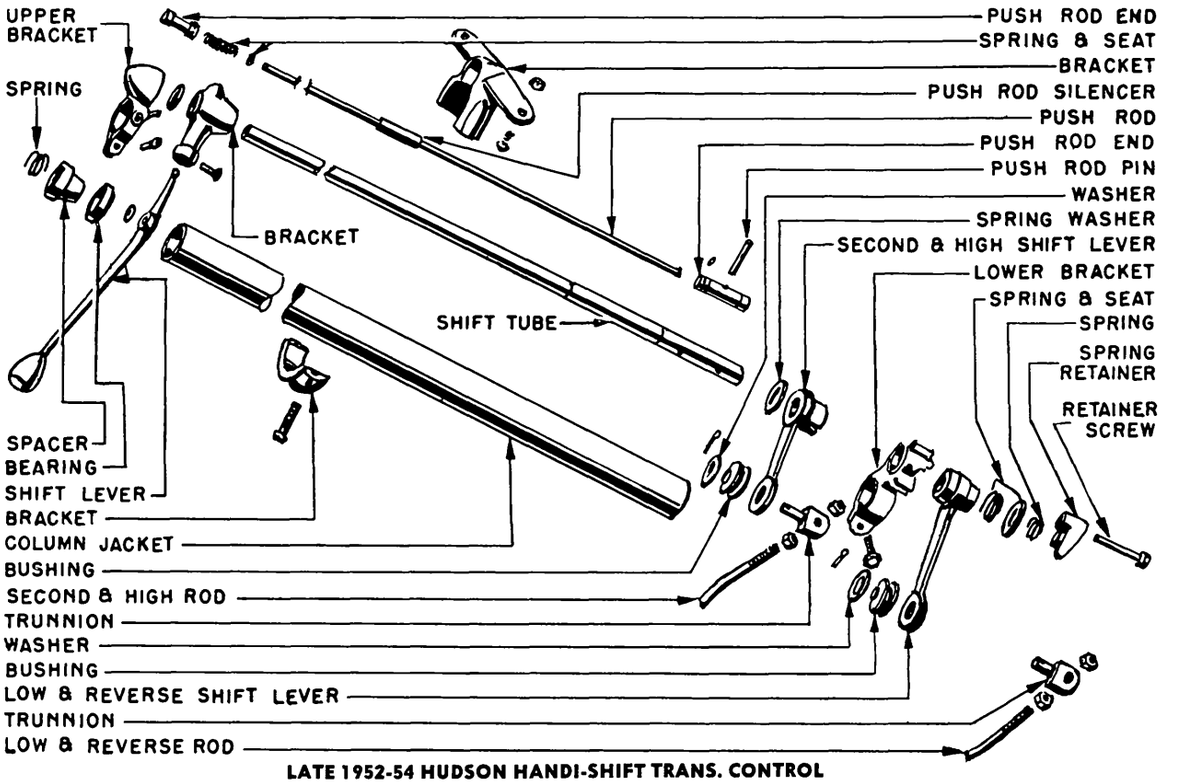
Installation: Assemble all parts by reversing removal instructions (above). Before installing control tube upper bracket, check condition of spacer ring (between gearshift lever fulcrum bracket and upper bracket) and replace ring if less than .025" thick. Adjust controls after installation completed.

►**Anchor Bracket & Cross-shift Cable Installation**

Caution—These parts must be correctly positioned during installation as follows: Move gearshift lever to extreme upper position (Low-Reverse side in neutral) and hold in this position, pull selector cable bracket and tube upward until all slack removed from casing and control wire with transmission case shift lever fully over on Low-Reverse side. Tighten anchor bracket capscrew and make certain that anchor has clearance at top and bottom of travel.

Transmission Case Shifter M chanism: *See "Hudson Transmission data.*

LATE 1952-54 HUDSON HANDI-SHIFT (USED WITH WARNER TRANS.)



6 & 8, All Models Exc. Jet (1952-54) See Note.

►**Transmission Control Note**—Used with Warner type transmissions. See "1948-52 Hudson Handi-Shift" for models with Hudson Type Transmission.

DESCRIPTION: Remote control with steering column mounted gearshift lever. Shift levers at lower end of steering column directly connected to transmission shift levers. Cross-over cable not used as on previous models.

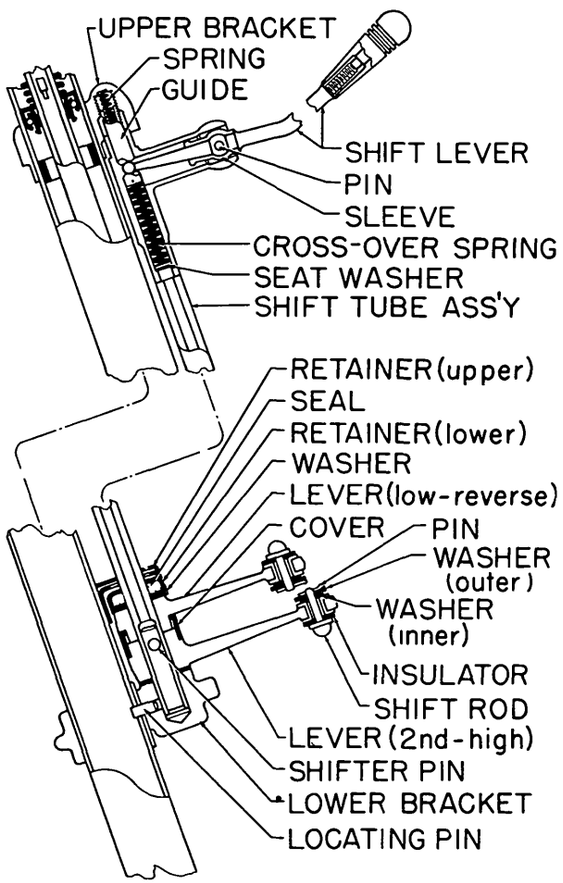
ADJUSTMENT: Before making any adjustments, be sure that Handi-Shift control tube is parallel to steering column jacket. If not parallel, loosen clamp in control tube lower bracket and move bracket until proper alignment is obtained. Be sure bracket is centrally located between second & high, and low & reverse. Check adjustment of spring retainer at lower end of steering column. With springs compressed, distance between spring retainer and fibre washer should be 27/64". Adjust by turning lower retainer bolt as necessary. With control lever in neutral, loosen low & reverse and second & high shift rod nuts at trunnion on shift levers. Back off nuts on each side of trunnion and insert a ¼" diameter rod about 4" long through holes in shift levers (holes located at end of levers closest to shift control tube), engaging slot in control tube lower bracket. This locks the levers in neutral position. Move the two outer shift levers on transmission by hand to make sure lock balls are fully seated in neutral detents in transmission shift shafts. Turn nuts on shift rods until they contact each side of trunnion and tighten nuts using care not to disturb position of rods or transmission shift lever. Remove ¼" rod from shift levers. Check manual shift cross-over by moving lever up and down. If cross-over is not smooth, shorten or lengthen low & reverse shift rod by adjusting nuts at trunnion ¼ turn at a time until smooth action is obtained. Check gear shifting for smooth action.

REMOVAL & INSTALLATION OF CONTROL ASSEMBLY: Remove control lever fulcrum screw, lockwasher and anti-rattle washer from upper fulcrum bracket and take out control lever. Remove dowel screw and loosen clamp screw at control tube upper lever bracket and take off bracket and thrust washer. Remove screws holding steering column bracket cap to bracket and remove cap. Remove cotter pins and trunnions from shift levers at lower end of steering column. Remove bolt, spring retainer, compression spring, fibre washer and upper compression spring. Slide low & reverse shift lever off end of control tube. Pull control tube out of lower bracket and push out control tube operating lever pin. **Do not loosen clamp bolt or alter position of bracket.** Remove second & high shift lever from tube.

LATE 1952-54 HUDSON HANDI-SHIFT TRANS. CONTROL (USED WITH WARNER TRANSMISSION)

Control Tube Disassembly—Push upward on lower end of lower pushrod end, exposing upper end of pushrod and pushrod end. Remove upper pushrod end key and remove end. Remove pushrod lower end assembly from bottom of control tube and take off lower rod end key and remove end from rod. Remove seat, pushrod upper compression spring and silencer from inside of tube. Remove second & high lever retaining ring from tube.

Installation: Reverse control assembly removal and note the following: When installing spring retainer, adjust bolt so there will be 27/64" space between fibre washer and top of the retainer. Be sure lower tube bracket is centrally located between second & high and low & reverse levers. See Adjustment (above).



1947-48 FRAZER & KAISER

Frazer & Kaiser, All Models (1947-48)

DESCRIPTION: Remote control with steering column mounted gearshift lever under the steering wheel.

ADJUSTMENT: With gearshift lever in neutral, disconnect control rods at transmission case, align levers at lower end of steering column by installing aligning pin (¼" drill rod) through hole in each lever and hole in bracket. See that each of the shifter shafts on the transmission is in neutral position (can be determined by feel of detents engaging neutral notch in shaft). Adjust each rod at transmission end by means of clevises provided so that shifter shafts will be in neutral position with steering column levers aligned with aligning pin. After adjustment completed, remove aligning pin from steering column levers.

►*CAUTION—Make certain that control rods do not extend through clevises far enough to bind on levers when operating control (correct this condition by shortening rods).*

1947-48 FRAZER & KAISER TRANSMISSION CONTR L

1949-51 FRAZER & KAISER

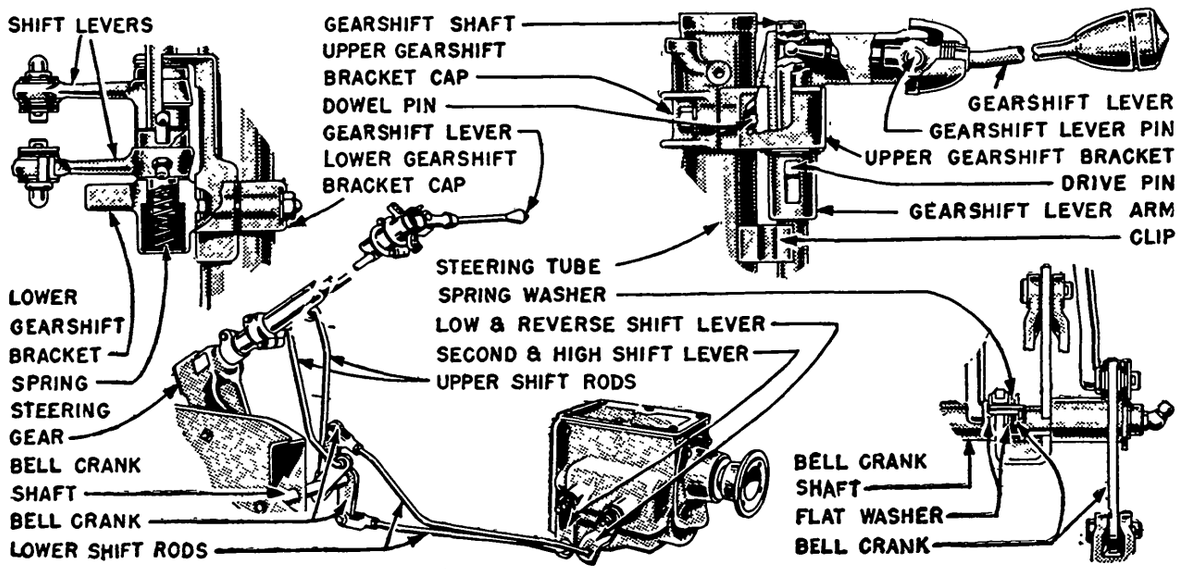
Frazer, All Models (1949-50-51)
Kaiser, All Models (1949-50)

DESCRIPTION: Remote control with steering column mounted gearshift lever. Design changed from that used on 1947-48 models in the following particulars:

Gearshift Lever & Upper Gearshift Bracket—New mounting bracket bolted on steering column tube with gearshift lever arm linked to shift shaft by drive pin in shaft. Cross-over spring which holds shaft and lever in lower (second-high) position located at lower end of shift shaft (no springs at upper end).

Shift Levers & Lower Gearshift Bracket—Similar to type used on previous cars except that cross-over spring located in bracket socket below shift shaft and levers **reversed from previous location** (second-high lever is UPPER lever).

Shift Rods & Idler Bellcrank—Idler bellcranks mounted on shaft on left frame side rail with upper (non-adjustable) shift rods linked to steering column shift rods, and lower (adjustable) rods linked to transmission case shift levers.



ADJUSTMENT: Shift Rods—Disconnect rear (adjustable) shift rods at idler bellcranks on left frame side rail, place gearshift lever in neutral position. Align lower shift levers and lock in this position by inserting ¼" drill rod through hole in each lever and locating hole in lower bracket. Check gearshift lever for free up-and-down movement in neutral to insure that shift shaft pin does not bind in shift lever slots. See that transmission gears and shift levers in neutral (can be determined by feel of detent poppet balls engaging neutral notches in shifter shaft cams). Adjust clevis on forward end of each rear shift rod so that rods can be connected without disturbing position of transmission gears and levers. Connect rods and remove locking rod from steering column levers.

Gearshift Lever Travel—Travel must be checked and adjusted to insure full gear engagement. Disconnect second-high shift rod at forward lever on transmission case, shift transmission into second gear by moving this lever to the forward position. Move gearshift lever and upper shift lever on steering column to second gear position (as far as possible upward). Check position of rod end in relation to hole in lever on transmission case. Rod end should be slightly short of lever hole to insure full engagement of gears before gearshift lever reaches end of travel. Do not change rod adjustment unless it is too long, or more than slightly short of lever hole. Repeat this check in each gear position (rod should be **slightly short** in Second & Reverse, **slightly long** in Low & High). Connect rods and recheck shift rod adjustment to see that gearshift lever has free up-and-down travel in neutral.

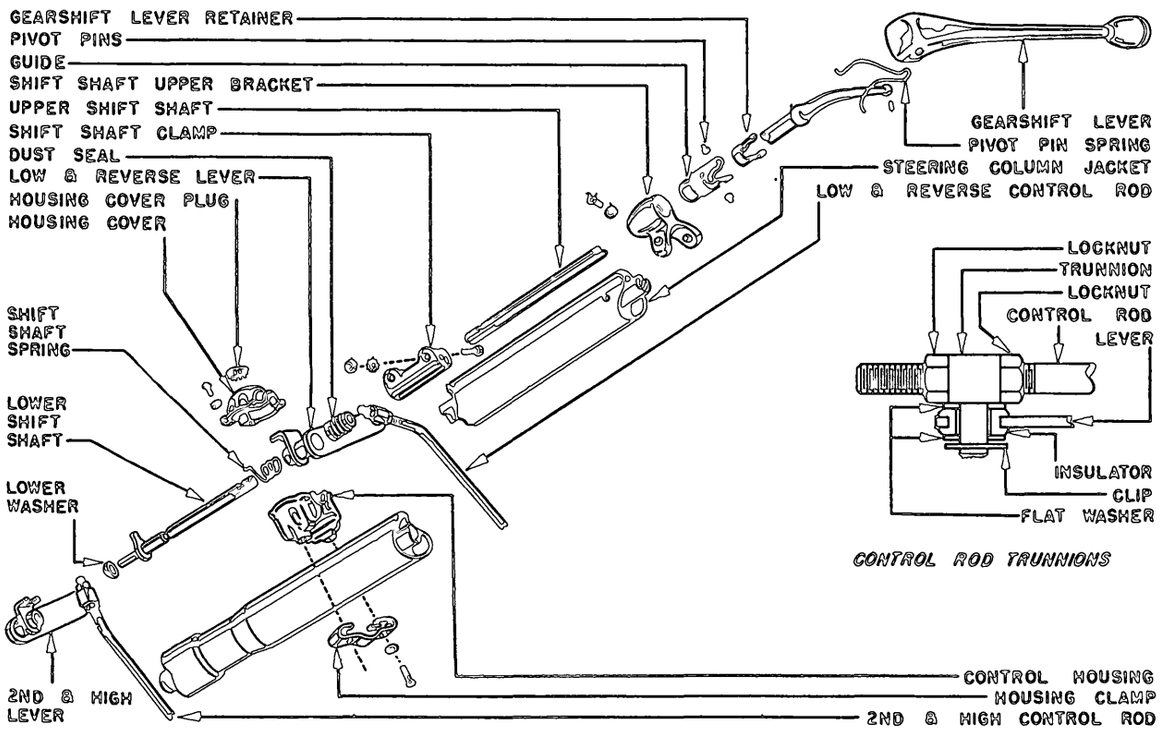
DISASSEMBLY: Disconnect shift rods at levers on lower end of steering column. Entire steering column unit can be freed from steering column tube by taking out upper and lower bracket bolts (steering column jacket cover can be removed for access to upper bracket by removing steering wheel and taking out attaching screws holding the two jacket cover sections together).

REASSEMBLY: Assemble parts by reversing disassembly order. When installing brackets on steering column, make certain that locating dowels enter holes in steering column tube.

TRANSMISSION CASE SHIFTER MECHANISM: *See Warner Transmission data.*

1949-51 FRAZER & 1949-50 KAISER TRANSMISSION C NTR L

1951-55 KAISER & HENRY J



Henry J, All Models (1951-53)
Kaiser, All Models (1951-55)

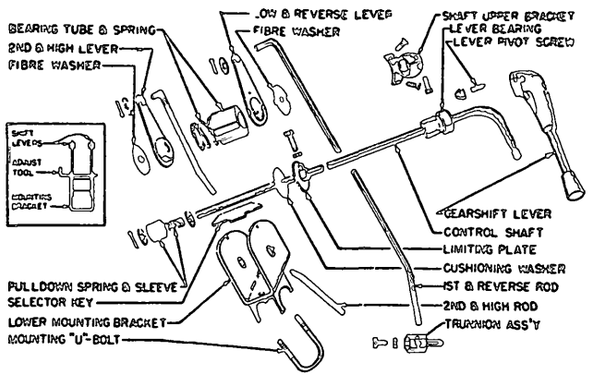
DESCRIPTION: Remote control type with gearshift lever mounted on steering column. Gearshift lever is pivoted in mounting bracket on upper end of steering column and has engaging dog or lug on lower end of control shaft which engages one or the other of the two "inner levers" in the housing at the lower end of the steering column. These inner levers are linked to the shifter levers on the side of the transmission case by means of adjustable rods (see Adjustment below). Gearshift lever is normally in the "Second-High" (lower) position in which it is held by a spring at the lower end of the control shaft and must be raised, against spring tension, to shift lug into engagement with the "Low-Reverse" lever and rod (upper position).

ADJUSTMENT: Place gearshift lever in neutral position, loosen both trunnion nuts on each shift rod at levers on lower end of steering column so that rods are free. Remove inspection cap on control housing cover, install special aligning plug Gauge KF-69 through this hole (gauge will align gates in inner levers in neutral position). Make certain that each transmission case shift lever is in neutral position (can be determined by feel of detent plungers engaging notches in shifter shaft sectors). Tighten both trunnion nuts on each shift rod securely against trunnion using care not to change rod and transmission lever positions or to spring control levers.

REMOVAL: Disconnect both shift rods at control housing levers on steering column by taking out trunnion pin cotter pins. Take out two mounting screws in gearshift lever housing bracket under steering wheel, remove two capscrews in shift control housing bracket at lower end of steering column, remove bracket cap. Control shaft can be split at coupling above lower shift control housing and each section lifted out separately.

TRANSMISSION CASE SHIFTER MECHANISM: *See Warner Transmission data.*

1951-55 KAISER & HENRY J TRANSMISSION CONTROL



CONTROL ROD TRUNNIONS

1941-48 NASH

"600" Six, All Models (1941 to 1948)
Ambassador Six, All Models (1940 to 1948)
Ambassador Eight, All Models (1941-42)

DESCRIPTION: Remote control type with steering column mounted gearshift lever.

ADJUSTMENT: With gearshift lever in neutral, install special aligning pin J-1390 through holes in both flanges of steering column lower bracket and through holes in both levers so that levers are aligned in this neutral position. Loosen locknut and back off setscrew on each rod trunnion on transmission case shifter shaft levers. Carefully position each shifter shaft so that gears are in neutral (can be determined by feel of detents engaging neutral notch in sector on inner end of shafts), tighten setscrews & locknuts, remove aligning pin.

NASH 1941-48 TRANSMISSION CONTROL

REMOVAL & DISASSEMBLY: Steering column unit must be disassembled to permit removal as follows:

Steering Column Unit—Disconnect rods at levers on steering column, remove cotter pin in lower end of control shaft, remove plain washer, pull-down spring, rubber sleeve, and second washer from end of shaft. Remove lower mounting bracket "U" bolt, free mounting bracket locating dowel from hole in steering column. Rotate control shaft until selector key lines up with notch in mounting bracket, work bracket assembly down and off shaft (shifter levers, washers, bearing tube and spring will come off with bracket as an assembly). Lift out selector key (1940-42 cars—not necessary on later cars). Remove setscrew in limiting plate, slide plate and rubber washer off lower end of shaft.

Gearshift Lever, Shaft, & Upper Bracket—Take out gearshift lever pivot screw and pin, remove lever. Loosen upper bracket clampscrew, remove bearing hub from bracket. Remove two bracket capscrews (see CAUTION below), lift out shaft and bracket assembly

▷*CAUTION*—Bracket screws must be removed as follows to prevent displacing split ring within column jacket: Remove top screw, loosen bottom screw, then insert small drift in upper screw hole to hold

CONTINUED ON NEXT PAGE

1941-48 NASH (C nt.)

split ring while bottom screw being removed. Remove bracket, replace one screw to hold ring in position until bracket re-installed.

INSTALLATION: Reverse the removal & disassembly directions above and note following points:

Gearshift Lever & Upper Bracket—Apply light film of Lubriplate to shaft and threaded part of bearing hub, screw bearing down in bracket so that clearance will exist between shift lever and bracket with lever in Low-Reverse position.

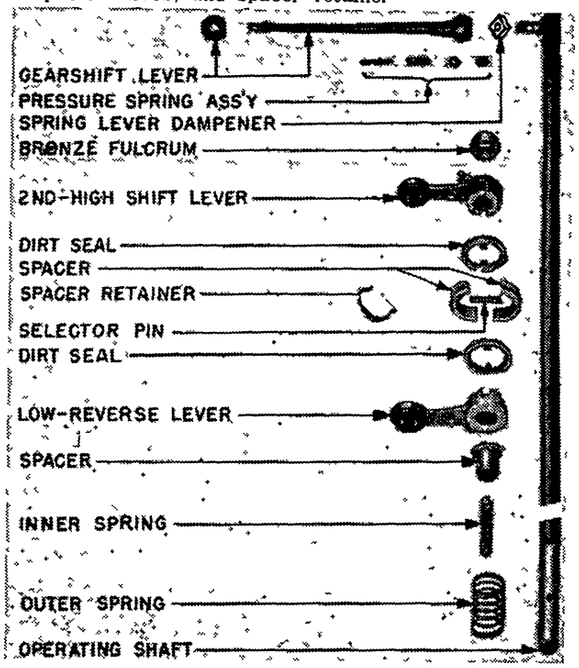
Limiting Plate Adjustment—Must be adjusted so that control shaft selector key does not rub on lower flange of mounting bracket. To adjust, loosen locknut and back off adjusting setscrew. Engage control shaft with Second-High lever fully, then raise shaft slightly to provide clearance between key and lower flange of bracket, position limiting plate so that rubber cushioning washer is against bracket top flange, tighten setscrew and locknut

1949-55 NASH & 1955 HUDSON (EXC. RAMBLER & METROPOLITAN)

Hudson, Exc. Rambler (1955)
Nash, Exc Metropolitan & Rambler (1949-55)

►*HUDSON & NASH RAMBLER, NASH METROPOLITAN NOTE. See Hudson & Nash Rambler, Nash Metropolitan (1950-55)*

►*HYDRA-MATIC DRIVE CONTROL NOTE· See Hydra-Matic Drive Transmission data for control adjustment on Hydra-Matic Drive cars,*



DESCRIPTION: Remote control type with steering column mounted gearshift lever Design similar to previous models except that entire steering column unit is enclosed within steering gear jacket tube

ADJUSTMENT: Place gearshift lever in neutral lock shift levers at lower end of steering column by inserting J-1390 Aligning Tool through hole in mounting bracket and hole in each lever Disconnect shift rods at levers on side of transmission case, check to see that transmission gears and shifter levers in neutral (can be determined by feel of detent balls engaging neutral notches of shifter shaft cams) Adjust transmission end of each shift rod so that rods can be connected without disturbing position of levers, connect rods remove aligning tool from steering column levers, check gearshift lever for smooth up-and-down (cross-over) action in neutral

DISASSEMBLY: (Ambassador, Statesman 1949-51): Place shift lever in neutral, disconnect both shift rods at shift levers on steering column Remove steering wheel (see steering gear), remove ignition switch mounting bolt (1949 models only) and three screws mounting bearing retainer on steering column tube, lift bearing retainer out Remove gearshift lever knob, use wrench flat on lever to unscrew lever *(NOTE*—On 1949 cars where this flat is not provided, screw two nuts on outer end of lever and lock nuts together, then use wrench on inner nut to unscrew lever), remove lever from housing Remove dirt seal spacer retainer from between the shift levers at lower end of steering column and remove both halves of the spacer Push selector pin in shifter operating shaft out and remove pin from beneath shaft Pull operating shaft out through upper end of steering jacket tube *(CAUTION*—Inner spring in lower end of operating shaft will come out with the shaft) Remove large Outer Spring and Spacer from below low-reverse shift lever, then remove shift levers dirt seals and bronze fulcrum from opening in jacket tube

DISASSEMBLY: Ambassador & Statesman (1952-55). Hornet & Wasp (1955)—Remove horn blowing parts and steering wheel Remove metal screws holding bearing retainer If equipped with directional signals, disconnect the six wire terminals under dash (tag each wire for identification) Slide rubber grommet upward on jacket tube and fold mat over toward center of floor Then slide rubber insulator pad up to rubber grommet *Remove rubber screws from clutch* and brake pedal opening cover, slide cover up on pedal shafts Loosen pedal capscrews and remove pedals and cover Disconnect gearshift rods from operating levers Loosen clamp bolt at lower end of jacket tube and steering gear housing On Ambassador & Hornet, remove upper and lower front steering gear mounting bolts Loosen lower bolt two turns, **but do not remove.** On Statesman & Wasp, remove three upper bolts and loosen the lower bolt Disconnect steering jacket tube bracket at instrument panel, and remove jacket tube and shifting assembly by lifting it through floor opening and over steering gear tube With jacket tube assembly on a cloth covered bench, remove dirt seal spacer retainer (clamp at lower end of steering column), remove the two halves of dirt seal spacers Turn operating levers upward, and then with a small punch, push selector pin out of operating shaft, turn levers down and remove pin from other operating lever *(NOTE*—Selector pin can only be removed through machined notch on second and high operating lever, this lever has lubricating fitting) Remove gearshift lever knob and remove gearshift operating lever by lifting it out of jacket tube Operating levers, outer spring, and spacer will remain in bearing housing at lower end of jacket tube after operating shaft is removed Lower spring may also remain in lower end of operating lever Remove dirt seals from operating levers and bearing housing from jacket tube

REASSEMBLY: (Ambassador, Statesman 1949-51): On both of these models, insert the operating shaft through upper end of column jacket tube until end just visible in shift lever opening, lubricate bronze fulcrum and install on tube, install inner spring in end of tube. Place rubber dirt seal on hub of second-high operating lever with metal side of tongue facing down (to provide seat for selector pin), install lever on operating shaft with notch for selector pin downward Place rubber dirt seal on low-reverse lever and install lever similarly except that metal tongue on seal and selector pin notch on this lever should face upward toward pin Install spacer and large spring over lower end of operating shaft and push shaft down into place in tube Turn shaft so that selector pin hole indexes with notches in shift levers, install selector pin, spacer halves, and spacer retainer

TYPICAL TRANSMISSION CONTROL

REASSEMBLY: Ambassador & Stat sman (1952-55), Hornet & Wasp (1955)—Install the bearing housing jacket tube *Replace dirt seals on both gearshift* operating levers locating the metal side of seal toward selector pin groove. Apply a coat of Lubriplate to to bronze fulcrum and place it in bearing housing, then insert the second & high, and low & reverse operating levers, outer spring, and spacer in bearing housing Install inner spring (holding it in place with Lubriplate) in lower end of operating shaft and insert shaft, from top of tube, down through bronze fulcrum and shift levers Align operating shaft selector pin hole with slot in second & high shift lever, and insert selector pin Install dirt seal spacers and seal retainer spring Apply Lubriplate to pressure spring pin and to ball end of gearshift lever and tighten lever to operating shaft Apply a thin coating of Lubriplate to rubber grommet at lower end of jacket tube, and install jacket tube in car Align jacket tube assembly and attach bracket to instrument panel Tighten clamp bolt at lower end of jacket tube and steering gear housing Install shifter rods to gear shift operating levers, then install bearing retainer, steering wheel and horn blowing parts. Replace clutch and brake pedal assembly, floor mat and rubber grommets.

1950-55 RAMBLER & 1954-55 METROPOLITAN (NASH & HUDSON)

Rambler (1950-55)
Metropolitan (1954-55)

DESCRIPTION: Remote control type with gearshift lever under steering wheel pivoted in lower edge of instrument panel to right of steering column (chrome ball in panel opening serves as pilot). Steering column unit is attached to steering column tube at lower end by a bracket and clamp.

ADJUSTMENT: Place shift lever in neutral, disconnect shift rods at swivel end of rods, place 3/16" (.1875") diameter rod through small holes in gear shift operating levers and grooves in bearing housing. With tool in position adjust trunnions at lower end of rods to permit trunnion pins to enter grommet in transmission lever freely. Remove aligning tool and check for free operation of both levers.

DISASSEMBLY: Remove gear shift lever knob and nut, push lever toward dash panel to loosen chrome ball so will slide off lever. Disconnect gear shift rods from levers at lower end of steering column, remove dirt seal spacer retainer from between operating levers and remove two halves of spacer. Remove two cap screws from body bracket and remove operating lever bearing assembly housing. Lower assembly into engine compartment, remove selector pin and remove housing assembly from operating shaft. With housing assembly in a vise, remove large outer spring and spacer, and remove both operating levers, bronze fulcrum and inner spring. The gear shift lever and operating shaft may be removed from passenger compartment. *CAUTION*—Note position of spring retainer, spring and washer before removing from shifting lever.

REASSEMBLY: With operating housing in vise, apply small amount of lubriplate to bronze fulcrum and insert in housing. Install rubber dirt shield on both gear shift levers with metal side of seal toward the selector pin groove, to provide hard surface for pin. Place operating levers in bearing housing and install large outer spring and spacer against the low and reverse operating lever. Line up holes in operating levers and bronze fulcrum with hole in bearing housing to provide ease of assembly on the operating shaft. Install operating shaft and lever assembly through hole in floor board and rubber dirt seal. Apply lubriplate to small inner spring, install spring in end of operating shaft, then assemble bearing housing to operating shaft. Turn operating shaft so that hole in shaft will index with notches in operating levers and install pin. Install two halves of dirt spacers, secure with dirt seal spacer retainer. *Note*—Start each half of spacer by turning end into groove. Install gear shift lever spring washer, pressure spring and spring retainer on gear shift lever and guide lever through hole in instrument panel. Lubriplate chrome ball, install ball, lever nut, and gear shift lever ball. Secure bearing housing assembly on body bracket. Fastening bracket has elongated holes for alignment. Centralize the shifting lever between the steering wheel and instrument panel with the shifting lever in the second and high speed position.

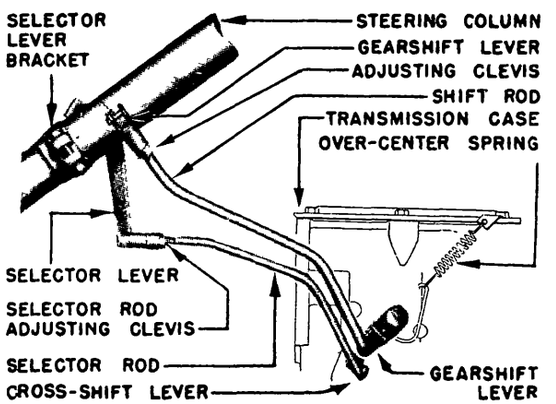
1951-55 OLDSMOBILE

8 Cyl., All Models (1951-55) with Synchro-mesh Trans.

►***This control not like type used on 1950 Series (requires different adjustment and disassembly procedure).***

DESCRIPTION: Remote control type with steering column mounted gearshift lever. Control mechanism in steering column is similar to type used on Oldsmobile prior to 1950 (not same as 1950 type) with separate gear engagement lever and gear selector lever on lower end of steering column (see illustration).

ADJUSTMENT: ***Two separate adjustments required.***



Shift Rod (Gear Engagement) Linkage—Set transmission case shift lever in neutral position. Measure horizontal distance from center of gearshift lever knob to horizontal centerline of steering wheel. If this distance is not 1¼" (1951-53), 2" (1954), 2 11/16" (1955), adjust by removing clevis pin on forward end of shift rod and adjust clevis on rod.

Selector Rod (Cross-shift) Linkage—Place gearshift lever in neutral position, disconnect selector rod at cross-shift lever on steering column, make certain that selector lever on transmission case is fully back against its rear stop. Adjust clevis on forward end of selector rod so that clevis pin enters clevis and cross-shift lever holes freely, **then lengthen rod by turning clevis three full turns,** connect rod by installing clevis pin. *NOTE*—This setting will provide correct clearance between gearshift knob and steering wheel.

DISASSEMBLY (1951-53): Disconnect battery cable and horn wire. Loosen all the steering gear-to-frame bolts. Remove filler plate screws on underside of floor panel at steering column. Disconnect shift rod from shifter lever on steering column. Remove selector lever from bracket on steering column, loosen selector lever bracket bolt, slide bracket down off upper jacket onto lower jacket. Remove nut and washer attaching brake pedal and rod to brake arm. Remove horn button and steering wheel (see Steering Gear data), remove spring and spring seat located directly below steering wheel. Remove gearshift lever. Turn back floor mat, remove brake pedal, take out remaining screws attaching filler pans to floor board, remove filler pans. Disconnect direction signal wires at connectors. Remove steering column-to-instrument panel bracket. Slide complete upper jacket assembly up off lower jacket and into driving compartment, remove this assembly from car. Remove ball stud from upper end of shift tube. Remove retainer ring at lower end of upper jacket assembly, slide shift tube and following parts out of upper jacket: large flat washer, rubber bumper, two small flat washers, coil spring, and spring retainer.

DISASSEMBLY (1954-55): Remove mast jacket—See Steering Assembly Removal. Remove turn signal wire retainer from side of mast jacket. Loosen turn signal housing mounting screws, remove housing and wire assembly. *NOTE*—Hold lower end of horn wire to prevent it from being pulled into mast jacket along with turn signal wires. Pull rubber boot back from shift lever retaining nut, unscrew and remove retaining nut and spring from shifter bowl. Remove shift lever, seat and anti-rattle spring, shifter stud, snap ring wave washer, flat washer, shifter bowl and special washer from end of mast jacket and slide shifter tube assembly out lower end of mast jacket. On 1955 models it is not necessary to remove horn contact bushing unless a new bushing is to be installed.

►*NOTE*—When installing special wave washer on mast jacket the relieved edge of washer should face the shoulder of the mast jacket.

1951-55 OLDSMOBILE TRANS. CONTROL

REASSEMBLY: Install all parts by reversing the disassembly procedure and note the following clearances:

Upper Jacket—Position upper jacket so that clearance between steering wheel and direction signal housing is 1/8-3/16".

Selector Lever Bracket—Position bracket so that clearance between bracket and lower shift lever is 1/16" with lever in its lowest position, then tighten bracket clamp bolt.

1940-50 OLDSMOBILE HANDI-SHIFT

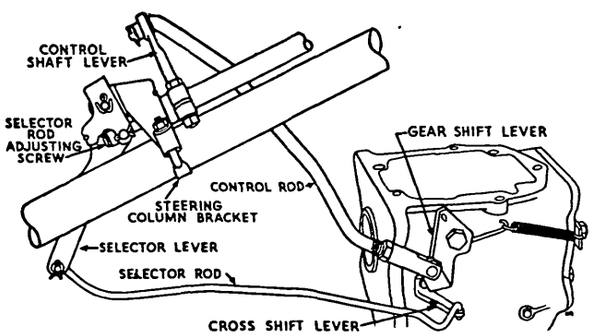
Six, All Models (1940 to 1950)

Eight, All Models (1940 to 1949)

►**HYDRA-MATIC DRIVE NOTE:** Control data below applies to Synchro-mesh transmission cars only. Hydra-Matic Drive control is of different design and adjusted differently. *See Hydra-Matic Drive Transmission data.*

DESCRIPTION: Remote control with steering column mounted gearshift lever. Design on all models is similar except for following changes:

1940 & Later Gearshift Lever & Selector Linkage: Changed from previous design as follows:



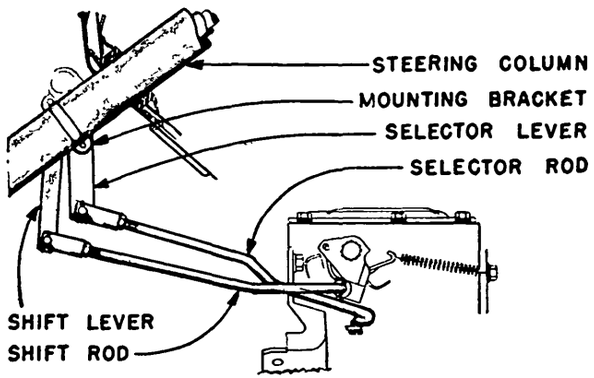
Gearshift Lever—Lever now pivoted on plain pin in control shaft bracket. Pin is retained by retainer ring and entire shift lever pivot assembly is enclosed by rubber boot.

Selector Rod & Lever Assembly—Selector control rod in control shaft on steering column now connected to new type selector lever and shaft assembly in transmission by connecting rod (no cable used). Adjustment provided on lower end of selector control rod at connection to lever.

1941 & Later Control Rod Linkage: New idler lever and redesigned linkage used as follows:

Control Rod (Gear Engagement) Linkage—New relay lever (idler lever) mounted on left side of engine with front non-adjustable rod connected between this idler lever and lever on steering column and additional rear adjustable rod connected between idler lever and gear shift lever on transmission case. Rear rod has adjusting clevis on transmission case end.

1949-50 Steering Column Unit: Design changed to new gearshift tube which is concentric with steering gear shaft in steering column and with different type shift levers and control rods (see illustration).



LDSM BILE 1940-48 HANDI-SHIFT

ADJUSTMENT (ALL 1940-48 MODELS): *Two separate adjustments required:*

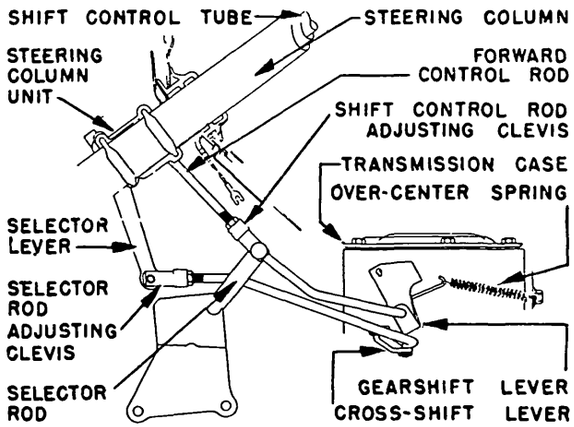
Selector Rod (Cross-shift) Linkage—See that both shift lever and transmission gears in neutral, check vertical distance from top of gearshift lever to lower face of steering wheel rim. This distance should be 2 11/16—2 13/16". To adjust, remove cotter pin and take out lock pin in lever which engages adjusting screw on lower end of selector rod, turn adjusting screw up to reduce lever-to-wheel distance, down to increase this distance. Install lock pin from engine side making certain that it passes through waved spring washer on inside of lever, install cotter pin.

Control Rod (Gear Engagement)—With transmission gears in neutral, gearshift lever should be 1½" (1940), ½" (1941-47) above the horizontal. To adjust, disconnect shift rod at lever on transmission case (upper gear engagement lever), see that this lever in neutral position (can be determined by feel of detent balls engaging notches in shifter shafts). Install aligning gauge J-1445 (1940), J-1609 (1941 on see Note) on lower end of control shaft and steering column so notch in gauge engages control shaft lever. Gauge will hold lever in correct neutral position 1½" (1940), ½" (1941 on) above the horizontal. Loosen locknut and turn adjusting clevis on transmission end of shift rod until clevis pin can just be inserted without disturbing position of transmission shift lever. Tighten locknut and connect rod, remove gauge. NOTE—This adjustment should be made each time shift rod is disconnected at either end. Improper adjustment may cause interference with brake pedal.

Aligning Gauge Note—New Part No. J-1872 gauge required for Series 66, 68 Convertible Models and all Series 98 Models which have larger (1¾") diameter steering column.

OLDSMOBILE 1949 HANDI-SHIFT

ADJUSTMENT (ALL 1949 & 1950 6 Cyl.): *Two separate adjustments required:*



(1) Selector Rod (Cross-shift) Linkage—Place gearshift lever in neutral, disconnect selector rod from selector lever on steering column (upper lever), loosen locknut and adjust clevis at forward end of selector rod so clevis pin can just be inserted when vertical distance from top of steering wheel rim to top of gearshift lever knob is exactly 2 11/16". Tighten clevis locknut and connect rod.

(2) Shift Control Rod (Gear Engagement) Linkage—Place gearshift lever in neutral, disconnect shift rod from shift lever on steering column (lower lever), make certain that transmission gears in neutral, loosen locknut and adjust clevis at forward end of shift rod so that clevis pin can just be inserted when horizontal distance of gearshift lever knob center-line is exactly 1 3/16" above steering wheel horizontal center-line. Tighten clevis locknut and connect rod.

DISASSEMBLY & REMOVAL: As follows:

Gearshift Lever Removal—To remove lever, slide rubber cover toward outer edge to expose retainer ring, remove retainer ring, take out shift lever pivot pin, remove lever being careful not to lose shims and washers between lever and bracket. When reinstalling lever, make certain that anti-rattle spring in place on inner end of lever and that spring washer installed on pin on one side of lever and install shims (as required) on opposite side of lever so that lever operates freely without excessive sideplay or rattles.

Transmission Case Shifter Mechanism—Selector shaft and shifter shafts (for gear engagement) are same design as used on previous models. See Transmission article for dismantling and servicing directions. CAUTION—Selector shaft must be removed through right side of case and installed on left side to avoid damage to oil seal. Lower lever must be removed from vertical cross-shift shaft before selector shaft is driven out (to permit upper lever on shaft to disengage from selector shaft).

LDSM BILE 1950 6 CYL. HANDI-SHIFT

1950 OLDSMOBILE 8

8 Cyl. Series 88 & 98 (1950)

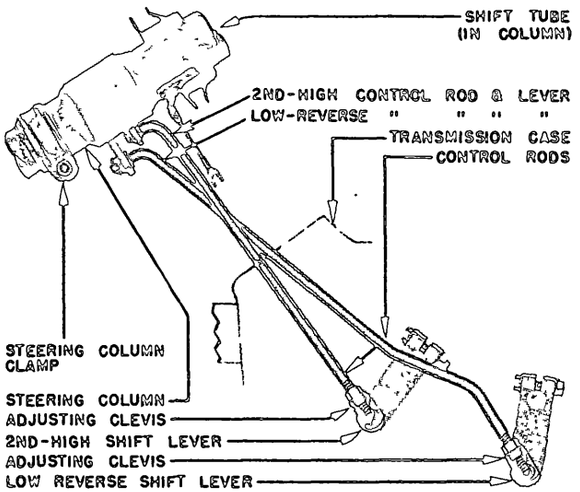
▷*This control not like type used on 1950 6 Cyl. or previous 8 Cyl. models.*

DESCRIPTION: Remote control type with steering column mounted gearshift lever.

ADJUSTMENT: *Horizontal adjustment only is required unless shift lever bowl (gearshift lever carrier) has been disturbed.*

Horizontal Adjustment—With both rods dis-connected at transmission case shift levers, move selector lever to Neutral, lift lever up midway through cross-over travel (shifter key will lock both lower shifter levers), move shift lever so that knob approximately 1 3/16" above steering wheel horizontal center-line, hold lever in this position while adjusting. Place both transmission case shift levers in neutral, adjust clevis on each rod so that rods can just be connected without disturbing lever positions, connect rods, check operation. If selector lever travel in neutral not smooth, or interference noted during the cross-over, recheck adjustment. Readjust either rod slightly to secure smooth cross-over.

Vertical Adjustment (when selector lever bowl removed or disturbed)—Disconnect both rods at shift levers on transmission case, allow lower (Low & Reverse) lever to swing counter-clockwise as far as possible (so that keyway out of alignment with key on shift tube). Remove horn button, steering wheel and direction signal switch assembly. Press shift lever tube assembly down until key contacts lower shift lever (pull up on selector lever in neutral), turn adjusting screw directly above selector lever in until it is tight against lever, then back screw off ½ turn, stake screw to prevent loosening in service.



NOTE—This setting will position selector lever for vertical clearance of approximately 2 31/32" from top edge of steering wheel to center line of lever knob with lever at rest in neutral (1/64" clearance between key in shift tube and lower lever).

DISASSEMBLY: Remove steering wheel (see Steering Gear data), remove upper bearing spring and seat. Unscrew and remove gearshift lever retainer cap, place lever in neutral position, drive pin out of lever boss on carrier, withdraw gearshift lever.. Unscrew and remove direction switch lever, disconnect direction signal feed wires at connectors near steering column, attach fishing wire to these feed wires (pull fishing wire into column as feed wires pulled out and leave this wire in column for use in re-installing feed wires). Take out four screws retaining direction signal switch and housing on upper bearing retainer, pull switch feed wires and housing off. Take out three capscrews retaining carrier assembly on jacket, remove carrier, remove bearing and retainer by rotating them counter-clockwise. Remove cotter pins and dustcovers from lower shift levers on steering column, remove felt dust seal, slide shifter tube up and out of upper steering column jacket. Disconnect shifter levers from control rods, loosen clamp holding upper and lower steering column jackets. Raise front end of car, disconnect steering rod at pitman arm, take out steering gear-to-frame bolts. Lower the steering gear housing and shaft (with cross-over spring and seat) out of steering column. Lift low-reverse lever out of jacket, remove fiber spacer from between levers, turn second-high lever for clearance and remove from slot in jacket. Remove felt washer from recess above and below shift lever opening in jacket. Inspect lower bushing, bumpers, and washers for wear and remove and replace if necessary.

REASSEMBLY: Install all parts in reverse order of disassembly as given above and note the following precautions and adjustments:

Sealing Ring & Shifter Lever Lubrication—Saturate rings with engine oil and lubricate levers with Lubriplate before installation.

Fiber Spacer Installation—Lubricate spacer before installation, see that notch in spacer in line with back edge of levers (to align slot in spacer with slots in lever to permit key on shift tube to be entered when tube installed).

OLDSMOBILE 1950 8 CYL. TRANS. CONTROL

Upper Bearing Retainer—Lubricate retainer threads with Lubriplate, screw retainer into carrier until top face of retainer is 21/32" above shoulder on rim of carrier, install carrier over shift tube so that shoulder on retainer seated against upper end of outer jacket, tighten retainer screws to 7-9 ft.lbs.

Gearshift Lever Bumper Screw Installation & Adjustment—With gearshift lever installed and ball end of lever engaged in hole in upper end of shift tube ,depress lever until shift tube key clears low-reverse lever, rotate lever so that keyway is out of line with key, pull up on gearshift lever until key contacts face of low-reverse lever. Install rubber bumper in bumper screw (bumper must be completely seated in screw), turn screw in until bumper just contacts pad on lever (check by shaking outer end of lever and tightening screw until all longitudinal play eliminated), then back off screw ½-turn and lock screw by staking carrier metal into screw slot.

1951-55 PACKARD

All Series (1951-55)

DESCRIPTION: Remote control type with steering column mounted gearshift lever. Design same as used on previous Packard models except for new idler lever assembly as follows:

Idler Lever Assembly—Idler levers mounted on horizontal shaft on left side of engine (inner end of shaft mounted on engine flywheel housing, outer end in bracket on top of left frame side rail).

Shift Lever Rods—Forward rods (from steering column levers to idler levers) have adjusting trunnion on forward end at steering column levers. Rear rods (from idler levers to transmission shifter levers) are non-adjustable.

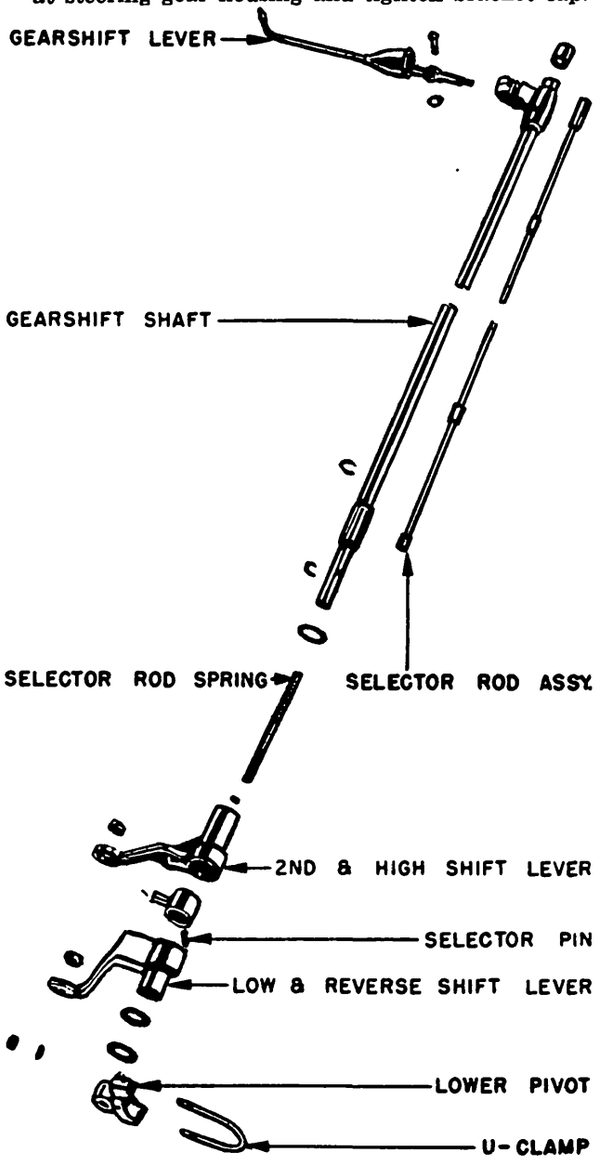
ADJUSTMENT: Disconnect both forward shift rods at idler levers on left side of engine. Place gearshift lever in neutral, install ⅛" pin or drill rod through holes in both levers on steering column to maintain this alignment during adjustment. Make certain that both transmission shifter levers are in neutral (can be determined by feel of detent ball engaging center notch on shifter lever shaft sector). Adjust each forward rod (loosen locknuts and turn turnbuckle) until rod end enters hole in idler lever freely without disturbing rod and lever positions. Connect rods and remove alignment pin from levers.

REMOVAL: Remove horn ring and steering wheel (see Steering Gear data). Lift front floor mat for access to area around steering column. Remove steering gear-and-brake pedal floor opening cover. Disconnect both shift rods at levers on steering column. Loosen steering column U-clamp at steering gear housing, remove steering column bracket cap at instrument panel. Disconnect direction signal switch cables. Remove steering column jacket and shroud assembly.

DISASSEMBLY: Remove U-clamp at gearshift shaft lower pivot, remove lower pivot by unscrewing it from the end of the shaft. Remove lower gearshift shaft lever, drive out selector pin, remove selector and selector rod spring, remove upper gearshift shaft lever. Remove direction signal switch and windshield wiper control from steering column shroud. Remove gearshift lever. Slide draft pads off over end of steering column. Remove gearshift shaft upper spring lock from upper end of shroud, take out shroud-to-jacket attaching screws. Remove shroud and gearshift shaft from steering column jacket, remove shaft from shroud. Withdraw selector rod from within gearshift shaft.

REASSEMBLY: Lubricate all moving parts with Lubriplate. Assembly parts by reversing the disassembly procedure and note the following points:

Gearshift Shaft—When installing gearshift shaft and shroud over steering column jacket, make certain that shaft enters bearing in jacket.



Selector Pin—After installing selector rod spring, spacer, and selector, hold spring compressed and drive pin into selector. Lubricate selector and shaft levers with Lubriplate.

Gearshift Shaft Lower Pivot—After installing lower lever and washer, lubricate lower pivot and thread it on end of gearshift shaft until clearance at lower shaft lever is .025". Engage pivot dowel in locating hole in column jacket and install the U-clamp.

CONTINUED ON NEXT PAGE

1951-55 PACKARD (C nt.)

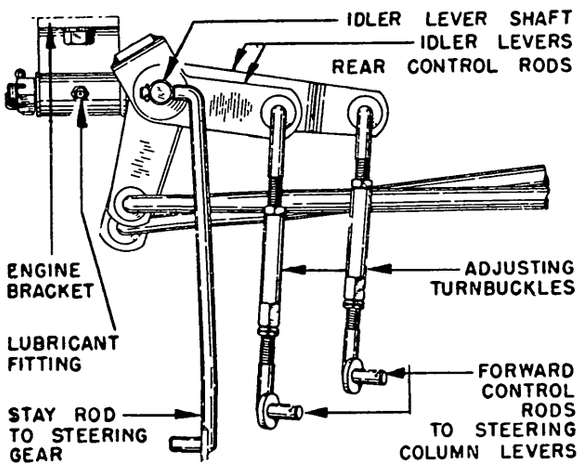
INSTALLATION: Install steering column jacket and shroud assembly in car, install bracket cap but **do not tighten cap at this point.** Connect direction signal cable and windshield wiper control. Install steering wheel and horn ring. Adjust position of steering column jacket and shroud assembly so that clearance between wheel and shroud is approximately 1/16", then tighten U-clamp on jacket at steering gear housing and tighten bracket cap.

PACKARD HANDI-SHIFT

1941-50 PACKARD "CLIPPERS"

ALL "CLIPPER" MODELS (1941-50)

►**Shifter Shaft Rattle Correction (1948 Cars)**—To correct complaints of shifter shaft rattles noted within steering column shroud, Anti-rattle Spring No. 377870, and Anti-rattle Spring Plug No. 338043, can be installed as follows: Remove steering wheel, install plug in end of shifter shaft, install spring by placing center of spring in groove around plug and snapping ends of spring in against re-inforcing wall of steering column wheel web cup.



NOTE—This spring and plug installed in production on later 1948 cars.

DESCRIPTION: Handi-shift, remote control with steering column mounted gearshift lever. Gearshift control is same design as used on previous models. Idler lever assembly and control rod linkage has been changed as follows:

Idler Lever Assembly (Clipper Models)—Idler levers mounted on hinged bracket on engine with stay rod connecting top of idler lever shaft to steering gear case. No assist spring used. Lubricant fitting on idler lever hinge should be lubricated with chassis lubricant at 1000 mile intervals (idler levers packed with lubricant and require no attention). **Shift Lever Rods**—Forward rods (steering column levers to idler levers) have adjusting turnbuckle on rod. Rear rods (from idler levers to transmission shifter levers) are non-adjustable.

ADJUSTMENT: Disconnect both forward shift rods at idler levers on left side of engine. Place gearshift lever in neutral, install 3/16" pin or drill rod through holes in both levers on steering column to maintain this alignment during adjustment. Make certain that both transmission shifter levers are in neutral (can be determined by feel of detent ball engaging center notch on shifter lever shaft sector). Adjust each forward rod (loosen locknuts and turn turnbuckle) until rod end enters hole in idler lever freely without disturbing rod and lever positions. Connect rods and remove alignment pin from levers.

DISASSEMBLY & REASSEMBLY: Control mechanism on steering column is same design used on 1951 cars. *See Packard 1951 control for all data.*

PACKARD CLIPPER IDLER LEVER ASSY.

1940-52 PONTIAC SAFETY SHIFT

6 & 8 Cyl., All Models (1953) With Synchro-mesh Transmission.

DESCRIPTION: Concentric tube type remote control with steering column mounted gearshift. The gearshift lever engages a concentric tube within steering column and movement of shift lever rotates the tube or moves it up and down. A gear-

►**1941 Control Rod Production Change (except Deluxe Models)**—A single shifter rod between steering column lever and shift lever on transmission case was used beginning with the following serial nos.

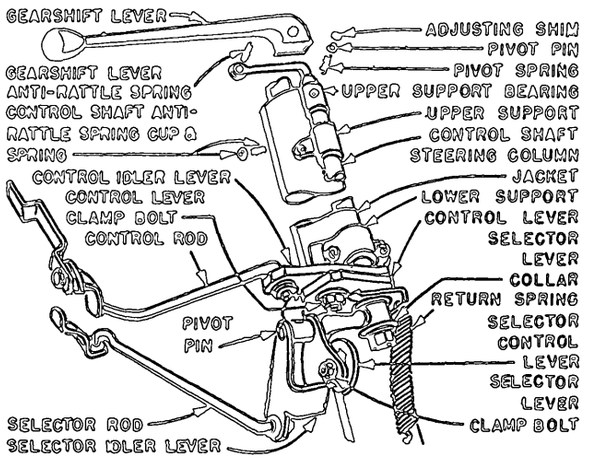
	Pontiac	Linden	South Gate
41-24	P6JB-25488	L6JB-6379	C6JB-4044
41-26	P6JC-4884	L6JC-2404	C6JC-1789
41-28	P8JB-19031	L8JB-4349	C8JB-3246
41-29	P8JC-7794	L8JC-3274	C8JC-1957

►**Installing Single Rod on First 1941 Cars**—New single rod furnished for service replacement on all cars. When installing new single rod on first cars (with front and rear rods and intermediate idler lever), proceed as follows: Remove clutch and brake pedal toe plate, cut off shifter rod idler lever bracket and re-install plate. Install the following new parts—506712 Gearshift Control Rod, 506713 Transmission Shifter Lever, 505760 Gearshift Control Shaft Idler Lever (these are levers to which rod attaches at front and rear ends). Discard old parts.

►**Hard Shifting Complaints**—To correct complaints, examine linkage and make following corrections:

Binding or Sticking of Clutch Driven Plate—Check for driven member hub binding on main drive gear splines, sticking of driven member to flywheel or pressure plate (caused by oil on facings resulting from oil leak at rear main bearing or at transmission case front bearing oil seal), or sticking of driven member facings due to vacuum between facings and flywheel or pressure plate. Correct by cleaning all mating surfaces (CAUTION—do not use petroleum products which may leave film). Facings on 6 Cyl. clutch driven members may be grooved to correct sticking due to vacuum (use 1950 8 Cyl. facings as guide in grooving facings).

Rear Shift Rod Alignment—On cars with front and rear control rods and intermediate idler lever, check rear shift rod and see that ends are parallel so that rod does not bind in transmission shift lever as gears engaged. See note above for installation of new type single rod to replace this double rod and idler lever assembly.



Idler Lever Bracket—Check idler lever bracket for looseness allowing lever to bind on rods. If bracket loose at mounting rivets, remove toe plate and securely weld bracket or remove idler lever and install new type single rod.

Control Shaft Toeboard Grommet—See that rubber grommet on steering column and shift control shaft at toeboard does not bind on shaft and prevent free up-and-down movement (required for cross-shift at neutral). Correct by trimming rubber at point where bind occurs and applying few drops of brake fluid to shaft.

CONTINUED N NEXT PAGE

1940-52 PONTIAC SAFETY SHIFT (Cont.)

Control Shaft & Gearshift Lever Clearance—If shoulders on shaft not machined low enough, they will strike gear shift lever fulcrum cups and prevent full Low and Reverse gear engagement causing hard shifting. To check this dimension, remove control shaft, place small square on shaft so that upper edge even with tops of shoulders on shaft, measure perpendicular distance from top of square to bottom of fulcrum ball on end of shaft. Distance should be 1 1/16". If incorrect, rework shaft as follows: If over-all length of shaft (from lower end to tops of shoulders at upper end) is more than 32 11/32" ± 1/32", file shoulders down to secure correct 1 1/16" fulcrum ball height. If over-all length of shaft within limits given above, bend ball end of shaft to secure correct fulcrum ball height.

1940-52 PONTIAC SAFETY SHIFT

DESCRIPTION: Remote control with steering column mounted gearshift lever. Same design as used on previous models except for new Selector Rod and Lever Assembly as follows (see Production Change Note above for different type used on late 1941 and and all later car models).

ADJUSTMENT: Gearshift Lever Clearance. Clearance between upper edge of control shaft upper support and shoulder on upper control shaft bearing which is screwed in the bracket must be ⅛" (1/8" min., 5/32" max.) to avoid interference when engaging gears. If clearance incorrect, remove gearshift lever (see Disassembly data), adjust by screwing bearing in or out of support bracket (½ turn of the bearing will change clearance 1/32").

Selector Rod (Cross-shift)—With gearshift lever in neutral on Second-High side (normal position), distance from lower edge of steering wheel rim to upper edge of gearshift lever should be 2 7/8" ± 1/8" (1940-48), 2¾" ± ⅛" (1949 on). To adjust with the shift lever in neutral, loosen clamp bolt holding selector control lever and selector control idler lever together (these are levers pivoted on lower suport bracket on steering column), see that selector rod and levers are in Second-High position (rod moved to rear as far as possible), place gearshift lever in correct position and tighten lever clamp bolt.

Control Rod (Gear Engagement)—With gearshift lever in neutral, lever should be approximately horizontal but can be varied approximately 1½" to suit individual operators. To adjust, loosen clamp bolt holding control shaft lever and control shaft idler lever together (these are levers mounted on lower end of control shaft on steering column), see that control rod and transmission case shifter lever are in neutral, move gearshift lever to desired position and tighten lever clamp bolt. Check to make certain that gearshift lever has full travel required for gear engagement without interference after making this adjustment.

REMOVAL & DISASSEMBLY: Remove front compartment floor mat and center floor panel. Remove horn button and steering wheel (see Steering Gear data). Disconnect return spring from lower end of control shaft, remove pivot pin from selector control lever and idler lever (CAUTION—do not loosen clamp bolts holding levers together which would disturb adjustment). Take out screw in lower end of control shaft, remove selector lever collar from shaft. Take out two screws (Phillips #2 screwdriver), pull upper support and control assembly straight up parallel to steering column CAUTION—do not lose anti-rattle spring and cup located in hole in underside of upper support). Remove gearshift lever using tool J-1044 to remove shift lever pins and springs. Unscrew upper bearing from upper support.

REASSEMBLY: Assemble all parts in reverse order of disassembly data above noting the special points listed below. Adjust gearshift lever position by screwing bearing in or out of bearing support (see Adjustment data above) before assembling the gearshift lever. Adjust control rods after assembly completed.

Lubrication of Moving Parts—Coat following parts and bearing points with Lubriplate before assembling: Control Shaft Upper Support Bearing, Anti-rattle Spring Cup, Gearshift Lever Pivot Pins, Springs & Shims, and inner surface of gearshift lever, Control Shaft flats and ball end, Anti-rattle Spring in ball end, Control Shaft bearing hole in lower support, and Selector Collar surface which contacts selector lever.

Gearshift Lever Assembly—One anti-rattle spring washer must always be used on gearshift lever pivot pin and shims should be installed as required to take up excessive clearance so that lever operates freely without excessive play or rattles. Re-install all shims found at this point and check lever after assembly completed. See Adjustment data for correct gearshift lever position.

Transmission Case Shifter Mechanism—Refer to Pontiac Transmission article for dismantling and servicing directions. CAUTION—Selector shaft must be removed through right side of case and installed on left side to avoid damage to oil seal. Lower lever must be removed from vertical cross-shift shaft before the selector shaft is driven out (to permit upper lever on shaft to disengage from selector shaft).

1953-55 PONTIAC SAFETY SHIFT

6 & 8 Cyl., All Models (1953-55) with Synchro-mesh Trans.

DESCRIPTION: Concentric tube type remote control with steering column mounted gearshift. The gearshift lever engages a concentric tube within steering column and movement of shift lever rotates the tube or moves it up and down.

ADJUSTMENT: (Gearshift Lever Position)—When gearshift lever is in neutral position, clearance between lever and steering wheel should be approximately 3 7/16" (1953-54), 3½" (1955). To adjust, hold transmission selector rod in its rearmost position (2nd & 3rd normal position) and adjust selector rod trunnion for proper gearshift lever position by shortening or lengthening selector rod. Neutral position of gearshift lever should be 9° (1953-54), 18° (1955) above horizontal. To raise or lower lever, adjust length of gearshift control rod (trunnion connected to upper shift lever at bottom of steering column) as necessary.

REMOVAL OF STEERING COLUMN SHIFT ASSEMBLY: 1—Remove horn button and steering wheel. Disconnect direction signal wires, horn wire from steering column brace. Remove steering wheel hub cover or directional signal housing by removing two attaching screws. Use care when withdrawing harness from opening in steering column. Using a 7/16" wrench remove four special screws which fasten gearshift lever bearing support to steering column. Remove gearshift lever rubber cover by pulling it over ridge.

2—Remove gearshift lever fulcrum pin retaining ring and pin and remove gearshift lever, being careful to catch anti-rattle shims which may be between shift lever and shift lever support. Remove anti-rattle spring from end of control lever (NOTE—Retainer spring on tube yoke pin which shift lever slot engages is used to keep pin from dropping out during assembly).

3—Remove gearshift lever support and bearing assembly from steering column by turning bearing support slightly to free horn contact wire, then pull assembly straight out. Remove horn contact and cable assembly from bearing support by prying gently with a screwdriver. Unscrew bearing support from gearshift lever support. If steering shaft upper bearing is to be replaced, remove it from bearing support by pushing it out with a tool that can be inserted through end of bearing support.

4—If disassembly is being made with steering column assembly in car, it will be necessary to remove left engine splash apron so that lower end of steering column jacket can be reached from beneath car.

5—Remove transmission control rods from levers and remove gearshift lever (selector) and bracket and remove pivot pin. Remove shift lever from tube yoke by loosening screw about ⅛" with an open end wrench and moving it down and out. Gearshift tube can be held down with a screw driver inserted through selector lever opening. Attaching screw need not be completely removed from bracket.

6—Gearshift tube can now be removed from top of steering column jacket. Insulating pads will come

CONTINUED ON NEXT PAGE

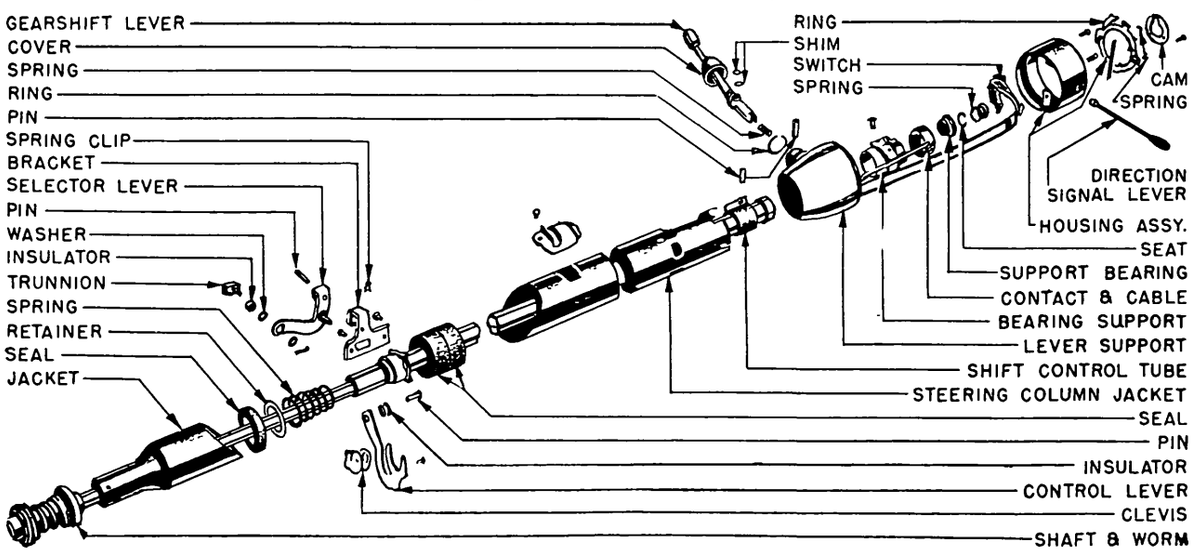
1953-55 PONTIAC SAFETY SHIFT (Cont.)

out with shift tube. Remove gearshift return spring, lower seal retainer and seal if they are to be replaced.

INSTALLATION OF STEERING COLUMN SHIFT ASSEMBLY:

1—Slide lower felt seal and retainer down inside steering column jacket against shift tube lower bearing plate. Coat both ends of shift tube return spring with Lubriplate and drop it down steering column jacket into place against lower seal retainer with large end down.

2—Apply a thin coating of Lubriplate to bearing surfaces at both ends of concentric gearshift tube including upper yoke pin and selector collar groove in which selector pin rides. Position insulating pads around shift tube beneath retainer plate and install shift tube in steering column with gearshift yoke facing opening in upper end of steering column.



3—With screw started in gearshift lower lever, position lever against bottom of lower lever drive plate engaging driving lugs and tighten cap securely. Shift tube can be held down with screwdriver inserted through selector lever opening. Coat selector lever pin with Lubriplate and assemble selector lever to bracket. Install pivot pin so hairpin retainer is on side which will be against steering column jacket. Place selector lever and bracket assembly on steering column jacket making sure selector pin engages collar on gearshift tube. Install attaching screws.

4—Connect selector rod trunnion and shift rod clevis to their respective levers using a flat washer on each side of insulator. Replace engine splash apron if unit is being assembled in car.

5—If steering shaft upper bearing was removed from bearing support, press new bearing in until flush (if on Power Steering equipped car, press in until flush with counter-bore). Screw bearing support (die cast) on bearing in gearshift lever support until bearing and support are flush at bottom end with gap in bearing support flange toward gearshift lever support. This adjustment determines clearance between gearshift lever support assembly and steering wheel hub cover or directional signal housing. Clearance should be approximately ⅛". Set steering wheel hub cover or direction signal housing on bearing support to check clearance before proceeding. If clearance not correct, turn bearing in complete turns as necessary for proper clearance.

6—Press horn contact and cable assembly in place over annular grooves in upper end of bearing support. Cable should lay in slot in upper end of bearing support. Install gearshift lever support and bearing assembly indexing gearshift tube yoke with lever support and indexing bearing support with attaching screw holes in steering column. While gearshift lever support is being lowered into position, guide horn wire into steering column jacket through openings, and back out of steering column jacket through hole just below column upper bracket. Clamp horn wire in position.

7—Install four bearing support attaching screws and tighten. Position gearshift lever anti-rattle spring (coil spring) in bore in lever and position lever in its support. Replace anti-rattle shims between lever and support and install gearshift lever fulcrum pin and retaining ring. Install gearshift control rubber cover making certain it is properly seated in groove. Install hub cover or direction signal housing with two attaching screws. To simplify installation of direction signal wiring, tape loose end with scotch tape so they will be easily guided through openings in jacket. Direction signal wire should be directed in to mast jacket through opening just below steering column upper bracket. Install steering wheel and horn button.

1953-55 PONTIAC SAFETY SHIFT

1947-50 STUDEBAKER

Champion, All Models (1947 to 1950)
Commander & Land Cruiser, All (1947 to 1950)

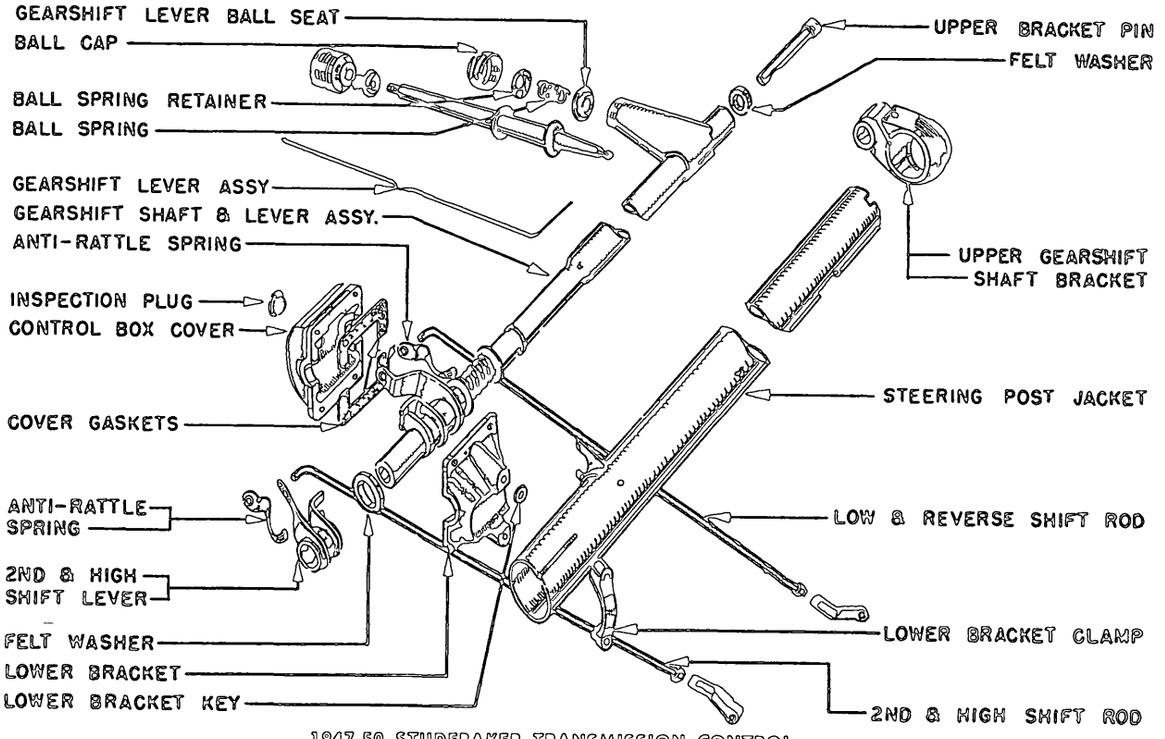
►**SPECIAL SERVICE TOOL NOTE:** New Gauge J-1308-B required for transmission control adjustment on these cars. Old type Gauge J-1308-A (1940-46 cars) can be reworked for use on these 1947 & later cars by milling out a section of the tool handle 7/16" by 1 3/8" long (at right angles to plane of gauge prongs) to provide clearance when gauge inserted in shift control box on steering column.

DESCRIPTION: Remote control with gearshift lever on steering column below steering wheel. Shift lever is pivoted at inner end in pin screwed in upper bracket and is linked to control shaft by fulcrum pin so that up-and-down movement of the lever (for cross-shift) lifts the entire control shaft; and backward-and-forward movement (for gear engagement) rotates the shaft. An integral lug or lever on the lower end of the control shaft (within control housing on steering column) engages a fork attached to the lower control lever (second-high) and is lifted to engage the fork attached to the upper control lever (Low-reverse) when shift lever is lifted up toward steering wheel (lug normally held down in second-high position by spring on lower end of control shaft below control housing). Control levers are connected to shift levers on side of transmission case by adjustable rods (forward lever for second-high, rear lever for low-reverse). Control housing is entirely enclosed and provided with lubricant fitting so that it can be kept filled with chassis lubricant.

ADJUSTMENT: Disconnect both shift rods at shifter levers on side of transmission case. Pry out inspection plug on control box cover on steering column, install special gauge J-1308-B (see Service Tool Note above) through plug hole to align control housing forks and levers in neutral. Make certain that both shift levers on transmission case are in neutral (can be determined by feel of detent plungers engaging notches in shift shaft sectors). Adjust each rod by turning clevis at transmission end of rod in **complete turns only** (required by shape of clevis) until rod can be connected without disturbing position of transmission levers. Connect rods, remove adjusting gauge, re-install control box plug.

REMOVAL: ***Procedure same for Champion & Commander except as noted:***

1) Disconnect battery cable (and horn wire on Champion).
2) Remove steering wheel (see Steering Gear data), remove steering post jacket bearing spring (and spring seat on Commander).
3) Remove gearshift lever ball cap, withdraw shift lever assembly from gearshift shaft. If shift lever to be disassembled, remove lever knob, retaining spring, and knob ferrule; then slide ball cap, spring retainer, and ball spring off lever; remove ball seat off opposite end of lever.
4) On Champion only, loosen gearshift shaft upper bracket clamp screw, remove bracket from post jacket, unscrew upper bracket pin, remove spring from within bracket, slip felt washer off pin. Remove lower half of steering post bracket, take out



CONTINUED ON NEXT PAGE

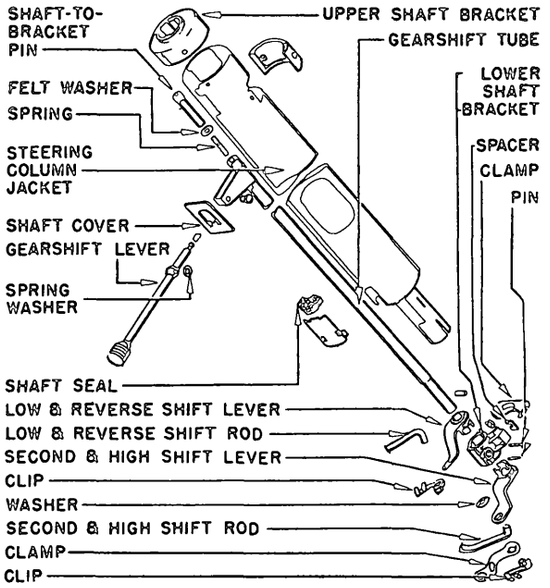
1947-50 STUDEBAKER (Cont.)

bolt and capscrew holding upper half of bracket on instrument panel, remove bracket, spacer, and anti-squeak pad. Remove steering post collar screws, slide collar and grommet up to end of jacket.
5) On Commander only, remove gearshift shaft upper bracket screws, remove bracket from post jacket. Unscrew upper bracket pin, remove felt washer from pin. Remove jacket bearing from bracket, remove spring from within end of shift shaft.
6) Disconnect both shift rods from control box levers on steering column.
7) On Champion only, loosen steering post jacket clamp, turn jacket and shift assembly so that control box is on left side of column, then pull entire assembly up through floor opening and into the car, slip jacket off steering post and remove assembly from the car.
8) On Commander only, remove control box upper clamp screw and key, loosen lower clamp screw, loosen steering gear housing-to-frame bolts. Remove lower half of steering post bracket, remove steering post collar screws, slide collar and grommet up on the jacket. Tip upper end of steering post down, slide jacket and shift assembly up and turn as necessary so that control box clears floor opening. Slide grommet and collar over control box, remove assembly from steering post, and lift out of the car.

DISASSEMBLY: *Procedure same for Champion and Commander except as noted:*
1) Remove control box clamp screws and clamp (and key on Champion).
2) On Champion only, lift shift shaft assembly out of jacket, remove jacket from collar and grommet. Remove collar and grommet from shift shaft using care not to tear rubber collar (use liquid soap).
3) On Commander only, remove rubber boot from upper end of shift shaft. Remove jacket lower plate screws, move plate toward control box and remove it from the shaft. Remove control box and shaft assembly from the jacket by pulling it out through lower hole in the jacket. Remove felt washer.
4) Remove inspection hole plug from control box cover, take out four screws and remove cover and gaskets. Lift shaft and lever assembly out of control box, slide second-and-high lever off end of shaft, remove lower felt washer from shaft.
NOTE—Shift shaft and low-and-reverse shift lever are serviced as an assembly (together with spring and washers on Champion).

REASSEMBLY & INSTALLATION: Assemble parts and install gearshift control in reverse order of removal and disassembly procedure (above). Note following points when installing assembly in car:
Gearshift Shaft Upper Bracket Pin Installation: Screw pin in tight and then back pin off about ½ turn so that hole in pin will face shaft lever opening in shaft when installed.
Collar & Grommet and Rubber Boot Installation: Use liquid soap to facilitate installation and to avoid tearing these parts during installation.
Shift Control Adjustment: Adjust shift rods after installation completed. See Adjustment (above).

1947-50 STUDEBAKER TRANSMISSION CONTROL



1951-52 STUDEBAKER

Champion, Models 10G, 12G (1951-52)
Commander & Landcruiser V8 (1951-52)

▷SPECIAL SERVICE TOOL NOTE—New Transmission Shift Rod Adjusting Gauge No. J-4690 required for these models due to redesigned control box housing. Previous type gauges cannot be used.

DESCRIPTION: Remote control type of same design used on previous models except for new Control Box design (on steering column) requiring new Adjusting Gauge and different disassembly procedure.

ADJUSTMENT: Disconnect both shift rods at shift levers on side of transmission case. Place gearshift lever in neutral, remove lubrication fitting from control box housing on steering column, insert Transmission Shift Rod Adjusting Gauge No. J-4690 through lubricant fitting hole, engaging the flat on the tool with flats on shift levers, so that levers are

1951-52 STUDEBAKER TRANS. CONTROL

aligned in neutral position. Make certain that transmission shift levers are in neutral (can be determined by feel of detent plungers engaging notches in shift lever shaft sectors). Adjust each rod by turning clevis on rear end of rod in complete turns only (required due to shape of clevis) until rods can be connected without disturbing lever position. Connect rods, remove adjusting gauge, replace lubricant fitting in control box housing.

REMOVAL: *Procedure for all models is same except as noted:*
1) Disconnect battery cable (and horn wire on Champion Custom models).
2) Remove steering wheel (see Steering Gear data), remove steering post jacket bearing spring (and spring seat on all models except Champion Custom).
3) Take out gearshift lever screw, withdraw lever assembly from shift shaft.

CONTINUED ON NEXT PAGE

1951-52 STUDEBAKER (C nt.)

4) On Champion Custom only, loosen gearshift shaft upper bracket clamp screw, remove bracket from post jacket, unscrew upper bracket pin, remove spring from within bracket, slip felt washer off pin. Remove lower half of steering post bracket, take out bolt and capscrew holding upper half of bracket on instrument panel, remove bracket, spacer, and anti-squeak pad. Remove steering post collar screws, slide collar and grommet up to end of jacket.
5) On all models except Champion Custom, remove gearshift shaft upper bracket screws, remove bracket from post jacket, unscrew pin from bracket, remove felt washer from pin. Remove jacket bearing from bracket and remove spring from within end of shift shaft.
6) Disconnect both shift rods from control box levers on steering column.
7) On Champion Custom only, loosen steering post jacket clamp and turn jacket so that control box assembly is on left side of column, then pull entire assembly up through floor opening and into the car, slip jacket off steering post, remove assembly from the car.
8) On all models except Champion Custom, loosen steering post jacket lower clamp and steering gear housing-to-frame bolts. Remove lower half of steering post bracket, remove collar screws and slide collar and grommet up on jacket. Tip upper end of steering post down, slide jacket and shift assembly up and turn as necessary so that control box clears floor opening. Slide grommet and collar over control box, remove assembly from steering post and lift it out of the car.

DISASSEMBLY: ***Procedure for all models is same except as noted:***

1) Remove control box clamp screws and clamp (and key on Champion).
2) On Champion Custom only, lift shift shaft assembly out of the jacket, remove jacket from collar and grommet. Remove collar and grommet from shift shaft using care not to tear the rubber collar (use liquid soap on collar to slide it off shaft).
3) On all models except Champion Custom, remove jacket lower plate screws, move plate toward control box and remove it from the shaft. Remove control box and shaft assembly from jacket by pulling it out through the lower hole in the jacket.
4) Use a small drift to drive out the second-and-high lever retaining pin (lower pin on side of control box housing), slide lever off shaft and out of control box housing. Drive out low-and-reverse lever retaining pin (upper pin), slide lever and shaft assembly out of control box housing. If low-and-reverse lever to be removed, press shift control pin out of shaft, slide lever off end of shaft.

REASSEMBLY & INSTALLATION: Assemble parts and install gearshift control in reverse order of removal and disassembly procedure (above). Note the following points when installing assembly in car:

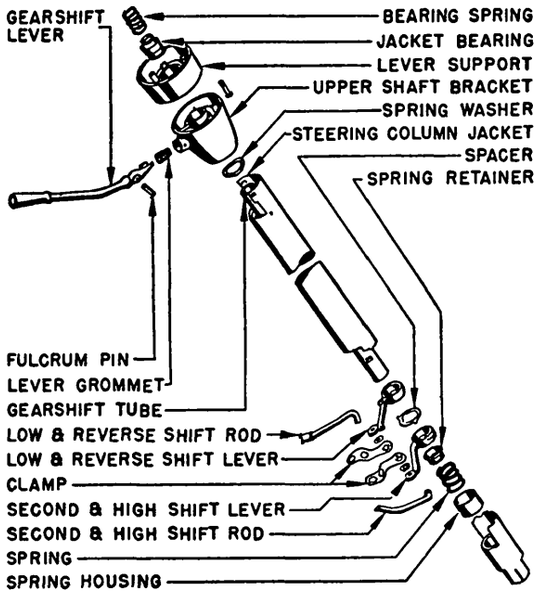
Gearshift Shaft Upper Bracket Pin Installation: Screw pin in tight and then back pin off about ½ turn so that hole in pin will face shift lever opening in shaft when installed.

Collar & Grommet Installation: Use liquid soap to facilitate installation and avoid tearing the rubber collar during installation.

Shift Control Adjustment: Adjust shift rods after installation completed. See Adjustment (above).

1953-55 STUDEBAKER

Champion, All Models (1953-55) With Synchro-mesh Trans.



Commander & President, All Models (1953-55) With Synchro-mesh Trans.

►*REMOTE CONTROL LOOSENESS OR POOR ADJUSTMENT CORRECTION:* When end play or looseness in remote control results in poor shift adjustment it can be corrected by installing a thicker remote control shift lever spacer (was .0478-.058" now .062") Studebaker Part No. 532554.

DESCRIPTION: Remote control gearshift with steering column mounted gearshift lever. Gearshift tube is concentric with steering gear shaft which operates within shift tube.

ADJUSTMENT: Disconnect both transmission gearshift rods at transmission. Place transmission shift levers in neutral (can be determined by feel of detent plungers engaging notches in shaft sectors). Index hand lever support by placing a pencil mark above hand lever support socket. Locate center of travel of gearshift hand lever by moving lever to extreme left and pencil mark steering column upper bracket opposite index mark on lever support. Move lever to extreme right and mark in same manner as above. Place hand lever index mark at the mid-position between the two marks on upper bracket and mark this position on upper bracket to indicate neutral. With an assistant holding the hand lever in neutral and the low-reverse gearshift lever engaged (hand lever toward steering wheel) adjust the low and reverse gearshift rod toward short side so there is no free play in rod and clevis pin will enter shift lever with a slight drag on forward side of hole. Secure all clevis pins and secure and tighten locknut. If interference is still encountered at the cross-over point from low to second due to high tolerances of levers and rods and engine movement, the low and reverse rod may be shortened an additional one or two turns.

REMOVAL OF GEARSHIFT CONTROL: Disconnect battery cable and remove steering wheel (see Steering Gear Section). Remove two nuts holding upper bracket in place. Slip bracket off post and remove bolts. Pull control tube, lever support and lever out of steering jacket as an assembly. To remove the lever, use a suitable drift and drive out the pin holding lever in lever support and pull lever out of support, then slip support off control tube. Disconnect shift rods at levers at bottom of steering column, and loosen clamp bolt at lower end of jacket. Remove jacket bracket retaining bolts at instrument panel and loosen jacket bracket clamp screw and turn bracket to avoid hitting instrument panel when removing jacket. Slip jacket off steering post as an assembly into inside of car. Remove 1st & reverse shift lever, spacer, 2nd & high shift lever, spring retainer, spring, and spring housing from steering jacket.

1953-55 STUDEBAKER TRANS. CONTROL

INSTALLATION OF GEARSHIFT CONTROL: Insert 1st & reverse shift lever, spacer, 2nd & high shift lever, spring retainer, spring, and spring housing in steering jacket. Install control tube into steering post jacket and engage key on tube with keyway of 1st & reverse shift lever, spacer, and 2nd & high shift lever. From inside car, slide jacket assembly down over steering post, turning as necessary to get shift levers through firewall. Connect shift lever rods to shift levers and install spring clamps. Leaving steering column jacket bolt loose, position jacket so shift levers can be operated in all positions of full travel, then tighten clamp bolt. Install jacket bracket-to-instrument panel clamp and tighten clamp bolt. Place spring washer in position and slip steering jacket lever support on steering jacket. Insert lever into lever support and install lever retaining pin. Slip bolts through holes of upper bracket and start nuts on bolts. Push down and shift nuts inward so that head of bolt will be shifted away from center of bracket, and slip bracket into place. With bracket in place, pull up on nuts which will allow heads of bolts to slip toward center into elongated slots of jacket. Tighten nuts securely. Install steering wheel.

1946-55 WILLYS

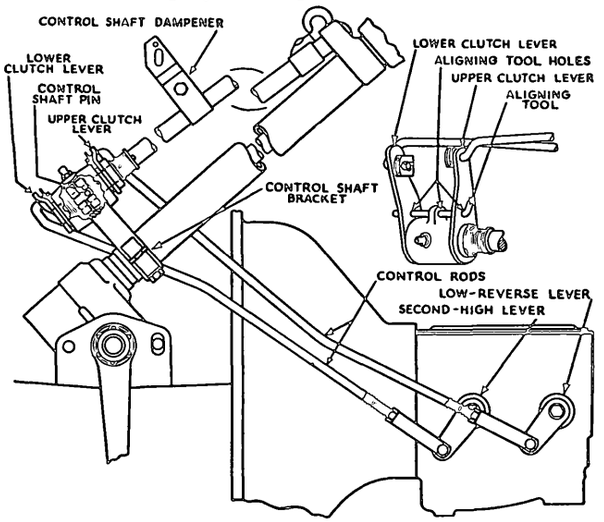
All Models (1946-55 With Steering Column Mounted Gearshift).

▷Hard Shifting & Gearshift Rattle Complaints on First Cars—If shift does not operate smoothly and positively, or rattles noted, correct as follows:

Shift Not Smooth & Positive—Check linkage and adjust control rods (see Adjustment).

Shift Sticks or does not Disengage—Check adjustment. If this does not correct trouble, check Clutch Clearance (see Removal & Installation data below), adjust clearance or replace Clutch Lever and Housing assembly.

Gearshift Rattles—Check Gearshift Lever Clearance and Control Shaft Dampener installation (see Removal & Installation data below).



NOTE—If gearshift lever is found to break at the weld (first cars only) and lever can not be welded, install new Control Shaft Assy. 638022.

DESCRIPTION: Remote control with shift lever on control shaft under steering wheel. Shaft has dog clutch at lower end (pin in shaft engages slots in levers) by which it is engaged with upper lever (connected to rear lever on transmission case) for Low-Reverse, or lower lever (connected to front lever on transmission case) for Second-High engagement. Control rods connecting steering column levers and transmission case levers have adjusting clevises at transmission case end.

ADJUSTMENT: Place shift lever in neutral position. Disconnect both control rods at the transmission levers. On all cars except 6-226, install ¼" rod through aligning holes in steering column. On 6-226 position Tool W-259 on slot and insert 3/16" rod through steering column shift levers and index rod in slot at top of gauge. On all cars, now adjust steering column end of shift rods so that lower ends will enter transmission levers freely. If shift pin strikes edges of slot in lever clutches, disconnect low and reverse control lever at transmission lever (rear lever) and lengthen or shorten rod slightly so that pin will engage both slots freely.

REMOVAL (Except 1952-55 Pass. Cars): To remove shift assembly from steering column, remove steering wheel and remove floor boards. Disconnect control shaft dampener at cowl. Assembly can then be removed by taking out gearshift lever and freeing housing assembly clamp bracket at lower end of steering column.

REMOVAL (1952-55 Passenger Cars): Unscrew the chrome ball cover at base of shift lever and pull out lever. Remove steering column cover and remove the two bolts from bracket attaching steering column to instrument panel and remove bracket. Remove heater grill on dash. Rubber seal at base of steering column must be slit in the space between steering column and remote control shaft. Remove heater and pull back floor mat. Remove control shaft damper. Remove two bolts from cross-shift bracket assembly and remove both shift control rods from levers at end of steering column. Raise front of car about 18" and remove remote control clutch housing and shaft from end of steering column by working them down through toe-panel and past steering gear housing. Remove upper and lower clutch levers from remote control clutch housing by turning counter-clockwise.

TYPICAL WILLYS TRANSMISSION CONTROL

Clutch Clearance—Clearance between faces of shift clutches must be .015-.031" (1/64" to 1/32"). Can be checked by removing lubrication fitting on clutch housing and inserting narrow feeler gauge through this hole. If clearance not correct or if clutch assembly has been dismantled, check clutch pin clearance in slots (must not exceed .009"—replace Clutch Lever and Housing Assembly #116221 if clearance excessive) and set up levers as follows: Screw upper clutch lever in housing as far as possible, then back lever out one full turn until alignment holes line up. Then screw lower clutch lever into housing until clutch face contacts upper clutch lever face, then back lever off ½ turn max. which will give correct clearance of .015-.031" between clutch faces. If alignment holes do not line up in this position, remove lower clutch lever and grind off clutch face squarely not more than .015". It is very important that lower clutch lever be backed off exactly ¼ turn from position where it contacts upper clutch lever and that alignment holes line up in this position. If correct clearance between clutch faces cannot be secured by this method, or if control shaft clutch pin has more than .009" clearance in clutch slots, replace entire clutch lever and housing assembly.

Control Shaft Bracket Position—When installing steering column assembly, see that steering gear outer casing or jacket is positioned so that gear shift control shaft clutch pin bottoms in upper clutch slot when gear shift lever and shaft is in the uppermost position (Low-Reverse). If jacket and brackets installed too far down on steering gear shaft, gear shift control shaft will bottom in upper bracket and prevent clutch pin fully disengaging from lower (Second-High) clutch slots.

Gearshift Lever Clearance—Lever sideplay at fulcrum pin must not exceed .005" (excessive play will cause rattles). To reduce sideplay, add thin washer (.005-.010") under head of fulcrum pin or grind down shoulder on pin so that it will squeeze stamping closer to lever when installed. Also see that anti-rattle trigger spring on gearshift lever has sufficient tension on lever to dampen rattles.

Control Shaft Dampener—When installing dampener, see that it is positioned on cowl so that tension applied to shaft and that dampener cross bolt spacer short enough so that slight drag results on shaft when cross bolt is tightened.

WARNER & SPICER TRANSFER CASE

Willys, All Models with 4-Wheel Drive (1946-55)

►*WARNER TRANSFER CASE NOTE—Both Warner and Spicer Transfer Cases used in production beginning in 1952. Design and repair procedures are similar.*

►**LUBRICATION CIRCULATION BETWEEN TRANSMISSION & TRANSFER CASE CHANGE**—Beginning with CJ-2A Serial Number 24196 (and all later models), two 7/16" holes and two 1/4" holes drilled on rear face of transmission case and two 7/16" holes drilled on front face of transfer case to provide circulation of lubricant between transmission and transfer case.

►***CAUTION—Correct gasket must be used to insure these lubrication holes being open.***

DESCRIPTION: Transfer case consists of an auxiliary transmission bolted on the rear face of the regular transmission and performing these functions:

1) Provides auxiliary speed range (Low & High) controlled by right hand shift lever (Low range useable only when Front Wheel Drive engaged).

2) Enables Front Wheel Drive to be engaged or disengaged (controlled by left hand shift lever).

3) Provides offset drive for front wheels to clear engine (drive for front and rear wheels taken from shaft at right of transfer case).

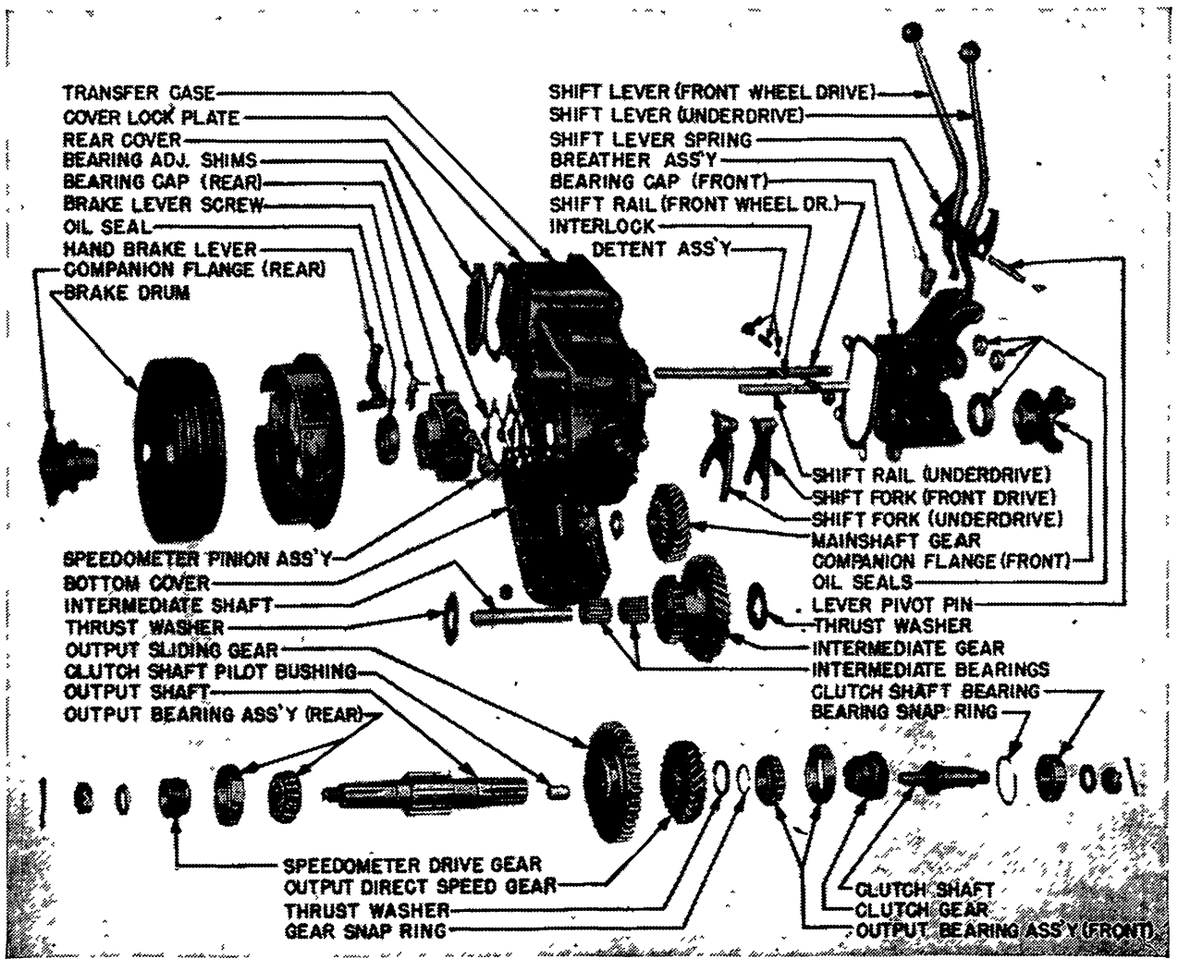
►***CAUTION—Manufacturer recommends that front-wheel drive not be used on dry hard-surfaced roads (will cause rapid tire wear and hard shifting of gears).***

REMOVAL: Transfer case is removed as a unit with transmission (see Transmission Removal data on car model page). Then separate transfer case from transmission as follows: Take out screws and remove rear cover, remove nut on end of shaft and pull gear off end of mainshaft, remove five transfer case mounting screws, pull transfer case off transmission while tapping on end of mainshaft with a soft hammer (CAUTION—Do not allow mainshaft to pull out of transmission case, this would allow transmission synchronizer parts to fall down in transmission case) leaving mainshaft and rear bearing in transmission, place transfer case on bench.

DISASSEMBLY: Take out four screws and remove rear propeller shaft universal yoke, hand brake assembly and brake linkage. Remove transfer case lower cover. Take out retaining screw and remove intermediate shaft lockplate (on rear face of case), drive intermediate shaft out toward rear of case, withdraw intermediate gear, thrust washers, and roller bearing from case. Take out plugs and remove detent poppet balls and springs from both shift rails, move front wheel drive shift rail to engaged (forward) position. Take out mounting screws and remove front output bearing cap and shaft assembly (see disassembly note below) taking care not to lose shift rail interlock plunger. Remove output shaft snap ring and thrust washer. Take out mounting screws and remove rear output bearing cap and shaft assembly (see disassembly note below) which will allow sliding gear and constant mesh gear to be removed from bottom of case. Remove setscrew in sliding gear shift fork, remove shift rail and lift out shift fork.

Front Output Bearing Cap Disassembly Note—Remove nut on end of shaft, pull universal joint yoke, remove oil seal. Take out setscrew in shift fork, remove front drive clutch gear and fork as a unit. Remove output shaft through rear of cap, pressing the shaft out of the bearing using care not to damage bearing. Remove bearing snap ring, remove bearing through rear of cap.

Rear Output Bearing Cap Disassembly Note—Remove nut on end of shaft, pull universal joint companion flange, remove oil seal. Remove speedometer driven gear assembly. Withdraw output shaft through inner end of cap. NOTE—Bearing cone is press fit on shaft and can be pressed off if necessary.



REASSEMBLY: Assemble parts in reverse order of disassembly directions given above and note the following points:

Output Shaft Bearing Adjustment—Install shims between rear output shaft bearing cap and transfer case, as necessary, so that shaft endplay is .004-.008" with front and rear bearing cap mounting screws tight.

Transfer Case Mounting n Transmissi n—Make certain that countershaft and reverse idler shaft lockplate (on rear face of transmission case) is properly positioned so that it fits into recess in front face of transfer case when transfer case installed.

Lubricating Hole Check—When replacing either transmission or transfer case, check for lubricating holes (see Lubrication Circulation Change above), use matching parts (drilled or undrilled) and correct gasket.

►***CAUTION—Gasket used with these drilled cases must have matching holes at these oil circulation holes.***

①—Overdrive with "Centered Ring Gear".
②—Steering column mounted gearshift.
③—Floor mounted gearshift.
④—AS1-T90D (with floor mounted gearshift) used beginning Serial No. 22536.
⑤—AS1-T90C (with floor mounted gearshift) used beginning Serial No. 34787.
⑥—Used beginning late 1952. See "Hudson Transmission" for earlier models.
⑦—Statesman type transmission used after 1953 Serial No. D150580.
⑧—With 4-Wheel Drive.
⑨—With 2-Wheel Drive.

►CHANGES, CAUTIONS, CORRECTIONS

►*1953 RAMBLER TRANSMISSION PRODUCTION CHANGE—"Statesman" Series standard transmission replaced "Warner" type at Car Serial No. D-150580.*

►*1953 RAMBLER & STATESMAN TRANSMISSION SYNCHRONIZER CLUTCH PRODUCTION CHANGE*—"Nash Type" synchronizer clutch replaced "Warner" type temporarily between Car Serial Nos. K-601840 & K-613887 (Statesman); Nos. D-152241 & D-172945 (Rambler). *"Nash Type" & "Warner Type" synchronizer clutch parts are not interchangeable.* If it is necessary to change from one type to the other, it will be necessary to also change the following parts: Clutch Shaft, Second Speed Gear, Shifter Fork (Second & High), Shifter Fork Shoe, and the complete Synchronizer Clutch.

►*HUDSON (EARLY 1952) TRANSMISSION—See "Hudson" transmission data.*

►**"CENTERED RING GEAR" TYPE OVERDRIVE:** These units do not have driveshaft front bearing (see illustration for location of this bearing) and shaft is piloted at the planetary ring gear in a flange which is integral with overdrive case.

►**Willys 4-Wheel Drive Transfer Case**—Two-speed Spicer or Warner Transfer Case mounted on transmission with transmission mainshaft rear bearing mounted in transfer case housing. See "Warner & Spicer Transfer Case" for data.

►*CAUTION—Transfer case must be partially dismantled before it can be removed from transmission.*

DESCRIPTION: 3-Speed, all helical gear type (except Willys 4-Whl. Dr. & Truck—See Note). Constant mesh, synchro-mesh (second & high), sliding gear (low & reverse). Synchronizers are double blocker, double spring type.

Willys 4-Whl. Drive & Truck Note—Transmission has spur type sliding gear and floor-mounted gearshift (entire gearshift mechanism lifts off as unit with top cover). Transfer case is mounted on rear end.

REMOVAL OF TRANSMISSION: *See "Transmission" on car model page.*

DISASSEMBLY OF TRANSMISSION (With Overdrive) Remove overdrive case *(see "Warner R-10 Overdrive" following)*, and then proceed as outlined in DISASSEMBLY OF TRANSMISSION (Without Overdrive), below.

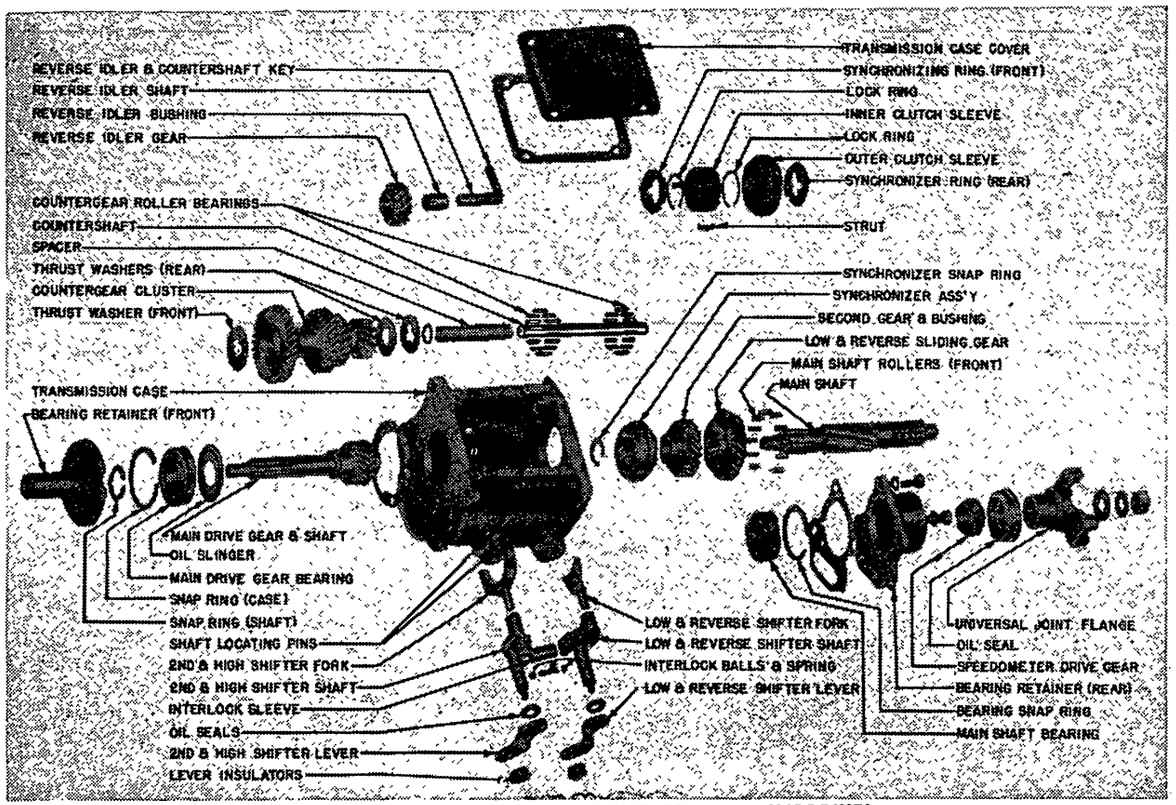
►**LOW & REVERSE SHIFTER FORK REMOVAL & INSTALLATION CAUTION**—Mark position of shifter fork to indicate if "offset" of fork is to front or rear, and install fork in transmission in same position at reassembly.

DISASSEMBLY OF TRANSMISSION (Without Overdrive): Take out cover screws, remove cover and gasket. Mark synchronizer parts (rings, sleeve, hub) to insure reassembly in same relative positions. Take out capscrews and remove bearing retainer on front of case. On Studebaker & Nash, take out bearing snap rings on bearing and shaft, install special Synchronizer Ring Protector J-3042 (Nash Ambassador), J-1525 (Stude. Champ. 1946), J-2040 (Nash Rambler 1950-55 & Stude. Champ 1947-55), J-2039 (Stude. Comm.) to prevent damage to synchronizer, use Puller HM-925 and Adapter Plate J-1298 (Studebaker), and Puller J-1298N (Nash) to remove bearing from shaft. (NOTE—on other cars, gear and bearing assembly can be removed after counter-

CONTINUED ON NEXT PAGE

1946-55
WARNER TRANSMISSIONS (C nt.)

gear cluster has been dropped to provide clearance). Take out rear bearing retainer capscrews, remove bearing retainer from shaft (on models where bearing mounted in recess in retainer, pry retainer out so that puller can be engaged, and use puller to remove retainer). Slide speedometer gear off main shaft (if gear does not come out with retainer and bearing assembly). Tip main shaft toward right as far as possible (on models where rear bearing mounted directly in case, move shaft to rear until bearing clears case), disengage Second & High Speed Shift Fork and Low & Reverse Shift Shoe *(CAUTION—Mark Low & Reverse Shift Shoe so that "offset" in shoe can be installed in correct position at reassembly)*, and lift these parts out. On models where opening in rear of case permits, withdraw complete main shaft assembly through this rear opening. On other models, remove main drive gear and lift it through top of case if bearing removed previously (otherwise tap it out through front of case using a soft drift, being careful not to damage gear teeth). If main shaft can not be removed as an assembly, remove snap ring from groove at forward end of shaft, slide synchronizer assembly, second speed gear, and sliding gear off shaft (lift these parts out through top of case). Lift out counter-gear assembly. Drive reverse idler shaft out through rear of case, using brass drift, and lift gear and bushing out. To remove shifter shaft assemblies, remove levers on outer ends of shafts, drive out lockpins in shaft bosses on side of case, push shaft and lever assemblies through and remove from case. (CAUTION—do not lose detent balls, springs and interlock plunger located in boss in case between lever sectors).



►**Nash Mainshaft & Bearing Retainer Disassembly Note**—To remove shaft from retainer (extension housing), remove bearing snap ring from groove in retainer, press shaft out toward front (bearing and speedometer gear will come out with shaft). To remove bearing from shaft, remove snap ring at rear of speedometer gear, remove gear, remove woodruff key from slot in shaft, then press bearing off shaft.

REASSEMBLY OF TRANSMISSION: Reverse the disassembly directions given above and note special data on all sub-assemblies as follows:

Shift Mechanism: Install complete detent and interlock assembly (plunger, spring, poppet balls, and spacer pin on Kaiser) in the boss in the case, insert shift shaft and levers from within, insert shift shaft lockpins loosely in holes in case to hold levers in place, check and adjust interlock plunger clearance (see below), then drive shaft lockpins down into place, install new oil seal on outer end of each shaft, install outer levers.

►***LOW & REVERSE SHIFTER FORK INSTALLATION CAUTION—Make sure that the Low & Reverse Shifter Fork is installed with the "offset" in the correct direction (as marked at removal).***

Interlock Plunger Clearance—.001-.007" (Willys & Nash), .001-.005" (All Others) clearance between end of plunger and shift lever sector with one lever in neutral and other lever in any gear. To check, place one lever in neutral, move other lever to any gear position, use feeler gauge between end of plunger and lever sector. Adjust by installing plunger of correct length. Plunger furnished in five lengths and marked for identification as follows: Unmarked —1.299", A—1.295", B—1.291", D—1.303".

TYPICAL 1946-55 WARNER TRANSMISSION (NO OVERDRIVE)

Reverse Idler Gear & Shaft: Position gear with offset (longer end of hub) toward front of case, drive shaft in until lockplate slot lines up with rear face of case.

Countergear Cluster: To assemble, install dummy shaft and spacer in gear cluster, install bearing rollers and bearing retainer washer in each end of gear, using grease to retain parts (see Willys note below), install bronze thrust washer on each end with tongue of front washer forward (to engage notch in case), tongue of rear washer forward (to engage notch in gear), install steel thrust washer on rear and install entire assembly in case. Drive countershaft in from rear (pushing dummy shaft out at forward end) until lockplate slot lines up with rear face of case. Check countergear endplay which should be .002-.006" (Kaiser), .006-.016" (Hudson), .004-.018" (Stude. Champ.), .005-.017" (Stude. Comm.), .012-.018" (Willys Jeep & Trucks). Install lockplate to retain counter shaft and reverse idler shaft.

Willys Jeep & 4-Whl. Dr. Truck Bearings—Countershaft has double bearings (two sets of bearing rollers in tandem) at each end of countergear. Install one set of bearing rollers, bearing washer, second set of rollers, second washer at each end.

Main Drive Gear Assembly: If removed and installed as an assembly, this assembly must be re-installed before countershaft inserted (countergear cluster at bottom of case to provide clearance). Use driver to install bearing on shaft. On Nash & Studebaker, install gear without bearing using Synchronizer Protector Ring J-3042 (Nash Ambassador), J-1525 (Stude. Champ. 1946), J-2040 (Stude. Champ. 1947-55, and Rambler 1950-51), J-2039 (Stude. Comm.) when driving bearing on shaft and into case. Select snap rings (large ring on bearing, small ring on shaft) for snug fit without endplay. Bearing snap rings furnished .086", .089", .092", .095" thick. With main drive gear installed in case select gasket of correct thickness (furnished in four thicknesses) so that retainer will be tight fit on case when installed.

►***CAUTION—Bearing must not have any endplay.***

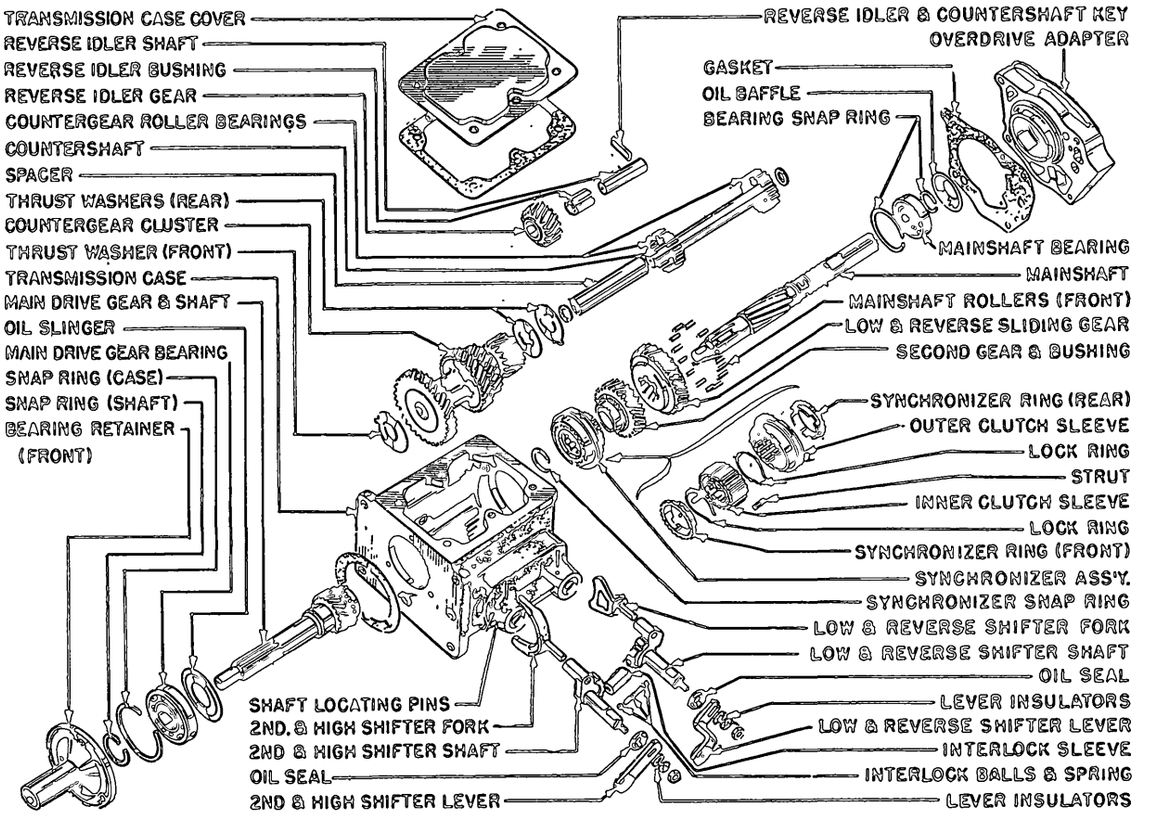
Mainshaft Assembly: When installing mainshaft in case, make certain that pilot bearing rollers in place in recess of main drive gear (use cup grease to hold rollers until shaft inserted). Install sliding gear with shift fork channel toward rear (Studebaker Champion, Willys (Exc. 4-Whl. Dr.), Hudson Jet, Nash Rambler, and Henry J); toward front (All Others), engage shifter shoe in gear (shifter shoe offset should be toward front or rear in relation to gear channel above). Install second speed gear with clutch teeth toward front, install syn-

CONTINUED ON NEXT PAGE

1946-55
WARNER TRANSMISSIONS (Cont.)

chronizer (see data below) with clutch sleeve offset toward front, install snap ring in shaft groove to retain these assemblies. Engage second-high shifter fork in channel of synchronizer sleeve.

Synchronizer Assembly—If synchronizer dismantled, assemble parts according to marks made previously. Install spring in each end of hub with free end of each spring engaging the same strut and springs pointing in opposite directions. Make certain that struts engage slots in synchronizer rings. Install snap ring in groove at forward end of shaft. Check endplay of synchronizer and second speed gear assembly with a feeler gauge between back face of gear and shoulder on shaft. Endplay should be .003-.014" (Kaiser), .003-.010" (Nash), .003-.016" (Hudson & Studebaker Commander), .003-.012" (Studebaker Champion), controlled by snap ring thickness.



Transmission Mainshaft Rear Bearing—To remove mainshaft and rear bearing from adapter plate, remove bearing snap ring from groove in front face of adapter. Use a soft hammer on rear end of shaft to tap shaft and bearing out, lift off oil baffle, remove bearing snap ring from groove in shaft, use puller to remove bearing from shaft.

Mainshaft Installation: When installing mainshaft in case, make certain that pilot bearing rollers in place in recess in main drive gear (use grease to hold rollers until mainshaft inserted). Engage Low & Reverse Shifter Shoe in sliding gear with offset in same direction as channel in gear (see above), engage Second & High Shifter Fork in synchronizer sleeve channel.

Rear Bearing Retainer: On models where rear bearing mounted in retainer, bearing can be lifted out after snap ring removed (speedometer gear accessible with bearing out). Oil seal should be replaced with special driver. When reassembling, make certain that bearing snap ring is snug fit in groove (furnished .086", .089", .092", .095" thick). When installing retainer, use new gasket, tap retainer in place on shaft with special driver (see special Nash Note below), install universal joint companion flange, flat washer, lockwasher, and nut. Tighten nut securely (90-100 ft. lbs.—Hudson).

▷*CAUTION—Speedometer drive gear will slip if companion flange nut not securely tightened.*

▷Nash Bearing Retainer Note—Bearing retainer has extension housing with additional driveshaft bearing (Oilite bushing) in front of oil seal at rear end of housing. To replace bushing (with oil seal removed), assemble felt oil ring on bushing, press bushing in from rear end of housing until shoulder on bushing is ¼" from shoulder in bearing cap (CAUTION—this clearance necessary to prevent compressing oil ring). To assemble retainer, install bearing on mainshaft, install speedometer gear (CAUTION—see that woodruff key in place in shaft groove within gear), install snap ring in shaft groove selecting ring for snug fit so that bearing is tight on shaft. Install shaft assembly in bearing retainer and install snap ring to retain bearing selecting snap ring for snug fit so that shaft and bearing do not have any endplay in retainer.

TYPICAL 1946-55 WARNER TRANSMISSION (WITH OVERDRIVE)

Transmission Cover & Gasket Installation: Some transmissions are vented by means of holes in cover and gasket. Install these parts as follows:

Nash—Gasket and cover marked "FRONT". Install with marks toward engine.

Studebaker & Hudson—Install gasket with two holes toward rear of case, cover with single hole toward front.

▷*CAUTION—Gasket and cover must be correctly installed to prevent lubricant loss through this vent.*

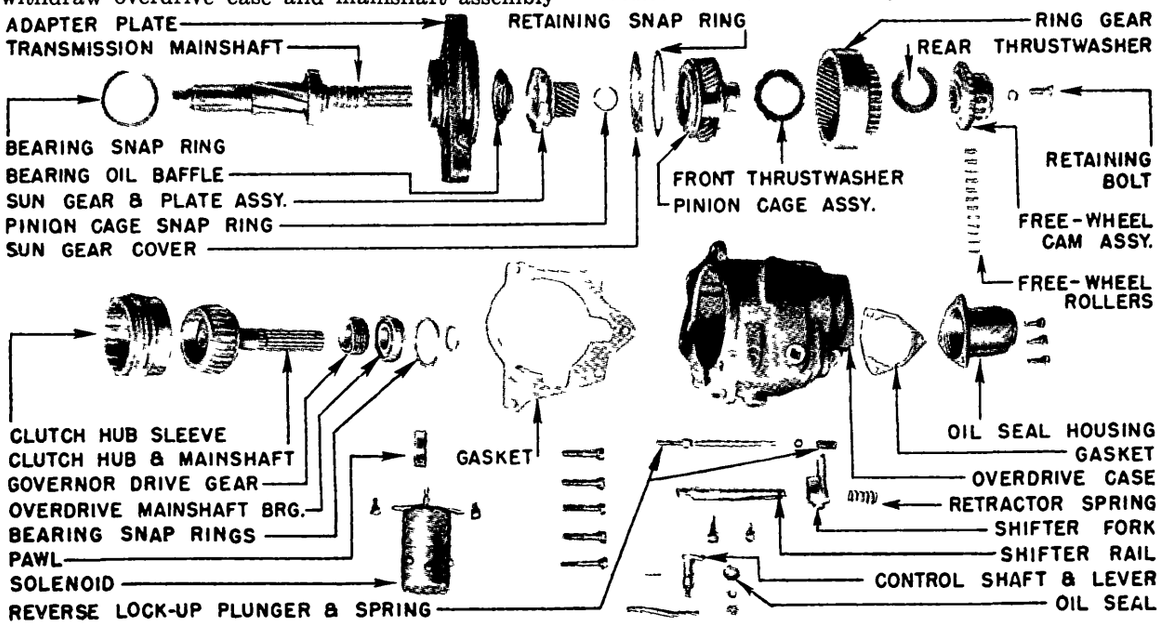
①—Overdrive only (used with own transmission).
②—Part of T86D-R9C Transmission & Overdrive.
③—R11 Overdrive also used on Eng. Nos. 272006 to 285157 and on all later cars.
④—R11 Overdrive also used on Eng. Nos. 424978 to 427710 and on all later cars.
⑤—R11 Overdrive also used on Eng. Nos. 610359 to 611500 and on all later cars

►CHANGES & CORRECTIONS

►**INSTALLATION OF R11 OVERDRIVE ON PACKARD CARS WITH R9 OVERDRIVE**—R9 Overdrive ASSEMBLIES not available (except as noted below—individual parts still available), and new R11 Overdrive Assembly is furnished for these cars in special kit containing necessary installation parts. **R11 Installation data**—See "Warner R11 Overdrive." *NOTE*—R9 Transmission & Overdrive Assembly, Part No. 901147, is available for "2000" & "2100" Series Packard Super Eight.

DESCRIPTION: Simplified overdrive without centrifugal clutch pawls.

REMOVAL OF OVERDRIVE: *See "Overdrive" on car model page.*



TROUBLE SHOOTING & TESTING: *See Warner R9 Overdrive Control data (following).*

DISASSEMBLY: After transmission and overdrive assembly removed from car, take out five bolts attaching overdrive case and adapter to transmission case, separate overdrive case from adapter, withdraw overdrive case and mainshaft assembly (CAUTION—free-wheel rollers will drop out, make certain that all of the 12 rollers are accounted for). Take out free-wheel cam retaining bolt (in rear end of mainshaft), remove lockwasher and retaining washer, then slide free-wheel cam assembly off shaft. Remove clutch hub rear thrustwasher from shaft. Remove clutch hub, ring gear, and pinion cage assembly as a unit (CAUTION—Split pinions will unwind if these parts separated). Remove pinion cage snap ring from groove in shaft, remove sun gear cover snap ring from groove in adapter plate, slide oil collector ring and cover off, remove sun gear assembly (gear, plate, and balk ring). Adapter plate and rear bearing are removed as an assembly with the transmission mainshaft (see Transmission disassembly data). Disasemble all sub-assemblies as follows:

Sun Gear & Plate Disassembly—Remove snap ring from sun gear plate, slide gear out of plate (CAUTION—do not attempt to remove balk ring from plate). Check balk ring friction drag on plate by mounting plate in vise and using spring scale to check pull required to rotate ring on plate (spring hooked to step in balk ring and parallel with step). Pull should be 8-10 lbs. (with ring rotating—greater pull required to start ring moving).

Hub, Ring Gear, & Pinion Cage Disassembly—Pull pinion cage assembly out of ring gear (split pinions will unwind as they are freed from ring gear). Remove ring gear snap ring, withdraw clutch hub from ring gear. Inspect clutch hub bushing. If bushing requires replacement, use Bushing Remover & Replacer J-1568 (Hudson) to install new bushing.

►*CAUTION—Pinions must be properly wound up when reassembled. See Reassembly data.*

WARNER TYPE R9 VERDRIVE

Free-wheel Cam Disassembly—Remove cam roller retainer snap ring, pull roller retainer partly off cam for access to retainer spring, pull end of spring out of hole in free-wheel cam, free second spring in same manner, remove retainer and springs from cam. Mainshaft pilot bushing is light press fit in cam and can be removed and replaced if required.

Overdrive Mainshaft Disassembly—Unscrew governor and remove from case. Remove nut and washers on rear end of shaft, use puller to remove universal joint companion flange from shaft. Pull mainshaft out through forward end of case (CAUTION—Clutch hub sleeve and governor drive gear will remain in case and should be lifted out after mainshaft removed). Take out mainshaft bearing inner snap ring, tap bearing out toward front of case, drive oil seal out toward rear of case.

Shift Control Disassembly—Remove nut and washers on outer end of control shaft, take off control lever. Remove control shaft setscrew, withdraw control shaft from case. Remove plug on side of case, use socket wrench inserted through plug hole to remove shifter head screw and lockwasher. Remove shifter rail stopscrew, withdraw shifter rail, retractor spring, and fork.

Adapter Plate Disassembly—After transmission disassembled, adapter plate parts can be removed as follows: Take out rear bearing snap ring, withdraw transmission mainshaft and bearing assembly. Take out two solenoid base-to-adapter screws, withdraw solenoid, solenoid base, and pawl. To remove interlock plungers, drive out expansion plugs in adapter at end of each plunger hole. To remove interlock lever, drive out lever fulcrum pin.

►*CAUTION—Interlock plungers furnished in different lengths and must be selected for correct reverse gear lock-out. See Reassembly data.*

REASSEMBLY: Reassemble all sub-assemblies and install these parts in case in reverse order of disassembly data and note the following:

Sun Gear Pawl Interlock Plunger (Hudson)—Consists of two plungers and an intermediate lever installed in the adapter plate flange so that one plunger engages the shifter rail and forces the other plunger into engagement with the sun gear pawl with the overdrive locked out which prevents the pawl operating. Long plunger (shift rail plunger) furnished in six different lengths. Install plunger of correct length so that clearance between lower end of plunger and tip of interlock intermediate lever is .008-.021" with long plunger in shift rail groove and top of short plunger against the sun gear pawl.

►*CAUTION—See Overdrive Installation data (at end) for special procedure to insure correct operation of interlock in service.*

Sun Gear & Plate Assembly Installation—Assemble sun gear in plate with two oil slots in gear aligned with slots in plate, install snap ring in plate to retain gear. When installing this assembly in adapter, make certain that solenoid pawl properly positioned in slot in balk ring.

Solenoid & Pawl Assembly—Install solenoid base and solenoid with one gasket between base and adapter, and one gasket between solenoid and base. After solenoid installed, check clearance between end of pawl and step on balk ring with pawl out to end of solenoid plunger maximum travel. Clearance must be .015". Adjust by using not more than two

CONTINUED N NEXT PA E

WARNER R9 OVERDRIVE (Continued)

gaskets between solenoid and base. *See Warner R9 Overdrive Control (following) for solenoid data.*

Shift Control Installation—Place shifter rail retractor spring and fork in case before inserting shift rail, make certain that wide groove in rail is in line with stopscrew hole in case. Install new control oil seal before installing control shaft. Make certain that shifter rail fork guide pin engages notch in shifter fork when installing this pin.

Overdrive Mainshaft Installation—When installing rear bearing, select snap ring for snug fit in groove. This ring furnished in five thicknesses for selective fit on Hudson (see Packard Note below). Install new oil seal in rear end of case (on Hudson, seal should protrude 9/32" beyond rear face of case). Make certain that clutch hub sleeve installed with shallow groove to front and that shifter rail fork engaged in fork groove in sleeve. Install speedometer gear with shoulder toward rear.

Free-wheel Cam & Roller Installation—If roller retainer removed, insert springs in retainer with ends pointing in clockwise direction, install retainer on cam, use small screwdriver to work springs around cam and insert ends in holes in cam. Install retainer snap ring (on Hudson, use Snap Ring Replacer J-1499 with Pilot J-1499-2). Use grease to hold free-wheel rollers in retainer until assembly inserted in pocket in mainshaft.

Hub, Ring Gear, & Pinion Gear Installation—After sun gear assembly installed, install pinion cage assembly and clutch hub front thrustwasher (CAUTION—lip on washer must be engaged in cutout in pinion cage on sun gear and washer should be coated with grease). Lock transmission gears (to facilitate winding up pinions), and use a punch or wedge inserted through side of pinion cage assembly to lock the forward halves of the three split pinions. Install ring gear to point where it engages the rear or narrow halves of all three pinions, then wind up pinions by rotating ring gear clockwise 1½ teeth (teeth on narrow half pass 1½ teeth on wide half of pinions) so that marked pinion teeth line up, push ring gear fully into place so that it meshes with both halves of all pinions. Remove wedges. Complete assembly by installing clutch hub rear thrustwasher (coat washer with grease) and free-wheel cam assembly, then install retaining washer, lockwasher, and bolt.

OVERDRIVE INSTALLATION (On Transmission Case): Use new gasket between overdrive case and adapter. Make certain that solenoid and pawl assembly correctly installed (pawl must engage notch in balk ring). Move shift control lever to forward position, tilt overdrive case at slight angle and rotate overdrive mainshaft in counter-clockwise direction while pushing case forward into position (CAUTION—this procedure necessary to enter free-wheel cam rollers in pocket in mainshaft). Align overdrive case, adapter, and transmission (see Hudson Note below), install and tighten all overdrive case-to-transmission bolts.

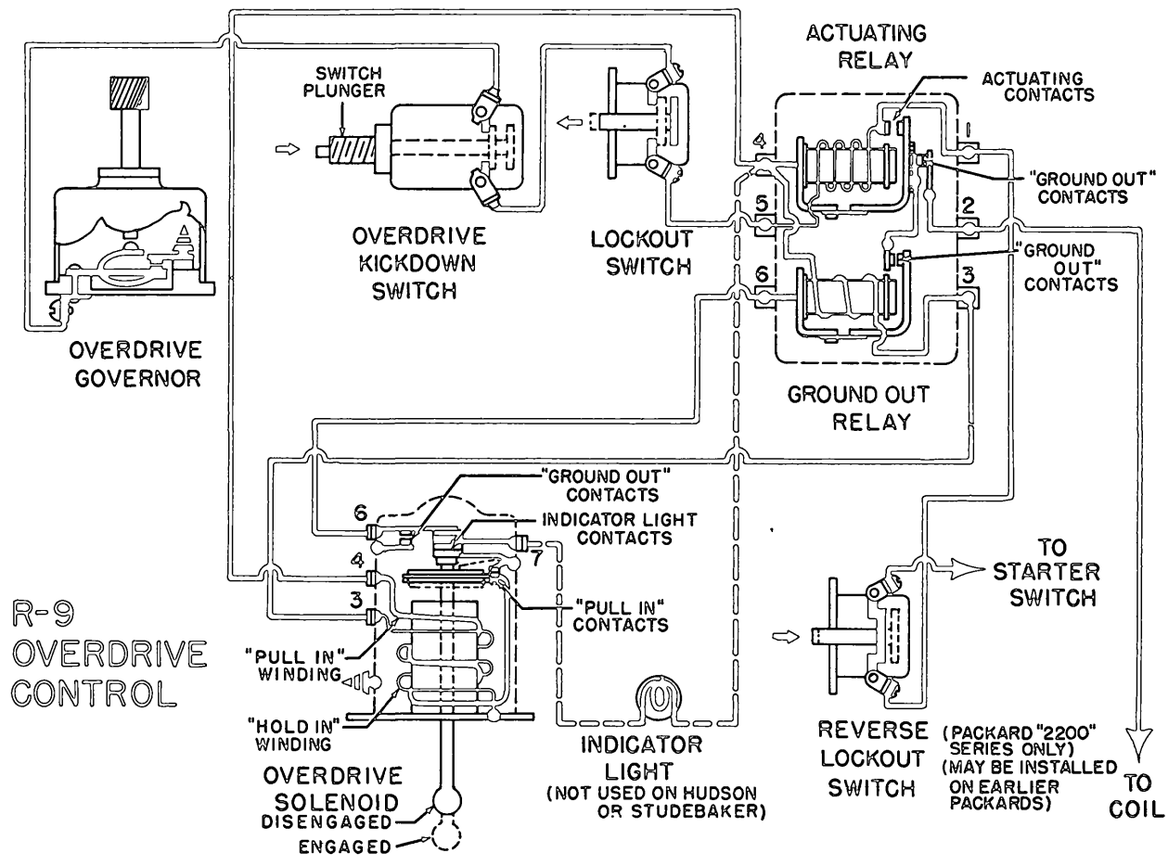
WARNER R9 OVERDRIVE CONTROL

Hudson 6 & 8, All Models (1941 to 1947)
Hudson 6 & 8, All Models (1948-49)
Packard 6 & 8, All Models (1940 to 1948)
Packard Super & Cust. 8, All (1940 to 1948)
Studebaker Pres., 8C (1942) No. 7147625 Up

▷NOTE: Hudson 1948-49 models have new R10 Overdrive, but use Warner R9 Overdrive Control.

DESCRIPTION: Special design, electrical control with 'kick-down' direct drive feature. New type Transmission Solenoid is 'push type' and pushes pawl in to engage sun gear mounting plate slot (to hold sun gear stationary for overdrive) when solenoid is energized. Spring in solenoid case pulls pawl

ADJUSTMENT: Lock-out Control Button Linkage. Button should clear bracket by ⅛" when pushed in to insure full travel of control travel on overdrive case. To adjust, loosen control cable at binding screw on lever on left side of overdrive case, push control button in as far as possible, then pull button out ⅛" (all models except Hudson), ½" (Hudson). Move the control lever on overdrive case to rear as far as possible, then move lever forward until a resistance just felt, tighten binding screw.



Throttle Kick-down Switch Adjustment:

Hudson Throttle Switch (1942-49). Switch must open and relay operate just after throttle is fully open. If relay does not operate, loosen locknut and adjust throttle switch up under accelerator pedal until pedal just contacts switch plunger with throttle wide open. If relay does not operate when pedal depressed beyond wide open throttle position, replace throttle switch.

Packard Throttle Switch—Should be adjusted whenever carburetor linkage adjusted or disconnected. To check setting, remove air cleaner (to observe throttle valve), open throttle until valve is just wide open. If tappet screw on accelerator link lever does not contact throttle switch plunger at this point, adjust by loosening locknut and turning screw in or out of lever.

Studebaker Throttle Switch—Depress accelerator pedal until throttle valve is wide open and throttle lever contacts wide open throttle stop, hold in this position, loosen locknut on switch mounting stud, adjust switch on mounting bracket until end of accelerator rod just contacts switch plunger.

CONTINUED ON NEXT PAGE

R9 OVERDRIVE CONTROL WIRING DIAGRAM

WARNER R9 OVERDRIVE CONTROL (C nt.)

G vernor: Mounted on rear end of overdrive case and driven from final driveshaft. Controls cut-in speed

►*CAUTION—Governor is not adjustable.*

Car Model	Cut-in Speed
Hudson (All Models)	22 MPH.
Packard '41-48 (Overdrive Only)	22 MPH.
Packard '41-42 (Electromatic Clutch)	20 MPH.
Studebaker '42	20 MPH.

FUSES: Hudson—No fuse is used.
Packard—30 ampere. Located in a fuse container in the line between the starting switch and the Solenoid Relay '1' terminal. Do not use fuse of any other capacity at this point.
Studebaker. Fuse is located in socket on side of control relay mounted on front of dash.

TROUBLE SHOOTING: Failure of the overdrive to operate satisfactorily may be caused by mechanical failure (of overdrive unit or control units) or by electrical failure (of control units and wiring).

OVERDRIVE DOES NOT ENGAGE

1. **Mechanical Causes:**
   1) Sun Gear Pawl sticking or broken, or Interlock Plungers sticking and locking pawl in outer position. Remove solenoid (see Solenoid Testing data), check pawl for free operation. *NOTE*—Overdrive must be disassembled for pawl removal.
   2) Solenoid Plunger sticking, Pawl Rod out of adjustment. Check for correct installation and adjustment. See Solenoid adjustment data.
   3) Balk Ring faulty or incorrectly installed (may be indicated by spasmodic or harsh engagement).
2. **Electrical Causes:**
   1) Fuse blown or open-circuit in control wiring.
   2) Governor, Relay, or Lock-out Switch defective (contacts sticking open). See Control Unit Testing (following).
   3) Solenoid defective (pull-in or hold-in coil open, pull-in coil contacts sticking open). See Control Unit Testing (following).

OVERDRIVE DOES NOT DISENGAGE OR NO "KICK-DOWN"

1. **Mechanical Causes:**
   1) Sun Gear Pawl sticking or broken. Remove solenoid (see Solenoid Testing data), check pawl for free operation and correct engagement with pawl rod ball end. *NOTE*—Overdrive must be disassembled for pawl removal.
2. **Electrical Causes:**
   1) Governor or Relay defective (contacts sticking closed). See Control Unit Testing (following).
   2) Ignition cut-out or ground wire open-circuited or disconnected at ignition coil or distributor.

OVERDRIVE CANNOT BE LOCKED OUT

1. **Mechanical Causes**—Shift control cable out of adjustment, disconnected, or broken. Shift control mechanism in overdrive case incorrectly assembled.
2. **Electrical Causes**—Lock-out Switch shorted.

OVERDRIVE NOT LOCKED OUT IN REVERSE

►*CAUTION*—Above condition may result in transmission being in two gears at once (overdrive and reverse) and this "lock up" will cause damage to overdrive mainshaft if engine power applied.

1. **Mechanical Causes:**
   1) Lock-out collar sticking. May be caused by wrong type or cold lubricant (drain and refill with correct type lubricant).
   2) Burred or worn splines on free-wheel clutch cam, overdrive mainshaft, or in lock-out collar. Check for free movement of lock-out collar by disconnecting control cable at shift control lever on overdrive case and operating control by hand.
   3) Sun Gear Pawl sticking, broken, or not properly engaged on pawl rod. Remove solenoid (see Solenoid Testing data), check pawl for free operation. NOTE—Overdrive must be disassembled for pawl removal.
   4) Solenoid Plunger sticking or Pawl Rod out of adjustment. Check for correct installation and adjustment. See Solenoid Testing & Adjustment data.
2. **Electrical Causes:**
   1) Governor or Relay contacts sticking in closed position.
   2) Control wiring or control unit terminals grounded.
   3) Lock-out Switch or Kick-down Switch grounded.

►*PACKARD REVERSE SWITCH NOTE*—This switch used on "2200" Series and can be installed on previous series cars to prevent locking up of transmission in reverse. *See Change & Correction data.*

TESTING & ADJUSTMENT (Control Units): Switches and Governor should be serviced by replacement. Relays and Solenoids should be checked and adjusted as follows:

Control Relay (Hudson & Packard Models): Delco-Remy No. 1116823 (std. 6 volt), 1116802 (Exp.12 volt). Relay is special two-unit type (Control Relay and Timing Relay) and each unit is adjusted differently as follows:

Control Relay

Air Gap—.012" (lower contacts closed), .032" (lower contacts open). Check first with armature held down so lower contacts closed, adjust by loosening two screws on hinge bracket on back of relay and raising or lowering armature, see that gap uniform across whole surface of core. Then check air gap with armature released (upper contacts closed), adjust by bending upper contact support—do not loosen hinge bracket screws.

Contact Gap—.022" (top contacts) with lower contacts held closed. Should be correct if air gaps correct (above) and contact spring not bent.

Closing Voltage—3.4-4.0 (6 volt units), 6.8-8.0 volts (12 volt units). CAUTION—This voltage will attract armature and close lower contacts (upper contacts open as lower contacts close). To check closing, connect battery and variable rheostat to relay terminals #1 and 5, increase voltage and note when contacts close. To adjust, bend spring hanger at upper and lower end of spiral armature spring.

Timing Relay

Air Gap—.031" with contacts open. Adjust by bending upper armature stop—do not disturb armature hinge bracket mounting screws.

Contact Gap—.022". Adjust by bending lower contact support.

Closing Voltage—.6-1.1 volt (6 volt units), 1.2-2.2 volts (12 volt units). To check closing, connect battery and variable rheostat to terminals #3 and 4, increase voltage and note when contacts close.

'Time Delay' Action—.1-.2 seconds (between instant current flow through winding is stopped and opening of contacts). To check timing action on car, operate engine at medium speed, close control relay lower contacts by hand (timing relay contacts will close), release control relay contacts and note interval before timing relay contacts open (lag should be noticeable). Adjust by bending spring hangers on upper and lower end of spiral armature spring (increase spring tension to shorten time interval).

Control Relay (Studebaker): Auto-Lite Model HRB-4301. This is a conventional single unit relay (similar to horn relays, etc.).

Contact Gap—.034-.038" (bend armature stop).

Air Gap—.012-.017" with contacts closed. Adjust by raising or lowering stationary contact support.

Closing Voltage—2.8-3.6 volts. Adjust by changing armature spring tension (bend lower sprg. hanger).

Coil Winding Current—.44-.46 amperes at 6.0 volts (coil winding resistance 12.9-13.5 ohms).

Transmission Solenoid (All Models): Delco-Remy No. 1118005 (Std. 6 volt), 1118007 (Export 12 volts). Solenoid cover can be removed for inspection and servicing by removing two nuts on studs on cover.

CAUTION—Pawl rod must not be forced into solenoid with cover removed. This will damage the contact plate flat springs.

►***SOLENOID REMOVAL (for Checking & Adjustment):*** The solenoid can be removed without disassembling the overdrive by following procedure: With ignition switch turned on and overdrive control button pushed in, ground the overdrive control terminal on the governor ("AD" terminal on Packard, Cadmium plated terminal on Hudson) which will energize the solenoid and extend the solenoid plunger. Take out two solenoid mounting screws, tilt solenoid to rear to disengage ball end on pawl rod from milled slot in pawl. Disconnect solenoid leads, withdraw solenoid assembly. **Installation Note**—Reverse the above procedure and energize the solenoid after the leads have been connected to facilitate engaging ball in pawl slot.

Solenoid Operation Test—Plunger actuating voltage should be 4.9 volts (6 volt units), 6.8 volts (12 volt units) max. at room temperature. To check performance, block pawl rod so that it cannot move out of solenoid when plunger is actuated, remove solenoid cover, connect voltmeter, battery, and variable rheostat between terminals #3 and 4 (connect these terminals together) and ground on solenoid case. Increase voltage and note voltage reading at point where plunger is actuated.

Pull-in Coil Contact Gap—With solenoid bottomed in coil, pull-in coil contact gap should be .018-.040". Remove solenoid cover to check these contacts. See Pawl Rod Adjustment below.

Solenoid Current Draw—To check current connect battery and ammeter between #4 terminal and ground on solenoid case (Pull-in Coil), or #3 terminal and case (Hold-in Coil). This check must be made at specified voltage. 'Both Coil' figure below is for both Pull-in and Hold-in Coil together, 'Hold-in Coil' figure is for Hold-in coil only.

6 Volt Units

Both Coils	31.0-36.0 amperes at 6.0 volts.
Hold-in Coil	1.4-1.6 amperes at 6.0 volts.

Pawl Rod Adjustment—With pawl rod assembly removed from solenoid, check length from lower face of adjusting nut on upper end of pawl rod to lower edge of plunger. This distance should be 2.022-2.037". To adjust, press down on locking spring below adjusting nut so that prong on spring clears notch in nut, turn nut on plunger. CAUTION—Use care not to distort locking spring and see that prong on spring engages notch in nut after adjustment completed.

⑧—Used with "Statesman" transmission after D-150580 (1953).
⑨—Beginning 1946 Service Serial No. N6-120026.

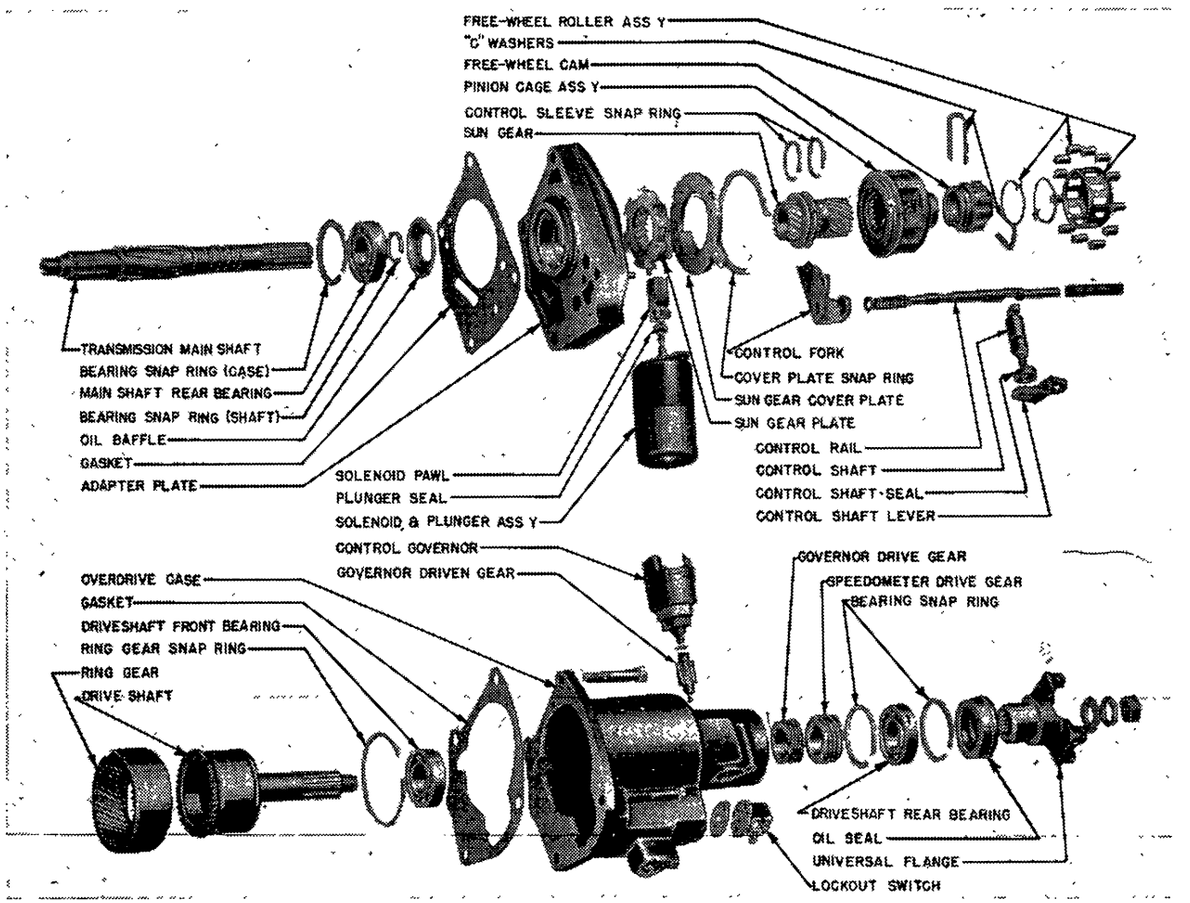
►CHANGES, CAUTIONS, CORRECTIONS

►**1949-55 FORD, LINCOLN, MERCURY OVERDRIVE:** See "Ford, Lincoln, Mercury Overdrive" (Warner R10).

►**1953-55 DESOTO, DODGE, PLYMOUTH**—*See DeSoto, Dodge, Plymouth (Warner R10)" Overdrive.*

►**1955 CHEVROLET OVERDRIVE:** *See "Chevrolet Overdrive" (Warner R10).*

DESCRIPTION: Overdrive is solenoid operated type (no centrifugal pawls) with governor control and accelerator controlled "kick-down."



►**CENTERED RING GEAR ON OVERDRIVE OUTPUT SHAFT:** Overdrive has one bearing on output shaft. Shaft is piloted at planetary ring gear in a machined flange integral with overdrive housing.

REMOVAL OF OVERDRIVE: *See car model page.*

TROUBLE SHOOTING & TESTING: *See "Warner R10 & R11 Overdrive Control" following.*

DISASSEMBLY OF OVERDRIVE: Remove Lock-out Switch, remove governor by unscrewing it from housing. On Nash models, take out mounting screws and remove Torque Tube Adapter, remove oil seal with Puller J-2497, then remove snap ring from shaft directly in back of driveshaft rear bearing. On all other cars, remove nut on rear end of shaft, use puller to remove universal joint companion flange. Drive out tapered pin holding control lever shaft in overdrive case, pull shaft out as far as possible to disengage operating cam from shift rail. Remove four mounting screws holding overdrive case on transmission case, withdraw case while tapping on rear end of shaft with a soft hammer to prevent the shaft coming off with the housing (this would

CONTINUED ON NEXT PAGE

WARNER TYPE R10 OVERDRIVE (FIRST TYPE—N T CENTERED RING GEAR)

WARNER R10 OVERDRIVE (C nt.)

allow free-wheel rollers to drop out). Then disassemble each part of the overdrive as follows:

Overdrive Solenoid—Remove mounting capscrews and lockwashers at mounting flange, rotate solenoid clockwise ¼ turn to disengage plunger from pawl, withdraw solenoid and plunger assembly.

Overdrive Case (incl. control parts)—Remove reverse lock-up spring from housing, take off nut and remove control lever from shaft, remove control shaft from within case, remove shaft oil seal. If both bearings remain within case (see "Driveshaft Bearing Change" above), use brass drift to tap front bearing out, lift out speedometer and governor drive gears, remove oil seal from rear of case, take out rear bearing rear snap ring, use brass drift to tap bearing out at rear of case.

Driveshaft & Planetary Gears—Install one screw to hold adapter plate in position on transmission case. Pull driveshaft off to rear (CAUTION—catch free-wheel rollers as they fall out). Ring gear can be removed from driveshaft by taking out snap ring at rear end of gear. Remove retaining clip ("C" washer) from shaft at rear of free-wheel cam, slide free-wheel unit and pinion cage assembly off rear of shaft (these units can be separated by taking out retaining clip or "C" washer at rear of pinion cage). Remove overdrive sun gear and shift rail assembly as a unit by sliding them off rear of shaft.

Adapter Plate Sun Gear Parts—Remove large snap ring from adapter plate (in front of sun gear cover plate), withdraw sun gear cover plate, sun gear blocker assembly (with balk ring), and solenoid pawl. NOTE—Adapter plate is removed as a unit with transmission mainshaft, gears, and synchronizer. Do not disturb adapter plate unless transmission being disassembled.

REASSEMBLY OF OVERDRIVE: Assemble parts in reverse order from disassembly directions (above) and note the following important points:

Transmission Mainshaft Rear Bearing Installation—After installing bearing on shaft, select proper thickness snap ring so that bearing will have no endplay when snap ring installed in shaft groove. Insert baffle in adapter, install mainshaft and bearing, select snap ring of correct thickness (furnished in various thicknesses) so that there will be no clearance between ring and bearing when snap ring installed in adapter groove.

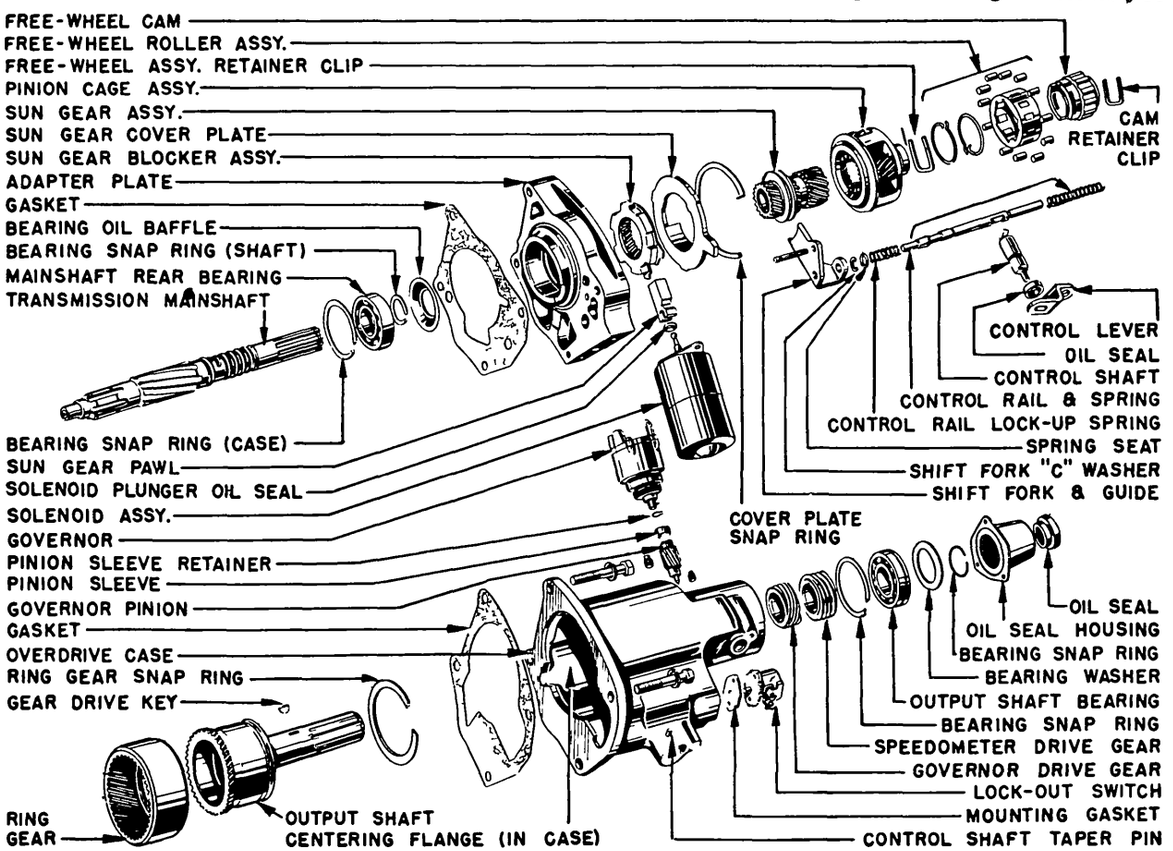
►*CAUTION—Bearing must not have endplay on shaft or in adapter plate.*

Sun Gear Balk Ring—With sun gear assembly removed, check friction drag of balk ring on plate by clamping the plate in a vise and using a spring scale hooked to the step on the balk ring (scale held parallel to step) to measure the pull required to rotate the ring on the plate. This pull should be 4-6 lbs. (new ring—may fall to 1-1½ lbs. after ring thoroughly broken in) with the ring turning (greater pull will be required to start ring rotating). Replace balk ring if friction drag not correct.

Sun Gear Blocker, Pawl & Solenoid—Install pawl with notched side upward, rotate blocker assembly so that opening in balk ring is opposite pawl. When installing solenoid, insert plunger stem with solenoid turned 90° from mounting position, then rotate solenoid 90° counter-clockwise to engage pawl and install mounting screws.

►**Hudson Interlock Plunger Note**—Interlock plunger must engage notch on side of pawl. This plunger furnished in six lengths for selective fitting so that clearance between end of plunger and side of pawl should be .008-.021" with opposite end of plunger contacting shifter rail (not sleeve). Check with pawl fully engaged in slot in sun gear.

Free-Wheel Assembly—If free-wheel cam retainer and springs removed from free-wheel cam, first note position of springs and replace in exactly same positions. Springs must plac tension on cam so that it is held normally in a counter-clockwise position (viewed from rear) in retainer with rollers on "high" ends of cam ramps (outward or engaged position).



Overdrive Pinion & Free-Wheel Installation—With these parts installed on shaft, and retaining clips ("C" washers) properly installed, insert free-wheeling rollers in cage and use heavy grease to hold them in position, turn cage and rollers counter-clockwise to low or disengaged position (use a rubber band looped around assembly to provide sufficient pressure on rollers to hold them in this position against the spring tension), then install driveshaft and ring gear assembly.

Overdrive Case and Control Mechanism—Make certain that rear bearing snap rings are properly seated and snug in grooves (rear snap ring furnished in various thicknesses). On Nash, install front bearing and speedometer and governor drive gears on driveshaft (CAUTION—make certain that woodruff key in place in shaft to position both gears). On other cars, install speedometer and governor gears in rear end of case, then tap front bearing in place. Install new shifter shaft oil seal in recess in case, then install shifter shaft from within case. When installing case, see that shift fork properly engaged in sun gear shifting collar and that shift rail parts correctly assembled. After case installed, push shifter shaft in to engage notch in shift rail, install shifter shaft lockpin, check operation of shift mechanism for correct operation without binding. On Nash, install snap ring in driveshaft groove directly back of rear bearing, install oil seal. On all models except Nash, install universal companion flange, tighten nut on end of shaft securely.

►*CAUTION—Universal companion flange nut must be securely tightened to prevent governor and speedometer drive gears slipping on shaft.*

OVERDRIVE CONTROL: *See Warner Type R10 & R11 Overdrive control data (following).*

TRANSMISSION DISASSEMBLY & REASSEMBLY: *See Warner Overdrive Transmission data.*

WARNER TYPE R10 OVERDRIVE (LATER—CENTERED RING GEAR)

WARNER R11 OVERDRIVE

PACKARD	①Warner Models
Eight, "2200" Series (1949)②	AS3-R11
Super 8, "2200" Series (1949)③	AS4-R11
Cust. 8, "2200" Series (1949)④	AS4-R11
Eight, "2300" & "2300-5" (1949-50)	AS3-R11
Super 8, "2300" & "2300-5" (1949-50)	AS4-R11
200 & 300 "2400" Series (1951)	AS6-R11
2500 Series (1952), 2600 Series (1953)	AS8-R11
5400 Series (1954), 5500 Series (1955)	AS8-R11

①—Overdrive unit only (used with Packard Transmission.

②—Beginning Engine No. 285157 (both R9 & R11 Overdrives used from Eng. No. 272006 to 285157).

③—Beginning Engine No. 427710 (both R9 & R11 Overdrives used from Eng. No. 424978 to 427710).

④—Beginning Engine No. 611500 (both R9 & R11 Overdrives used from Eng. No. 610359 to 611500).

▷CHANGES, CAUTIONS, CORRECTIONS

▷PACKARD OVERDRIVE FAILURE TO ENGAGE (First cars with R11 Overdrive)—Caused by incorrect length of Overdrive Reverse Plunger (Overdrive will not engage in 2nd. or High—may be engaged in Low), or of Overdrive Shift Rail (Overdrive will not engage in Low). After determining exact cause by road-testing car (make certain that electrical control system not at fault if overdrive will not engage in any gear), correct trouble as follows:

Will not engage in 2nd. & High—Remove transmission case cover, grind approximately .020" from face of left hand pad on Low-Reverse Shifter Fork to permit full forward travel of overdrive reverse plunger.

Will not engage in Low—If this condition not caused by failure of electrical control system, disassemble overdrive and check overdrive shifter rail to make certain that rail moves far enough forward so that undercut in rail aligns with solenoid pawl (to permit pawl to operate). If not, grind approximately .020" off end of shifter rail.

▷INSTALLATION OF R11 OVERDRIVE ON PREVIOUS MODELS (to replace original R9 Assembly)—R11 Overdrive Assembly and other necessary parts furnished in kits (Part No. 410603 for 2201, 02, 11, 22, 32; No. 410604 for 2206, 13, 26, 33). Install these assemblies as follows:

"2100" Series Cars

1. Remove transmission cover and change Direct & Second Speed Shifter Fork Shaft. Install new shaft No. 379004 or remove shaft from old cover and install in new one.

2. Install Overdrive Assembly and control units in same manner as on "2200" series (following).

"2200" Series Cars

1. Remove old Overdrive Relay. Cut off all six wires close to harness and tape wire ends.

2. Drill 9/64" hole at point 1½" toward center of car from outer attaching screw hole of relay, use rubber spacer at this hole and install new Relay.

3. Remove old Kick-down Switch. Cut off wires and tape wire ends. Install new Kick-down Switch.

4. Install new Wiring Harness along main wiring harness and attach with strap clamps (8 provided). Connect harness wires at relay, starter, ignition coil, kickdown switch, ignition switch and lockout switch.

See Warner R11 Overdrive Wiring diagram on following page.

5. Check type of front universal joint and if car equipped with Spicer Universal, remove flange from old overdrive and install this flange on new R11 overdrive (Overdrive furnished with flange for Mechanics Universal—not necessary to make this change if car has Mechanics universals).

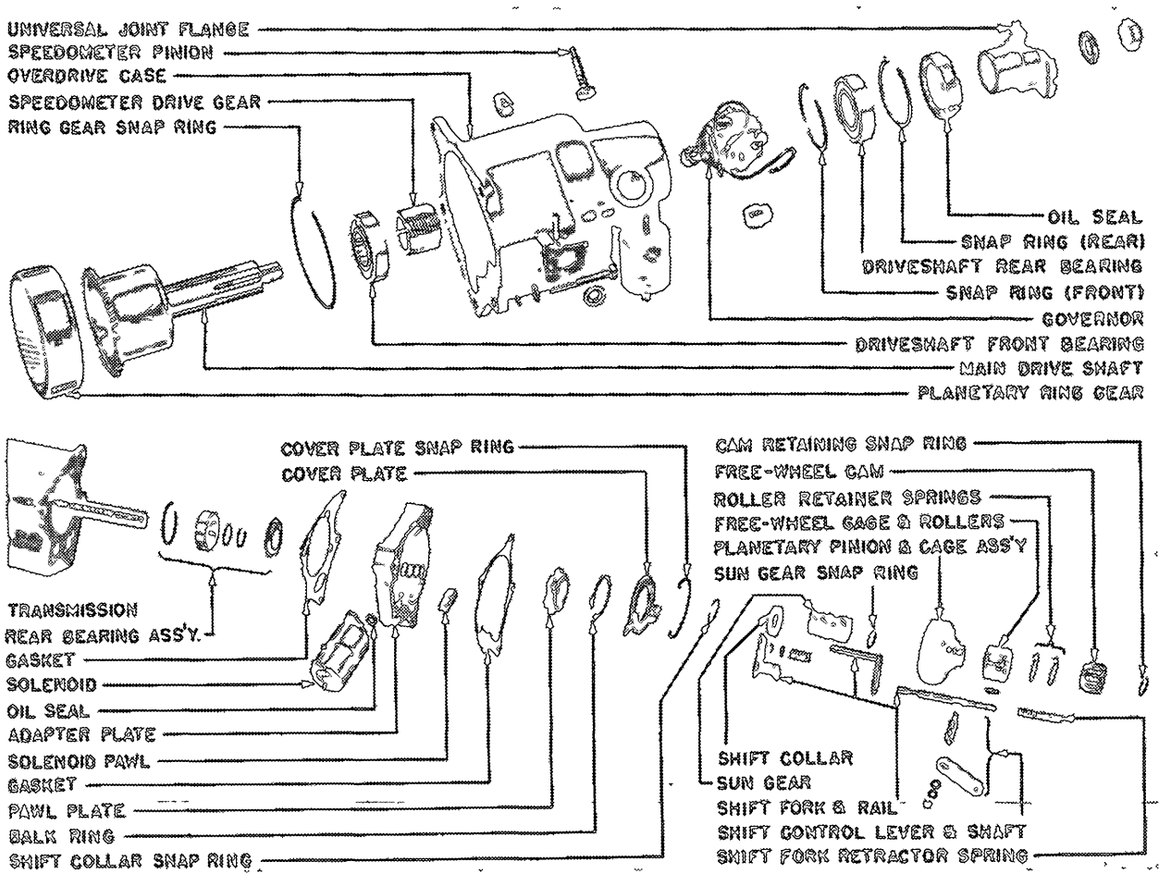
6. Install R11 Transmission and Overdrive assembly. Re-install rear engine support channel turned end-for-end so that lockout cable bracket holes are on left side.

7. Cut solenoid wires and governor OVERDRIVE wire close to old harness and tape wire ends. Do not cut governor ELECTROMATIC CLUTCH wire. Connect wires in new auxiliary harness to solenoid and governor, connect Electromatic Clutch wire in old harness to governor.

▷*CAUTION—Do not disturb Electromatic Clutch wire in old harness. This wire must be connected to governor.*

8. Replace original speedometer pinion with correct replacement type: No. 412442 (17 tooth), No. 412443 (18 tooth), No. 412444 (19 tooth).

▷*CAUTION—Speedometer gear in R11 overdrive is different than R9 type and will not operate with R9 pinion.*



9. Move overdrive lockout cable to left side of engine and install new cable bracket and clamp at support channel mounting holes. Install cable clamps at Electromatic Clutch control valve rear mounting screw hole and at lower flywheel cover mounting screw hole.

DESCRIPTION: The R11 overdrive differs from the R9 overdrive used on previous models as follows:

Overdrive Lockout Shift Mechanism—Overdrive is locked out by shifting the sun gear to the rear, out of engagement with the stationary sun gear plate, and into engagement with planetary pinion cage assembly, so that the gears are locked together. No separate shift collar is used.

Sun Gear Pawl Lockout Mechanism—Pawl is held

CONTINUED ON NEXT PAGE

WARNER R11 OVERDRIVE

WARNER R11 OVERDRIVE (C nt.)

in disengaged position (for Reverse and when overdrive locked out) by engagement of the shift rail in a notch on the side of the pawl (no interlock plungers used).

Control System—New two-terminal solenoid and single unit relay used with simplified circuits. *See wiring diagram for units and connections.*

REMOVAL OF OVERDRIVE: *See "Overdrive" on car model page.*

TROUBLE SHOOTING & TESTING: *See "Warner R10 & R11 Overdrive Control" following.*

DISASSEMBLY OF OVERDRIVE: Remove governor (special wrench J3227), remove solenoid by taking out two retaining screws and rotating solenoid approximately ¼ turn clockwise to disengage plunger from pawl. Drive tapered pin retaining control shaft up and out of boss in case, work shaft and lever outward as far as possible to disengage shaft from shifter rail. Take out five overdrive case-to-adapter mounting screws CAUTION—do not disturb two screws retaining adapter on transmission). Remove overdrive case and drive shaft by pulling to rear away from the adapter (CAUTION—do not lose shift rail retractor spring or free-wheel rollers which may drop down into case). Then disassemble all parts of overdrive as follows:

Overdrive Case (including Control Parts)—Remove nut retaining universal joint flange on rear end of shaft, use puller J2576 to remove flange from shaft. Remove shaft through forward end of case by tapping on rear end with soft hammer to free shaft from bearing. Drive front bearing out of case using a brass drift inserted through rear bearing. Lift speedometer gear out. Pull oil seal at rear end of housing (Axle Shaft Oil Seal Remover J943-B may be used by grinding down tool legs to engage retainer). Remove rear bearing rear snap ring from housing, drive rear bearing out through rear of case. Remove control lever retaining nut, remove lever from shaft, work shaft through into case and remove. Remove large snap ring at rear of planetary ring gear, remove gear from shaft hub.

Planetary Gears & Free-wheel Parts—Remove snap ring which retains free-wheel cam on mainshaft, slide free-wheel roller retainer and cam assembly, and planetary pinion and cage assembly, off shaft (CAUTION—see that none of the 12 free-wheel rollers are lost). Remove forward pinion cage assembly retaining snap ring from shaft (CAUTION—mark this ring to insure re-installation of same ring or similar thickness—this ring thickness not variable). Pull reverse plunger, shift fork, and shift fork assembly out of adapter and at same time slide sun gear to rear and off end of shaft.

Adapter Plate Sun Gear Parts—Remove snap ring retaining stationary sun gear plate cover in adapter, remove cover, sun gear plate and balk ring, and pawl.

REASSEMBLY OF OVERDRIVE: Wash all parts thoroughly in kerosene and check for broken, chipped, or scored gear teeth; nicked or burred splines; rough bearings; roughness or flat spots on free-wheel rollers. Lubricate all parts with transmission oil and reassemble in reverse order of disassembly, noting the following important points:

Sun Gear Balk Ring—See that ring installed on gear plate with chamfered side of ring toward slotted hub on plate. Check balk ring friction or drag by lubricating plate and ring with transmission oil and using spring scale hooked to balk ring step. Pull required to turn ring on plate (scale held parallel to step on ring) should be 3½-5½ lbs. (CAUTION—this is pull while turning ring—greater pull may be required to start ring turning).

Stationary Sun Gear Assembly—Install sun gear plate, then install pawl with groove upward, install sun gear plate cover, install retaining ring of correct thickness so that plate held tightly against seat in adapter (this ring furnished .062", .066", .070"), install solenoid (see note below). Engage shift fork in sun gear groove, then install reverse plunger, shift rail, shift fork, and sun gear as an assembly.

Solenoid Installation Note—Insert plunger in adapter with solenoid turned ¼-turn to right or clockwise from normal mounting position, push solenoid in until plunger engages pawl, then rotate solenoid ¼-turn counter-clockwise to lock plunger in pawl, install and tighten solenoid mounting screws.

►*CAUTION—Solenoid terminal screws must be toward rear (toward overdrive case) when installed.*

Planetary Gears & Free-wheel Assembly—Install marked pinion cage assembly retaining snap ring in groove in shaft behind sun gear (CAUTION—If same ring as marked during disassembly not re-installed, use new ring .062" ± .002" thick at this point). After installing pinion and cage assembly and the free-wheel cam assembly, install retaining snap ring in groove in shaft, selecting ring of correct thickness to prevent any endplay of pinion or free-wheel cam assembly on shaft (this ring furnished .062", .068", .074" thick). Install free-wheel rollers in retainer, use rubber band looped around retainer to hold them in place, rotate retainer to left or counter-clockwise so that rollers on lowest point of cam.

Overdriv Case & Drive Shaft—Parts are first assembled in case and then installed as follows: **Assembly**—Install lockout lever shaft from within case, turn shaft so that cam on inner end upward, install lever on shaft in overdrive position (nearly against bottom of stop on case. Press rear bearing into case or tap bearing in with brass or fiber drift until bearing seated against forward snap ring (NOTE—if this front snap ring removed, use ring .087" ± .002" thick at this point). Install bearing rear retaining snap ring, selecting ring of correct thickness so that bearing held tightly against front ring (this ring furnished .087", .090", .093", .096" thick). Install new oil seal in rear of case, pressing seal in until shoulder on seal retainer is flush with end of case. Insert speedometer driving gear through front end of case, press or tap front bearing in place in case. Assemble planetary ring gear on drive shaft hub, selecting retaining snap ring of correct thickness so that ring gear has no endplay (this ring furnished .055", .057", .059" thick). Coat bearing and seal surfaces on drive shaft with Lubriplate, install shaft through front end of case (align speedometer gear with finger inserted through rear of case to permit entering shaft). Install universal joint flange, tighten retaining nut to 200-225 ft. lbs. Install governor and speedometer pinion and shaft.

Installation—Work lockout shaft and lever as far as possible out of case, install shift rail retractor spring on end of shift rail, place new gasket on face of adapter. Install case assembly (may be necessary to turn mainshaft to line up pinions and ring gear, or to rotate case slightly to permit shift rail to enter pilot hole in case). Do not attempt to remove rubber band from free-wheel rollers (band will be pushed off by roller race and will be dissolved by lubricant). Install and tighten overdrive case retainer screws (CAUTION—use copper gasket between case and washer on screws having drilled heads—these screws must be secured with lockwire). Push lockout shaft and lever inward to engage shift rail, install tapered retaining pin to lock shaft in position.

►*CAUTION—Universal companion flange nut must be securely tightened (200-225 ft. lbs.) to prevent speedometer drive gear slipping on shaft which would cause faulty overdrive action (this gear drives governor) as well as speedometer fluctuation.*

OVERDRIVE CONTROL: *See "Warner Type R10 & R11 Overdrive Control" data.*

►*WIRING DIAGRAM NOTE—See wiring diagram on this page for connections when installing this R11 Overdrive on previous Packard models.*

TRANSMISSION DISASSEMBLY & REASSEMBLY: *See Packard Transmission data.*

Nash (1946-55)③⑤
Packard (1949-55)
Plymouth (1952-55)
Rambler (1950-55)③
Studebaker (1947-55)④
Willys (1946-55)

①—Lockout Switch not used.
②—Lockout Switch not used after Early 1951.
③—Lockout Switch not used after Late 1953.
④—Lockout Switch not used after Early 1955.
⑤—For Nash models with "Pushbutton Kickdown Switch" *see Warner Overdrive Control "Pushbutton" Type.*
⑥—With simplified control. *See "Warner R9 Overdrive Control" for data on 1948-49 models.*

▷1941-48 LINCOLN—*See "1941-48 Lincoln Overdrive Control" for 1941-48 Special R10 control data.*

▷CHANGES, CAUTIONS, CORRECTIONS

▷*LOCKOUT SWITCH SERVICE REPLACEMENT NOTE:* If lockout switch defective on units where switch installed originally, both switch wires should be detached and connected together so that switch is eliminated from circuit (*CAUTION*—Wires should be soldered together and taped for protection from moisture and grease). Leave switch installed to act as cover for switch mounting hole. If switch cannot be used for this purpose, make up sheet metal cover for installation over switch mounting hole.

▷*1955 FORD OVERDRIVE SOLENOID FAILURE NOTE:* Solenoid failure may be caused by excessive resistance in wire leading to solenoid. To correct, parallel the existing 14 gauge wire from ignition switch to relay and from relay to solenoid with a 12 gauge wire. Attach both wires to a common-terminal at ignition switch, "IGN" terminal of relay, and "SOL" terminal of relay. Replace the single "bullet" connector at solenoid with a double "bullet" connector and attach both the 14 gauge and 12 gauge wires.

▷Hudson R10 Overdrive Control Production Change: Simplified control system described below used only on 1950 and later Hudson cars. 1948-49 cars with R10 Overdrive have same type control used with previous R9 Overdrive. *See "Warner R9 Overdrive Control" for data on 1948-49 cars.*

▷Ford, Lincoln, Mercury Prolonged Shorting-out of Ignition on Kick-down: See "Ford, Lincoln, Mercury Overdrive" for instructions on installation of insulating strip in solenoid cover.

▷Ford & Mercury Overdrive Production Change (Elimination of Lock-out Switch): Ford Overdrives (beginning with 1951 production) and Mercury Overdrives (beginning January 1951) do not have any provision for Lock-out Switch and Governor is connected to "A" terminal on Kick-down Switch.

▷Ford Overdrive Governor Production Change: First type governor superseded by later type which is interchangeable with first type on all cars except Convertible. Identify governors as follows:
First Type—Unpainted body with Bakelite top.
Later Type—Body painted Black, top unpainted.

▷Overdrive failure to engage or improper cut-in and cut-out speed Correction Caution: Before replacing governor to correct this condition, make certain that companion flange nut on rear end of overdrive mainshaft is tight (looseness of this nut will allow governor drive gear to slip on shaft).

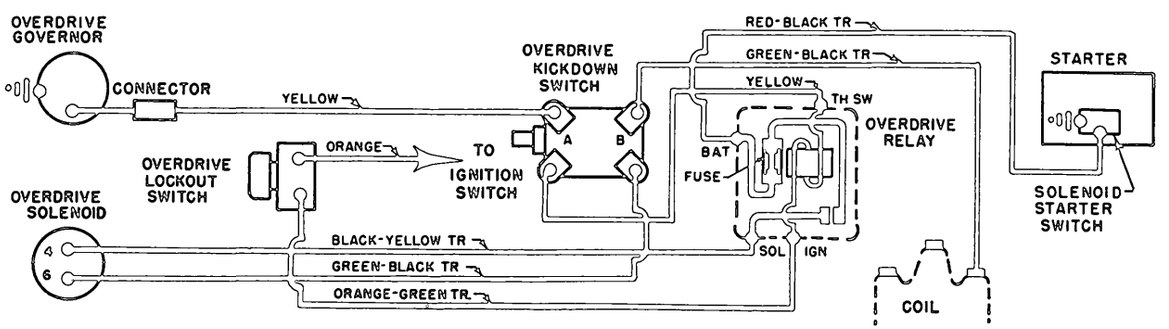
DESCRIPTION: Control units consist of a Governor (cut-in speed controlled by closing of governor contacts, cut-out speed by opening of contacts), Solenoid (solenoid pushes pawl in to engage overdrive, return spring on solenoid plunger pulls pawl out to disengage overdrive). Throttle Kick-down Switch (switch breaks solenoid circuit when accelerator pedal fully depressed causing overdrive to disengage for "kick-down" direct drive), Control Relay, and Lock-out Switch (switch mounted on overdrive case and actuated by control shaft to open governor circuit when overdrive "locked out" by control button on instrument panel.

TROUBLE SHOOTING: Failure of the overdrive to operate satisfactorily may be caused by mechanical failure (of overdrive unit or control units), or by electrical failure (of control units and wiring).

OVERDRIVE DOES NOT ENGAGE

1. Mechanical Causes:
1) Dash control out-of-adjustment or not correctly positioned (control button on instrument panel should be ¼" out with shift lever on overdrive case in extreme rear position).
2) Shift Rail (in overdrive case) binding due to incorrect assembly or housing misalignment.
3) Balk ring faulty or incorrectly installed (may be indicated by spasmodic or harsh engagement). Check balk ring friction drag (see Disassembly data above). Make certain that sun gear plate and balk ring correctly installed with pawl in slot in balk ring (overdrive cannot engage if pawl rides on solid portion of ring).
4) Sun gear pawl broken, sticking or incorrectly installed. Remove solenoid (see Solenoid Testing) and check pawl for free operation.
5) Solenoid plunger sticking. See Solenoid Testing.
6) Governor drive pinion broken, driving gear on overdrive mainshaft loose.

2. Electrical Causes:
1) Fuse blown or open circuit between governor and relay, control wiring incorrect, loose connections or broken wires.
2) Governor, Relay, Lock-out Switch, or Kick-down Switch defective or plunger sticking.
3) Solenoid defective (pull-in or hold-in coil open, pull-in coil contacts sticking open). See Solenoid Testing.



OVERDRIVE DOES NOT DISENGAGE OR NO "KICK-DOWN"

1. Mechanical Causes:
1) Solenoid incorrectly installed (jamming pawl in overdrive position) or solenoid pawl rod sticking. Plunger spring weak or broken.
2) Sun gear pawl sticking, broken, or not properly engaged on pawl rod ball end. Remove solenoid and check pawl for free operation.
2. Electrical Causes:
1) Governor, Relay, or Kick-down Switch defective. Control wiring incorrect. Kick-down Switch out of adjustment.
2) Ignition cut-out or ground wire broken or disconnected (between Solenoid terminal #6 and kick-down switch, or between kick-down switch and distributor or ignition coil).

ENGINE STALLS ON "KICK-DOWN"

1. Electrical Causes:
1) Solenoid defective. Ignition ground contacts sticking closed or grounded.
2) Ignition cut-out or ground wire between Solenoid terminal #6 and kick-down switch.

CONTINUED ON NEXT PAGE

WARNER R11 OVERDRIVE CONTROL WIRING

WARNER R10 & R11 OVERDRIVE CONTROL (C nt.)

3) Kick-down Switch defective (ignition cut-out terminals grounded).

ENGINE DOES NOT DRIVE CAR IN OVERDRIVE POSITION (Drives only when Overdrive locked out).
1. Mechanical Causes: Free-wheel clutch rollers broken, roller cage sticking in disengaged position, clutch cam or rollers worn.

TESTING & ADJUSTMENT OF CONTROL UNITS: Control units should be serviced by replacement.
Governor: Governor should be replaced if operation unsatisfactory or cut-in and cut-out speeds not correct. See CAUTION below before replacing unit.

►***CAUTION—Before replacing governor*** **(if overdrive does not engage, or if cut-in and cut-out speeds not correct, make certain that universal joint companion flange nut on rear end of overdrive driveshaft is tight. Looseness of this nut will allow governor and speedometer drive gears to slip on overdrive shaft.**

Governor Testing—Governors can be tested by being driven on the bench and the RPM. noted at which the contacts close (on acceleration) and open (on deceleration). Contact closing and opening RPM. should be correct and the difference between these two points must not be less than the "Min. Diff." figure listed in the table below. Parts are not furnished for service and defective governors should be replaced.

►***CAUTION—On some governors, one set of contacts open and second set of contacts close AT THE SAME RPM.***

Solenoid Testing—Solenoid can be tested on the bench (after removal from transmission) as follows:

Solenoid Winding—Connect battery to solenoid terminal #4, ground other battery terminal to solenoid mounting flange (meters can be used to check winding current draw—see specifications below). With solenoid energized, solenoid pawl rod should move out and hold in the outward position. If pawl does not move out, coils are defective. If pawl chatters, hold-in coil is defective.

Ignition Grounding Contacts—With solenoid energized as for coil test (above), connect test lamp between battery terminal and solenoid terminal #6. Lamp should light indicating that ignition ground contacts are closed. Disconnect battery lead at solenoid #4 terminal. Pawl rod should snap in and test lamp should go out (indicating that ignition ground contacts have opened).

Solenoid Specifications
(6 Volt)

Current Draw (Both Coils)—26.2-28.4 amperes at 5 volts.

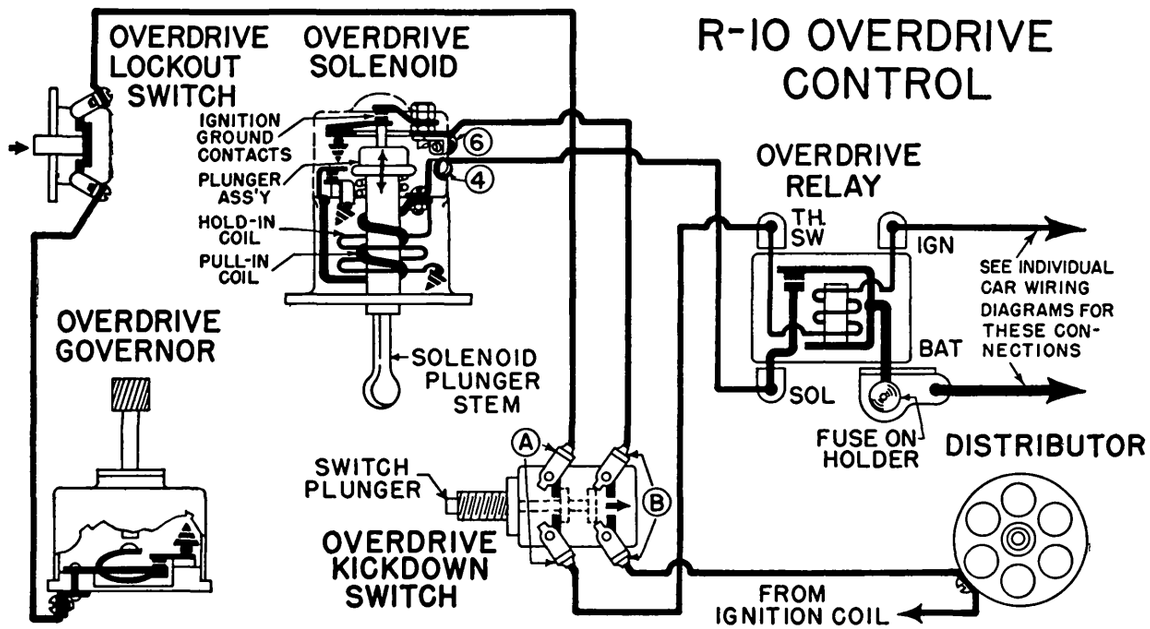
①—Also used on 1952-55 Models with "Pushbutton Control" having kickdown switch on steering wheel spoke

②—Used on 1952-55 Models with "Pushbutton Control" having kickdown switch in cap

Control Relay Specifications (Auto-Lite HRT-4001, 4001A, 4101)

Contacts Close—4 0 volts maximum. Adjust by bending lower spring hanger to change spring tension

Contacts Open—.6-1.0 volt. Adjust by varying height of stationary contact



Contact Gap— 015" minimum.

Air Gap—.031-.034" with contacts open. Adjust by bending armature stop.

Overdrive Fuse: In cartridge type holder or on fuse block attached to control relay on all cars.

Fuse Capacity

DeSoto, Dodge, Plymouth	20 amperes
Ford	30 amperes
Frazer, Henry J, Kaiser	20 amperes
Hudson	30 amperes
Lincoln & Mercury	30 amperes
Nash (1949 & earlier)	20 amperes
Nash (1950 & later)	30 amperes
Packard	30 amperes
Studebaker	20 amperes
Willys	20 amperes

WARNER R10 OVERDRIVE CONTROL WIRING

1952-53 WARNER OVERDRIVE CONTROL "PUSH BUTTON" TYPE

Nash Ambassador (Dual Jet Fire Series) 1952-53

►***LOCKOUT SWITCH PRODUCTION CHANGE***—Lockout switch eliminated in later production cars. If switch in early cars becomes defective, disconnect both wires from switch terminals and reconnect them to one terminal, bypassing switch. Cover plate No. 3136445 can be installed to replace switch.

DESCRIPTION: ***NOTE—Mechanical control of overdrive is same as used on other cars with Warner R10 & R11 Overdrives.*** The electrical control is different, having a new type Overdrive Relay which permits instant "kick-down" control by use of a pushbutton on steering wheel. An Indicator Light and Relay is incorporated in the electrical control system to indicate "overdrive" and "conventional" positions. A Vacuum Control Switch located in the interrupter circuit between ignition coil and Overdrive Relay prevents ignition interruption during deceleration.

OPERATION (Electrical Controls): With engine running and overdrive control on dash pushed in for overdrive operation (closing lockout switch), battery voltage is supplied to relay armature coil. When car speed of 29-30 MPH is reached, overdrive governor contacts close. This completes governor to ground circuit and energizes relay armature. Lower overdrive relay contacts close supplying battery voltage through 30-ampere fuse to overdrive solenoid terminal No. 4, energizing overdrive solenoid, permitting overdrive engagement with momentary release of throttle. At same time, upper contacts of overdrive relay open, breaking ignition interrupter circuit between ignition coil and interrupter points (No. 6) of overdrive solenoid, which close to ground on overdrive engagement. Closing the lower overdrive relay contacts also energizes armature coil of indicator light relay, closing indicator light relay points, completing the circuit between grounded solenoid interrupter points and one side of indicator light. Since indicator light is connected across overdrive relay terminal "NO" and terminal "NC", circuit is completed to ground, and indicator bulb lights. For kick-down operation, pressing steering wheel pushbutton bypasses to ground, overdrive terminal post No. 2, de-energizing overdrive relay armature coil, and opening lower relay contacts which in turn de-energizes overdrive solenoid, and opens upper overdrive relay contacts. This completes ignition interrupter circuit, opening points in indicator light relay, causing indicator light to go out. Car is now in conventional gear.

TROUBLE SHOOTING (Electrical Controls): ***NOTE—For Mechanical Trouble shooting see "Warner R10 & R11 Overdrives."***

OVERDRIVE DOES NOT ENGAGE—

(1) Fuse blown or open circuit between governor and relay, control wiring incorrect, loose connections or broken wires.

(2) Governor, relay, lockout switch, or kick-down switch defective. Solenoid plunger sticking.

(3) Solenoid defective (pull-in or hold-in coil open, contacts sticking open). See Solenoid Testing.

OVERDRIVE DOES NOT DISENGAGE OR NO "KICK-DOWN"—

(1) Governor, relay, vacuum switch, or pushbutton switch defective. Control wiring incorrect.

(2) Ignition cut-out or ground wire broken or disconnected (between solenoid and relay terminals, between relay terminal and vacuum switch, or between vacuum switch and ignition coil).

(3) Ignition ground contacts in solenoid sticking open or broken (indicator light on instrument panel will not light when overdrive is engaged if ignition ground contacts in solenoid stuck or broken).

(4) Throttle not open far enough at time of kick-down to allow vacuum switch to close.

ENGINE STALLS ON KICK-DOWN—

(1) Solenoid defective. Ignition ground contacts sticking closed or grounded.

TESTING CONTROL UNITS: Service by replacement.

Governor: Replace if cut-in or cut-out not correct.

Overdrive Control Governor
A-L No. TGE-4005; Nash No. 3112914

Test	Cut-In Speed	Cut-Out Speed
In Car	29-30 MPH	(Approx.) 25 MPH
On Bench	740-RPM	535 RPM

Testing—Test by checking governor cut-in and cut-out speed (distributor tester can be used). Opening and closing should be correct (see table above) and there must not be less than **80 RPM difference** between contact closing and opening.

Solenoid: Delco-Remy No. 1118155. Nash No. 3123433.

►***SOLENOID REMOVAL CAUTION***—Solenoid must be disengaged from pawl for removal as follows: Take out two mounting cap screws, rotate solenoid clockwise ¼ turn, to disengage plunger from pawl (will align pawl flats with pawl slot), withdraw solenoid

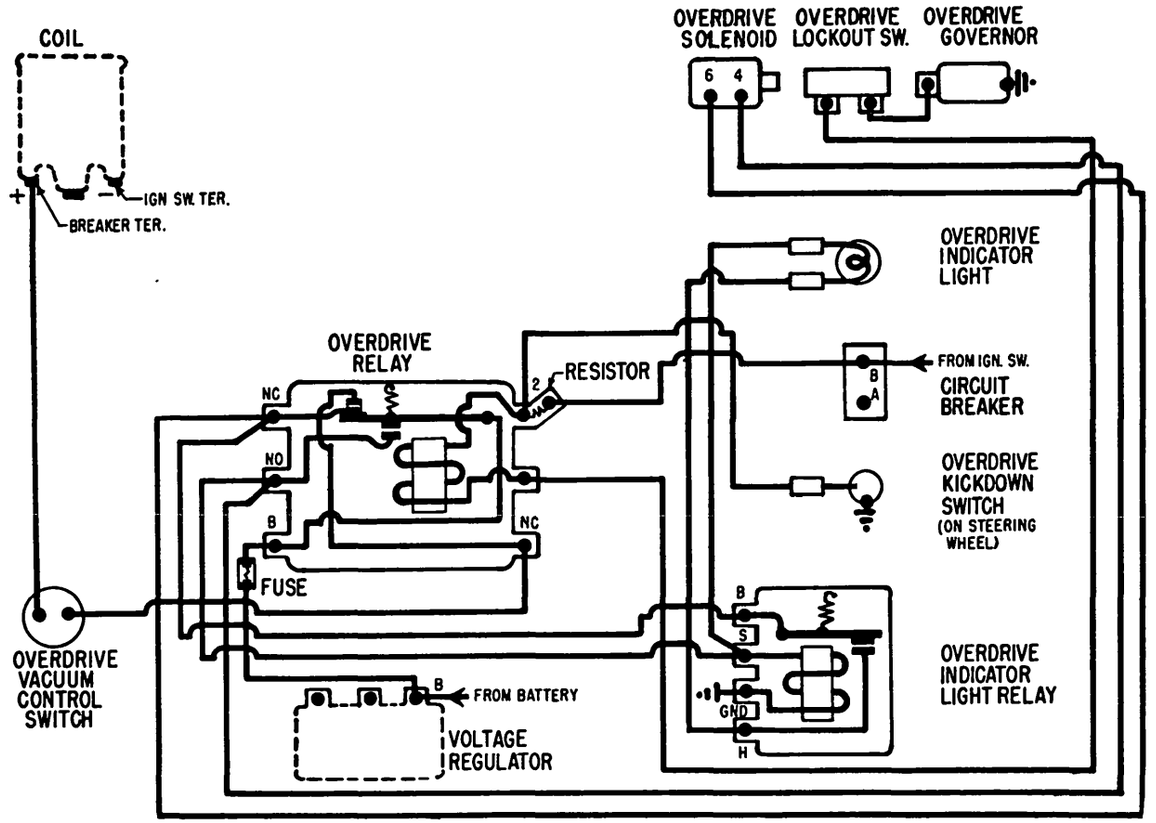
Solenoid Testing—Test on bench as follows:

Winding—Connect battery to No. 4 terminal, ground other battery terminal to solenoid mounting flange (meters can be used to test winding current draw—See specifications below). With solenoid energized, solenoid pawl rod should move out and hold in the outward position. If pawl does not move out, coils are defective. If pawl chatters, hold-in coil is defective.

Ignition Grounding Contacts—With solenoid as for coil test (above), connect test lamp between battery terminal and No. 6 terminal on solenoid. Lamp should light indicating that ignition ground contacts are closed. Disconnect battery lead at solenoid terminal No. 4. Pawl rod should snap in and test lamp should go out (indicating that ignition ground contacts have opened).

Solenoid Specifications

Current Draw (Both Coils)—26.2-28.4 amps. 5.0 V.



Current Draw—Hold-in Coil (Pawl Rod in Overdrive Position)—1.2-1.4 amperes at 5.0 volts.

Overdrive Control Relay—Nash No. 3136172.

Light Indicator Relay—3136173.

Vacuum Control Switch—Delco-Remy No. 1997900.

Overdrive Fuse—30 amps. Cartridge in feed wire.

1952-53 WARNER OVERDRIVE "PUSH BUTTON" CONTROL WIRING

1954-55 WARNER OVERDRIVE CONTROL "PUSH-BUTTON" TYPE

Nash Ambassador & Stat sman (1954-55)

DESCRIPTION: *NOTE–Mechanical control of overdrive is sam as us d on oth r cars with Warner R10 and R11 Ov rdriv s.* Electrical control is different, having Overdrive Relay which permits instant "kick-down" control by either a pushbutton on steering wheel or by the conventional pedal control. A vacuum control switch located in the interrupter circuit, between ignition coil and overdrive relay prevents ignition interruption during deceleration.

OPERATION (ELECTRICAL CONTROLS): With engine running and overdrive control pushed in for overdrive operation, battery voltage is supplied to relay armature coil. When car speed of 29-30 MPH is reached, overdrive governor contacts close. This completes governor to ground circuit and energizes relay armature. Lower overdrive relay contacts closed supplying battery voltage, through 30 ampere fuse, to overdrive solenoid terminal No. 4, energizing overdrive solenoid, and permitting overdrive engagement with momentary release of throttle. At same time, upper contacts of overdrive relay open, breaking ignition interrupter circuit between ignition coil and interrupter points (No. 6) of overdrive solenoid, which close to ground on overdrive engagement. For kick-down operation, pressing steering wheel button or by conventional pedal operation, system bypasses to ground overdrive terminal post No. 2, de-energizing overdrive relay armature coil, and opening lower relay contacts which in turn de-energize overdrive solenoid, and open upper overdrive relay contacts. This completes ignition interrupter circuit. Car is now in conventional gear.

TROUBLE SHOOTING (ELECTRICAL CONTROLS): *NOTE–For Mechanical Trouble Shooting see "Warner R10 & R11 Overdrives".*

OVERDRIVE DOES NOT ENGAGE–(1) Fuse blown or open circuit between governor and relay, control wiring incorrect, loose connections or broken wires.
(2) Governor, relay, or kick-down switch defective. Solenoid plunger sticking.
(3) Solenoid defective (pull-in or hold-in coil open, contacts sticking open). See Solenoid Testing.

OVERDRIVE DOES NOT DISENGAGE OR NO "KICK-DOWN"–(1) Governor, relay, vacuum switch, control switch (pushbutton or pedal) defective. Control wiring incorrect.
(2) Ignition cut-out or ground wire broken or disconnected (between solenoid and relay terminals, between relay terminal and vacuum switch, or between vacuum switch and ignition coil).
(3) Ignition ground contacts in solenoid sticking open or broken.
(4) Throttle not open far enough at time of kick-down to allow vacuum switch to close.

ENGINE STALLS ON "KICK-DOWN"– (1) Solenoid defective, ignition ground contacts sticking closed or grounded.

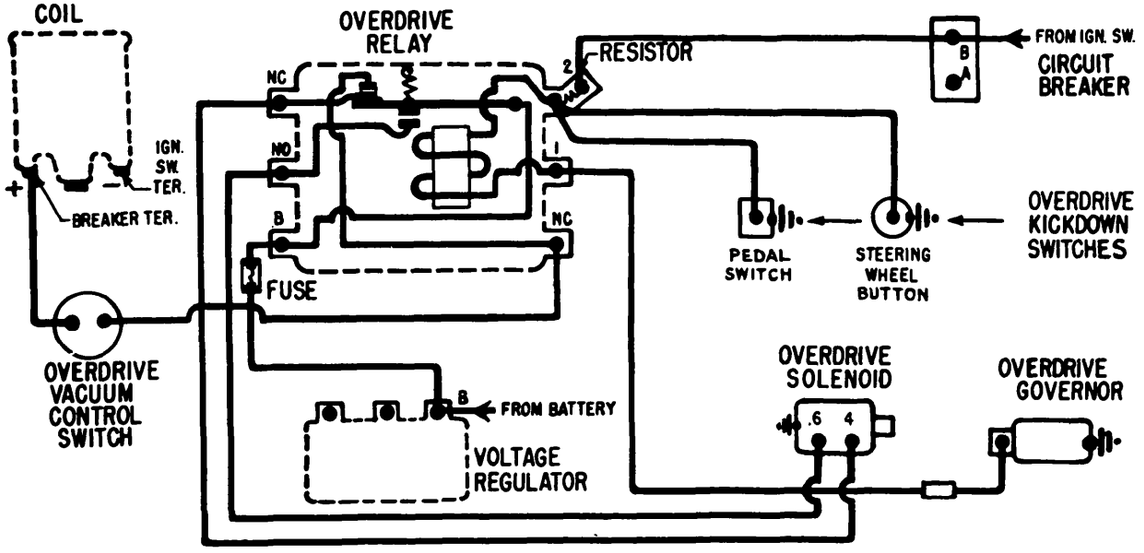
TESTING CONTROL UNITS: Serviced by replacement.

Governor: Replace if cut-in or cut-out not correct.

Governor
Auto-Lite TGE-4005, Nash No. 3112914

Test	Cut-In Speed	Cut-Out Speed
In Car	29-30 MPH	25 MPH (Approx.)
On Bench	740 RPM	535 RPM.

Testing—Test by checking governor cut-in and cut-out speed (distributor tester can be used). Opening and closing should be correct (see table above) and there must not be less than 80 RPM difference between contact closing and opening.



Solenoid: Delco-Remy No. 1118155, Nash No. 3114537.

► *SOLENOID REMOVAL CAUTION:* Solenoid must be disengaged from pawl for removal as follows: Take out two mounting capscrews, rotate solenoid clockwise ¼ turn (to disengage plunger from pawl—will align pawl flats with pawl slot) withdraw solenoid.

Testing—Test on bench as follows:

Winding—Connect battery to No. 4 terminal, ground other battery terminal to solenoid mounting flange (meters can be used to test winding current draw—see specifications below). With solenoid energized, solenoid pawl rod should move out and hold in out ward position. If pawl does not move out, coils are defective If pawl chatters, hold-in coil is defective.

Ignition Grounding Contacts—With solenoid as for coil test (above), connect test lamp between battery terminal and No. 6 terminal on solenoid. Disconnect battery lead at solenoid terminal No. 4. Pawl rod should snap in and test lamp should go out (indicating that ignition ground contacts have opened).

1954-55 NASH OVERDRIVE CONTROL "PUSH BUTTON" TYPE WIRING

Solenoid Specifications

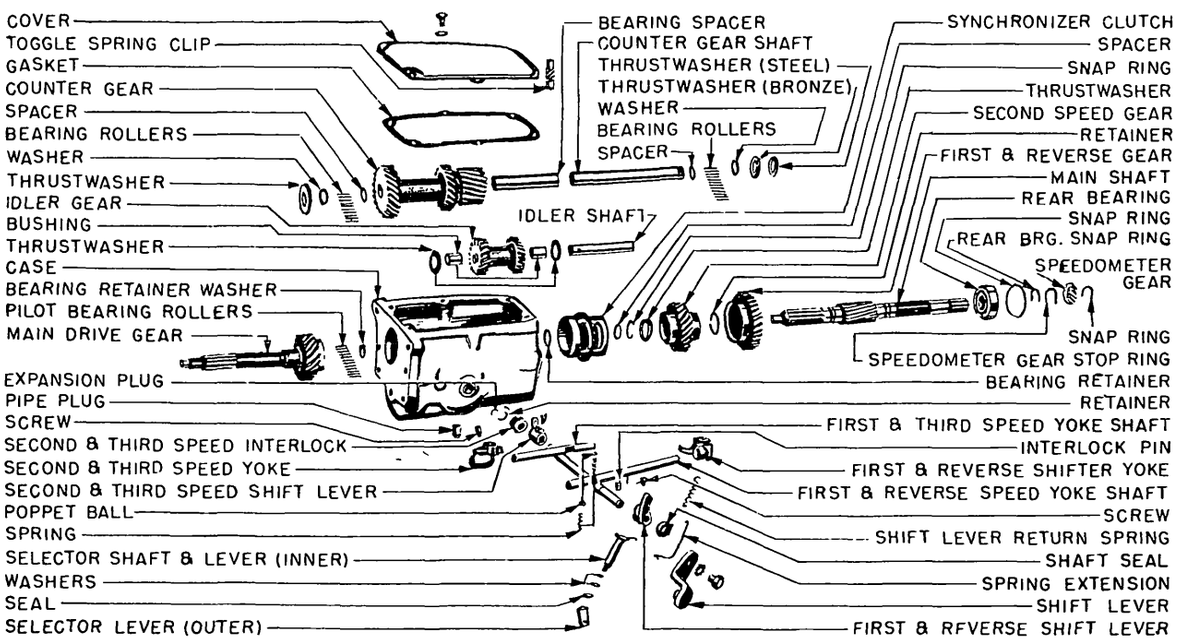
Current Draw (Both Coils)—26.2-28.4 amperes at 5.0 volts.
Current Draw of Hold-In Coil (Pawl Rod in Overdriv Position)—1.2-1.4 amperes at 5.0 volts.
Overdrive Control Relay: (With Pushbutton) Nash No. 3136172.
Vacuum Control Switch: (Early) Nash No. 3132550, (Later) Nash No. 3139862.
Overdrive Fuse—30 ampere. Cartridge in feed wire.

1946-48 BUICK 70 & 1953-55 BUICK 50, 1951-55 OLDSMOBILE

Buick, Series 70 (1946-48)
Buick, Series 50 (1953-55)
Oldsmobile, Series 88 & 98 (1951-55)

►***OPTIONAL TRANSMISSION NOTE: Dynaflow Drive optional on Buick and 1953 Oldsmobile. Hydra-Matic Drive optional on Oldsmobile.***
See "Buick Dynaflow Drive" or "Hydra-Matic Transmission" for data.

►CHANGES, CAUTIONS, CORRECTIONS



►*1954 OLDSMOBILE TRANSMISSION LEAK CORRECTION:* **Leak at Front Face of Transmission**—Caused by transmission to clutch housing gasket not being compressed sufficiently. Correct by installing TWO gaskets, Part No. 1308193, at this point, and sealing around lip of the Main Drive Shaft Sleeve, where it contacts clutch housing. Use P.O.B. #2 sealer.

Leak Into Clutch—This leak is caused by excessive clearance between mainshaft and bearing retainer sleeve and is noticed on cars driven at high speeds. check the clearance between Main Drive Shaft and Main Drive Shaft Sleeve by mounting a dial indicator on the case with indicator button contacting the sleeve, then move sleeve up and down. The clearance should not be greater than .012". Also check six points on sleeve (marked with chalk 30° apart) to determine if sleeve is out-of-round. If clearance not within limits at all points install a new sleeve, Part No. 560770, and seal around lip of retainer with P.O.B. #2 Sealer.

DESCRIPTION: Constant mesh, synchro-mesh (second & high), sliding gear (low & reverse). Transmission shift levers mounted on side of case.

DISASSEMBLY: (1)—Remove transmission cover and gasket, shift lever, toggle spring, spring clip and spring extension. Remove speedometer gear (driven). **On Oldsmobile** remove rear bearing retainer and gasket. **On Buick 50** mark top edge of outer retainer so that it can be reinstalled in original position. Remove thrust plate and gasket, retainers, shims and torque ball from rear bearing retainer. Remove retaining bolt and washer, then pull universal joint from mainshaft, using Puller J-682A. To use puller, install pressure plug in transmission mainshaft, insert puller body in universal joint rear yoke and install "C" washer in groove in puller body on front side of yoke, turn screw handle clockwise. Remove universal joint spacer from mainshaft. Remove transmission rear bearings snap ring. Tap rear of mainshaft with soft hammer or hardwood block, remove mainshaft and bearing.
(2)—Shift transmission gears to second speed. Move mainshaft back until rear bearing clears case. Disengage shifter yoke from synchronizer. Lift front end of mainshaft up and slide synchronizer assembly from shaft.

(3)—Remove snap ring retaining 2nd speed gear on shaft. Line up small wire spacer ring in bottom of snap ring groove with thrust washer key and remove thrust washer and second speed gear. Remove snap ring retaining sliding gear, slide gear off shaft as shaft is withdrawn through rear of case.

BUICK 70 (1946-48), BUICK 50 (1953-55), OLDSMOBILE (1951-55) SYNCHRO-MESH

(4)—Place transmission shift levers in neutral, remove set screws retaining shifter yokes and lever on shafts. Slide shifter lever and interlock away from second-and-high yoke shaft, and remove interlock retainer from groove in right end of selector shaft. Remove outer shift lever and lockwasher from left end selector shaft. With transmission shift mechanism in neutral drive shaft out through right side of transmission case using a soft hammer (welch plug in case will be driven out with shaft), taking care not allow shifter levers and interlock to drop into case.
(5)—Push second-and-high shifter yoke shaft out through **rear** end of transmission case ***(CAUTION—do not allow poppet balls and spring to fly out)***, lift out shifter yoke, poppet balls and spring. Remove low-and-reverse shifter yoke shaft similarly through **rear** end of transmission case.
(6)—Drive countershaft lock pin in until it is completely within shaft, use Bearing Loader Tool J-1001 to drive shaft out through rear of case ***(CAUTION***—allow tool to remain within gear cluster to retain bearing rollers and thrust washers). Remove snap ring from main drive gear bearing, tap drive gear and bearing assembly into case and lift out.
(7)—Lift out counter gear assembly taking care not to lose washers and bearing rollers within gear cluster ***(CAUTION***—note location of each type thrust washer to insure correct assembly). Remove nut and lockwasher and take off outer selector lever, remove inner lever and shaft (with spring washer and oil seal) from within case. Drive locking pin completely into idler gear shaft, remove shaft through rear of case, lift out idler and thrust washers.

OVERHAUL (Component Parts after Disassembly):
Countershaft Assembly—Remove countershaft removing Tool J-1001 and remove roller bearings, thrust washers, retaining washers and bearing spacer. To reassemble, place countershaft removing Tool J-1001 into cluster gear and install bearing spacer tube and bearing inner retainer washers over the tool. Assemble a sufficient number of bearings under end of tool so it is evenly spaced in bore of gear. Finish assembling a total of 26 bearings at each end of gear. Leave Tool J-1001 in place until gear is assembled in transmission case.
Main Drive Gear—Remove snap ring and washer holding main drive gear bearing to gear. Remove bearing by jarring shaft on block of wood. Remove wire lock ring, washer and 14 roller bearings from counterbore in gear. To replace, reverse removal procedure ***(CAUTION***—Press on inner race of bearing when installing).
Main Shaft—Remove rear bearing snap ring. Remove speedometer using Tool J-4390 and remove gear spacer. (NOTE—If flange at inside diameter of each plate is too thick to slide easily between speedometer gear and bearing, grind down at this point to permit free movement). To assemble, install bearing up against shoulder (pressing on inner race). Install snap ring and speedometer gear on shaft. Press or tap speedometer drive gear on shaft against spacer, using Tool J-4390.
Rear Bearing Retainer Bushing (Oldsmobile)—Remove old bushing with Tool J-1450-4. Install new bushing using Tool J-1450-4 and Stop Guide Tool J-1450-5. Assemble reamer pilot into rear end of retainer housing. (NOTE—Pilot has two diameters; select pilot diameter which fits tightly into hous-

CONTINUED ON NEXT PAGE

1946-48 BUICK 70 & 1953-55 BUICK 50, 1951-55 OLDSMOBILE (Cont.)

ing). Place reamer J-1450 into housing and assemble Front Pilot J-1450-9 over shaft down into counterbore of housing. Tighten pilot in place with clamps J-1450-8. Ream inside diameter of bushing.

Rear Bearing Retainer Seal & Shield (Oldsmobile)—Remove seal from retainer. Line up new seal over bore in housing and tap lightly on outer edge to just start seal in place. Finish driving seal into retainer housing with Tool J-1354.

Synchronizing Clutch—Assembly cannot be dismantled and should be replaced as a unit. Synchronized springs are furnished and can be replaced as follows: Remove old springs by prying spring loose from gear and pushing it out of groove, then place new spring over clutch and pull synchronizer coupling up into place over spring.

REASSEMBLY: (1)—Install reverse idler gear, bronze thrust washer and shaft into transmission case. *Note that set of teeth with chamfers at hub should be at rear of case when replaced.* Make sure that end of shaft with larger diameter is at rear when replaced and that small hole in opposite end lines up with lock pin hole in transmission case. Install a new lock pin 1" below surface of boss on case.

(2)—Place spring washer, flat washer, and oil seal on selector shaft in order named, with crowned side of spring washer against flat washer. Apply lubriplate to shaft and assemble into transmission case. Install outer selector lever.

(3)—Lay countergear assembly (gear, bearings, spacer, and Bearing Loader Tool J-1001) into bottom of transmission case. Install small diameter bronze washer and a steel washer at rear of gear (with bronze washer next to gear) and a larger bronze washer at front.

(4)—Install main drive gear into front wall of transmission case and install snap ring. Mesh teeth of countergear with teeth on main drive gear and reverse idler gear. Drive countershaft into place from rear of transmission, being careful that it closely follows Bearing Loader Tool J-1001 so that bearings and washers are held in proper position. Be sure that larger end of shaft is in rear wall of transmission when assembled and that lock pin holes in shaft and transmission case are in line. Install new countershaft lock pin coated with white lead, drive pin in flush with surface of case.

(5)—Replace poppet ball and spring, interlock pin, and low-and-reverse shaft with yoke. Place both yoke shafts in neutral position (NOTE—Each yoke shaft is in neutral when notch for shifter lever is directly over selector shaft bore in case). Install a new welch plug (coat with white lead) in case.

(6)—Raise low-and-reverse interlock pin into groove in yoke shaft, then from left side of case install selector shaft. Place low-and-reverse shifter lever on shaft, making sure selector lever engages notch in bottom of shifter lever. Install second-and-high shifter lever and interlock on shaft. Install new second-and-high interlock retainer on shaft.

Torque Ball Installation & Adjustment (Buick)—*See Buick Special Data.*

1946-55 BUICK, OLDSMOBILE, PONTIAC SYNCHRO-MESH

BUICK MODELS

Series 40 & 50 (1946-52)
Series 40 (1953-55)

OLDSMOBILE MODELS

Six, All Models (1946-50)
Eight, All Models (1946-49)

PONTIAC MODELS

Six & Eight, All Models (1946-55)

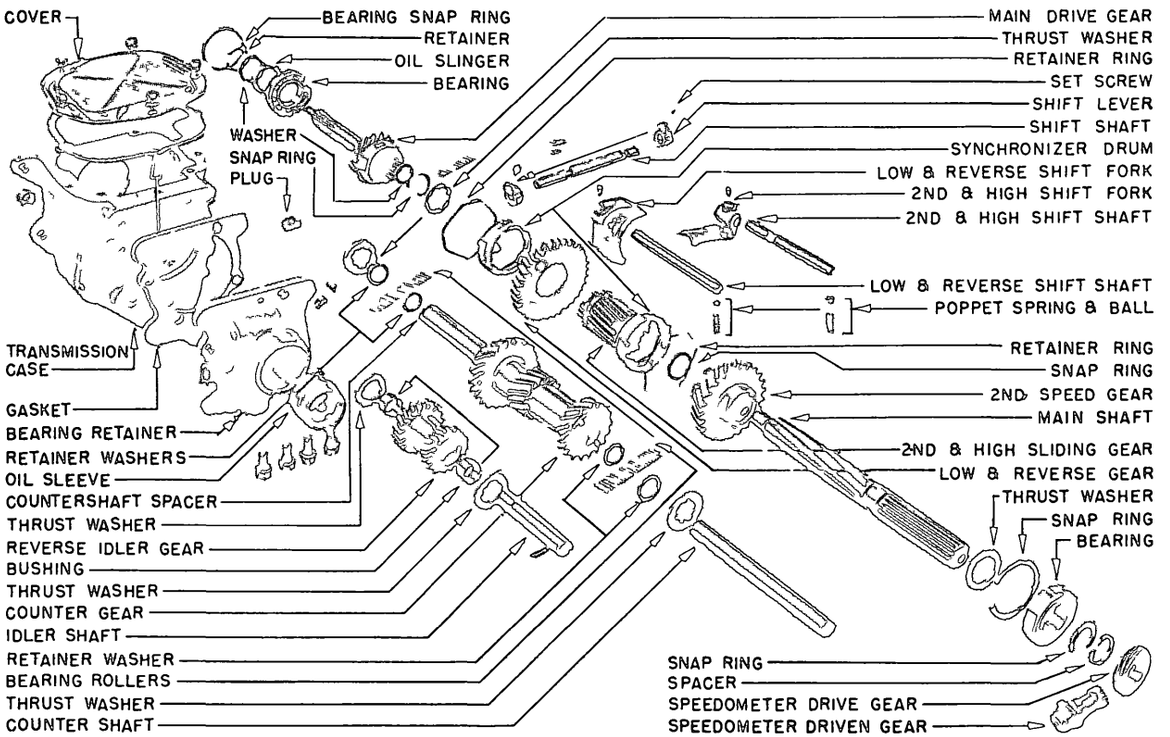
▷CHANGES, CAUTIONS, CORRECTIONS

▷*1954 PONTIAC MAINSHAFT PRODUCTION CHANGE.* A new mainshaft with a 1/32" wider second speed sleeve snap ring groove and a heavier snap ring is now used in production and for service replacement on all 1954 transmissions. The heavier snap ring, Part No. 1321312 must be used in conjunction with the new shaft, Part No. 1166418.

▷*OPTIONAL TRANSMISSION NOTE: Dynaflow Drive optional on Buick and 1953 Oldsmobile. Chevrolet Powerglide optional on 1953 Pontiac. Hydra-Matic Drive optional on Oldsmobile & Pontiac.* *See "Buick Dynaflow Drive," "Chevrolet Powerglide" or "Hydra-Matic Drive."*

▷*1953 BUICK SERIES 40 TRANSMISSION INTERCHANGE NOTE*—The 1953 transmission is not interchangable with previous model transmissions.

DESCRIPTION: Constant-mesh, synchro-mesh (2nd. & High), sliding gear (Low & Reverse), all helical gear type. Same design as used on preceding car models except for the following changes:



Shifter Mechanism—New cross-shift mechanism consisting of a vertical shaft on side of transmission case with inner lever at upper end engaging selector shaft so that movement of selector lever on transmission case (small forward lever) shifts the selector shaft sideways in the transmission to engage the Low-Reverse or Second-High shifter rail.

Countershaft Bearings—Countergear cluster now mounted on roller bearings (loose rollers) at either end with spacer on shaft between bearings. Special service tool (dummy shaft) must be used when removing countershaft to retain bearing rollers.

Synchronizer Cones & Gears (Buick only)—Synchronizing cones have 8° angle and must be used with new gears marked '8' (do not confuse these gears with gears used on previous models). Bronze cones must always be used with Second Speed Gear.

REMOVAL OF TRANSMISSION: *See "Transmission" on car model page.*

CONTINUED ON NEXT PAGE

TYPICAL BUICK, OLDSMOBILE, PONTIAC SYNCHRO-MESH TRANSMISSION

1946-55 BUICK, OLDSMOBILE, PONTIAC SYNCHRO-MESH (Con.inued)

DISASSEMBLY: Remove transmission cover and speedometer driven gear assembly. Disconnect spring on shifter lever on left side of case. Take out rear bearing retainer screws, set transmission in high gear position (to prevent sliding sleeve and low speed gear from dropping down into case), withdraw bearing retainer, second speed gear, and mainshaft assembly through rear of case. Remove setscrews from shifter forks and selector shaft cams (tool J-2895 or KMO-244), take out screw and remove lever from left end of selector shaft, remove lever from lower end of vertical shaft (necessary to permit inner lever on upper end of shaft to disengage from selector shaft), drive selector shaft out through right side of case (this is important to prevent damage to oil seal on lever end of shaft), remove selector cams from case. Remove shifter rails at front of case (on Buick & Oldsmobile, plug at front end of Second-High rail must be removed—see Note), through rear of case (Pontiac), do not lose the detent balls and springs which are located under rails on all models. Lift out shifter forks, sliding sleeve and low speed gear. Use special tool (arbor or dummy shaft) J-1334 (Buick & Pontiac), J-1449 (Oldsmobile) to drive countershaft out through rear of case, leaving tool within counter gear cluster to retain bearing rollers until shaft is replaced. Remove snap ring on main drive gear bearing (on front of case), tap main drive gear and bearing through into case and lift out. Lift countergear cluster out being careful not to lose thrust washers on either end of cluster or bearing rollers. To remove reverse idler, drive locking pin into shaft, drive shaft out, remove gear.

►**Buick & Oldsmobile Shifter Rail Note**—Forks can be removed without entirely removing shifter rails by pushing rails toward back of case sufficiently to slip forks off (will not disturb poppet balls and springs or second-high rail welch plug).

REASSEMBLY: Reverse disassembly directions above and note following data on servicing of sub-assemblies.

Synchronizing Unit:—No detent springs used. Synchronizer drums are retained on gears by snap rings (remove by releasing snap rings).

Buick Note—Make certain that drum used on second speed gear is Bronze (aluminum drums used on some models for high gear).

Mainshaft & Rear Bearing Assembly: To disassemble parts, remove second speed synchronizing drum by prying retainer over shoulder on gear (leave retainer in drum). Remove snap ring from shaft, using Remover Tool J-1019 (Buick), J-1130 (Oldsmobile & Pontiac), remove thrustwasher and second speed gear. On Buick models, remove retaining bolt and washer on end of shaft and use Puller J-682-A to remove universal joint (install pressure plug in rear end of shaft, insert puller body in universal rear yoke and install "C" washer in puller groove ahead of yoke to take thrust). On all models, remove rear bearing snap ring, remove mainshaft and bearing from retainer or extension housing by tapping rear end of shaft with soft hammer or wooden block. To remove bearing from shaft, press or pull speedometer gear off shaft, remove spacer, use tool J-1041 to remove bearing rear snap ring ("C" type ring used on Oldsmobile and Pontiac only), press or pull bearing off shaft. Install bearing with shielded side forward or toward second speed gear. Bearing should be .0007" tight to .0002" loose on shaft and .0011" tight to .0005" loose in housing.

Oldsmobile Extension Housing: The housing has steel-backed, bronze bushing at rear to support mainshaft. Bushing can be replaced after oil seal removed from housing by using tool J-1450 and new bushing installed with same tool. Bushing must be reamed after installation using reamer which is part of J-1450 tool to provide .0025-.004" clearance on shaft.

►***CAUTION—Tool J-1450 must be used to ream bushing accurately (tool pilots in ends of housing).***

IMPORTANT INSTALLATION NOTE (OLDSMOBILE)—When transmission installed on above models, fill the transmission rear bearing housing assembly with ½ pint transmission lubricant after transmission has been installed in car.

Rear Oil Seal (Oldsmobile)—New oil seal must be installed in rear end of rear bearing retainer whenever oil seal removed. Soak new seals in engine oil for 5 minutes, install seal with felt to rear using tool J-1050. NOTE—New type oil seal shoulder for locating it in retainer. See that housing vent is open.

Pontiac Extension Housing (1949-55): Housing has graphite-bronze bushing (1.159" x 1 5/16" x 1 1/4") at rear end to support mainshaft. This bushing located in housing directly in front of oil seal.

Rear Oil Seal (Pontiac)—Oil seal can be removed by prying with a screwdriver. Use tool J-1323 to install new oil seals (seal has extension rim which will be damaged if tool not used). Oil the felt of the new oil seal, and coat inner surface of housing and outer rim of seal with Permatex No. 3 or other sealer before installing it in housing.

Main Drive Gear & Bearing: Bearing can be removed from shaft after lock ring has been removed by tapping end of shaft on wooden block. When installing bearing, see that shielded side is toward gear. Bearing should be .0003" tight to .0007" loose on shaft and .0002" tight to .001" loose in case.

Pilot Bearing (Oldsmobile Models)—Pilot bearing in flywheel consists of special Durex bushing installed with flat end in (no felt used on 1942 models—front wheel bearing lubricant used in reservoir). Bushing is retained by special sheet metal retainer pressed in end of crankshaft. To replace bearing, use puller J-1448 to remove old bushing, clean out all old lubricant, use tool J-1329 to install new bushing (install bushing with flat end in), use adapter J-1329-2 on tool J-1329 to install new retainer, insert ¼ oz. front wheel bearing lubricant in recess in front of bushing.

NOTE—An oil-soaked felt is installed in recess in back of bushing on Oldsmobile 1940-41 cars. Soak felt in #30 SAE. engine oil before installation. This felt not used on later cars.

Pontiac Main Drive Gear Oil Slinger and Oil Seal (1946 On)—An oil slinger and spring washer are installed on main drive gear hub ahead of the bearing (retained by bearing snap ring). Install new felt oil seal (lubricate felt with engine oil) against shoulder on shaft directly forward of oil slinger each time transmission is installed in car.

►***CAUTION*—Do not install oil seal in groove in main drive gear shaft (on 1946-47 cars—seal location changed from this groove). Later gears do not have this groove.**

Second Speed Gear: Gear clearance on mainshaft should be .001-.028" (Buick), .0005-.0027" (1946-48 Pontiac), .0012-.0028" (1949-54 Pontiac), .0015-.003" (1955 Pontiac). Gear endplay should be .000-.010" (Buick & 1946-48 Pontiac), .0001-.0231" (1949-54 Pontiac), .0061-.0261" (1955 Pontiac). When installing gear, coat thrust washer with lubricant and install against gear, use Tool J-1130 to install retaining snap ring.

Countergear Assembly:—If rollers removed from gear cluster, use arbor as assembly tool, make certain that spacer and thrust washers assembled in gear cluster, then install rollers, using grease to retain them in place. Install assembly in case, making certain that small steel thrust washer installed next to bearing rollers and large bronze thrust washer between gear cluster and case at each end, insert countershaft from rear and push arbor out through front of case. See that lock ball in place in rear end of shaft and that ball engages groove in case to prevent shaft from turning. Countergear clearance should be .0005-.0024". Endplay should be .0176-.0296" (Buick), .009-.021" (Pontiac 1940-48), .0176-.0306" (Pontiac 1949 on).

Reverse Idler Gear Assembly:—Remove old lockpin from reverse idler gear shaft and discard pin (use new pin for reassembly). Idler gear bushing clearance on shaft should be .0002-.0042". When installing gear, line up lock pin hole in shaft and case and install NEW lock pin as follows:

Lock Pin Installation—Use new lock pin, coat pin with white lead or other sealing compound, drive pin in until head of pin is correct distance below surface of boss on case:

Buick—(1946-47) ⅝-¾", (1948 & Later) 25/32".
Oldsmobile—¾".
Pontiac—(1946-48) ¾", (1949 & Later) 25/32".

Shifter Mechanism: Selector shaft must be removed when transmission disassembled (see disassembly instructions above). To remove shaft, use KMO-244 or J-2895 tool to remove cam setscrews, remove lever on left end of shaft by taking out retainer screw, remove lever on lower end of cross-shift shaft (necessary to allow inner selector lever on upper end of shaft to disengage from selector shaft). Drive selector shaft out through right side of case (this is important to avoid damge to oil seal on lever end of shaft). With selector shaft out, inner selector lever and shaft can be lifted out. See that this shaft and hole in case are clean, lubricate with Lubriplate when shaft replaced, being certain that spring washer, plain washer and seal installed on upper end of shaft within case. Install selector shaft through left side of case and install new welch plug to close hole on right side (use white lead or other sealing compound to seal plug).

►***CAUTION*—When installing lever on selector shaft, hold shaft with wrench to avoid damaging selector cams. Make certain that lockwasher installed on lever retainer screw.**

1941-53 CADILLAC, 1950 OLDSMOBILE SYNCHRO-MESH

Cadillac V8, All Series (1941-53)
Oldsmobile 8, Series 88 & 98 (1950)

▷CHANGES, CAUTIONS, CORRECTIONS

▷Cadillac & Oldsmobile Optl. Hydra-Matic Drive Transmission—Data below applies only to standard synchro-mesh transmission. *See "Hydra-Matic Drive" transmission.*

▷Cadillac 1941 Extension Housing Change—See Extension Housing data for special type used on first Housing data below for special type used on first 1941 cars which must be replaced to allow installation of special speedometer gears if optional ratio rear axles being installed on these cars.

DESCRIPTION: Constant-mesh, synchro-mesh, all helical gears (low & reverse sliding gear).

Synchronizing Unit. Consists of two synchronizing drums mounted on the ends of three pin cams which extend through cam holes in the center ring of the clutch sleeve. Synchronizing drum assembly is centered on the clutch sleeve by detent springs which engage the notches in the pin cams. The entire assembly moves as a unit when the clutch sleeve is shifted until the synchronizing drums and cones engage, synchronizing unit then rotates (relative to clutch sleeve) until cam surfaces on clutch ring engage pin cams. Drums are driven through this engagement until synchronization is completed.

Interlock Assembly—Ball seat tube installed in interlock boss in transmission case (spring located within tube interlock ball in tube at each end). When gear is engaged, shoulder on shifter shaft quadrant forces tube toward opposite quadrant so that lock ball seated in end of tube and prevents from releasing this shifter shaft.

REMOVAL OF TRANSMISSION: *See "Transmission" on car model page.*

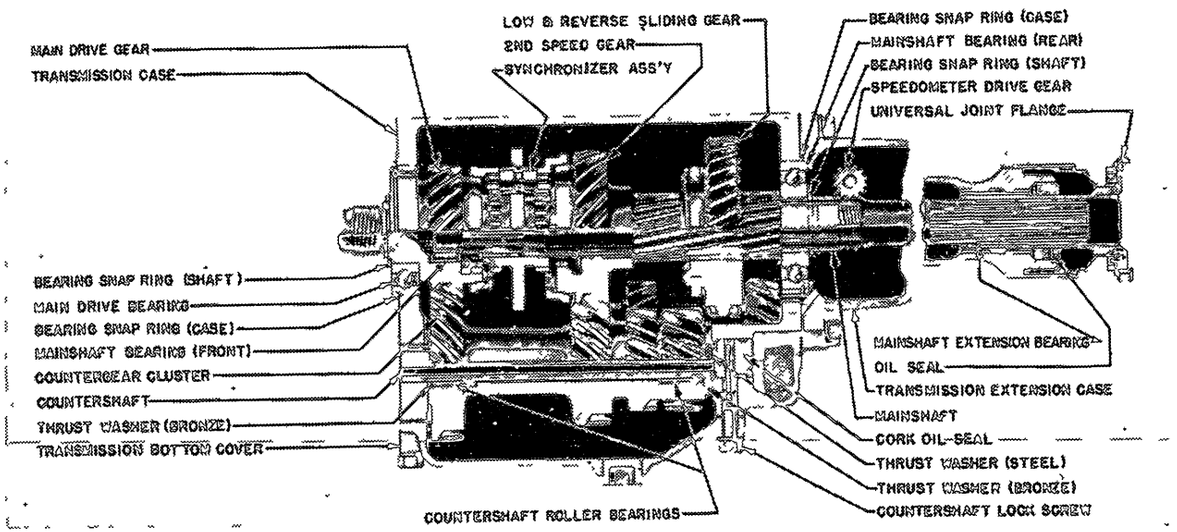
DISASSEMBLY (1941-48): Remove speedometer gear adapter housing and gear assembly. If universal joint flange not removed previously with propeller shaft, slide flange off rear end of extension shaft. Take out extension housing mounting capscrews and remove extension housing. Remove bottom cover from transmission case. Remove countershaft through rear end of case, lift out gear cluster and thrust washers (CAUTION—do not lose bearing rollers and spacer). Remove lockscrews on front of case, pry main drive gear and bearing assembly out through front of case. Slide the clutch sleeve and synchronizer assembly off front end of mainshaft and lift out. Use tool J-1007 to free second speed gear lock ring. Tap mainshaft and bearing assembly out of rear end of case and remove while sliding the second speed gear and low & reverse sliding gear off forward end of shaft (lift these gears out through opening in case). Tap reverse idler gear out through rear of case, lift out reverse idler gear and thrust bearings. Remove shifter levers on outside of case, remove shifter lever shafts from within the case (CAUTION—use care not to lose interlock spring, balls, or tubes).

DISASSEMBLY (1949 ON): Remove the speedometer driven gear and sleeve assembly. Take out extension housing capscrews, remove housing and bushing assembly. Remove transmission lower cover (CAUTION—note location of two longer screws which lock countershaft and reverse idler shaft). Check cluster gear endplay with feeler gauge (for selection of correct thrustwashers when re-installing gears). Push countershaft out through rear of case with tool J-1184 leaving tool in cluster gear to retain bearing roller assembly. Remove cluster gear assembly and thrustwashers from case. Take out lockscrew on front of case, remove bearing lock ring from drive gear bearing outer race. Slide mainshaft and rear bearing out through rear of case as far as possible and tip assembly to one side to provide clearance. Tap drive gear and bearing back into transmission case and remove through opening in case (CAUTION—use care not to damage mainshaft assembly). Slide synchronizer unit off end of mainshaft and remove from case. Remove second speed gear lock ring from mainshaft groove, slide second speed gear, thrustwasher, and low speed gear off shaft while withdrawing mainshaft and rear bearing through rear of case. Lift out second speed gear and low speed gear (turn gear to free it from shifting lever shoe). To remove reverse idler gear, tap shaft out through back of case (or use tool J-1010 to push shaft out), lift out reverse idler gear and thrustwashers. Remove shifter levers from outer driven gear and sleeve assembly. Take out extension ends of shifter shafts, remove shifter lever shafts from within case.

▷*CAUTION—Do not lose interlock springs, balls, or tubes when removing shifter shafts.*

REASSEMBLY: Reverse disassembly directions and note following data on sub-assemblies:

Mainshaft Rear Bearing: If bearing being replaced, use tool J-4390 to remove speedometer drive gear from shaft, remove bearing snap ring, remove bearing by jarring end of shaft on wood block or press bearing off in arbor press. Use tool J-4390 to press or tap new bearing against shoulder on shaft, install snap ring, then install speedometer drive gear similarly.



Mainshaft & Second Speed Gear Assembly. Cannot be installed as an assembly (to install, reverse disassembly directions above). See that second speed gear thrustwasher installed with key engaged in groove in shaft. Use new lock ring to retain second speed gear (install ring with J-1466A pliers). Low gear backlash on mainshaft splines should be .004-.007" (new), .010" (worn limit). Synchronizer hub backlash on mainshaft splines should be .0005-.001" (new), .003" (worn limit). Second speed gear clearance on mainshaft should be .001-.0015" (new), .00175" (worn limit), and endplay should be .004-.008" (new), .012" (worn limit).

Shifter Shaft Assembly: Install the second & high lever and shaft in neutral position making certain that shoe is properly located. Install interlock ball, tubes, and spring assembly in case with counterbored end of tube toward ball, compress the spring and locking balls with tool J-1168, install low-and-reverse shaft with sector in neutral position making certain that shoe is in place. Install new cork seals on outer ends of shafts (use tool J-1169), tap shifter levers into place on shafts (brace inner ends).

Synchronizing Unit:—Should not be dismantled and cannot be serviced except for removal of detent springs (installed directly below each pin cam and accessible without dismantling unit. To remove detent spring, pry top edge of spring out of gear, push spring out of groove. Install new springs with long end of spring facing long end of gear, pull coupling up in place over springs.

Main Drive Gear & Clutch Shaft Bearing:—Bearing is press fit on shaft. To replace bearing, remove snap ring from shaft groove, jar end of shaft on

CONTINUED ON NEXT PAGE

CADILLAC, OLDSMOBILE, SYNCHRO-MESH TRANSMISSION

CADILLAC & OLDSMOBILE (Continued)

wood block to remove bearing or press shaft off in arbor press. Press new bearing on shaft (CAUTION —press on inner race only), install snap ring. To remove mainshaft pilot bearing rollers from drive gear recess, remove and discard locking ring (use new locking ring when installing rollers).

Counter Gear Cluster: Needle bearings are loose and will fall out when shaft removed unless a dummy shaft or Tool J-1184 used to retain them. Use this special tool J-1184 to assemble bearings (rollers, spacer, and the retaining washer at each end) before installing counter gear. Leave tool in gear until it is pushed out by countershaft when shaft inserted. Install thrust washer at each end with steel spacer between thrust washer and case at rear. See that locking screw hole in countershaft lines up with cover screw hole so that shaft will be locked in place when cover screws installed and that new cork seal installed in groove near rear end of shaft to prevent oil leaks. Countergear endplay should be .005-.012" (new), .018" (worn limit).

NOTE—If endplay exceeds .018", install special oversize thrust washers.

Reverse Idler Gear:—Clearance on shaft should be .005-.010" (new), .015" (worn limit). When installing shaft, use special tool J-1010 to align front thrust washer (on 1939 and later models, thrust washers are steel-backed, babbitt faced type), see that thrust washers installed at each end of shaft with prongs on washers engaging slots in case, use new cork seal in groove on rear end of shaft to prevent oil leaks, align locking screw hole in shaft and case (shaft locked by cover screw). Endplay should be .005-.010" (new), .015" (worn limit).

Extension Housing & Oil Seal (Cadillac): Install extension housing on transmission case and tighten screws securely. Then install oil seal in rear end of housing using tool J-1942. Extension housing bushings are not furnished separately and housing should be replaced if bushing requires replacing. NOTE—Extension housing used on approximately first 3500 cars in 1941 permits use of speedometer pinion for standard rear axle ratio only and housing must be replaced if optional rear axle installed. Second type housing (with provision for installation of optional axle ratio speedometer drive pinions) only is furnished for service and is marked 'R' on case under speedometer cable opening. *See Cadillac Special Data in Car Model Section.*

Extension Housing & Oil Seal (Oldsmobile): Bronze bushing in housing is furnished separately and can be replaced. Remove old bushing with tool J-1150-4, install new bushing using same tool and adapter J-1150-5 (stop guide which will position bushing correctly). **New bushing must be reamed** using Reamer Tool J-1450 and pilots J-1450-2 (rear) and J-1450-7 (front—this pilot must be tightened in place with clamps J-1450-8).

Oil Seal Replacement—Pry old seal out, start new seal squarely in bore by tapping lightly on outer edge, then drive seal into place with tool J-1354.

1946-54 CHEVROLET 3-SPEED

Pass. Cars & Sed. Delivery (1946-54)
Half-Ton & ¾-Ton Trucks (1947-54)
Half-Ton & ¾-Ton Trucks (1st Series 1955)
One-Ton Trucks (1947)

►CHANGES, CAUTIONS, CORRECTIONS

►*1952 COUNTERSHAFT PRODUCTION CHANGE:* Beginning with 1952 Transmission Serial No. JA-14026, countershaft changed to include a 60° notch cut into top side of front counter gear shaft hole boss in transmission case, and a 3/16" angular hole drilled in countershaft to align with notch. These changes provide better lubrication. Old and new type transmission parts have same part numbers.

►*1949-52 HIGH GEAR DISENGAGEMENT CORRECTION:* Correct by installing either the "First Design" or "Second Design" 1953 parts listed below. *CAUTION—All 1st or 2nd design parts listed must be used together.*

Transmission Part Nos. (1st Design)

Part No.	Passenger	Commercial
Trans. Main Drive Gear	3699250	3699251
Rollers (24 each)	7450247	7450247
Mainshaft	3699258	3699259
Spacer (Front)	591851	591851
(Rear)	591852	591852

NOTE—Front bearing unchanged (14 rollers—3/16" x 33/64"). New bearing has 24 rollers (⅛" x ½").

►*1953 PASS. CARS & COMM'L. TRANSMISSION GEAR RATTLE IN LOW & REVERSE CORRECTION (Cars before Transmission Serial Nos. M8-18 & S8-26):* Gear tolerances and lash were reduced and other changes in design were made (as required by addition of two teeth in Synchronizing Rings) on transmissions beginning with above serial numbers. If later design parts (as listed in "Transmission Second Design Parts" below) are installed on earlier transmissions, all parts listed must be installed as a unit.

Transmission Part Nos. (2nd Design)

Part	Pass. Cars	Comm'l.
Main Drive Gear	3705066	3705067
Second Spd. Gear	591877	591889
Clutch (2nd & 3rd)	3705112	3705112
Synchronizer Ring	591886	591886

►*1955 PASS. CAR HARD SHIFTING CORRECTION:* Install the three new gears listed below, which have a greater tooth chamfer, a new Transmission Conversion Kit, Part No. 3731061. *See "Transmission Control" for installation of the conversion kit.*

Description	Old No.	New No.
1st & Reverse Gear	3845056	3725646
Counter Gear	3845051	3845201
Reverse Idler Gear	3845052	3845203

►*SHIFT LEVER RATTLE CORRECTION*—Rattle may be caused by a small hour-glass shaped spring in lever working loose from ball on end of gear shift control lever. To correct, remove shift lever and spring, install a #6 x ½" sheet metal screw in lower side of lever at point 3 3/16" from pivot hole toward outer end of lever. Screw will provide seat for spring and prevent disengagement NOTE—Gearshift lever on later 1953 cars has metal tang at this point to provide a spring seat and does not require reworking.

►*1953 MAINSHAFT PILOT BEARING CHANGE*—Pilot bearing on 1953 models consists of two separate roller assemblies in main drive gear recess. Forward bearing is positioned by spacer fitting against shoulder on mainshaft, rear bearing is positioned by snap ring in groove in main drive gear directly ahead of the bearing.

DESCRIPTION: Constant Mesh, Synchro-mesh, (second & high), sliding gear (low & reverse), all helical gear type.

REMOVAL OF TRANSMISSION: *See "Transmission" on car model page.*

DISASSEMBLY: On all Pass. Cars and trucks (1948 & later), remove screws and take off cover on side of case (see Shifter data). On earlier trucks, take out screws and remove gear shift lever and transmission cover assembly (turn screws out evenly to relieve spring pressure), remove shifter shafts and forks (see Shifter servicing data below). On all models, remove universal joint capscrew and washer, slide joint off shaft. Remove drive gear bearing retainer screws on front of case, take off retainer. Mark main drive gear, second speed gear, and both synchronizing rings to insure reassembly in same relative positions. Use special puller, J-937, to remove main drive gear and drive gear bearing, take out 14 loose rollers (mainshaft front bearing). Use special tool, J-938, installed on back of transmission case and push mainshaft out toward front (IMPORTANT—front synchronizer ring must be turned so that lugs line up with slots in splines on mainshaft to avoid damage to lugs and splines), remove mainshaft from front end. Engage second speed gear and clutch sleeve, remove clutch sleeve assembly, low and reverse gear, second speed gear thrustwasher. Remove rear bearing support assembly, remove speedometer drive gear and gear spacer from shaft. Expand rear bearing lock ring into case (use tool J-3185), tap bearing out toward front (bearing must be removed before countershaft can be removed). Drive countershaft out toward front. To remove reverse idler, drive idler shaft lockpin into shaft (pin shorter than shaft diameter), drive out expansion plug at rear of case, remove idler shaft through this hole.

REASSEMBLY: Reverse disassembly directions (above) and note following data on servicing of all sub-assemblies.

Main Drive Gear & Clutch Shaft Bearing: Bearing retaining nut and oil slinger are single unit with a left hand thread and are staked in hole in shaft. Clamp shaft in vise, remove nut with wrench J-933. Use special press-plate J-936 to press bearing on or off shaft. Bearing retainer mounting holes on front of case spaced irregularly to insure assembly in correct position (to align oil return holes). NOTE—Special Malleable Iron Clutch Gear Bearing Retainer, No. 604932, available for installation on all 1940 and later 3-speed transmissions for severe service (will prevent lubricant loss due to cracked retainers).

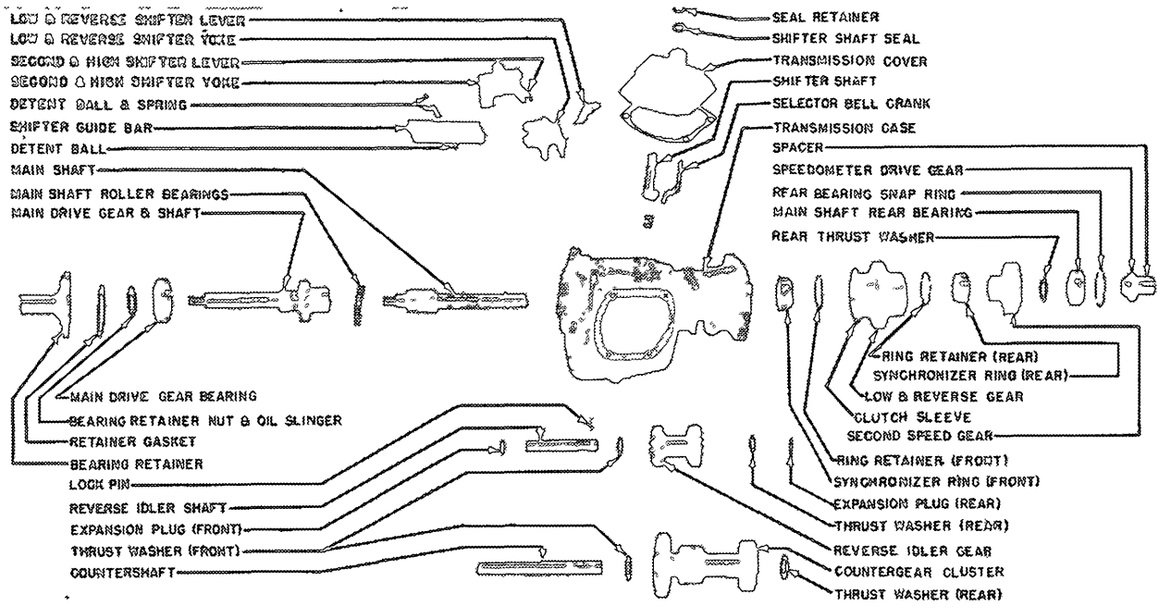
Clutch Sleeve & Synchronizing Rings:—To disassemble rings, turn ring until ends of ring retainer is visible through slot in sleeve, insert special pliers J-932 in slot, expand retainer to free ring, pull ring out. See that synchronizing cones are tight in sleeve (replace clutch sleeve and cone assembly if cones loose or worn). Check rings to see that they do not rock in cones.

CONTINUED ON NEXT PAGE

1946-54 CHEVROLET 3-SPEED (Continued)

Energizing Springs:—Use new spring whenever spring is removed. When installing springs, do not expand more than necessary to clear clutch teeth. Install springs with offset end between third and fourth teeth of any bank of the clutch teeth (offset prevents spring rotation).

Mainshaft & Rear Bearing:—To install bearing, first install bearing lock ring in case, expand lock ring with tool J-3185, tap bearing outer race with soft steel drift until it is halfway in case, release snap ring, continue to tap bearing until lock ring engages slot in bearing race. Lubricate second speed area of mainshaft, install shaft with lugs on front synchronizer aligned with slots in mainshaft spline (to avoid damage to lugs and splines), use replacing tool J-938 to pull shaft into place. Second speed gear endplay should be .010" with shaft installed.



Rear Bearing Support (Truck 1948 On): Support and bushing furnished as an assembly to maintain the transmission alignment. Replacement of bushing requires replacement of complete Support as follows: Split universal joint, take out transmission support to frame bolts, push front end of propeller shaft up out of the way. Remove universal capscrew and take off yoke. Remove Support Pipe Plug from case and pull Support out through rear of case with hook puller. When installing Support, align pipe plug hole in support with tapped hole in case.

▷*CAUTION—Speedometer Drive Gear Spacer installed* ahead of speedometer drive gear on these trucks.

Counter Gear Cluster:—Bushings staked in place and clearance on shaft is .002-.004". When installing countershaft, see that thrust washers are in place at each end of counter gear cluster and that flat on forward end of shaft is horizontal and on top (flat engages clutch housing to prevent shaft turning, transmission cannot be installed unless flat properly located).

Countergear Cluster Bushing Installation—Rear bushing must not close up rear holes in countergear cluster (hole opening must be 3/32" minimum—bushing must project partly over hole to permit staking it in place). These openings necessary to permit oil circulation around shaft for lubrication. When bushings installed, stake bushings in place by expanding bushings into the front and rear holes in countergear cluster. Check rear bushing and if hole opening is not 3/32" minimum, drill 1/8" hole in bushing at each rear hole (drill at front edge of countergear cluster hole to avoid disturbing bushing stakings).

Roller Bearing Type—Used on trucks and furnished as service replacement on Passenger cars (Carburized Gear type). To install bearing rollers, install shaft in countergear cluster, coat roller recess with cup grease, install 25 rollers in each end, remove countershaft and install gear cluster in transmission case. Install forward thrust washer between gears and case (lubricate washer), feed assembly tool T-1617 in from front end (tapered end first), lubricate countershaft and install at front end and pushing assembly tool out at rear end (lubricate rear thrust washer and install in case before assembly tool reaches this point). See that flat on forward end of shaft is horizontal and flush with case (not more than 1/64" below face).

TYPICAL CHEVROLET 3-SPEED SYNCHRO-MESH TRANSMISSION

▷1953 Countershaft Note—Countershaft has 60° notch cut into top side of front counter gear shaft hole boss in transmission case, and a 3/16" angular hole drilled in countershaft to align with notch.

▷1953 Mainshaft Pilot Bearing—Two separate roller bearings used. Front bearing and spacer must be installed first in drive gear recess, then rear bearing snap ring installed in groove in recess and rear bearing rollers installed. Mainshaft pilot must be inserted through rear bearing rollers, spacer, and front bearing rollers.

Reverse Idler Gear:—Remove old lockpin from shaft before installing, line up holes in case and shaft, use new lockpin and drive pin in so that head is approximately 1/16" beyond surface of case, peen hole to prevent pin coming out. Pin must be tight in hole to prevent oil leaks. Install new expansion plug in shaft hole in rear of case.

Reassembly—Install long shifter fork on guide bar with fork end toward nearest mounting screw hole, line up lock ball recess in fork with hole in guide bar, install one lock ball and spring in hole, start opposite shifter fork on guide bar, assemble other lock ball on spring, use flat tool to compress spring and slide fork into position over lock ball. Check operating shaft cork seal and retainer, replace if worn. Install operating shaft in cover, assemble anti-rattle spring and shifter yoke lever on bell crank end of operating lever, move selector (cross-shift) bell crank over center of shifter yoke lever. Press on outer end of operating shaft so that shifter yoke lever held firmly against selector lever bell crank, make certain that both shifter forks in neutral position on guide bar, then assemble guide bar and shifter fork assembly on cover with low-reverse shifter fork toward bottom (narrow side) of cover. Make certain that selector lever bell crank engages slots in shifter forks and that pins in forks engage slots in end of shifter yoke lever. Bolt guide bar to cover. CAUTION—Low-reverse sliding gear and clutch sleeve must be in neutral position when shifter mechanism installed on transmission case. See Chevrolet Vacuum Power Transmission Control for gearshift lever adjustment on the car.

Shifter Mechanism (1948 & Later Trucks, 1949 & Later Pass. Cars): In transmission cover. Requires removal of cover as follows: Drain transmission, take out shift lever lock bolts, and pull lever off each shifter shaft. Remove cover from transmission. Take out shifter interlock retainer nuts and locks, remove shifter interlock retainer, then remove shifter shaft and fork assemblies, shaft seals, poppets and springs, or interlock from cover.

Cover Installation—Hump on side of First and Reverse Shifter Fork must be toward rear of transmission. Install cover (using new cover gasket) with gears and shifter forks in neutral. Install shift lever on each shifter shaft and tighten lock bolts.

Universal Joint Ball Adjustment: Should be checked each time propeller shaft disconnected (before transmission reinstalled). Remove ball housing from torque tube, clean ball with cleaning solvent, check for roughness and clean up with emery cloth, see that torque tube is clean. Install new torque ball outer retainer seal and packing. Assemble ball housing on back of transmission using four new shims for a trial fit, tighten attaching capscrews securely. Check adjustment by moving rear end of ball housing. If adjustment correct, torque tube ball should be snug fit but should move with hand pressure. If ball housing cannot be moved, add shims under ball retainer flange, if ball housing moves very freely, remove shims at this point until correct adjustment secured.

1955 CHEVROLET 3-SPEED

Pass. Cars & S dan Deliv ry (1955)
Half-Ton & 3/4-Ton Trucks (1955 Second Series)

►*OVERDRIVE TRANSMISSION OVERHAUL NOTE: Transmission overhaul is the same with or without overdrive. See "Chevrolet Overdrive" for removal of overdrive unit.*

DESCRIPTION: Constant mesh, synchro-mesh (second & high), sliding gear (low & reverse), all helical gear, similar in design to previous transmission.

TRANSMISSION REMOVAL: *See Car Model pages.*

TRANSMISSION DISASSEMBLY: **1)** Remove capscrews from transmission side cover and remove cover and gasket. *NOTE–Under ordinary circumstances it is not necessary to disassemble cover assembly.*

2) Remove four clutch gear bearing retainer screws and shakeproof washers and remove the retainer. Install clutch gear and bearing puller J-937 by screwing the threaded sleeve (left hand thread) onto clutch gear shaft, and remove gear and bearing.

3) Remove 24 roller rear pilot bearings, 2 washers and 14 front roller bearings. Remove extension to transmission case bolts and lockwashers and pull extension and mainshaft out of transmission case, leaving second and third speed clutch assembly and first and reverse gears in case. Do not force mainshaft. Rotate mainshaft and second and third speed clutch gear to obtain alignment of clutching teeth and splines.

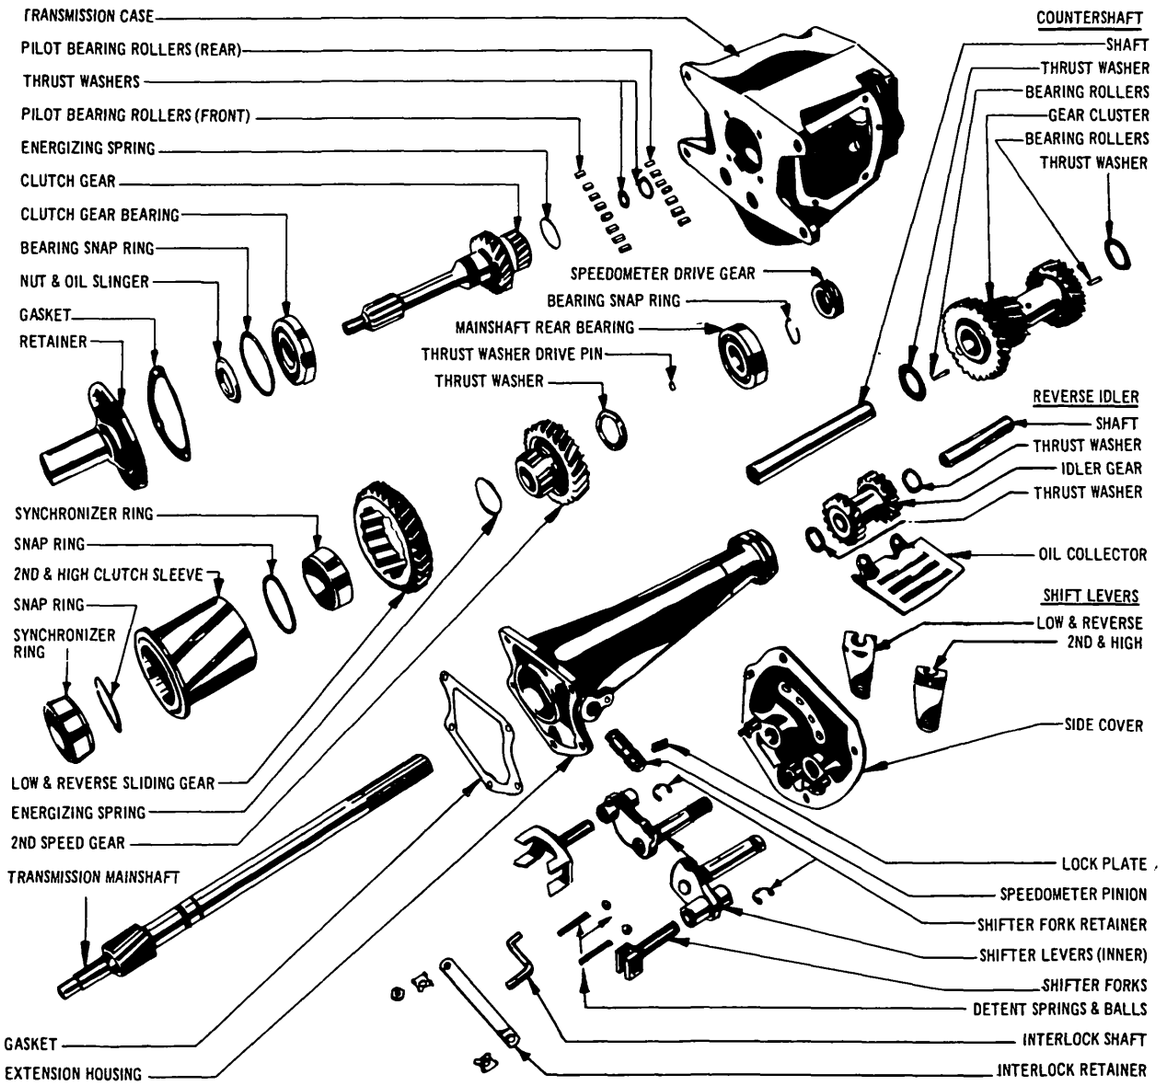
4) Remove second and third speed clutch sleeve assembly and first and reverse gear through side opening in transmission case. Remove counter-shaft by driving it from the front to rear of case, using a soft steel drift. Remove countergear rollers and front and rear thrust washers. *NOTE*–Countergear must be removed before removing reverse idler shaft.

5) Drive idler shaft lock pin into shaft (pin is shorter than diameter of shaft so shaft may be slipped out when pin driven in). Using a drift pin, tap rear of shaft to drive plug ahead of shaft *(CAUTION*–Do not rotate shaft while driving it out as lock pin may drop down between idler gear bushings). Remove reverse idler gear and thrust washers.

6) To remove mainshaft from extension, expand snap ring and tap rear of shaft with a soft hammer to bring shaft, speedometer gear, second speed gear and bearings as an assembly forward out of extension.

SUB-ASSEMBLY OVERHAUL: Wash all parts thoroughly. Inspect case for cracks and check front face of case for burrs. Check gears and shafts for wear or damage. Check first and reverse sliding gear for free movement on clutch sleeve. Check clutch sleeve for free movement on mainshaft.

Mainshaft, Rear Bearing, Second Speed Gear & Speedometer Gear: Disassembly–Press speedometer drive gear off mainshaft, using a suitable split plate in an arbor press. Remove bearing to mainshaft snap ring and press bearing off shaft. Remove second speed gear thrust washer, pull drive pin out of shaft and remove second speed gear.



Reass mbly–Slide second speed gear on mainshaft, insert drive pin in shaft and install thrustwasher against gear. Install new bearing (groove in bearing toward second speed gear). Select one of four selective fit snap rings (see table below) so endplay of bearing on shaft is a maximum of .004" (this may be determined by installing successively larger rings. Use the thickest ring that will enter snap ring groove on shaft). Start speedometer drive gear on shaft with the chamfered inside diameter of gear toward bearing. Press gear on shaft until forward face of gear is 7/8" from rear face of bearing.

R ar B aring Snap Rings

Thickn ss	Part N .
.086-.088"	3707188
.089-.091"	3707189
.092-.094"	3707190
.095"-.097"	3707191

Clutch Gear Bearing: Removal–Place clutch gear in a vise with soft jaws, and remove bearing retainer nut and oil slinger, using special wrench J-933. The retaining nut and oil slinger is a one-piece steel casting machined with a left handed thread and is locked in place on clutch gearshaft by being staked into a hole

CONTINUED ON NEXT PAGE

CHEVR LET "SYNCHRO-MESH" TRANSMISSI N (EXPLODED VIEW)

1955 CHEVROLET 3-SPEED (C ntinued)

provided for that purpose. To remove clutch gear bearing place the special press plate J-936 over gear and against bearing. Using an arbor press, press shaft out of bearing. *CAUTION–Do not attempt to drive shaft out of bearing or bearing will be damaged.*

Installati n–Using an arbor press, press clutch gear bearing on clutch gear with the locating ring toward front of the gearshaft so that bearing will enter case to maximum possible depth. Install combination clutch bearing retainer nut and oil slinger on clutch gearshaft and draw it up tight, using special wrench J-933. Lock the retainer nut oil slinger in place by staking it into hole with a center punch, being careful not to damage threads on shaft. *CAUTION–The bearing must turn as freely after it is installed on the shaft as it did before b ing placed on shaft.*

Clutch Sl eve & Synchronizer Rings: Disassembly–Remove first and reverse sliding gear. Turn synchronizer ring in clutch sleeve until ends of synchronizer ring retainer can be seen through slots in clutch sleeve. Using special pliers J-932, expand the retainer into counterbore in clutch sleeve. This raises the retainer from groove in ring so ring may be easily slipped out. Check synchronizer cones for wear or being loose in clutch sleeve. If cones are damaged, it will be necessary to replace the clutch sleeve assembly and both synchronizer rings. Inspect synchronizer rings for smoothness. Place rings in synchronizer cones and check with thumbs to see that rings do not rock. Excessive rocking indicates a poor fit between rings and cone, which will not permit proper synchronization of gears during shifting.

R assembly–Install synchronizer ring retainers in counterbores in ends of clutch sleeve. Using special pliers J-932 in slot in clutch sleeve, expand each retainer in counterbore, lubricate each synchronizer ring with light oil and install clutch sleeve. (make sure retainers seat in groove all the way around rings so rings will turn freely). Install first and reverse sliding gear on clutch sleeve.

►*SYNCHRONIZER ENERGIZING SPRING REPLACEMENT CAUTION:* It will be noticed that one end of these springs is slightly offset. Each spring must be assembled in its groove in the clutch gear and the second speed gear with the offset or locking end between the third and fourth teeth of either of the two banks of teeth on these gears, thus keeping the spring from turning in its groove. It should not be necessary to replace these springs, however, if spring is removed, a new spring should be installed. The spring may be removed by slipping a thin blade under the spring and raising it sufficiently to slide it over clutch gear teeth. *CAUTION–*In replacing either energizing spring, be very careful not to distort it when slipping it over clutch teeth.

►*REVERSE IDLER GEAR INSPECTION NOTE:* Check bushing for excessive wear by using a narrow feeler gauge between shaft and bushing. The proper clearance is .002-.004". *Reverse idler gear bushings are not serviced separately.*

Side Cover & Shift Shafts: Disassembly–Remove cover assembly from transmission and remove outer shift lever clamp bolts. Pull levers from shafts. Remove nuts and locks and remove shifter interlock retainer. Remove shifter shaft and fork assemblies, poppets and springs, or interlock from cover.

Reassembly–*(CAUTION–Side cover must be removed to install shifter levers to shift fork shafts in side cover. If shift levers are installed with the side cover on on transmission, shifter forks will be forced against gears causing hard shifting).* Install shifter interlock retainer. Install outer shifter levers on shafts and install clamp bolts. With transmission gears in neutral and shifter forks in neutral, install cover to transmission using a new gasket.

►*CAUTION: The hump on the first and reverse shifter fork must be toward rear of transmission when installed.*

TRANSMISSION REASSEMBLY: 1) Lubricate the reverse idler thrustwashers and install gear and thrustwashers in transmission case with the gear having the chamfered teeth to rear of case. Install idler shaft, making sure that lockpin hole in shaft lines up with hole in case at same angle.

2) Using a new idler shaft lock pin, coat pin with Permatex and drive it in approximately 1/16" beyond flush-with-case position. Peen hole slightly to retain it in position. *(CAUTION–This lock pin must be a tight fit in case to prevent oil leaks).* Install idler shaft expansion plug in case, using a new plug when possible.

3) Place some cup grease on roller bearing area in each end of countergear and install the 25 rollers in each end, (the grease will hold rollers in place during installation). Install countergear assembly tool J-5777 in countergear. Lubricate thrustwashers with grease and place one at each end of gear. Insert countergear (with Tool J-5777) in transmission case and align tool with countergear holes in case. Lubricate countershaft and insert it in rear of case, pushing assembly tool out front of case. Turn countershaft so flat on end of shaft is horizontal and at bottom of shaft. Make sure front end of shaft is in line with hole in front of case and drive shaft in until flat on shaft is flush with rear of case.

►*CAUTION:* Flat on bottom of shaft must be horizontal and at BOTTOM or the transmission case extension cannot be assembled to transmission case. On OVERDRIVE equipped transmissions, flat must be horizontal and at TOP of shaft to engage overdrive adapter.

4) Install synchronizing clutch sleeve assembly, with first and reverse sliding gear, in transmission case. Install mainshaft assembly in transmission case or in overdrive adapter. Install transmission case gasket.

5) Align lugs on synchronizer rings with slots in mainshaft helical spline, and turn second speed gear on mainshaft so lugs on synchronizer rings slide in slots on gear. Push shaft into clutch sleeve until transmission case extension (or overdrive adapter) is tight against case. Install bolts and lockwashers.

6) Lubricate mainshaft pilot hole in clutch gear with cup grease and install the two groups of roller bearings (install the 14 group and small spacer, then the large spacer and the 24 group). After being assembled in pilot hole, these bearings will lock themselves in place and cannot fall out. Install clutch gear in transmission case.

7) Using a brass drift, tap outer race of clutch gear bearing until bearing locating ring seats against case, being careful to drive the assembly straight to prevent damage to mainshaft pilot and pilot bearing. *CAUTION–*During this operation make sure that synchronizer ring lugs line up with slots between clutch teeth on clutch gear.

8) Install clutch gear bearing retainer and gasket, making sure that oil slot in retainer lines up with oil slot in front face of case. Do not allow gasket to protrude beyond edge of retainer. Install retainer screws, using special shakeproof washers. Tighten retaining capscrews to 10-12 ft. lbs.

CHEVROLET OVERDRIVE

Pass. Car & Sedan Delivery (1955)
Half-T n Truck (1955 Sec nd Series)

►*OVERDRIVE TRANSMISSION OVERHAUL NOTE: Transmission overhaul is the same with or without verdriv . S "1955 Ch vrolet 3-Speed Synchro-mesh" f r transmissi n ov rhaul.*

DESCRIPTION: Solenoid operated type (no centrifugal pawls) with governor control and accelerator controlled "kickdown". Engagement and disengagement of overdrive is made by movement of the sun gear pawl. The solenoid plunger pushes the pawl in to engage sun gear for overdrive and withdraws the pawl for direct drive (direct drive below cut-in speed and "kick-down" direct drive). *See "Chevrolet Overdrive Control".*

►*OVERDRIVE REMOVAL NOTE:* Due to interference of X-member on convertible models, transmission and overdrive must be removed as an assembly for repairs. On other models all repairs to overdrive except those involving transmission mainshaft, overdrive adapter, or transmission rear bearing, can be made under the car with overdrive housing removed.

OVERDRIVE HOUSING: R moval–1) Place car on jack stands, remove drain plugs and drain transmission and overdrive. Disconnect wires from solenoid and governor switch. Disconnect cable from speedometer driven gear fitting.

2) Remove nuts and U-bolt retaining rear universal joint trunnion bearings to drive flange. Lower rear of propeller shaft and slide shaft to rear to remove universal joint front flange from output shaft. Remove speedometer driven gear fitting, gear and shaft.

3) Disconnect control cable from control lever. Drive

CONTINUED ON NEXT PAGE

CHEVROLET OVERDRIVE (C nt.)

out control shaft tapered pin and pull control shaft out.

4) Remove bolts and lockwashers attaching overdrive housing to transmission case and adapter and pull overdrive housing including overdrive output shaft and ring gear assembly to rear *(CAUTION–Be careful to keep adapter from pulling away from transmission case. If this happens, transmission mainshaft pilot bearings will drop out of clutch gear and necessitate disassembly of transmission).* As output shaft is pulled toward rear, catch the clutch rollers as they drop out of retainer.

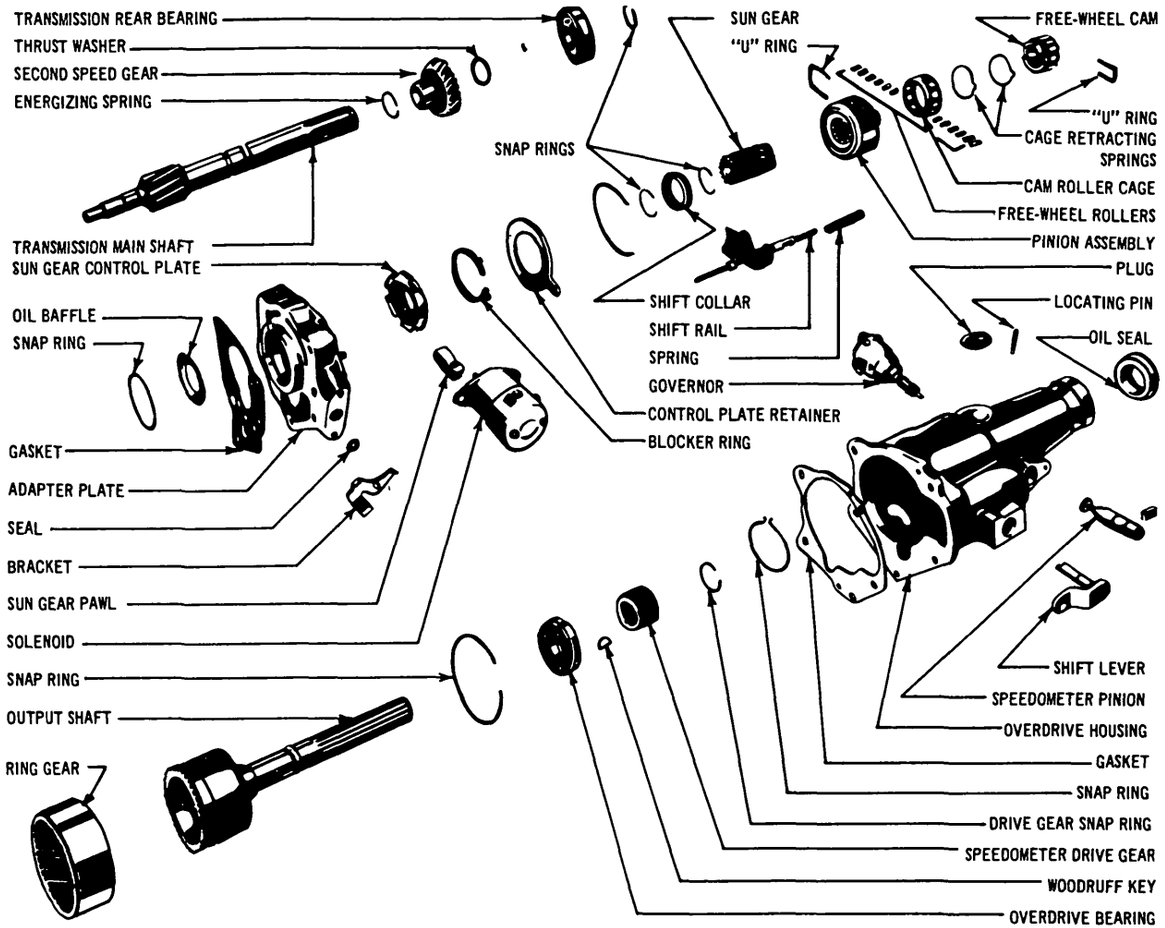
5) Remove gasket from adapter and install one bolt removed from housing to hold the adapter plate to transmission housing.

OVERDRIVE DISASSEMBLY: 1) Remove governor and pinion if not previously removed. Pierce plug in rear bearing snap ring access hole in top of housing and pry out the plug.

2) Spread rear bearing snap ring with snap ring pliers and lightly tap end of shaft with a soft hammer to free bearing from snap ring, then pull shaft, including ring gear, speedometer drive gear and rear bearing from housing.

3) Remove shift rail retractor spring from housing and output shaft rear bearing snap ring. Press bushing from rear of housing, using tool J-5778.

4) Remove ring gear snap ring (large) and slide ring gear off shaft, (the oil collector ring is spun to shaft to provide an oil tight seal). Remove speedometer snap ring (small) from output shaft.



5) Support front face of bearing and tap end of shaft to start speedometer drive gear off shaft. *If necessary to use arbor press to start gear do not press shaft more than 3/8" through bearing or woodruff key in shaft may damage bearing.* Remove woodruff key and slide bearing off.

6) Disassemble parts remaining on transmission mainshaft as follows: Pull the "U" clips at each end of clutch cam and slide cam and roller retainer from pinion cage hub and transmission shaft. If roller retainer or cam is to be replaced, separate these pieces by pulling retainer out until hooked ends of spring can be pulled out of holes in cam.

7) Slide pinion cage assembly off sun gear and mainshaft. Remove sun gear and shift rail assemblies from shaft. Shift rail collar may be separated from sun gear by removing snap rings at either end of collar. Shift rail, fork, and spring may be separated by removing snap ring between cupped washer and shift fork.

8) Remove sun gear solenoid, oil seal and cable bracket. Remove large snap ring from adapter and remove sun gear control plate retainer. Then slide control plate and blocker ring out of adapter. If control plate or blocker ring is to be replaced they may be separated by pulling blocker ring off plate. Lift sun gear pawl out of adapter.

CLEANING & INSPECTION: Wash all parts thoroughly in solvent and blow dry with air. Inspect housing, shift rail retractor spring, snap rings, gears and bearings for cracks, defects or damage and substitute new

CHEVROLET OVERDRIVE (EXPLODED VIEW)

parts where necessary. If clutch rollers show surface markings of any kind, they should be replaced. Inspect "U" clips, control plate retainer, control plate, blocker ring and pawl for defects or damage.

Blocker Ring Fit & Tension on Hub–Push one end of ring toward the other. The ring should grip and hold to the hub. If ring does not hold when correctly installed (flat surface of ring facing out), it should be replaced. Push one end of ring away from opposite end and check frictional drag required to slide ring around hub as follows: (a) Hold one lug of control plate in a soft jawed vise and hook a spring scale into the notch of the nearest blocker ring lug. (b) Measure pull required to rotate ring after it has started moving. The pull should be 4-6 lbs. on new parts, which will fall to 1-1½ lbs. when thoroughly broken in. While low friction may be corrected by squeezing the ring together for a tight fit, installation of new parts is recommended.

Clutch Cam–Inspect clutch cam and if the 12 flat surfaces show slight lengthwise indentations, replace the cam. If rollers show markings of any kind, they should all be replaced. Test tension of cam retaining springs after the assembly has been thoroughly washed. *(NOTE–*The springs are designed to twist the cam to return the rollers to high side of the cam). Hold hub of cam and turn roller retainer counter-clockwise, then release retainer. The retainer should snap back quickly. If the action is slow or retarded, replace springs or the complete assembly. *(CAUTION–*If spring tension is weak or retarded, the unit will free-wheel at all times). When installing springs be sure both springs are coiled in the same direction (clockwise when looking toward flanged end of retainer), with "S" of springs hooked into holes in retainer and opposite ends hooked into holes in cam.

OVERDRIVE REASSEMBLY: 1) Insert sun gear pawl in adapter with notched side up. If blocker ring was removed from control plate, position ring on plate with

CONTINUED ON NEXT PAGE

CHEVROLET OVERDRIVE (Cont.)

surface of ring facing out, then start assembly over transmission mainshaft with ring toward rear. Slide the assembly into position with slot in ring toward sun gear pawl.

2) Slide control plate retainer over mainshaft against control plate and install snap ring in adapter. Install solenoid oil seal, solenoid and cable bracket.

3) Start the sun gear onto mainshaft. Hold shift rail so arm of fork fits in collar on sun gear and forward end of shift rail enters opening in adapter and transmission case. Slide both assemblies forward so pin in adapter locates the fork, and sun gear engages control plate.

4) Install pinion cage assembly over mainshaft and sun gear, turning cage assembly clockwise to engage sun gear. If free wheeling cam and roller retainer were separated, assemble these parts by positioning springs so both are coiled clockwise when looking at flanged end of retainer then place retainer over slotted end of cam, hook free ends of springs in holes in cam, turn retainer clockwise and push springs into place around cam.

5) Slide cam and roller retainer assembly over mainshaft and pinion cage hub. Install "U" clips at each end of free wheeling cam.

6) To reassemble overdrive housing, slide rear bearing straight on shaft with snap ring slot in bearing closer to ring gear end of shaft. Install woodruff key in shaft, start speedometer drive gear onto shaft and align keyway in gear with key in shaft. Tap gear tight against bearing and install small snap ring.

7) Engage ring gear on teeth of overdrive shaft and install large snap ring in ring gear. Using tool J-5778, install bushing into housing so it is flush with bore for seal.

8) Install output shaft rear bearing snap ring in slot in housing. Install shift rail retractor spring inside housing and insert a long 3/8" drift pin through spring to align spring with holes in housing. Slide output shaft assembly into housing until rear bearing contacts snap ring. Spread snap ring and push shaft in until snap ring engages bearing. Install new plug in snap ring access hole in top of housing.

OVERDRIVE HOUSING: Installation—1) Snap a tight fitting rubber band around clutch cam roller retainer, insert rollers under rubber band in retainer and, with low gear of transmission engaged, turn retainer and rollers counter-clockwise until rollers are in their low position.

2) Remove the one bolt holding adapter to transmission case and install gasket on case. Position shift rail so flat for control shaft faces outward, then start housing, output shaft and ring gear assembly into place with shift rail entering spring in housing. Slide housing against adapter. Install seven bolts and lockwashers to adapter and case.

3) Install control shaft lever oil seal, shaft and lever and connect control cable to lever. Install governor assembly and speedometer driven gear, shaft and fitting. Install propeller shaft.

OVERDRIVE CONTROL: *See "Warner R10 & R11 Overdrive Control" in 1954 Annual Data.*

CHEVROLET TRUCK 3-SPEED (HEAVY DUTY)

Half-Ton & 3/4-Ton Trucks (1954-55) Opt.
1-Ton Trucks (1954-55) Opt.

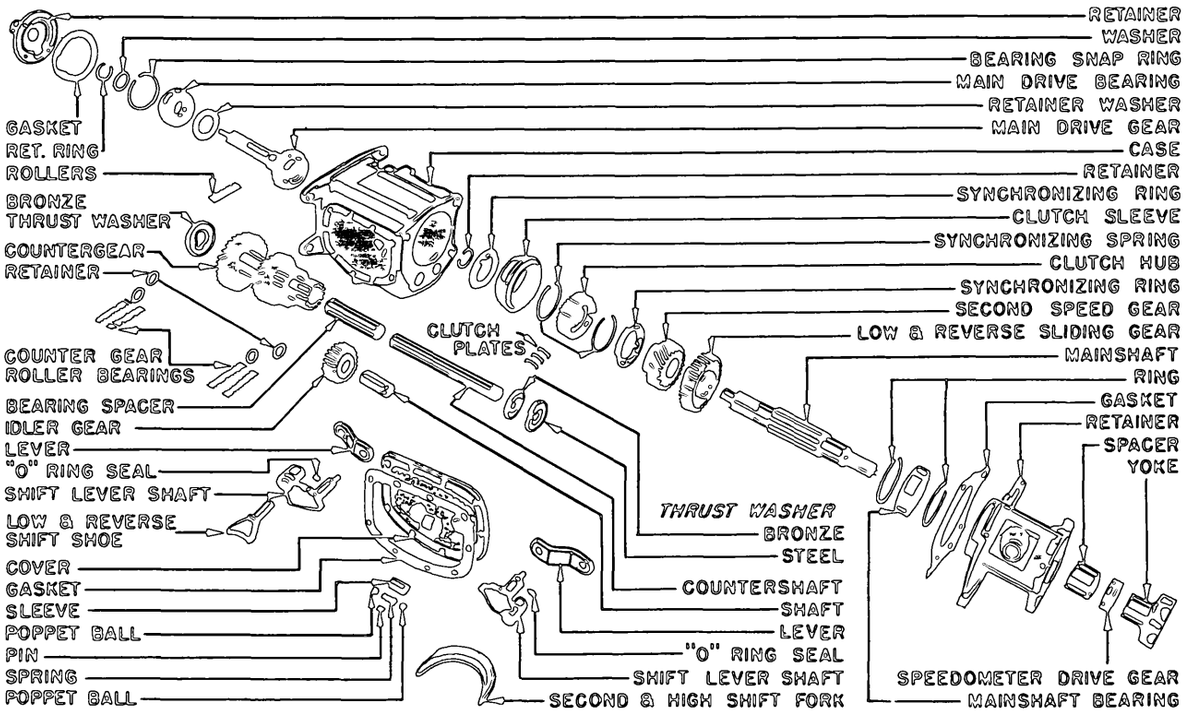
DESCRIPTION: Constant mesh synchro-mesh (second & high), sliding gear (low & reverse). Gears are helical design (except low & reverse).

REMOVAL OF TRANSMISSION: *See "Transmission" on Truck Model pages.*

DISASSEMBLY: 1) Secure transmission in heavy vise and remove the screws attaching side cover assembly to case and remove cover, shifting forks and gasket.

2) Place transmission in two gears at once to lock mainshaft and remove universal joint or yoke retaining capscrew, lockwasher and on ¾ & 1-Ton models, special washer. Slide yoke, speedometer driven gear and spacer from mainshaft. On ¾ & 1-Ton models, remove bearing support and rear oil seal from rear extension.

3) Remove clutch gear bearing retainer screws and washers and remove retainer and gasket. Remove bolts from rear extension and move extension away from case approximately ½", then rotate rear retainer to permit removal of countershaft.



4) From front of transmission, drive countershaft to rear with tool J-5589 (NOTE—When rear end of countershaft clears case, remove the woodruff key to allow countershaft to clear rear bearing retainer). Remove countergear and leave tool J-5589 in the countergear to retain roller bearings.

5) Drop countergear down in case and remove rear bearing retainer, gasket and mainshaft assembly from rear of case. Remove snap ring from clutch shaft and press the clutch gear out of bearing. Remove oil retaining washer from clutch gear shaft, being careful not to lose the 14 roller bearings from gear end of clutch shaft. Remove snap ring from clutch gear bearing and tap bearing out through front of case.

6) Drive reverse idler gear to rear of transmission case and remove woodruff key, shaft and idler gear. Remove countergear assembly and thrust washers from case (CAUTION—Use care when removing countergear to prevent possible loss or damage of roller bearings). Remove roller bearings (80), bearing retainers and spacer from countergear.

Mainshaft & Rear Bearing Retainer Disassembly: Remove clutch hub retaining snap ring from end of mainshaft, and take off third speed synchronizer ring. Remove synchronizer sleeve from clutch hub and remove hub from mainshaft *(CAUTION—If relation of clutch hub and sleeve are not already marked, mark clearly to insure reassembly in the same location).* Remove the two synchronizer springs and the three clutch plates from hub. Remove synchronizer ring and second speed gear and low & reverse sliding gear from shaft. Remove mainshaft bearing snap ring and press shaft from bearing.

CONTINUED ON NEXT PAGE

CHEVROLET TRUCK 3-SPEED (HEAVY DUTY) SYNCHRO-MESH

CHEVROLET TRUCK 3-SPEED (HEAVY DUTY) (Continued)

►*REASSEMBLY NOTE:* Clean and inspect all transmission parts for wear or damage. If the second speed gear and idler gear bushings are worn or damaged, replace the complete assembly as the bushings are not furnished separately. Lubricate all parts before reassembly.

Mainshaft & Rear Bearing Retainer Reassembly: Press bearing on mainshaft with outer raised section of oil retainer toward front of shaft. Install bearing snap ring into rear retainer and install mainshaft and bearing assembly into rear retainer, securing it in position with the bearing front snap ring *(CAUTION– Make sure the front snap ring is a tight fit in groove. These snap rings are furnished in the following sizes for selective fitting: .088", .091", .094", .100").* Install speedometer gear spacer and speedometer driven gear. Install oil seal in rear bearing support with tool J-5154 and install bearing support to rear retainer on ¾ & 1-Ton models (oil slot in support goes toward bottom of retainer). Install sliding gear and second speed gear on mainshaft. Assemble synchronizer springs to hub with one end of each spring in same slot and outer end free. Install the three clutch plates to hub. Align marks made at disassembly on hub and sleeve and push synchronizer sleeve over clutch hub. Place synchronizer rings on the assembly, making sure slots are in line with the clutch plates, and place synchronizer assembly on the mainshaft. Install snap ring and check to see that gears rotate freely in synchronizer.

Side Cover Disassembly: Remove shifter forks from shift lever assembly and remove nut and lockwasher from each shift lever shaft. Remove outer levers and lightly tap shift lever shafts from assembly. Remove two steel balls, poppet springs, interlock pin and interlock sleeve from housing. Remove "O" ring seals from shift lever shafts.

Side Cover Reassembly: Install new "O" ring seals to shift lever shafts and install low and reverse shift lever to cover. Place shift lever in neutral position, middle detent, and install interlock sleeve, ball, poppet spring and interlock pin. Install remaining poppet ball and spring and then install second and third speed shift lever. Check clearance between end of interlock sleeve and shift lever cams when one lever is in neutral and the other is shifted into gear position. Clearance should be .001" to .007". Interlock sleeves are available in the following sizes to provide proper clearance: 1.0235", 1.0185", 1.0135" & 1.0085". Install outer shift levers to shafts with lockwashers and nuts and install forks to shift levers.

REASSEMBLY: 1) Insert spacer and countershaft assembly tool J-5589 into countergear. Install a double row of roller bearings (20 rollers in each row) and bearing retainers at each end of countergear. Place front and rear tabbed BRONZE washers on countergear. Place transmission in vise and install countergear in case through gearshift control housing opening (install large end first). Install a tabbed STEEL washer at rear of countergear between bronze thrust washer and case, and allow entire assembly to rest in bottom of case.

2) Install transmission case front bearing from front of case and install snap ring. Install the 14 roller bearings in mainshaft pilot recess in main driveshaft, retaining in place with a solidified lubricant. Install oil retainer washer next to gear on shaft, and install assembly into front case bearing by pressing or driving into place with tool J-5590. Install main drive gear special washer and snap ring on main drive shaft making sure that snap ring is a good fit in groove (six sizes of snap rings are available as follows for selective fitting: .086-..088"; .089-.091"; .092-.094"; .095-.097"; .098-.100"; .101-.103").

3) From rear of case, install idler gear, shaft and woodruff key. Install complete mainshaft assembly *(CAUTION–When installing mainshaft assembly make sure the pilot bearings in main drive gear remain in place and that one is not forced up into lubrication hole in in gear).*

4) Turn transmission over in vise and install countershaft and woodruff key from rear of case, driving it into position in countergear, forcing countergear tool J-5589 out front of case. Use care to avoid damage to thrust washers on countershaft.

5) Install maindrive gear retainer on front of case and check clearance between retainer and case to determine thickness of gaskets necessary to seal retainer to case (front retainer gaskets are furnished in .010" and .015" thicknesses and may be used in combination to provide a seal). Align rear extension with case and install lockwashers and capscrews.

6) Place synchronizer assembly in neutral position and low and reverse sliding gear in neutral position. Install side cover to case and at the same time enter second & high shifter fork in groove of synchronizer sleeve, and low and reverse shifter shoe in groove of sliding gear. Install a couple of side cover capscrews and check shifting operation. If operation all right, install remaining capscrews and tighten.

CHEVROLET 4-SPEED HELICAL GEAR (SYNCHRO-MESH)

1, 1½, 2-Ton Trucks (1948-55)

►CHANGES, CAUTIONS, CORRECTIONS

►*1952 REVERSE IDLER LEVER PRODUCTION CHANGE (For Eccentric Adjustment of Reverse Idler Gear)*—Transmission now includes an eccentric adjustment for positioning reverse idler gear. See "Reassembly" below for Gear Adjustment.

►*1952 & EARLIER ADJUSTABLE TYPE REVERSE IDLER GEAR LEVERS*—1948-Early 1952 4-Speed Synchro-mesh transmissions can be reworked to include eccentric adjustment for Reverse Idler Gear. Ream out the ½"—13 threaded hole at reverse shifter lever pivot to .500"—.503" diameter and install Eccentric Kit No. 3704888, consisting of Reverse Shifter Lever, Part No. 591949; Eccentric Bolt, Part No. 591950; Special Slotted Hex Nut, Part No. 591951; and Bolt Lock Nut, Part No. 591952. Eccentric is installed with nut and lock on outside of transmission case.

►*1953 4-SPEED TRANSMISSION PRODUCTION CHANGE:* To eliminate gear rattle, beginning with Transmission No. WP-34257 a .120-.125" annular groove in splined inside diameter which accomodates synthetic rubber friction strip and steel friction ring has been added to first and reverse sliding gear hub. Some transmissions prior to No. WP-34257 have groove, and ring and strip can be installed. Parts are available as follows: 1st & rev. Sliding Gear Assy., No. 3705458, Friction Ring, No. 591956, and Friction Strip No. 591955.

►**GEAR DISENGAGEMENT (1ST, 2ND, REVERSE) & HIGH GEAR NOISE (15-40 MPH):** May be caused by excessive clearance between splines of First & Reverse Sliding Gear and mainshaft. Check clearance when this trouble experienced, or when new parts installed, as follows: Disassemble transmission, re-install universal joint yoke on rear end of mainshaft and tighten attaching bolt. Clamp yoke in vise with shaft vertical. Slide gear on shaft splines, shifting gear on shaft to obtain best possible fit, position gear in approximate first-speed position on shaft (CAUTION—see that energizing lugs are not touching mainshaft), place a supporting block of wood under one side of gear. Mount dial indicator so that it contacts upper edge of gear at shifter yoke groove on opposite (unsupported) side of gear. Hold supported side of gear tightly against block, lift gear at point under dial indicator so that total play or rocking motion of gear indicated. This play or movement must not exceed .017". If gear fit satisfactory, mark matching splines on gear and shaft to insure installation in this position.

►**SHIFTER HEAD & YOKE PRODUCTION CHANGE:** Beginning Transmission No. RC-53869, mating tongues and grooves in Reverse Shifter Head and First-&-Second Shifter Yoke were removed and new type parts used as follows:

Reverse Shifter Head.....No. 591905
First-&-Second Shifter Yoke.....No. 591906

***INTERCHANGEABILITY OF PARTS*—New type yoke can be used in earlier transmissions with first type shifter head. If new type shifter head installed, new type yoke must also be used.**

►**LOCKING IN 3RD OR 4TH GEAR (Transmissi n before Serial No. SC-103207):** Caused by overshift condition permitting clutch keys to cock and ride up on bronze synchronizer cone. Correct by installing new design 3rd. & 4th. Speed Clutch Hub and Clutch Keys as listed below. On these parts, key slots in hub are machined at outer edges to provide shoulders to retain keys and prevent endwise cocking. Keys used with this hub do not have hump at sides and new square section retainer spring is also used. Install all new type parts as an assembly as follows:

Clutch Hub .....No. 591912
Clutch Key (3 used) .....N . 591913
Clutch Key Retainer Spring (2 used).....No. 591914

DESCRIPTION: Four speed type with helical con-

CONTINUED ON NEXT PAGE

CHEVROLET 4-SPEED HELICAL GEAR (SYNCHRO-MESH) (Continued)

stant-mesh, synchro-mesh gears (2nd, 3rd, 4th), sliding spur gears (1st & Reverse). Sliding 1st speed gear serves as the clutch member for engaging the 2nd Speed Gear.

REMOVAL OF TRANSMISSION: *See "Transmission" on car model page.*

TRANSMISSION DISASSEMBLY: Remove transmission cover assembly (with complete gearshift mechanism) by lifting straight up off case. Take out Reverse Shifter Lever (remove nut, screw bolt out of case, remove lever, bolt spacer, and large flat washer). Remove clutch gear bearing retainer on front end of case, remove clutch gear using J-2669 Remover (CAUTION—index cutout section of clutch gear with countershaft driven gear for clearance). Remove synchronizer ring and roller bearing spacer from end of mainshaft. Remove speedometer pinion from rear bearing retainer. Lock mainshaft by shifting into two gears at once, remove universal flange retaining screw, lockwasher, plain washer, and flange. Take out retaining screws and remove rear bearing retainer. Install J-2667 Remover on rear end of mainshaft and pull shaft to the rear until rear bearing is free of case, use J-1619 Remover to remove bearing from shaft, then remove shaft and gear assembly through top of case (tilt forward end of shaft up, move 1st speed gear as far forward on shaft as possible). Drive reverse gear shaft locking pin through into the shaft (use small punch), then drive shaft out toward rear of case, lift reverse idler gear out of case. To remove countershaft, drive punch through front bearing spacer and pry spacer out. Use brass drift on forward end of countershaft and drive shaft to rear until rear bearing is free of case. Take out rear bearing retainer screws, lift off lock plate and retainer, use TR-278-R (Differential Side Bearing Puller) to remove bearing and oil deflector from shaft. Raise front end of countershaft and remove assembly through top of case. Remove chip collector from bottom of case.

Main Drive Gear (Clutch Gear) & Shaft: Lift out mainshaft pilot bearing rollers and roller retainer from recess in shaft. Mount shaft in vise, use special spanner wrench J-2670 to remove retaining nut, remove oil slinger and oil deflector. To remove bearing, use J-2228 press plate mounted in holder to press gear and shaft out of bearing. Install bearing with J-1453 press plate. CAUTION—Make certain oil deflector centered around retainer nut and stake nut after it has been securely tightened.

Mainshaft Assembly: To disassemble, remove retainer ring from pilot end of mainshaft, support assembly on 1st speed sliding gear in arbor press, press shaft out of gear cluster. Remove synchronizer key springs from synchronizer hub, remove outer sleeve from hub (CAUTION—do not lose the 3 keys). Remove synchronizer ring from 3rd speed gear, lift off gear, 2nd speed gear thrust washer, and 2nd speed gear. Remove synchronizing ring retainer from 1st speed gear, remove synchronizing ring. Wash all parts in cleaning solvent and inspect as follows:

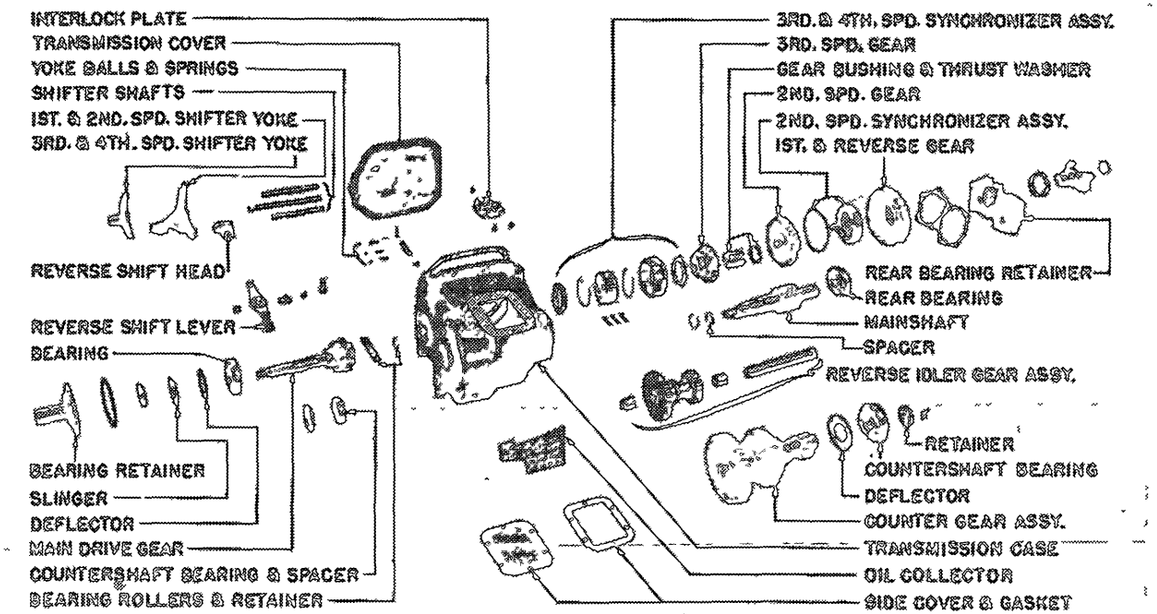
Synchronizer—Outer sleeve should slide freely on hub but hub should be snug fit on shaft splines. Synchronizer rings and cones must not be scored, excessively worn, or damaged.

3rd Speed Gear—Gear should be running fit on bushing and bushing must be press fit on shaft. Thrust surfaces must not be scored or worn.

2nd Speed Gear & Thrustwasher—Washer and gear must not be scored or worn excessively on thrust surfaces. Replace synchronizer springs if broken or loose (use special rivets). Replace gear if bushing worn excessively. Inspect synchronizing ring for wear and scoring.

1st Speed Gear—Gear must be sliding fit on mainshaft splines. Synchronizer cone in gear must not be scored or worn excessively.

Countershaft Assembly: Gears can be removed from shaft by removing lockring on forward end and pressing shaft out in an arbor press. Install gears on shaft as follows: 2nd Speed Gear (radius end toward rear or low speed gear end), 3rd Speed Gear (may be installed either way), Revere Gear (chamfered end of teeth forward or toward driven gear), Spacer, Driven Gear. Use new Countershaft Drive Pins when installing gears, after all gears in place, drive pins 1/32" past flush with shoulder on driven gear hub. Select lock ring of correct thickness and install on shaft to retain gears.



Countershaft Front Bearing—Press fit in case. To remove bearing for replacement, drive old bearing through into case using J-994 Differential Side Bearing Replacer. Drive new bearing in using same tool until it is flush with inner face of case.

Reverse Idler Gears: Replace bushings if worn. Remove old bushings with tool J-1614 (Pitman Shaft Bushing Remover). Press new bushings in (using same tool) until flush with ends of gear. Stake bushings in place with tool J-2680. (CAUTION—bushings are split type and may creep in service if not properly staked). Line ream bushings using J-2668 Reamer.

TRANSMISSION REASSEMBLY: Assemble in reverse order of disassembly, and note following:

Mainshaft Assembly: Install 1st speed gear on shaft with 2nd speed synchronizer forward (synchronizer ring must be held in gear hub by retainer ring), install 2nd speed gear with synchronizer springs toward synchronizer ring and prongs aligned with slots in gear hub, install thrust washer. Press 3rd speed gear bushing on shaft until it bottoms on thrustwasher. Check 2nd speed gear endplay which must be .012" plus or minus .003". Install synchronizer assembly (see data below), pressing clutch hub on shaft until it bottoms against shoulder on shaft. Check 3rd speed gear endplay which must be .012" plus or minus .002". Select lockring of correct thickness and install on forward end of shaft to retain assemblies. NOTE—This lockring furnished in four thicknesses and marked for identification as follows: .083",.087"—Red, .091"—Blue, .095"—Yellow.

Synchronizer Assembly—Install outer sleeve on hub with taper on sleeve toward long shoulder on hub, slip three synchronizer keys in slots, install spring on each side of hub to hold keys out against sleeve (CAUTION—Both springs must be installed in same relative position so that even tension applied on keys). When installing assembly on mainshaft, long shoulder on hub should be out toward pilot end of shaft and synchronizer keys must index with slots in synchronizer rings.

CHEVROLET TRUCK 4-SPEED SYNCHRO-MESH TRANSMISSION

CONTINUED ON NEXT PAGE

CHEVROLET 4-SPEED HELICAL GEAR (Cont.)

Reverse Idler Shaft & Lockpin: Drive shaft in from rear, aligning lockpin hole in shaft with hole in case Install lockpin to retain shaft

Main Drive Gear Bearing Retainer: When installing gear, align cutout portion of clutch gear teeth for clearance with countershaft driven gear Use new gasket under bearing retainer, use Permatex or other sealing compound on retainer screw threads and tighten these screws to 15-18 ft lbs

Mainshaft Rear Bearing Retainer: Use new gasket Coat retainer screw threads with Permatex or other sealing compound tighten screws to 20-25 ft lbs

Reverse Shifter Lever: Lever bolt has sleeve which acts as shoulder for lever to pivot on and must be installed as follows· Place reverse shifter lever in position, thread bolt with sleeve and flat washer through lever and into case from inside Tighten bolt to 25-30 ft lbs in case, then install bolt nut and tighten nut to 60-65 ft lbs

►*REVERSE IDLER GEAR ECCENTRIC ADJUSTMENT (1953 & Earlier Models with Eccentric Adjustment)*· Fully assemble transmission except for power take-off cover Proceed as follows Loosen eccentric nut, rotate eccentric using screw driver in slot in outer end of eccentric, until dot on end of eccentric bolt is to rear Shift transmission into 2nd gear Check for interference between reverse idler and 1st & reverse gear If interference exists, rotate eccentric in counter-clockwise direction to obtain approximately 1/32 running clearance (clearance can be observed through power take-off opening) Shift transmission into reverse and check for clearance between reverse idler gear and transmission case at rear If necessary, rotate eccentric an additional amount in counter-clockwise direction to obtain running clearance at this point Tighten eccentric to 40 ft lbs , and to next lock index

GEARSHIFT LEVER & COVER ASSY.: Gearshift lever assembly and transmission cover can be removed without removing transmission as follows

Gearshift Lever Removal: See Cab-Over-Engine Note below On all models, slide open side of K-353 Gearshift Lever Remover & Replacer over the lever and engage lugs on tool in open slot of retainer Press down on tool and rotate it to left to disengage lugs on retainer, lift lever out of cover Install lever by reversing this procedure

Cab-Over-Engine Truck Note—For access to lever, disconnect gearshift lever from top of engine cover, lower cloth boot wire and raise boot above transmission tower, remove nut from stub gearshift lever, raise lever link assembly from top of lever

Transmission Cover Removal (Except C-O-E): Remove accelerator pedal, floor mat and cover from body floor On forward control models, remove front floor pan Remove gearshift lever (see above) Take out capscrews and remove transmission cover

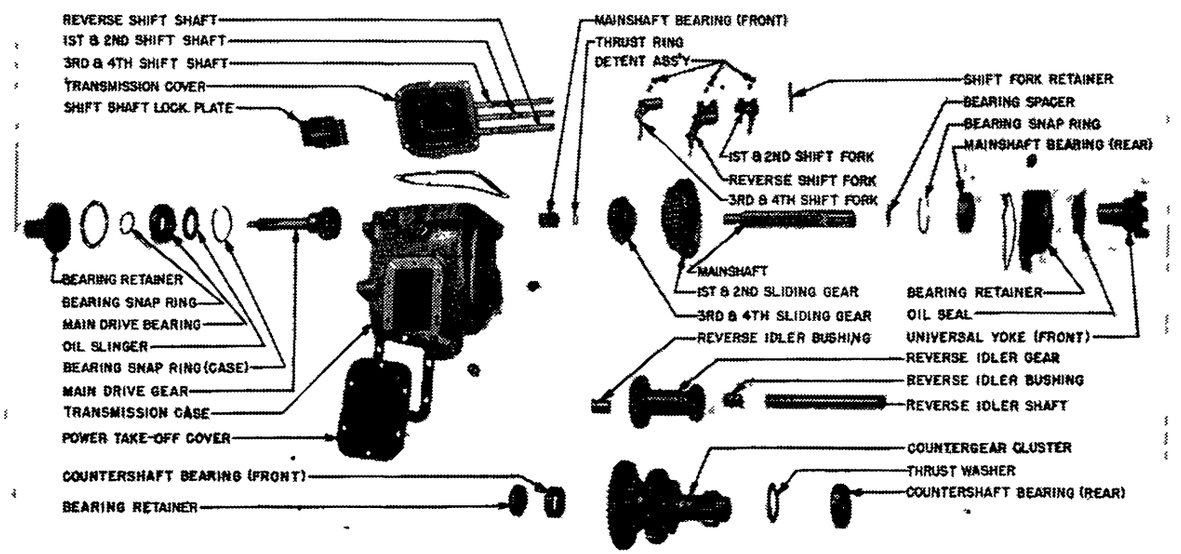
CHEVROLET TRUCK 4-SPEED (SPUR GEAR)

1½ & 2-Ton Trucks (1947)
Cab-Over-Engine Trucks (1947)

DESCRIPTION: Four speed, spur gear. Clutch shaft and main drive gear mounted on ball bearing at front end of transmission case. Mainshaft mounted on roller bearing at front, ball bearing at rear.

REMOVAL OF TRANSMISSION: *See "Transmission" on car model page.*

DISASSEMBLY (1947): Remove the gearshift lever using K-353 remover tool, engaging tool lugs in gearshift lever retainer slot and turning tool counter-clockwise to disengage retainer, lift lever out (see Cab-Over-Engine Note below). Remove transmission cover assembly. Lock transmission mainshaft by engaging two gears at once, remove speedometer driven gear, remove universal joint retaining screw on rear end of mainshaft, pull universal joint on ½ & ¾ Ton Models (on 1½ Ton model, take out bearing retainer screws and remove universal joint yoke and bearing retainer as an assembly—necessary because speedometer pinion installed on front end of yoke will not permit yoke to be pulled out through oil seal). Remove screws in main drive gear bearing retainer on front end of case, remove retainer, tap drive gear and bearing out through front of case (use soft steel drift to avoid damage to gear teeth). Remove mainshaft pilot bearing from front end of shaft, drive mainshaft and bearing out through rear end of case slipping the sliding gears off the shaft and removing these gears through top of case. Drive reverse gear idler shaft out through rear of case, remove idler gear. Drive counter gear assembly to rear until rear bearing and retainer clear rear of case, remove bearing and retainer, remove countergear through top of case. Drive out front bearing and retainer by tapping around bearing outer race



REASSEMBLY: Reverse disassembly directions and note following data on sub-assemblies:

Main Drive Gear & Mainshaft Bearings:—Bearings are press fit on shafts and should be removed and installed in an arbor press (remove snap ring from gear hub in front of bearing before pressing bearing off drive gear). When reassembling transmission, see that snap rings are in place in each end of case to retain bearings.

Countergear Assembly:—Low speed gear is integral with shaft, other gears are keyed on shaft with spacers to position each gear. If gears removed from shaft, assemble gears and spacers in this order: Second Speed Gear (chamfered side toward low speed gear), ¼" Spacer, Third Speed Gear (chamfered side away from second speed gear), ⅞" Spacer, Reverse Gear (chamfered side toward third speed gear—chamfered sides of these two gears face each other), 5/32" Spacer, Counter Drive Gear. The round keys should be used to keep keyways lined up while pressing gears on shaft. After gears installed, drive keys down 1/32" below flush with gear, prick-punch keys and remove all burrs

Countergear Endplay—When installing countergear, check clearance between rear thrust washer and shoulder on gear. Endplay should be .015-.045" If clearance greater than .045", install shims between front bearing and retainer.

Reverse Idler Gear & Bushings:—Use special tool J-1662 to remove old bushings and install new bushings in idler gear. Ream new bushings with KMO-349 Reamer to provide minimum shaft clearance of .002" (bushing size .877-.878").

CHEVROLET TRUCK 4-SPEED SPUR GEAR TRANSMISSION

CHRYSLER, DESOTO, DODGE FLUID DRIVE

Chrysler 6, DeSoto (1946-53)
Chrysler 8 (1946-53)
Dodge 6 (1946-54)

▷*NOTE: Not used when Fluid-Torque Unit installed.*

▷INSTALLATION OF FLUID DRIVE SEAL DAMPER (To correct squeal on Early 1946 Chrysler 6 & 8, DeSoto, & Dodge Cars with carbon type seal). To correct complaints of a "squeal" in this seal, install seal damper as follows: With Fluid Drive unit removed from car (see directions below), remove clutch plate nut using tool C-607. Pull clutch plate using tool C-665. Remove snap ring and seal spring (use sleeve C-613 and clutch plate nut to relieve spring tension). Install damper (consists of a ribbed sleeve) on inner end of spring, re-install spring, spring retainer, and snap ring. Reassemble fluid drive unit and re-install in car.

▷FLUID DRIVE SEAL NOTE: Both "Bellows Type" and "Housing Type" seals have been used. *See illustration and seal installation data.*

DESCRIPTION & OPERATION: The Fluid Drive (Fluid Coupling) Assembly consists of a self-contained, factory-sealed assembly which is mounted on the rear end of the crankshaft in place of the conventional flywheel (unit has ring gear for starter mesh on outer rim and separate clutch driving plate for clutch mounting bolted on end of runner shaft at rear end). The case and integral 'driver' vanes rotate with the crankshaft and transmit power to the 'runner' or free vane assembly within the case without any mechanical connection through the oil with which the case is filled. The 'Runner' is integral with the hub (short hollow shaft extending through rear of case with clutch driving shaft mounted on rear end) and is mounted on a large ball bearing within the fluid drive case at the forward end and piloted on the clutch shaft at the rear end (clutch shaft mounted on needle bearings within runner hub at each end). Oil leakage is prevented by spring-loaded Sylphon Assembly and Sealing Ring.

1946 & Later Note—A Driver Flange Plug is installed in the forward end of the driver hub (or the fluid drive case is continuous at this point) to prevent leakage and no rubber grommets are required on the mounting bolts. Fluid drive housing is provided with cooling fins.

Chrysler 6, DeSoto, Dodge Note—On these cars, Runner Hub Nut, which retains clutch driving plate is threaded in end of hub (no leather oil seal used). A leather type oil seal is installed within the retainer nut on Chrysler 8 Cylinder cars to prevent leakage at this point.

FLUID DRIVE ASSEMBLY REMOVAL & INSTALLATION: Unit should be removed as an assembly and all service work performed on the bench.

Removal (All Models): Remove transmission (see Transmission Removal on car model pages), remove clutch release bearing, clutch housing pan, and dust shield. Remove clutch (see Clutch Removal on car model pages). Take off nuts on mounting bolts on front face of crankshaft flange (use special box wrench C-589), pull fluid drive unit back free of the crankshaft flange and remove from below.

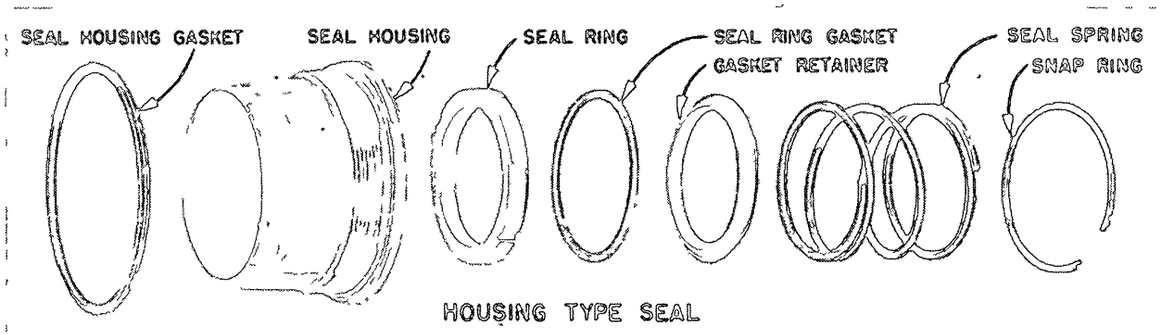
Installation (1946 & Later Cars): Clean back face of crankshaft flange and mating face of fluid drive unit thoroughly (remove all burrs, dirt and other particles), place fluid drive unit in position on crankshaft flange and install mounting nuts, tighten nuts evenly to torque of 135-145 ft. lbs.

SERVICING:—Unit is sealed and no adjustment required. Service operations are restricted to keeping unit filled with oil (inspect at end of first 1000 miles and at 10000 mile intervals in service) and renewal of seal parts to correct leakage.

Checking Oil Level: Fluid drive case filled to 80% volume and level should be checked as follows to prevent overfilling. Turn crankshaft until one fluid drive filler (2 plugs—180° apart) is at filler hole in upper right hand surface of clutch housing, remove filler plug. Fluid level should be even with bottom of filler plug opening. Add fluid as required

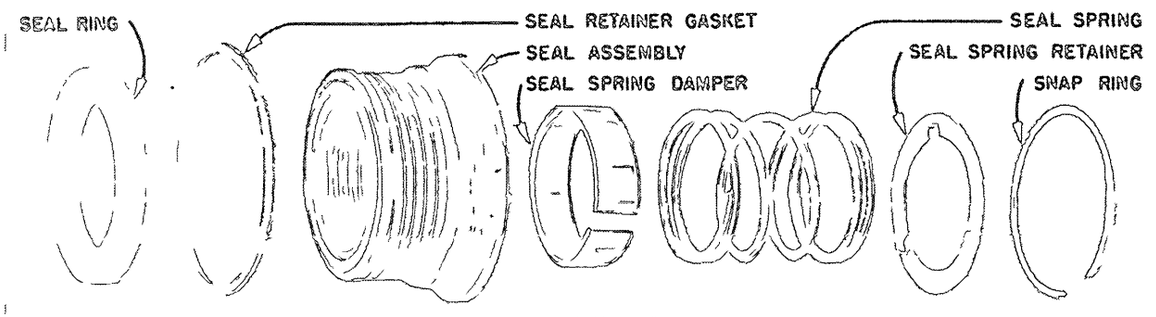
▷*CAUTION: Always check fluid with unit COLD.*
Capacity—Approx. 8 qts. (8's), 6 qts. (6's).
NOTE—Use only Mopar Fluid Drive Fluid.

Bellows Type Seal Ring & Sylphon Assembly Renewal: Remove fluid drive unit (see Removal) and drain. Bend down tab on lockwasher, use special socket wrench C-607 (Chrysler 6, DeSoto, Dodge), C-541 (Chrysler 8) and remove clutch driving plate retainer nut. Mark one spline on runner hub and mating spline on clutch driving plate (to insure reassembly in correct position), use special puller C-665 (Chrysler 6, DeSoto, Dodge), C-692 (Chrysler 8) to remove clutch driving plate. Use special bellows seal spring compressing sleeve C-613 (Chrysler 6, DeSoto, Dodge), C-614 (Chrysler 8) to compress spring within bellows (use clutch driving plate retainer nut to push sleeve in to compress spring), remove spring retainer snap ring, remove nut, sleeve, and spring (CAUTION—Spring must be removed before bellows seal removed or seal will be damaged). Use special spanner wrench C-545 to unscrew bellows seal, remove bellows seal and floating seal ring.



IMPORTANT NOTE—Bearing surfaces on Sylphon and Sealing Ring must be smooth and show continuous line of contact over entire circumference. Replace Sylphon and Sealing Ring if surfaces damaged in any manner (rough, scratched, or marred).

Installation—Install sealing ring and sylphon seal (see that gasket in place), tighten bellows retainer securely. Install seal spring (and damper—see Seal Spring Damper Note below), and retaining snap ring (use sleeve to compress spring so that retainer can be installed), install clutch driving plate making certain that marks on plate and runner hub are lined up, tighten clutch driving plate retainer nut securely. Fill unit with fluid (see directions above. Install Fluid Drive unit on car.



Seal Spring Damper Note (All Cars with Carbon type Seal)—Damper consists of a ribbed sleeve which should be installed on inner end of spring before spring is installed in bellows, and this assembly should be rotated counter-clockwise while it is being installed.

Housing Type Seal Ring Assembly Renewal: Remove fluid drive unit (see Removal) and drain unit. Bend

CONTINUED ON NEXT PAGE

HOUSING TYPE SEAL

BELLOWS TYPE SEAL

CHRYSLER, DESOTO, DODGE FLUID DRIVE (Cont.)

back tab on lockwasher, use special socket wrench C-607 to remove drive plate retainer nut, use Puller C-665 to remove drive plate (CAUTION—remove key). Clean area on fluid drive adjacent to seal ring. Use towel or other cloth to protect hands while prying out snap ring (CAUTION—spring will spring out if not restrained), remove snap ring and spring. Use special Spanner Wrench C-545 to unscrew seal housing (screw retainer nut on hub above wrench to hold wrench in place), lift out seal housing, seal ring gasket, and seal ring gasket retainer. Lift out seal ring (use two pieces of wire bent to form hooks).

►*CAUTION: Use care not to scratch or damage sealing faces and do not attempt to remove seal housing without first removing snap ring and spring.*

Installation—Make certain that sealing surfaces are clean and free from scratches, **replace seal ring** if surface is damaged (surfaces can be cleaned with cloth followed by chamois applied with soft pressure preferably eraser end of a pencil but no attempt should be made to recondition these surfaces.) Remove all burrs from spanner wrench slots, chamfer, top edge of bore, and snap ring groove. Screw seal housing in place finger tight so that gasket contacts seal housing flange and machined face on back plate. Wipe seal ring clean with chamois and install ring using tools SP-788 and SP-791 (place seal ring squarely on locators of aligning tool SP-791, insert in seal housing with button on tool aligned with wrench slot nearest center punch mark, slide pilot sleeve down inside tool and push seal ring off onto the two small indentations at the bottom of the seal housing), remove installing tools. Install seal ring gasket, gasket retainer (angular face down), and spring. Use special tool C-884 to compress spring and install snap ring. Tighten seal housing with spanner wrench to 270 ft. lbs. torque. Install drive plate and key, tighten retainer nut securely and lock nut by bending edge of washer up and center-punching washer at drive plate hole.

Fluid Drive Bushing Replacement: Remove old bushings by first removing the clutch driving plate nut (special socket wrench C-607). **Do not remove clutch driving plate.** Pull outer hub bushing with special puller, sleeve, and expansion jaw (C-680 tool kit). Remove inner bushing similarly using puller and expansion jaw without sleeve. Clean inside of hub thoroughly.

Bushing Installation—Place new Inner and Outer Oilite Bushings on special drift C-708. Position drift in fluid drive hub, drive bushings into hub with a mallet until bushings are firmly seated. Bushings will be burnished by the tool as it is withdrawn. Reinstall clutch driving plate nut, tighten nut securely and lock it by bending edge of washer up. CAUTION—Use only Oilite bushings for replacement.

Fluid Drive Bearing Replacement: When replacing needle roller bearings (used on some cars), install new Oilite bushings as replacement. See Bushing data above.

FLUID DRIVE SLIPPAGE TEST: To determine definitely if fluid drive coupling slipping, connect one wire of motor analyzer tachometer to distributor and other wire to a good ground. With engine properly tuned, apply hand brake and foot brake firmly, place transmission in direct drive, operate engine with wide open throttle and note speed. (CAUTION—Above test should not take more than one minute. If test prolonged seal may blow off and leakage result.) If engine speed excessive (1100 RPM De Soto and Dodge), slipping is occuring. Check fluid level in coupling. (CAUTION—Do not check level until coupling has cooled off.) Fill to correct level, repeat test. Check for oil leaks if fluid level found low.

STARTER RING GEAR REPLACEMENT ON FLUID DRIVE: Removing Old Ring Gear—With fluid drive unit removed from car, use hacksaw to cut six weld spots around ring gear parallel with back face of gear and to within 1/16-1/32" of the housing using care **not to cut too deep.** Scribe a line around housing at back face of gear (for use is positioning new gear), drive ring gear off using a heavy drift and hammer with fluid drive unit resting face down on bench. Remove all remaining weld material from housing with a bastard file (CAUTION—do not file more than necessary to remove weld material).

Installing New Ring Gear—Heat new ring gear to uniform temperature of not more than 212°F. (see Heating Note below), place gear on fluid coupling with chamfered teeth up (pointing to front), use rawhide mallet or fibre block to drive gear down until scribed mark on housing is just visible above gear. Check gear position with aligning gauge C-896 placed in crankshaft counterbore. Clearance between gauging leg and face of gear should be uniform and should not exceed .020" (use .020" feeler gauge as "No Go"). Adjust by tapping gear up or down on housing. Reweld ring gear at same spots used previously applying **equal amount of welding material at each point to maintain balance and using ARC welding equipment only.**

►*CAUTION—Arc should be directed at approximately 45 angle from face of gear to avoid burning through housing, and GAS WELDING EQUIPMENT MUST NEVER BE USED.*

Heating Note—Use Oven C-794 or submerge gear in boiling water for approximately 5 minutes. If torch used, direct flame at outer face of ring gear at inner diameter **not on the gear teeth** and use drops of water on ring gear to check temperature (gear will probably be expanded enough for installation before water begins to boil).

CHRYSLER, DESOTO, DODGE, PLYMOUTH SYNCHRO-MESH

Chrysler, DeSoto, Dodge, Plymouth—All Models with Synchro-mesh Trans. (1946-55)—See Note.

Chrysler 6 & 8, DeSoto (1946-48)—*See "Chrysler Hydraulically Operated, DeSoto Tip Toe Shift Transmission.*

Chrysler 6 & 8, DeSoto, Dodge (1949-53)—*See "Chrysler Prestomatic & Fluidmatic," "DeSoto Tip-Toe Shift," "Dodge Gyromatic" Transmissions.*

Chrysler, DeSoto, Dodge, Plymouth (1954-55)—*See "PowerFlite" Transmission.*

►*1953 PLYMOUTH HY-DRIVE NOTE*—Transmission used with Hy-Drive is similar to, but not interchangeable with this standard synchro-mesh transmission.

►*1955 PLYMOUTH TRANSMISSION PRODUCTION CHANGE (Some P-26 & P-27 Models):* A three-speed transmission identified by the letters "CK" stamped on the left side of the case (following date) has different gear ratios for increased speed in second gear. *NOTE—Some parts in this transmission are not interchangeable with the other model transmissions.*

►*PIN-TYPE SYNCHRONIZER NOTE*—This type assembly, Part No. 1326778, used on some transmissions (in place of "Plate Type" Synchronizer). Transmissions with Pin-Type Synchronizer can be identified by letters "PT" on date line of transmission case. See "Synchronizer Assembly" below.

►**HARD SHIFTING CORRECTION:** If hard shifting complaints can not be corrected by transmission control adjustment, replace original type stamped synchronizer plates with new solid machined type plates (furnished in package with needed springs). *See Transmission Disassembly and Reassembly data below.*

DESCRIPTION: Own Make, constant-mesh synchro-mesh, all helical gear type (sliding gear for low-reverse).

REMOVAL OF TRANSMISSION: *See "Transmission" on car model page.*

OVERDRIVE DISASSEMBLY NOTE: When used, overdrive adapter plate is fastened to overdrive case by special screws installed in recesses in front face of adapter plate. Overdrive and adapter must be removed as an assembly (after taking out capscrews mounting adapter on rear of transmission case) before adapter plate can be removed (use special wrench C-577 to remove the three screws which mount the adapter plate on the overdrive case. *See Warner Overdrive for all Overdrive data.*

DISASSEMBLY OF TRANSMISSION: On cars with Power Shift, disconnect link and remove power shift assembly. Then remove speedometer drive pinion, remove nut on rear end of driveshaft. pull universal joint yoke flange and brake drum assembly. Take out two plugs on transmission side cover, remove detent balls and springs, remove cover and gear selector assembly. Unscrew shifter fork guide rail and remove guide rail through front end of case. See that gears in neutral, take out lockscrews holding shifter forks on shift rails, remove welch plug in lower shifter rail hole on front of case (collapse plug by striking in center with punch), remove shifter rails through front of case, lift out shifter forks (use care not to lose gear selector balls). Remove interlock plug on top of case (drive plug down into interlock hole), lift out the interlock plunger. Take out the four capscrews in extension housing on transmission case, remove extension and mainshaft assembly through rear of case using care that synchronizer assembly does not slide off shaft. Use special arbor C-578 and soft hammer to drive countershaft out toward rear of

C NTINUED N NEXT PAGE

CHRYSLER, DESOTO, DODGE, PLYMOUTH SYNCHRO-MESH (Continued)

case (remove locking key from shaft as soon as it is exposed at rear of case), allowing counter gear cluster to drop down in case. Take out mounting screws and remove main drive gear bearing retainer from front end of case, pull main drive gear and bearing assembly out toward front. Lift counter gear cluster, thrust washers, and bearing rollers out of case. To remove reverse idler, drive shaft out toward rear using special arbor C-464 to retain bearing rollers in gear (remove locking key from shaft when exposed at rear of case), lift out idler gear thrust washers, and bearing rollers.

REASSEMBLY OF TRANSMISSION: Reverse disassembly directions (above) and note following data on servicing of sub-assemblies.

Mainshaft & Bearing Assembly:—To remove mainshaft from extension housing, take out snap ring at forward end of synchronizer unit, remove synchronizer assembly, second speed gear, and low speed gear from shaft. Remove snap ring in housing in front of bearing outer race, withdraw shaft from housing, then remove bearing, spacer, and speedometer drive gear from housing. Remove oil seal and bearing from rear end of housing (bearing is press fit in housing and is positioned by spacer on shaft—no snap rings used). When reassembling mainshaft, use new snap rings. If oil seal being replaced, soak leather in thin oil for 30 minutes and work leather with smooth bar. Seal must protrude 7/32" from end of case (use C-579 drift to install seal) to prevent damage to seal and bearing.

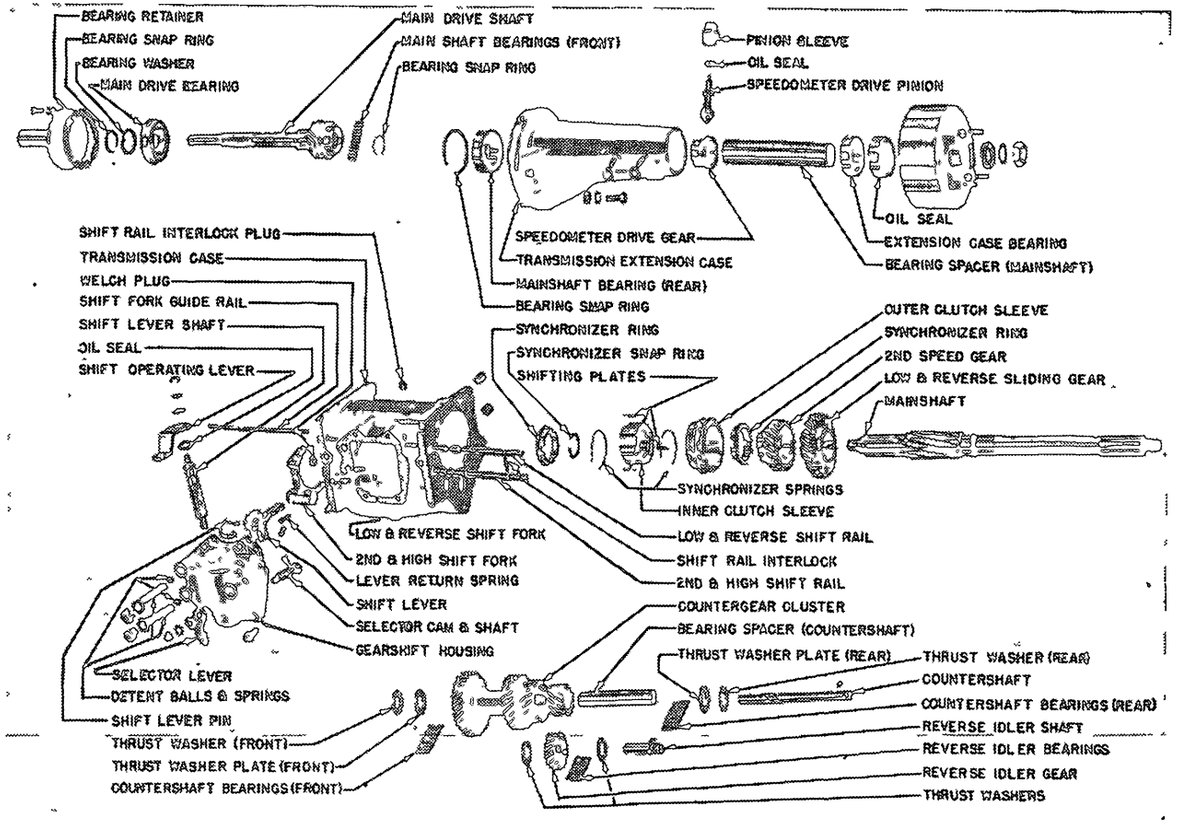
Plate Type Synchronizer Assembly: Install struts or shifting plates in slots in inner clutch sleeve with open face of strut in, assemble outer clutch sleeve and synchronizer springs making certain that hooked ends of both springs engage same strut, install synchronizer rings with notches engaging ends of struts. Synchronizer assembly is retained on shaft with second speed gear by single snap ring.

Pin-Type Synchronizer Assembly: Index etched mark on clutch gear with mark on clutch gear sleeve. (CAUTION—these parts selectively fitted and alignment necessary to insure free sliding fit). Install Stop Ring Inner Assembly with pins extending through holes in sleeve, then place assembly on transmission mainshaft with flat face of clutch gear toward second speed gear (opposite face has raised surface), install Stop Ring Outer Assembly with pins extending through the second set of holes in sleeve. When assembling transmission make certain that Spreader Spring is correctly installed.

Second Speed Gear:—Gear endplay on shaft should be .003" min., .008" max. To install gear, place gear on shaft, install synchronizer assembly, install snap ring in groove in shaft in front of synchronizer.

Main Drive Gear & Bearing:—Bearing retained on shaft by snap ring and can be removed after snap ring taken out and thrust washer removed. Use new snap ring when re-installing bearing. Mainshaft pilot bearing rollers are retained in drive gear recess by snap ring. Use cup grease to hold rollers in position until mainshaft is installed.

Counter Gear Cluster:—When replacing this assembly, use arbor C-578 to position bearing rollers and pack rollers with cup grease to hold rollers in place. Install steel washer next to gear cluster at each end and bronze thrust washer between steel washer and case. Endplay should be .002" min., .008" max. Adjust by selecting washers of correct thickness (furnished in three thicknesses—'A' thinnest, 'B', 'C' thickest). Make certain that locking key is in place in slot in rear end of countershaft.



Reverse Idler Gear:—Use C-464 arbor to retain bearing rollers when idler gear being installed. See that thrust washer installed at each end of gear and that locking key is in place in rear end of shaft.

Oil Seal Replacement: Use Puller C-497 to remove old seal and special drift to install new seal. This drift will locate seal in correct position (protruding 7/32" from housing).

Gearshift Mechanism:—To assemble gearshift mechanism, hold shifter forks in position and insert guide rail through front end of case. Install lower shift rail, insert interlock plunger down through hole in top of case so that plunger engages groove in shift rail, then install upper shift rail (see Note below). Lock shifter forks to rails by installing lockscrews and locknuts, make certain that locking washers are crimped in place. Install welch plug in forward end of lower shift rail. CAUTION—This hole is below lubricant level and plug must be installed tightly to prevent lubricant loss. Install two C-590 cover locating pilots in cover screw holes on case, install cover and gear selector assembly, making certain that selector lever enters shifter fork slots. Install two cover capscrews, remove pilots, install remaining cover screws. Install detent balls and springs, tighten retaining plugs. Install new plug in interlock plunger hole (cup shaped plug), driving the plug in with a hammer.

See Chrysler Transmission Control articles for adjustment directions when transmission installed on car.

Shift Rail Note—Rails are similar in appearance but Low-Reverse rail has detent grooves farther apart. This rail should be installed on top.

CHRYSLER, DE SOTO, DODGE, PLYMOUTH SYNCHRO-MESH TRANSMISSION

DESOTO, DODGE, PLYMOUTH (WARNER R10) OVERDRIVE

DeSoto, Plymouth (1952-55)
Dodge (1953-55)

DESCRIPTION: Similar to other Warner R10 Overdrives.

►***DISASSEMBLY CAUTION—To disassemble overdrive, standard transmission must be disassembled to gain access to screws holding adapter plate to O.D. housing.***

REMOVAL: *See "Overdrive" on car model page.*

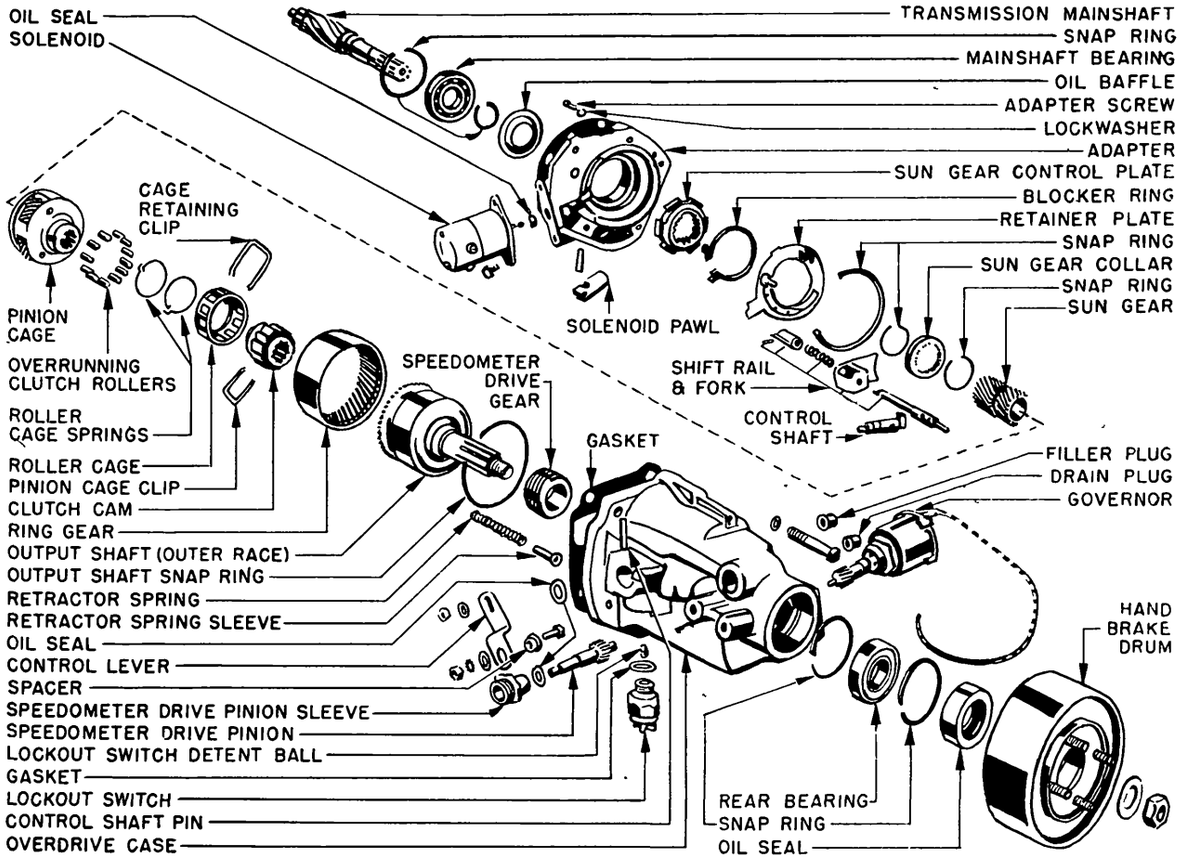
OVERDRIVE DISASSEMBLY: Remove handbrake drum, gearshift housing, shift forks, and rail guide from standard transmission. Remove governor, lockout switch, and speedometer pinion from overdrive housing. Remove four screws that hold overdrive unit and adapter plate to transmission. Tap adapter plate with rawhide hammer to loosen it from transmission. Drive tapered pin from overdrive housing. Pull control shaft out as far as possible to disengage it from shift rail. Rotate shaft ¼ turn counter-clockwise to hold it in position. Remove two recessed screws and lockwashers from front face of adapter plate. Tap end of overdrive mainshaft with soft hammer to free it from bearing. Separate overdrive unit assembly from overdrive case by carefully sliding housing from overdrive mainshaft to prevent spilling overrunning clutch rollers. Remove retractor spring and sleeve from housing. Disassemble units as follows:

Rear Bearing Oil Seal: Use Puller C-748 to remove seal from housing. Use Tool C-579 to install new seal. Seal must extend 9/32" from end of housing.

Rear Bearing: Remove front and rear snap ring, drive bearing from housing with driver C-3204. Install bearing open end first, with driver C-3204. Use new, selective fit, snap rings to eliminate endplay.

Control Shaft Oil Seal: Remove control lever from control shaft, pull shaft out from inside housing. Pry out seal, install new seal with tool C-3198.

Mainshaft & Ring Gear Assembly: Carefully remove ring gear and shaft assembly from over-running clutch to avoid spilling rollers. If necessary to replace outer race or ring gear, pry off snap ring and remove ring gear from outer race.



Pinion Cage & Over-running Clutch: Remove clutch cam retaining clip, slide clutch and pinion cage assembly from transmission mainshaft splines. Pry off pinion cage retaining clip. If necessary to replace rollers, replace all (12). Replace clutch cam if any marks or indentations. Do not separate cam from retainer unless necessary for parts replacement. Pinion cage cannot be disassembled.

Pawl Rod Oil Seal: Remove old seal with screwdriver. Install new seal with driver C-3207.

Sun Gear & Manual Control Fork: Slide gear and fork from mainshaft at same time. Pry off forward snap ring, remove shift collar from sun gear.

Sun Gear Control Plate & Balk Ring: Remove adapter snap ring and retainer plate from adapter. Test balk ring spring tension by hooking scale on one finger of balk ring (should be 3½-5½ lbs. with ring moving). To install, place embossed face forward against control place. Install assembly in adapter plate. Control pawl should index exactly with notch in both fingers of balk ring.

Adapter Bearing: Remove snap ring holding bearing in adapter plate. Remove mainshaft, bearing and oil baffle, then small snap ring. Press bearing from shaft. Install bearing with tool C-3194.

DE SOTO, DODGE, PLYMOUTH OVERDRIVE ASSEMBLY

OVERDRIVE REASSEMBLY: Assemble as follows:

Adapter Plate: Install oil baffle in adapter with pressed out section toward rear. Install transmission mainshaft and bearing in adapter plate, secure assembly with selective fit snap ring **(loose bearing may result in partial engagement or interlocking gears).** Install interlock plunger in adapter and control pawl in cavity (notched side up) to engage plunger. Slide sun gear control plate and balk ring into position **with engaging end of locking pawl between open ends of balk ring.** Slide retainer plate over mainshaft into position in adapter **with ear of plate in slot provided.** Secure with new snap ring.

Sun Gear & Shift Fork: Slide gear on transmission mainshaft. Engage shift fork in sun gear shift collar. Guide shift rail into its hole in adapter and mesh sun gear with control plate.

Pinion Cage & Over-running Clutch: Assemble clutch cam and roller cage to pinion cage retaining clip. Slide assembly on splines of mainshaft, install clutch cam retaining clip. Be sure clip notches into groove at end of mainshaft. Apply grease to pockets of roller retainer, insert 12 rollers.

Mainshaft & Ring Gear Assembly: Hold mainshaft with one hand. With other hand turn shaft counter-clockwise, push ring gear into mesh with pinions. *CAUTION—Do not force mainshaft. Roller may be dislodged causing damage to unit.*

Retractor Spring & Control Lever: Slide tool C-3195 into manual control shaft oil seal from outside case. Insert control shaft from inside case, cam pointing up. Push shaft into tool, through oil seal and out of case as far as possible. Remove tool, slide control lever on end of control shaft (offset away from case, pointing down). Install washer and nut. With control shaft pulled away from case as far as possible, install retractor spring and sleeve.

Overdrive Case: Install new gasket, guide case over end of mainshaft. Ease shift rail through hole in case and retractor spring. Line up gasket, secure assembly with adapter screws and lockwashers. Position control shaft, check shift rail for free operation (work manual lever). Drive retaining pin in from top.

LUBRICATION: First fill overdrive unit with good grade S.A.E. 80 transmission gear lubricant, then fill transmission. Recheck both levels. *CAUTION—Do not use extreme pressure lubricant in unit.*

OVERDRIVE CONTROL: *See Warner Type R10 & R11 Overdrive Control data.*

TRANSMISSION OVERHAUL: *See "Chrysler, DeSoto, Dodge, Plymouth Synchro-mesh Transmission" data.*

PLYMOUTH HY-DRIVE

Plymouth (1953-54)

▷*1953 TURBINE SHAFT & REACTION SHAFT PRODUCTION CHANGE:* Turbine Shaft, Part No. 1552121 and Reaction Shaft, Part No. 1538866 replaces old type Turbine Shaft, Part No. 1408449, and Reaction Shaft, Part No. 1486732. New type Turbine Shaft does not have ring land used on previous assembly and MUST be used when new type Reaction Shaft installed to prevent interference between front oil ring lands of old turbine and inside diameter of reaction shaft. A new type Turbine Shaft can be installed with the old type Reaction Shaft. The front turbine shaft oil seal ring is also omitted on the new Turbine Shaft assembly. This ring need not be installed on torque converters built prior to this change.

▷*"PIN TYPE" TRANSMISSION SYNCHRONIZER PRODUCTION CHANGE:* Some "Hydrive" transmissions are now equipped with "Pin Type" synchronizer. See complete "Chrysler, DeSoto, Dodge, Plymouth Synchro-mesh Transmission" for complete data.

DESCRIPTION: This transmission consists of the conventional torque converter used on Chrysler, De Soto, and Dodge cars combined with a three-speed, constant-mesh, synchro-mesh type transmission modified to absorb the added Hy-Drive torque. Transmission is similar to but not interchangeable with standard synchro-mesh transmission.

▷*PARKING CARS WITH "HY-DRIVE" CAUTION—When parking cars with "Hy-drive" Transmission it is very important to set the Parking Brake as there is no solid connection between engine and rear wheels.*

REMOVAL: Disconnect battery cables and two wires leading to transmission neutral safety switch, drain crankcase and torque converter. Then proceed as follows:

1) Remove transmission. *See "Transmission Removal" on car model page.*

2) Remove clutch release fork, pull back spring and disconnect rear end of clutch fork rod assembly. Remove pivot bracket assembly from clutch housing, then remove torque shaft.

3) Remove rear engine-to-crossmember bolts, install engine support fixture Tool C-3162. Insert hooks of fixture firmly into holes on either side of frame sub side rails with support ends up against underside of cylinder block. Adjust support fixture adjusting bolt so it will support engine while removing rear engine crossmember. Remove crossmember-to-frame bolts, remove crossmember. Lower engine approximately 3 or 4 inches to permit access to upper clutch housing-to-torque converter housing bolts. Remove bolts and carefully remove clutch housing from underneath car.

▷*CAUTION—Do not pry between housing flanges or pound housing to loosen. This would distort housing and result in misalignment.*

4) Punch mark clutch cover and clutch driving plate to insure reinstallation in same position. Remove clutch cover and pressure plate assembly and clutch disc from clutch driving plate.

▷*CAUTION—Torque converter housing and clutch housing machined as assembly. If necessary to replace one or the other, replace both housings.*

5) Remove torque converter housing-to-adapter plate bolts and lockwashers. Three bolts are located on engine side of adapter plate. Housing is doweled to adapter plate and care should be exercised when removing housing. Do not pry between flanges to loosen as this will distort metal and result in misalignment. Carefully move housing straight back to avoid damage to torque converter impeller hub oil seal and turbine shaft oil seal ring. Remove seal rings between converter housing and adapter plate. Inspect mating surfaces of adapter plate and torque converter housing, remove burrs or rough spots with emery cloth.

6) Remove six bolts that hold metal dust shield to adapter plate, lift shield out. Remove eight nuts and lockwashers that hold converter unit to crankshaft (use Tool C-811). *The torque converter assembly is a welded unit and cannot be serviced except as an assembly.*

7) Remove bolts which hold adapter plate to engine block, carefully remove adapter plate. *Do not pry or pound on adapter plate to loosen it.* Remove oil rings and thoroughly inspect mating surfaces of adapter plate and engine block. Remove burrs and rough spots with emery cloth.

CONVERTER DISASSEMBLY & REASSEMBLY:

See "Chrysler, DeSoto, Dodge, Plymouth Fluid Torque Drive" for complete data.

INSTALLATION: To reinstall, reverse removal procedures and note the following:

Tightening Torques: Converter unit-crankshaft flange nuts should be tightened to 55-60 ft. lbs. torque. Clutch housing-torque converter housing bolts should be tightened to 25 ft. lbs. torque.

Converter Hub Runout: Should be checked with dial indicator with indicator plunger bearing on hub of converter ¼ inch forward of rear edge. Runout should not exceed .008".

Mating Surfaces: All mating surfaces must be clean and free of rough spots or burrs, otherwise excessive converter runout will result.

Torque Converter Housing: Extreme care must be exercised when installing torque converter housing to prevent damage to turbine shaft and reaction shaft splines, the impeller hub oil seal and oil seal ring. *Use gentle pressure and not force.*

TRANSMISSION OVERHAUL: *See complete "Chrysler, DeSoto, Dodge, Plymouth (Synchro-mesh) Transmission for complete data. See Gear Ratio Note below.*

Gear Ratio Note: Hy-Drive Transmission has heavier gear teeth in order to transmit greater torque loads. Gear ratios are: First Gear—2.37:1, Second Gear—1.68:1, Third Gear—1:1, Reverse Gear—3.46:1.

1941-48 FORD, LINCOLN, MERCURY SYNCHRO-MESH
1941-47 FORD TRUCK

Ford ½-Ton Truck (1941-47)
Ford ¾-Ton Truck (1941-47)
Ford 1-Ton Truck (1941-47)
Lincoln, All Models (1941-48)
Mercury, All Models (1941-48)

▷NOTES, CAUTIONS, & CHANGES

▷Ford Truck Optl. Transmission—Four-speed type optional on these truck models. *See preceding pages for 4-Speed Transmission data.*

▷Lincoln 1941-48 Overdrive—*Special Warner Optl. See "1941-48 Lincoln Overdrive" for complete data.*

DESCRIPTION: Constant-mesh, synchro-mesh, helical gear (Second & High), sliding gear (Low & Reverse). Main drive gear mounted on ball bearing in case. Mainshaft mounted on roller bearing (front), ball bearing (rear). Countershaft mounted on roller bearings on stationary countershaft with thrust washer at each end. Gears are engaged by a sliding clutch sleeve (outer sleeve of synchronizing unit) which engages clutch teeth on the main drive gear and second speed gear hubs.

Synchronizing Unit: Various types used as follows:

Ball & Strut Type Blocking Synchronizer—With this type synchronizer unit, both synchronizer rings are loose in ends of clutch sleeve and are actuated by struts assembled in slots in inner clutch sleeve and engaging notches in synchronizer rings. Struts are centralized in clutch sleeve assembly by the regular poppet balls and springs so that struts move with the outer clutch sleeve during initial movement to engage the synchronizer rings with the cones on the gear hubs. Teeth on outer rim of synchronizer rings block or prevent gear engagement until synchronization completed when the final movement of the outer clutch sleeve causes the clutch teeth on the inner rim of the sleeve to slide through the synchronizer ring teeth to engage clutch teeth on gear hubs. Inner clutch sleeve is stationary on mainshaft (retained as unit with second speed gear by snap ring in groove on shaft). NOTE—This Ball & Strut type synchronizer can be distinguished from Wire-Bound Strut type synchronizer (below) by absence of shoulder on second speed gear end of outer clutch sleeve.

Wire Bound Strut Type Blocking Synchronizer—Both synchronizer rings are loose in ends of clutch sleeve and are actuated by struts assembled in slots in inner clutch sleeve and engaging notches in synchronizer rings. Struts are centralized in clutch sleeve assembly by lock ring or wire installed in outer clutch sleeve which engages notches on struts. Struts move with the outer clutch sleeve during initial movement to engage synchronizer rings with cones on gear hubs. Teeth on outer rim of rings "block" or prevent gear engagement until synchronization completed when the final movement of the clutch sleeve causes clutch teeth on sleeve to slide through the synchronizer ring teeth to engage clutch teeth on gear hubs.

REMOVAL OF TRANSMISSION: *See "Transmission" on car model page.*

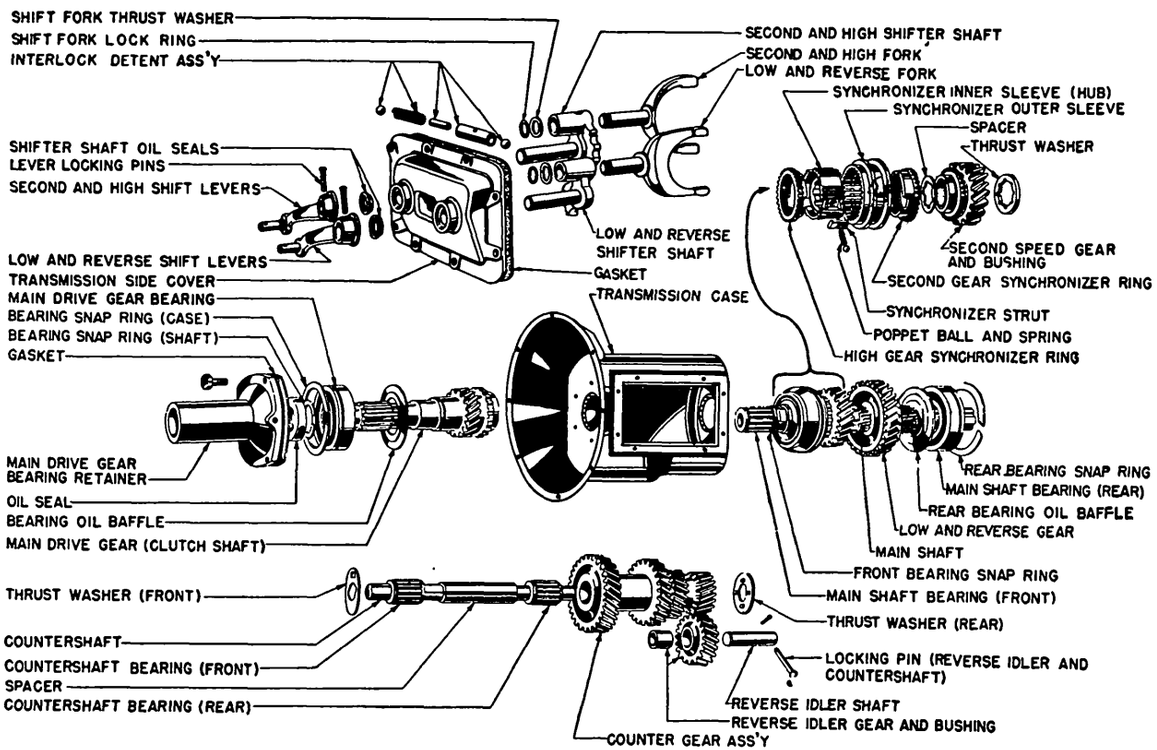
CONTINUED ON NEXT PAGE

1941-48 FORD, LINCOLN, MERCURY (Cont.)

DISASSEMBLY (1941-48 All Models): Remove the transmission side cover and shifter mechanism as an assembly. Take out capscrews in universal joint front yoke and remove yoke from shaft. Remove universal joint housing on rear of transmission case. Remove locking pin and drive out countershaft. Take out bearing retainer screws on front of transmission case, withdraw clutch shaft main drive gear and bearing assembly (On 1942 & later Lincoln, gear can be removed without dropping counter gear by turning drive gear until "cutout" section of clutch teeth provide clearance for counter gear). Tap mainshaft back in case until rear bearing clears rear face of case, remove snap ring from bearing. Tap mainshaft forward until bearing clears inner face of case, remove mainshaft, synchronizer, and gears from case as an assembly (lift out bearing end of shaft first). Lift out countergear cluster and thrustwashers. If reverse idler gear to be removed, tap shaft out rear end of case (retained by same lockpin as countershaft), lift gear out.

REASSEMBLY: Reverse disassembly instructions above and note following points:

Mainshaft Assembly: See Synchronizer, Second Speed Gear, and Sliding Gear for removal and installation of these parts. Rear bearing should be replaced as follows:



Mainshaft Rear Bearing—Press old bearing off shaft. Install oil baffle on shaft with outer edge of baffle away from bearing, press new bearing on shaft until seated against shoulder.

Synchronizing Unit: Can be removed from front end of mainshaft without dismantling. Mark both rings as well as inner and outer clutch sleeves before disassembly to insure reassembly in same relative position. When installing struts, make certain that they engage poppet balls.

Second Speed Gear Assembly (With Blocker Type Synchronizer): Gear and inner sleeve or hub of synchronizer are mounted as an assembly on the mainshaft with a thrustwasher (spacer) between the gear and synchronizer. Assembly is retained on shaft by snap ring at forward end of synchronizer clutch sleeve. To dismantle assembly, remove snap ring from groove at forward end of shaft, withdraw synchronizer assembly, thrustwasher, and second speed gear. NOTE—Gear and bushing are furnished as an assembly.

Gear Endplay—.004-.008" (new), .020" (worn). Install spacer (front thrustwasher) of the correct thickness for this endplay as follows:

81A-7069-A—.0630-.06355" (new), .060" (worn limit).
81A-7069-B—.068-.071" (new), .066" (worn limit).

1941-48 FORD, LINCOLN, MERCURY SYNCHRO-MESH TRANSMISSION

Rear thrustwasher furnished in one thickness only: 81A-7071—.184-.185" (new), .179" (worn limit).

with spacer on shaft between bearings. When installing gear cluster, make certain that tongue on thrust washer at forward end engages slot in case and that rear thrust washer prongs engage gear.

NOTE—On '60' models, floating bushings are used. Spacer (74-7115) installed between bushings.

Countergear Assembly:—Counter shaft is retained by locking pin driven in through hole in case and rear end of shaft (pin also locks reverse idler gear shaft in place) and shaft can be driven out after pin removed. Gear cluster is mounted on roller bearings

Countergear Endplay—Endplay must not exceed following specifications (replace thrustwashers if excessive):

1941-48 Pass. Cars —.005-.015" (new), .025 (worn).
1941-47 Trucks—.005-.017" (new), .025" (worn).

Reverse Idler Gear:—Shaft retained by countershaft locking pin, may be removed after pin driven out. Install gear with shoulder toward rear of case. See that locking pin hole in shaft lined up with hole in case and install locking pin after countershaft installed (same pin locks both shafts).

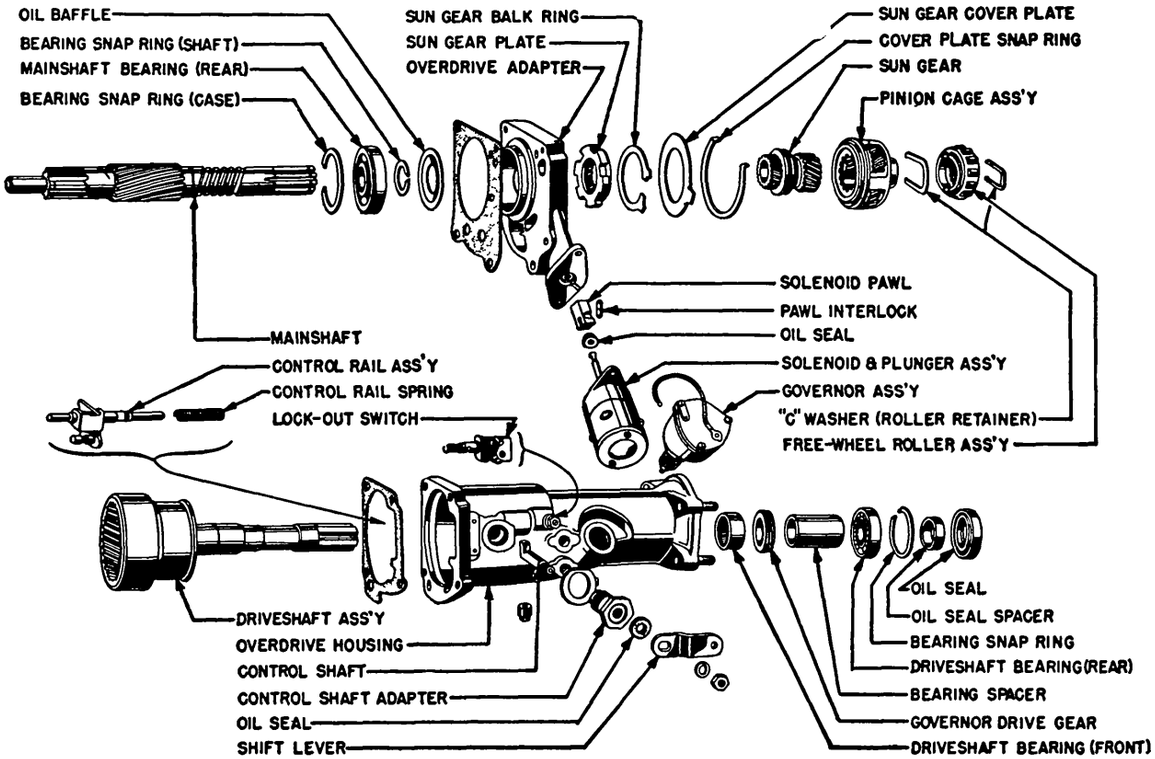
GEARSHIFT ASSEMBLY (Pass. Cars): To dismantle shift assembly, remove lockrings on shifter shaft ends of forks, remove forks from shifter shafts. Drive out locking pins in lever at outer ends of shifter shafts, withdraw shafts from inside of cover using extreme care not to lose detent balls, spring, and plunger. Reassemble shifter mechanism in same manner. See that oil seal in recess in cover at outer end of each shifter shaft is in good condition. See Ford & Lincoln Transmission Control articles for adjustment directions.

1941-48 LINCOLN OVERDRIVE (SPECIAL WARNER R10)

Car Model	Warner Model
Lincoln, All Models (1941-42)	AS1-R10
Lincoln, All Models (1946-47)	AS2-R10
Lincoln, All Models (1947-48)①	AS3-R10

①—After approximately March 1, 1947.

DESCRIPTION: Warner special R10. New design overdrive unit with solenoid control (no centrifugal clutch pawls). This R10 type similar to Type R9 (Hudson, Packard models) except for control circuits and lockout mechanism which are entirely new design as described below. Solenoid pushes sun gear pawl in (to engage Overdrive), withdraws pawl (for Direct Drive). Solenoid is controlled by Governor Switch (Overdrive does not engage above cut-in speed until accelerator pedal released momentarily) and has 'kick-down' direct drive feature.



REMOVAL OF OVERDRIVE: *See "Overdrive" on car model page.*

TRANSMISSION DISASSEMBLY & REASSEMBLY: See "Ford-Lincoln-Mercury 3-Speed" Transmission (transmission is same as std. type without overdrive) except that mainshaft is extended back into overdrive case and has pinion assembly and freewheel cam mounted on this extension.

SOLENOID REMOVAL & INSTALLATION: Disconnect wires at terminals, take out mounting screws in base flange, **rotate solenoid approximately 60° to right** to disengage pawl rod from pawl (this will line up flats on end of rod with slot in pawl), withdraw solenoid and pawl rod assembly. To install solenoid, insert pawl rod in adapter with flats horizontal, make certain that short pilot on end of solenoid body enters counterbore in adapter casting, **rotate solenoid approximately 60° to left to engage pawl rod end in pawl** and line up solenoid flange with mounting holes. Check engagement of pawl rod and pawl by attempting to pull solenoid off (solenoid should not come out and resistance of solenoid spring should be felt). Install solenoid mounting screws and connect wires at terminals.

CAUTION—Solenoid must be installed with wire terminals "up".

ASSEMBLY OF OVERDRIVE: Install rear bearing on transmission shaft, install bearing lock ring (see end play note below), install oil baffle, transmission shaft and bearing in adapter plate, install bearing snap ring (see bearing endplay note below), install sun gear plate and balk ring assembly in adapter, install pawl in adapter slot. Install cover plate with tongue over pawl, install cover plate snap ring. Install interlock plunger in hole between pawl and shifter shaft, install shifter shaft assembly. Slide sun gear in place on transmission shaft and enter shifting fork in sun gear groove. Assemble overrunning clutch on pinion cage assembly and fasten with retainer, then install assembly on rear end of transmission shaft and install retainer on rear end of overrunning clutch. Install rear shaft assembly over pinion cage assembly and push it forward until overrunning clutch enters its outer race (use a rubber band to hold clutch rollers in place and rotate shaft counter-clockwise to facilitate assembly). Install shifter shaft retractor spring in housing, install housing and attach to adapter plate using gasket 16H-7661. Install governor gear and spacer

1941-48 LINCOLN OVERDRIVE (SPECIAL WARNER R10)

on shaft. Install rear bearing and bearing snap ring (see Overdrive rear bearing endplay note below). Install oil seal and spacer at rear of case. Install universal joint yoke and tighten mounting screw securely. Install governor, lock-out switch (fasten with setscrew), and solenoid grease retainer. Install shift lever in bushing, install grease retainer in hexagonal end of bushing, place lever in position and install in overdrive case with lever "up." Install solenoid (see Solenoid data above).

Transmission Rear Bearing Endplay—When installing bearing on shaft, select snap ring of correct clearance so that there is no endplay but bearing turns freely. Snap ring supplied in following thicknesses: .087"—16H-7667A, .090"—16H-7667B, .093"—16H-7667C, .096"—16H-7667D, .102"—16H-7667E. Snap ring which retains this bearing in adapter plate should also be selected to control endplay and is furnished in following thicknesses: .087"—16H-7669A, .090"—16H-7669B, .093"—16H-7669C, .096"—16H-7669D.

Solenoid Pawl Interlock—Consists of a short plunger installed in hole in adapter plate between pawl and shifter shaft. Install plunger in hole before installing shifter shaft assembly.

Overdrive Rear Bearing Endplay—Endplay is controlled by thickness of snap ring which retains bearing in overdrive case. Snap rings furnished as follows: .062"—16H-7656A, .065"—16H-7656B, .068"—16H-7656C, .071"—16H-7656D.

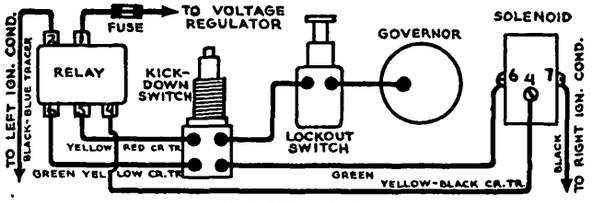
Governor Drive Gear—Gear is free on overdrive shaft and will turn with universal joint yoke not tightened on shaft (gear clamped in place by yoke when yoke retaining screw is properly tightened)

1941-48 LINCOLN OVERDRIVE CONTROL

Lincoln, All Models (1941 to 1948)

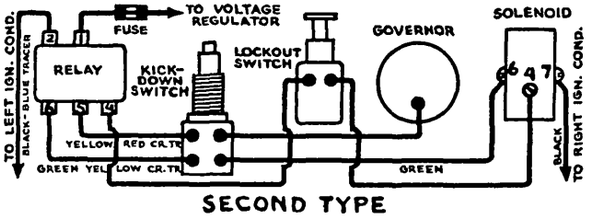
DESCRIPTION: Note—Overdrive operates similarly to R9 type with "push type" solenoid controlled by Governor Switch and throttle operated kick-down switch as described below. A lock-out switch is also provided which is operated by the overdrive lock-out mechanism.

OPERATION & ADJUSTMENT:—Lockout Control—If dash control button is to be pulled out (to lockout overdrive), accelerator pedal should first be fully depressed (to place overdrive in direct drive), button then pulled out, and accelerator pedal released. NOTE—Lockout will not engage unless overdrive in direct drive (sun gear teeth will strike lock plate clutch teeth causing 'buzzing' sound) and accelera-



CONTINUED ON NEXT PAGE

1941-48 LINCOLN OVERDRIVE CONTROL (C nt.)



tor pedal must be fully depressed to complete lock-out engagement.

Adjustment—If dash control button cable is adjusted too short, buzzing sound will be noticed when button pushed all the way in. Noise will disappear when operated with engine pulling car below cut-in speed and will reappear when accelerator pedal released. To adjust cable, turn adjusting nuts at end of cable where it is attached to lever.

Cut-in Speed—25 MPH (governor switch contacts close). Overdrive does not engage until accelerator pedal released momentarily. Overdrive cuts out at 22 MPH (or at any speed if 'kick-down' operated). No cut-in speed adjustment provided.

FIRST TYPE

SECOND TYPE

TROUBLE SHOOTING:—If overdrive does not operate satisfactorily after adjustments have been made correctly, determine trouble as follows:

Overdrive remains engaged, Will not 'kick-down', Car will not roll backward in Neutral—Caused by ground in lead between #5 relay terminal and governor switch. Check by disconnecting lead at #5 terminal and noting if relay 'clicks' when wire touched to terminal (click indicates ground or other defect). Check lead, relay terminals, and kickdown switch for grounds (see Special Service Notes above). To check relay, remove fuse. If relay 'clicks' as fuse removed, relay is defective.

IMPORTANT NOTE—If attempt made to reverse car under above conditions (ground in #5 circuit), overdrive unit may be seriously damaged.

Ignition Cuts Out—If left cylinder bank cuts out when idling, check for grounded relay (internally or at terminals #2 & 6), ground between #6 relay terminal and kickdown switch or in kickdown switch, ground in lead between #2 terminal and distributor or within distributor (if ignition restored when lead disconnected from #2 relay terminal, this lead and distributor are not at fault). If right cylinder bank cuts out when idling, check for ground in lead between #7 solenoid terminal and distributor, in solenoid, and in distributor (if ignition restored when lead disconnected from #7 solenoid terminal, this lead and distributor not at fault). If one bank of cylinders cuts out when overdrive engaged, check for defective solenoid or ground between solenoid terminal #6 and kick-down switch lower terminals.

Overdrive will not engage—Check for open-circuit between relay terminal #5 and governor switch. Check by grounding #5 relay terminal (relay and solenoid should 'click' simultaneously). If relay does not click, check for blown fuse or defective relay. If relay clicks but solenoid does not, check for defective relay, defective solenoid or open-circuit between #4 relay and solenoid terminals. If both relay and solenoid click but overdrive will not engage, check for jammed solenoid or damage within overdrive unit.

Overdrive will not kick-down—Check for ground between relay and kick-down switch or at upper terminals of kickdown switch (see Special Service Note above). Check for open-circuit between relay terminal #2 and ignition condenser, solenoid terminal #7 and ignition condenser, solenoid terminal #6 and kick-down switch, relay terminal #6 and kick-down switch, or within relay. Check for defective kick-down switch.

FUSE:—15 ampere. In connector in control relay lead. Serviced with 20 ampere capacity fuse.

1949-51 FORD, LINCOLN, MERCURY SYNCHRO-MESH

Ford, 6 Cyl. & V8 Pass. Car Models (1949-51)
Lincoln & Cosmopolitan Models (1949-51)
Mercury, V8 Models (1949-51)

►CHANGES, CAUTIONS, CORRECTIONS

►**Lincoln Transmission Note**—Transmission is Warner Type AS1-T85B (No Overdrive), AS2-T85B (With Overdrive. *Data below applies to these transmissions.*

►**Elimination of Overdrive Lock-out Switch (1949-50 Cars)**—Switch not furnished for service and can be wired out of control circuit if defective. *See Ford, Lincoln, Mercury Overdrive data.*

►**Transmission Jumping out of Low Gear (1951 Ford & Mercury Cars)**—May be caused by excessive clearance between major diameters of mainshaft splines and internal splines on low and reverse sliding gear. This clearance should be .000-.0015". To correct this complaint, measure outside diameter of splines on mainshaft with a micrometer. If shaft does not check to 1.6235-1.6240", replace the shaft. If outside diameter is correct, replace the low and reverse sliding gear. If shaft clearance is correct (.000-.0015"), slight pressure should be required to push the sliding gear on the shaft.

►**Ford Transmission Locking In Reverse Complaints (Transmission without Overdrive)**—May be caused by mainshaft drive gear snap ring or mainshaft rear bearing snap ring not correctly installed (see illustration). Correct by disassembling transmission (remove mainshaft assembly from extension housing) and checking these snap rings.

See Disassembly & Reassembly data below.

►**Ford Overdrive Transmission on First Cars Inoperative in Reverse (Reverse Lock-out Inoperative)**—May be due to use of wrong Reverse Shifter Fork Cam & Shaft (8A-7282-A instead of 8A-7282-B). Check and correct this condition as follows:

To Check—Place gearshift lever in Reverse position. Release hand brake. Push car **forward.** If car rolls freely, this indicates wrong cam installed.

To Correct—Disassemble Overdrive and install new No. 8A-7282-B Reverse Shifter Fork Cam & Shaft which provides automatic lock-out for Reverse Gear.

See "Ford, Lincoln, Mercury Overdrive" (following) for disassembly directions.

►**Ford Overdrive Transmission Noisy in Operation**—May be caused by interference between overdrive case and rear engine support. Correct as follows:

(1) Interference between Rear Engine Support Bolt and Overdrive Case—Correct by grinding off head of bolt for clearance. Thin head bolt No. 355519-S2 used at this point on later cars.

►*CAUTION—Bolt head thickness must be at least ⅛".*

(2) Interference between Rear Engine Support & Overdrive Case—Case is grooved for clearance at flanges on support. If grooves in case not deep enough (particularly at ends where casting flash protrudes), clean up this flash and deepen grooves by filing.

DESCRIPTION: Three-speed, all helical gear type with constant-mesh, synchro-mesh (Second & High), sliding gear (Low & Reverse). Overdrive is optional. Std. transmission has extension housing at rear which has rear engine mounting. Mainshaft extends through extension housing with splines at rear end for propeller shaft engagement (front universal yoke hub slides on shaft—no slip-joint used on propeller shaft).

REMOVAL OF TRANSMISSION: *See "Transmission" on car model page.*

OVERDRIVE SERVICING NOTE: On transmission with Overdrive, overdrive unit can be disassembled separately without disturbing transmission.
See "Ford, Lincoln, Mercury Overdrive" (following).

TRANSMISSION DISASSEMBLY: Take out mounting screws and remove gearshift housing (side cover) assembly. Drive countershaft and reverse idler shaft pin out through case side (Ford & Mercury, Lincoln shafts locked by separate key in rear end of each shaft). Take out extension housing screws, rotate extension housing ¼ turn to expose end of countershaft, drive countershaft to rear until it clears front of case, use Tool 7121-N (or counter shaft cut to length of countergear cluster) to push countershaft out through rear of case (leave tool or dummy shaft in gear cluster to retain bearing rollers), drop gear cluster to bottom of case. Tap lightly on extension housing to loosen it from case, withdraw housing and mainshaft assembly from case (CAUTION—use care not to lose mainshaft pilot bearing rollers). Lift countergear cluster and

CONTINUED ON NEXT PAGE

1949-51 FORD, LINCOLN, MERCURY SYNCHRO-MESH (Cont.)

thrustwashers from case, remove tool and take out bearing retainers, rollers, and spacer. Take out capscrews in bearing retainer on front of case, remove retainer and gasket. Tap main drive gear assembly out through front of case, using a soft hammer. To remove reverse idler gear, use brass drift to drive shaft out, lift gear out. Disassemble and service subassemblies as follows:

Mainshaft & Extension Housing Assembly: Remove snap ring in front of rear bearing in extension housing, use a soft hammer to tap mainshaft and bearing out of housing. Remove snap ring on forward end of mainshaft, pull or press synchronizer assembly, 2nd speed gear, and sliding gear off shaft. On Lincoln, remove speedometer gear snap rings, remove speedometer gear and woodruff key. On all models, remove bearing snap ring from groove in shaft (on Ford & Mercury, this snap ring retains speedometer gear also—note position of shoulder on gear to insure correct reassembly—remove gear and woodruff key). Press rear bearing off shaft.

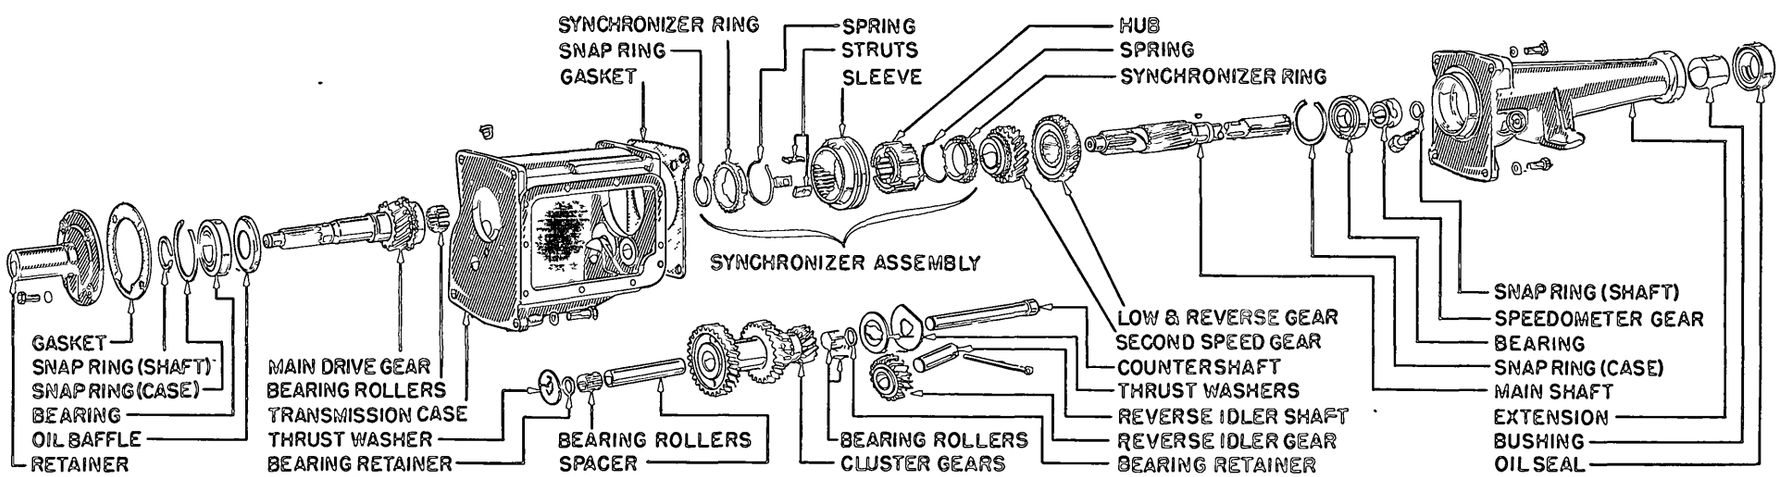
Extension Housing Oil Seal & Bushing: Oil seal and bushing can be replaced after mainshaft removed from housing.

TRANSMISSION REASSEMBLY: Assemble all subassemblies as noted below and install in transmission by reversing the disassembly directions given above.

Reverse Idler Gear: Ford & Mercury gear has bushing, Lincoln gear has 25 bearing rollers and thrust washer at each end. Install gear with chamfered end of teeth forward, see that locking pin hole in line with hole in case (Ford & Mercury), install key in slot in rear end of shaft (Lincoln).

Countergear Cluster: Place bearing spacer in gear cluster, insert tool 7121-N (or dummy countershaft cut to length of gear cluster), install bearing rollers in each end (on Lincoln, two sets of 20 bearing rollers used at each end with retainer washer at outer end of each set). Coat thrustwashers with grease to hold them in position, install bearing retainer in each end of gear cluster. Install front thrust washer so that tongue will enter groove in case when assembly installed, place rear thrust washer with slotted hole on gear cluster with babbitted face out toward steel washer which must be next to case. Place this assembly in the case and after mainshaft installed, raise assembly and insert countershaft from rear, pushing dummy shaft out at front of case. On Ford & Mercury, align locking pin hole in shaft with hole in case, install locking pin through reverse idler and countershafts. On Lincoln, install locking key in slot in rear end of shaft before shaft fully inserted in case. On Ford & Mercury, countergear endplay should be .0045-.0185"

Main Drive Gear Assembly: Install oil baffle and drive gear bearing on shaft, press bearing in place firmly, install snap ring in shaft groove (see Lincoln Note below). Install snap ring in groove in bearing. Install main drive gear in case. Use new gasket with retainer (Lincoln gasket furnished in thicknesses of .010", .015", .020", .025" for selective fitting), make certain oil drain groove in retainer is at bottom.



Lincoln Snap Ring Note—This shaft snap ring furnished in thicknesses of .086-.088", .089-.091", .092-.094", .095-.097" for selective fitting).

Synchronizer Assembly: Install synchronizer springs at each end of hub with spring openings staggered. Install three struts on hub, slide outer clutch sleeve over the assembly. Place synchronizer ring on each end of assembly making certain that struts engage slots in rings. Backlash of synchronizer sleeve on hub must not exceed .001".

Mainshaft Assembly: Use special press tool 7699-N to install new bushing in rear end of extension housing, install oil seal. Press rear bearing in place on mainshaft. On Ford & Mercury, install speedometer gear key and gear (on Lincoln, speedometer gear is mounted separately on shaft). Select snap ring of correct thickness and install in groove in shaft. This snap ring furnished in following thicknesses: (Ford & Mercury) .090", .093", .096", .100". On Lincoln, install speedometer gear on shaft with woodruff key in gear and snap ring in shaft groove. Install sliding gear, 2nd. speed gear, and synchronizer assembly on shaft, install snap ring in shaft groove to retain assemblies. Check 2nd. speed gear endplay which should be .002-.011" on Ford & Mercury. Clearance between outside diameter of splines on mainshaft and internal splines on low and reverse gear should be .000-.0015" and shaft or gear should be replaced if clearance exceeds .002" (see Transmission jumping out of Low Gear Correction above).

Mainshaft & Extension Housing Installation: Install mainshaft assembly in extension housing, seating rear bearing firmly in housing recess (Ford and Mercury), against bearing rear snap ring (Lincoln). Select snap ring for correct fit—this ring furnished in following sizes (Ford & Mercury) Thin .086-.088", Medium .089-.091", Thick .092-.094", Extra Thick .095-.097", (Lincoln) .087-.089", .090-.092", .093-.095", .096-.098", .099-.101" for selective fitting, install ring in housing to retain bearing. Make certain pilot bearing rollers in place in recess in main drive gear (use cup grease to hold rollers in place), use new gasket on extension housing, insert mainshaft assembly through rear of case and enter shaft in pilot bearing. Turn extension housing to permit countershaft to be installed (see Countergear Cluster above), install extension case washers and capscrews.

▷*CAUTION—On Ford & Mercury, use lead washers on two lower extension case capscrews and secure these screws with lockwire.*

1949-51 FORD & MERCURY TRANSMISSION (LINCOLN SIMILAR)

1952-55 FORD & MERCURY 3-SPEED SYNCHRO-MESH

Ford & Mercury (1952-55)

►***SYNCHRO-MESH TRANSMISSION CHANGE (To prevent possibility of shifting into two gears at once):*** Interlock Pin, Part No. 01A-7235 can be installed inside Interlock Plunger Spring between shifter cams.

DESCRIPTION: Three-speed, all helical gear type with constant-mesh, synchro-mesh (Second & High), sliding gear (Low & Reverse).

►***1954 FORD INTERMEDIATE GEAR PRODUCTION CHANGE:*** The design of the intermediate gear is changed eliminating the bushing used in earlier cars. The later gear, Part No. 1A-7102-A2 is interchangeable with the earlier type.

►***1955 FORD LOW GEAR JUMP-OUT OR PREMATURE LOW GEAR WEAR CORRECTION (Station Wagon, Thunderbird, & Sedan Delivery):*** This may be due to insufficient clearance between detent boss on transmission side cover and the low gear shift cam. Correct as follows: Remove side cover, and grind corner of detent boss to provide sufficient clearance between shift cam and detent boss.

►***1955 FORD PASS. CARS & F-100 TRUCKS INTERMEDIATE & HIGH GEAR JUMP-OUT NOTE:*** Before attempting to overhaul transmission to correct the above condition. Check alignment of transmission shift rods, wear at ends of rods and interference between clutch release rod and high and intermediate shift rods.

►***1952-54 SERVICE REPLACEMENT OUTPUT SHAFT NOTE:*** When installing the later type shaft, Part No. AF-7061-D (Service Part No. B6A-7061-A) it will also be necessary to change the speedometer gear and retaining lock rings.

REMOVAL OF TRANSMISSION: *See "Transmission" on car model page.*

►***OVERDRIVE DISASSEMBLY NOTE:*** Overdrive can be disassembled separately without disturbing transmission.
See "Ford & Mercury Overdrive" (following).

TRANSMISSION DISASSEMBLY: Take out mounting screws and remove gearshift housing (side cover) assembly. Drive countershaft and reverse idler shaft pin out through case side. Take out extension housing screws, rotate extension housing ¼ turn to expose end of countershaft, drive countershaft to rear until it clears front of case, use cluster gear roller retainer shaft tool or a countershaft cut to the length of the countershaft cluster gear to push countershaft out through rear of case (Leave cluster gear and dummy shaft in case). Remove extension and mainshaft assembly from rear of transmission case. Drive reverse idler gear out of case with brass drift, then remove reverse idler gear. Remove capscrews that secure drive gear bearing retainer to transmission, then remove retainer and gasket. Tap drive gear assembly out through front of transmission case with soft hammer. Disassemble sub-assemblies as follows:

Mainshaft Assembly: Remove snap ring that holds mainshaft assembly in extension. Tap mainshaft out of extension with soft hammer. Remove transmission mainshaft synchronizer snap ring and pull or press the synchronizer assembly, intermediate gear, and sliding gear off the mainshaft. Remove snap ring that secures speedometer driving gear on mainshaft, then remove gear. Remove speedometer gear key. Press mainshaft rear bearing off mainshaft. Remove oil seal and rear bushing from transmission extension.

Synchronizer Assembly: Push synchronizer hub out of sleeve. This releases three synchronizer blocks. Remove synchronizer block springs from each end of synchronizer hub.

Main Drive Gear Assembly: Remove snap ring that secures bearing on shaft, press bearing off shaft. Remove oil baffle from shaft.

Countershaft Gear Assembly: Remove countershaft gear, thrust washers, and tool from transmission case. Remove bearing retainers, bearing rollers, spacers, and dummy shaft from countershaft gear.

Gearshift Housing Assembly: Remove shift levers from camshafts. Remove camshaft retaining pins and pull shifter fork and cams out of gearshift housing. With cams removed, the interlock balls, retainer, and spring will fall out of gearshift housing. Pull shifter forks out of cams, then remove seal rings from cams. *See NOTE following.*

NOTE—Condition of housing parts can be determined without removing gearshift housing assembly. Observe condition of shift levers and forks for evidence of binding or possibility of shifting into two gears at once when lever operated.

Transmission Extension Housing: Using Tool T52P-7000-GAE (Ford) or Tool 7041 (Mercury) remove oil seal and bushing from housing.

CLEANING, INSPECTION & ADJUSTMENT:

Cleaning: Wash all parts with suitable cleaning fluid.

Inspection: Inspect transmission parts before installation as follows:

Transmission Case—Inspect for cracks, worn bearing bores, damaged threads or other damage. Replace case if any of above conditions found.

Gears & Shafts—Inspect gears for excessive wear and chipped or cracked teeth. Replace as necessary.

1) Check endplay between cluster gear and thrust surfaces of transmission case. Replace cluster gear if endplay not between .004-.018".

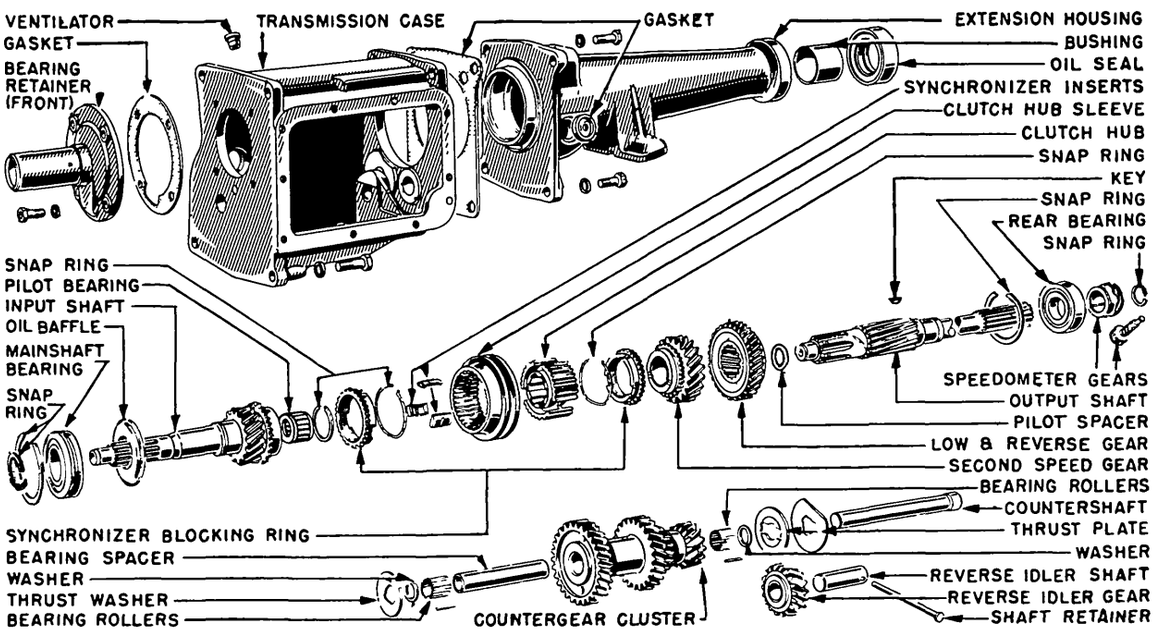
2) Check intermediate gear endplay. Replace gear if endplay not between .002-.011".

3) Check fit of low and reverse sliding gear. Replace gear or mainshaft if outside diameter fit of helical splines exceeds .002".

4) Inspect idler gear bushing for wear. Replace if worn excessively.

5) Check bearing surfaces of all shafts for wear. Replace if worn excessively.

Bearings—Inspect for loose races, discoloration due to overheating, and free rotation on mating shafts. Replace as necessary.



Adjustments: Flywheel housing must be accurately aligned with crankshaft. Face of housing must be parallel with flywheel to within .007" and bore concentric with centerline of crankshaft to within .010". Use dial indicator to measure runout. If highest point of parallel runout exceeds .007" install shims of required thickness between housing and cylinder block. If highest point on cencentricity with centerline of crankshaft exceeds .010" housing should be replaced.

NOTE—If shims used, small amount of gasket-forming cement may be used to eliminate air gaps between shims.

TRANSMISSION SUB-ASSEMBLY REASSEMBLY: During assembly of transmission, each splined shaft and its mating parts should be carefully selected to obtain sliding fit with no backlash. Assemble sub-assemblies as follows:

Countershaft Gear: Position countershaft bearing spacer in countershaft gear. Insert countershaft gear roller retainer shaft tool (or dummy counter-

CONTINUED N NEXT PAGE

1952-55 FORD & MERCURY SYNCHRO-MESH TRANSMISSION

1952-55 FORD & MERCURY SYNCHRO-MESH (Cont.)

shaft cut to length of gear cluster) in countershaft gear assembly. Install rollers in each end of gear cluster. Coat bearing retainers and thrust washers with grease to hold in position. Install bearing retainer at each end of countershaft gear. Place thrust washer with slotted hole next to cluster assembly, with babbitt side toward steel washer and steel thrust washer next to transmission case. Install front thrust washer between transmission case and cluster making sure tongue on thrust washer is entered in groove provided in case. Place cluster gear assembly with dummy shaft in place in transmission case, allowing it to rest on bottom of case.

Main Drive Gear: Install oil baffle and drive gear bearing on drive gear shaft. Press bearing into place, applying pressure to inner race. Install snap ring on shaft to secure bearing. Install snap ring on drive gear bearing. Coat mainshaft front bearing rollers with cup grease, install rollers in main drive gear shaft.

Synchronizer: Install synchronizer snap ring at each end of hub with ends of springs between same two inserts. Place synchronizer inserts on synchronizer hub. Align etch mark on sleeve and push hub inside synchronizer sleeve. If new hub or sleeve installed, be sure backlash between hub and sleeve does not exceed .001". Place synchronizer ring on synchronizer assembly, making sure slots in line with synchronizer inserts.

Mainshaft: Using Tool T52P-7000-HAE (Ford) or Tool 7041 (Mercury) install extension rear bushing, install oil seal. Install mainshaft rear bearing on shaft, press into place. Install speedometer gear key in shaft, install speedometer gear on shaft, secure with largest snap ring that will enter groove. Install sliding gear, intermediate gear, and synchronizer assembly on mainshaft, secure with snap ring.

Housing: Install new seal rings in grooves in shifter cams. Place one cam assembly in position in gearshift housing, install retaining pin. Assemble interlock spring and balls in interlock and install assembly in gearshift housing. Place other cam assembly in position in housing, install retaining pin. Install gearshift levers on camshafts, assemble shifter forks to cams.

TRANSMISSION REASSEMBLY: Place reverse idler gear in position in transmission case, install reverse idler gear shaft, making sure to align retainer pin hole with hole in transmission case. Position main drive gear in front of transmission case, making sure snap ring on bearing is firmly seated against case. Install retainer with new gasket, on main drive gear shaft with drain groove at bottom. Install cap screws and lock washers that secure retainer to transmission case. Install mainshaft assembly in transmission extension, securing it with snap ring. Place new gasket on front of extension, install mainshaft assembly and extension on transmission case. Use care not to displace rollers when entering front end of main drive gear shaft. Turn extension to provide access to countershaft, raise countershaft gear assembly and thrust washers into position, install countershaft from rear of case, pushing dummy shaft out front of case. *CAUTION—Great care must be exercised when installing countershaft to avoid damaging thrust washers, bearing spacer, or bearing rollers.* Align retainer pin hole with hole in case, install countershaft and reverse idler shaft retainer pin. Turn extension on transmission case, aligning capscrew holes. Install washer and capscrews, using internal tooth lock washers on two lower capscrews. Install gearshift housing on transmission case, using new gasket, secure with lock washers and capscrews.

1949-55 FORD, LINCOLN, MERCURY (WARNER) OVERDRIVE

Car Model	Warner Model
Ford 6 Cyl. & V8 Pass. Cars (1949-50)	AS1-R10E
Ford 6 Cyl. & V8 Pass. Cars (1951)	②AS4-R10E
Ford Sta. Wgn. & Convt. (1949-51)	AS3-R10E
Ford, All Models (1952-55)	AS1-R10F
Lincoln & Cosmopolitan (1949-51)	①AS2-T85B
Mercury, V8 Models (1949-50)	AS1-R10C
Mercury, V8 Models (Early 1951)	AS1-R10E
Mercury, V8 Models (Late 1951)	②AS4-R10E
Mercury, All Models (1952-55)	AS1-R10F

①—Transmission & R10 Overdrive Assembly.
②—New type without Lock-out Switch.

▷CHANGES, CAUTIONS, CORRECTIONS

▷FORD & MERCURY OVERDRIVE LOCK-OUT SWITCH PRODUCTION CHANGE: Ford Overdrives (beginning with 1951 production) and Mercury Overdrives (beginning January 1951) do not have any provision for Lock-out Switch and Governor is connected to "A" terminal on Kick-down Switch.

▷FORD, LINCOLN, MERCURY OVERDRIVE LOCK-OUT SWITCH REMOVAL: If Lock-out Switch defective on early overdrive units where this switch installed originally (see Production Change above), both switch wires should be detached and connected together so that switch eliminated from the circuit (CAUTION—wires should be soldered together for good connection and taped for protection from moisture and grease). Leave switch installed to act as cover for switch mounting hole (if switch cannot be used for this purpose, make up sheet metal cover for installation over switch mounting hole).

OVERDRIVE NOISE (EARLY 1949 CARS): Can be caused by Overdrive case interference at Rear Engine Support at two points as follows:
1)—Rear Engine Support Bolt. Head of bolt may be interfering with underside of Overdrive Case. Correct by grinding off head of bolt (do not grind head to less than ⅛" thick). Thin head bolt No. 355519-S2 used on later cars in production.
2)—Overdrive Case. Grooves on underside of case at engine mounting too shallow so that flanges on engine support interferes with Overdrive case at this point. Correct by filing grooves in case and cleaning up ends of grooves if casting flash evident.

▷PROLONGED SHORTING OF IGNITION CORRECTION: If shorting out of ignition during Overdrive Kick-down is prolonged (normal shorting out period is very brief), correct by installing insulator inside solenoid cover as follows: Make up insulator strip from treated paper .03" thick, .76" wide, 2.38" long with hole for cover screw .25" from each end. To install insulator, remove terminal screws, nuts, and lockwashers on side of cover, remove cover, place insulator over cover studs, re-install cover.

▷OVERDRIVE NOT ENGAGING CORRECTION (Convertible Models): Check sliding pawl operating rod lever (in adapter) for binding or sticking. If this condition noted, remove solenoid and adapter, disassemble linkage, polish pins and pawl operating rod to provide free movement of rod through seals in plate.

▷OVERDRIVE GOVERNOR PRODUCTION CHANGE: New type governor used which is interchangeable with first type except on Convertibles. Governors can be distinguished as follows:
First Type—Unpainted Body with Bakelite Top.
Later Type—Body painted Black, Top unpainted.

▷*CAUTION—Later type governor cannot be installed on Convertible models (will not clear X-member).*

DESCRIPTION: Solenoid operated type similar in design to other Warner Type R10 Overdrives

REMOVAL OF OVERDRIVE: *See "Overdrive" on car model page.*

DISASSEMBLY OF OVERDRIVE: Remove Lock-out Switch and switch operating balls, remove governor and speedometer drive pinion. Remove solenoid by taking out mounting screws and rotating solenoid clockwise to disengage plunger from pawl, then pull solenoid and plunger out. Drive out tapered pin holding control lever shaft in overdrive case, pull shaft out as far as possible to disengage operating cam from shift rail. Take out four mounting screws holding overdrive case and adapter on transmission case. Remove small rectangular cover plate on top of case by taking out two screws. Working through slot under this plate, spread bearing snap ring with special pliers 7059-N to free rear bearing. Withdraw overdrive case while pressing forward on rear end of shaft to prevent shaft coming off with housing. CAUTION—Do not allow adapter plate to separate from transmission case. Disassemble.

Overdrive Case & Control Mechanism: Remove reverse lock-up spring from case. Remove lever on end of control shaft, push shaft through and remove from within housing, remove shaft oil seal from case. Compress rear bearing snap ring (insert pliers through slot in case), remove ring. Bushing and oil seal at rear end of case are similar to regular transmission. *See Extension Housing data in Ford-Lincoln-Mercury Transmission article.*

Driveshaft & Gear Assembly: Install one screw to retain adapter plate on transmission case, pull driveshaft off to rear (CAUTION—catch free-wheel rollers as they drop out). If bearing to be removed from shaft, take out snap ring and remove speedometer gear taking care not to lose woodruff key from gear (on Lincoln, remove both speedometer gear snap rings and additional snap ring at rear of bearing), remove bearing. Take out retaining clip ("C" washer) at rear of free-wheel cam, withdraw free-wheel unit and pinion assembly (these two parts can be separated by removing "C" washer ahead of free wheel cam). Remove overdrive sun gear and shift rail assembly as a unit by sliding them off rear of shaft.

Adapter Plate & Sun Gear Mounting: Remove large snap ring from adapter plate, withdraw sun gear cover plate, balk ring blocker assy., solenoid pawl. NOTE—Adapter plate is removed as a unit with transmission mainshaft. Do not disturb unless transmission being disassembled.

CONTINUED ON NEXT PAGE

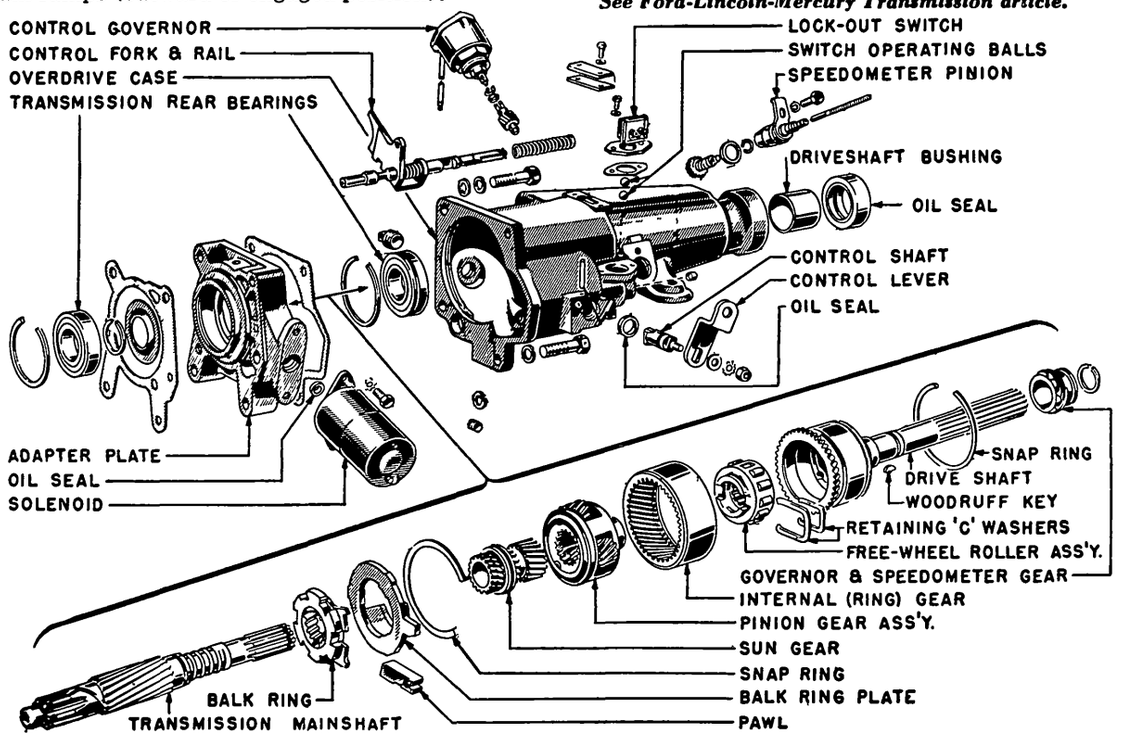
1949-55 FORD, LINCOLN MERCURY OVERDRIVE (C nt.)

Checking Balk Ring Tension: Place balk ring and gear plate assembly in vise. Place hook of scale on shoulder of balk ring. Pull in direction of drag should be 3½-5½ lbs. Reading should be taken while balk ring turning as initial effort may give reading considerably higher than specified. Replace assembly if not within specifications.

REASSEMBLY OF OVERDRIVE: Assemble in reverse order of disassembly. Note following:

Sun Gear Balk Ring, Pawl & Solenoid: After balk ring installed, insert pawl with notch on side downward (Ford), upward (Lincoln & Mercury—on Mercury, interlock plunger engages this notch), position cover plate with tongue over pawl, install large snap ring (this ring furnished in three thicknesses for selective fitting). When installing solenoid (after assembly completed), insert plunger stem with solenoid rotated clockwise 55° (85° on Convertible & Station Wagon) from mounted position to align plunger flats with pawl slot, then rotate solenoid counter-clockwise until mounting screw holes aligned. This will engage plunger in pawl.

Free-wheel Assembly: If free-wheel roller retainer and springs removed from cam, first note position of springs and replace in exact same positions. Springs must place tension on cam so that it is normally rotated counter-clockwise in retainer (viewed from rear) with rollers on "high" ends of cam ramps (outward or engaged position).



Overdrive Pinion & Free-wheel Assemblies: With these parts installed and retaining clips in place, insert free-wheel rollers in retainer and use rubber band to hold them while mainshaft installed.

Overdrive Mainshaft: Bearing should be installed on shaft with snap ring groove toward front (Ford & Mercury), toward rear (Lincoln), speedometer and governor drive gear must be keyed on shaft and placed with long shoulder on gear toward bearing (Ford & Mercury only—gear installed separately on Lincoln). Snap ring behind gear (directly behind bearing on Lincoln) must be tight fit and prevent all endplay in shaft. This snap ring furnished in four thicknesses for selective fit. When installing shaft over free-wheel cam & roller assembly, rotate shaft counter-clockwise to move rollers to low or disengaged position.

Overdrive Case & Control Mechanism: Install bearing outer snap ring in groove in case with lugs on ring toward slot in housing and expand ring with pliers inserted through slot while case is being pushed on over mainshaft. Insert control shaft in case before case installed on shaft but do not install shaft lock-pin until after assembly completed and cam on shaft engaged in slot in shift rail. Install new oil seal on control shaft and position control lever upward (Ford & Lincoln), downward (Mercury).

OVERDRIVE CONTROL: *See Warner Type R10 Overdrive Controls for complete data.*

TRANSMISSION DISASSEMBLY & REASSEMBLY: *See Ford-Lincoln-Mercury Transmission article.*

1949-55 FORD & MERCURY WARNER OVERDRIVE (LINCOLN SIMILAR)

1948-55 FORD TRUCK 3-SPEED (LIGHT DUTY)

1948-52—F-1, ½ Ton Truck (Std.)

1953-55 F-100 (Std.)

F-1 Optional Equipment—4-Speed Spur Gear Trans., and 3-Speed Heavy Duty Trans.

F-100 Optional Equipment—4-Speed Synchro-Silent Trans., 3-Speed Heavy Duty Trans., Overdrive (with 3-Speed H.D. Trans.), & Fordomatic Drive Trans.

►*1948-53 TRANSMISSION SHIFTER FORK CAM INTERLOCK CHANGE (To prevent possibility of shifting into two gears at once):* Interlock Pin, Part No. 01A-7235 can be installed inside Interlock Plunger Spring between shifter cams.

►*1955 TRUCKS (WITH 239" ENGINE) HARD SHIFTING CORRECTION:* If hard shifting occurs with the truck standing and the clutch completely disengaged, the pilot bearing bore in the crankshaft may not be deep enough. To correct this condition, grind approximately ⅛" off the pilot bearing end of transmission input shaft to provide clearance between end of shaft and counterbore in crankshaft.

DESCRIPTION: Constant-mesh, synchro-mesh, all helical gear.

REMOVAL OF TRANSMISSION: *See "Transmission" on truck model page.*

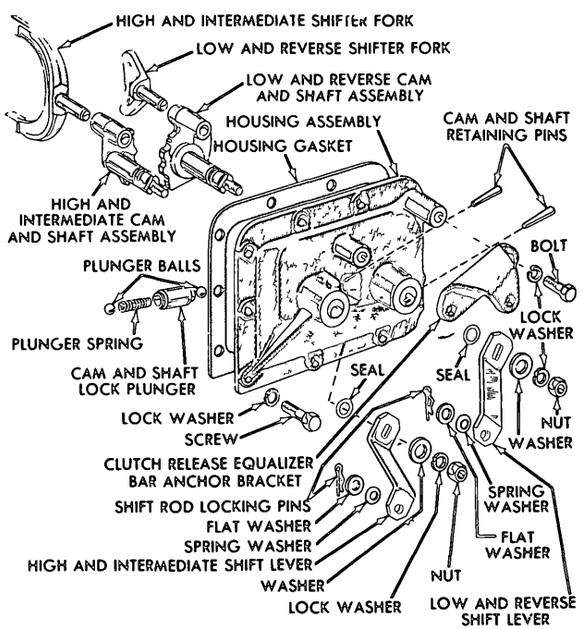
DISASSEMBLY: Remove gearshift housing and gasket. Remove screws which secure front bearing retainer to transmission case, tap retainer lightly, then slide retainer and gasket off main drive gear shaft. Remove lockpin securing countershaft and reverse idler gear shaft in case. Remove capscrews and lockwashers which attach extension to transmission case. Turn extension ¼ turn counter-clockwise to expose end of countershaft. Drive countershaft to rear until clear of front of case. Push countershaft out through rear of case with dummy shaft cut to length of countershaft cluster gear. Leave cluster gear and dummy shaft in case. Pull extension and mainshaft assembly out through rear of transmission case. Remove snap ring from main drive gear bearing. Tap gently on end of shaft with lead hammer until bearings free. Place one hand over gear end of main drive gear to prevent loss of or damage to main shaft pilot bearings, then lift main drive gear out of transmission case. Lift cluster gear assembly out of case, remove thrust washer and thrust plates located at each end of cluster gear. Remove two roller bearing (or needle bearing) assemblies and spacer from inside cluster gear. Drive reverse idler shaft toward front of case until free, then lift idler gear and shaft out of case.

Main Shaft: Remove snap ring that holds main shaft assembly in extension. Tap main shaft out of extension, using soft hammer. Remove transmission main shaft synchronizer snap ring, then pull or press synchronizer assembly and second speed gear off main shaft. Slide low and reverse gear off mainshaft. Remove snap ring that secures speedometer driving gear on main shaft, then remove gear. Press

C NTINUED N NEXT PAGE

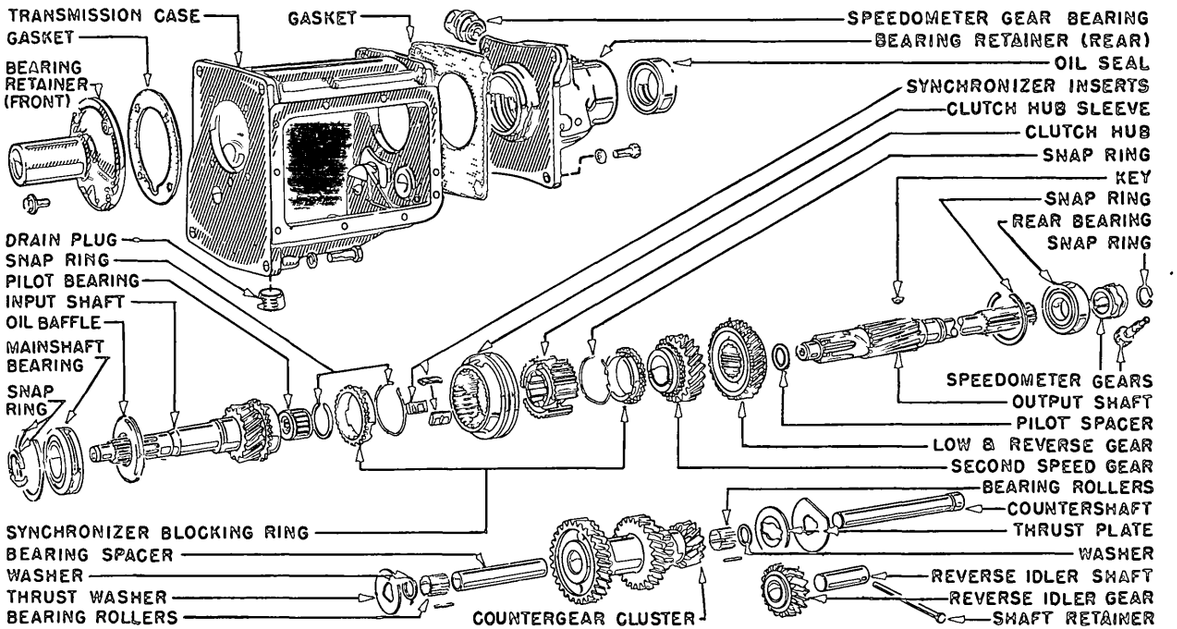
1948-55 FORD TRUCK 3-SPEED (LIGHT DUTY) (Cont.)

main shaft rear bearing off main shaft. Remove oil seal from transmission extension.



Synchronizer: Slide synchronizer hub assembly out of sleeve. Remove snap rings located on each side of hub, then remove inserts. NOTE—Blocker rings are removed separately from assembly. One ring is removed with second speed gear, and other is removed with main drive gear.

Main Drive Shaft: Remove synchronizer ring, then remove roller bearing assembly or needle bearings from inside drive gear. Remove snap ring from end of shaft. Using an arbor press or puller, remove bearing from shaft and take off oil baffle.



Gearshift Housing: Remove shift lever retaining pins and levers from camshaft. Pull shifter fork and cams out of gearshift housing. With cams removed the interlock balls, retainer, and spring will fall out of gearshift housing. Pull shifter forks out of shifter cam and shaft assemblies. Remove oil seals from shifter cam and shaft assemblies.

REASSEMBLY (Of Component Assemblies): All parts should be cleaned and inspected before assembly.

Main Shaft: Slide second speed gear onto front end of shaft. Coat synchronizer ring with grease, then install ring on shaft. Install synchronizer assembly on shaft, making sure the cutouts on synchronizer ring mate with inserts in hub, then install snap ring. Check endplay between second speed gear and shaft

3-SPEED (LIGHT DUTY) SHIFT ASSEMBLY

1948-55 FORD TRUCK 3-SPEED (LIGHT DUTY) TRANSMISSION

spline shoulder with a feeler gauge. Endplay should not exceed .020". Install first and reverse sliding gear on rear end of shaft. Press main shaft rear bearing on shaft. Install speedometer drive gear and snap ring. Press new oil seal in transmission extension on shaft until bearing is seated in bore of extension, then install bearing snap ring.

Synchronizer: Install inserts in hub, then position two snap rings on each side of hub. Slide hub assembly into sleeve.

Main Drive Gear: Install oil baffle, bearing and bearing snap ring (small) on shaft. Coat cavity in rear end of shaft with grease, then install roller bearing assembly (or needle bearings).

Cluster Gear: Install spacer and front and rear roller bearing assemblies (or needle bearings) in cluster gear. Place thick coating of grease on thrust washer and thrust plates, then position two rear thrust plates on rear end of cluster gear.

Gearshift Housing: Install new oil seals on shifter cam and shaft assemblies. Place one shifter cam and shaft assembly in position in gearshift housing. Assemble interlock spring and balls in retainer, then install interlock assembly in gearshift housing. Place other cam and shaft assembly in position in gearshift housing. Install gearshift levers on camshafts, then install retaining pins. Assemble shifter forks in cam and shaft assemblies.

TRANSMISSION ASSEMBLY: Lubricate all parts with transmission lubricant. Position reverse idler gear in case, then install idler shaft. Drive idler shaft into case until retainer pin hole in shaft is aligned with hole in case. Install countershaft gear front thrust washer with tip on washer hooked into groove on inside of case. Position cluster gear assembly in case with larger gear toward front. Make sure thrust washer and plates remain in position. Coat synchronizer blocker ring. Place ring on front end of main drive gear, install main drive gear assembly in case. Install snap ring in groove on main drive gear bearing, making sure that snap ring is flush with side of case. Position new gasket on transmission case, then install main drive gear bearing retainer on case. Tighten capscrews securely. Position new gasket on extension, then position main shaft and extension assembly in transmission case. Raise cluster gear assembly until bore of gear is aligned with countershaft holes in transmission case. Make sure that thrust washer and plates are also in alignment. Insert end of countershaft in hole in rear end of case. Push shaft forward until retainer pin hole in shaft is aligned with retainer pin hole in case. Install retainer pin. Install capscrews and lockwashers which attach extension to case, then tighten screws securely. Position new gasket on case, then place shift forks in neutral position. Place housing assembly on case making sure shift forks are located in proper channels on sliding gear and synchronizer sleeve.

▷*CAUTION—Position low and reverse fork with smooth side of fork toward gear, or transmission will not shift into first speed.*

Install capscrews and lockwashers that secure gearshift housing to case. Install drain plug. Turn main drive gear by hand to make sure the gears do not bind and that shift forks are in proper position.

1948-55 FORD TRUCK 3-SPEED (HEAVY DUTY)

Standard Equipment

1948-52—F-3 & F-5 Parcel Delivery①

1953-55—P-350 & P-500 Series Parcel Delivery①

Optional Equipment

1948-52—F-1 through F-5 Series Trucks②
1953—F-100 & F-500 Series Trucks①
1953—B-500 School Bus①

1954-55—F-100 Series Trucks①

①—Remote Shift Control.
②—Center Shift Control.

►***1953-55 HARD SHIFTING DURING COLD WEATHER CORRECTION (MODELS WITH 3-SPEED HEAVY DUTY TRANS.):*** Longer shift levers and stronger shift rods have been released for service replacement as follows: Lever (B5C-7285-B); Lever (B5C-7290-B); Lever (B5C-7303-A); Rod (B5C-7236-A); Rod (B5C-7328-A).

►***1955 TRUCKS (WITH 239" ENGINE) HARD SHIFTING CORRECTION:*** If hard shifting occurs with the truck standing and the clutch completely disengaged, the pilot bearing bore in the crankshaft may not be deep enough. To correct this condition, grind approximately ⅛" off the pilot bearing end of transmission input shaft to provide clearance between end of shaft and counterbore in crankshaft.

DESCRIPTION: Constant-mesh, synchro-mesh, helical gear (2nd & high), spur gear (low & reverse).

REMOVAL OF TRANSMISSION: *See "Transmission" on truck model page.*

DISASSEMBLY: Remove gearshift housing and gasket. Remove screws that secure front bearing retainer to transmission case, tap retainer lightly, then slide retainer and gasket off main drive gear shaft. Remove parking brake assembly, then remove screws, countershaft locking plate and gasket located at lower rear end of case. Remove mainshaft rear bearing retainer, slide speedometer driving gear and spacer off shaft, then remove snap ring from bearing. Using a puller, remove bearing from main shaft, and take off the oil baffle. Drive the countershaft out through rear of case with a punch or dummy countershaft. Pull main drive gear as far forward as possible and lift main shaft assembly out of case. Remove snap ring from main drive gear bearing. Tap gently on end of shaft with a lead hammer until bearing is free. Place one hand over gear end of shaft to prevent loss or damage of roller bearings, and lift main drive gear out of case. Lift cluster gear assembly out of case, and remove thrust washer and thrust plate at each end of cluster gear. Remove the two roller bearing assemblies and spacer from inside cluster gear. Drive reverse idler shaft toward front of case until shaft is free, and remove from case.

Main Shaft: Slide first and reverse sliding gear off main shaft. Remove snap ring from synchronizer end of shaft and slide synchronizer off shaft together with second speed gear.

Synchronizer: Slide synchronizer hub assembly out of sleeve. Remove snap rings located on each side of hub, then remove the inserts. NOTE—Blocker rings are removed separately from assembly. One ring is removed with second speed gear, and other is removed with main drive gear.

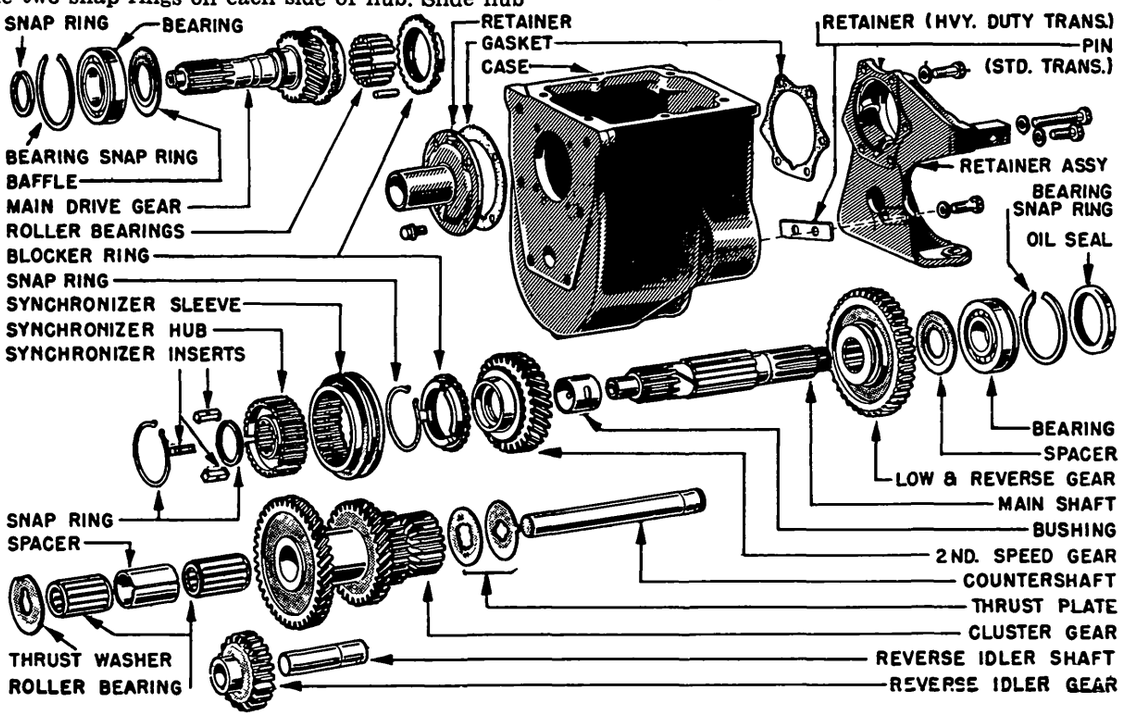
Main Drive Shaft: Remove synchronizer ring, then remove roller bearings from inside drive gear. Remove snap ring from end of shaft. Using an arbor press or puller, remove bearing from shaft and take off the oil baffle.

Floorboard Shift: Remove lock wires and screws attaching shifter forks to shifter shafts. Insert a drift in lockscrew hole of one of the shafts and gently tap shaft and expansion plugs out of housing. Repeat with other shaft ***(CAUTION—While removing shaft, place one hand over plunger spring and ball hole to prevent these parts from flying out. Tag or mark each shaft and fork and side of housing as its position to assure correct reassembly).*** Remove expansion plug at opposite end of housing from which shafts removed, remove plunger plug and plunger.

REASSEMBLY (Of Component Assemblies): All parts should be cleaned and inspected before assembly.

Main Shaft: Slide second speed gear on to front end of shaft. Coat synchronizer ring with grease, then install ring on shaft. Install synchronizer assembly on shaft, making sure the cutouts on synchronizer ring mate with inserts in hub, then install snap ring. Check endplay between second speed gear and shaft spline shoulder with a feeler gauge. Endplay should not exceed .020". Install first and reverse gear on rear end of shaft.

Synchronizer: Install inserts in hub, then position the two snap rings on each side of hub. Slide hub assembly into the sleeve.



Main Drive Shaft (Gear): Install the oil baffle, bearing and bearing snap ring (small) on end of shaft. Coat roller bearing cavity in rear end of shaft with grease and install bearing rollers.

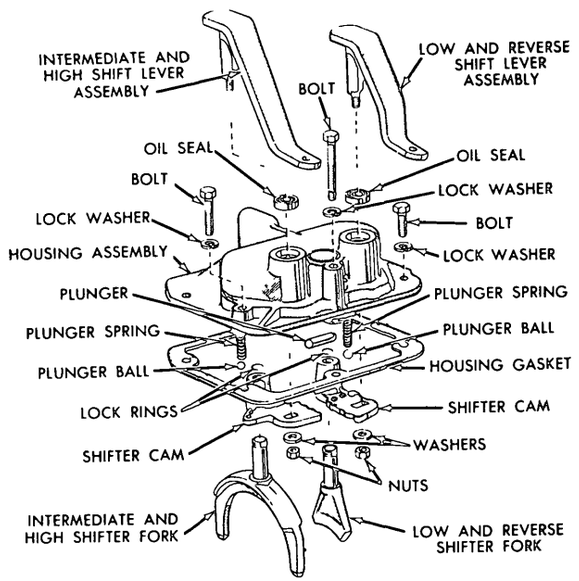
Cluster Gear: Install spacer and the front and rear roller bearings in cluster gear. Place a thick coat of grease on thrust washer and thrust plates, then position two thrust plates on rear end of cluster.

Floorboard Shift: Slide plunger in position in housing and install plunger plug. Drop a spring and ball into one of the holes in housing, then position the proper fork in place. Hold the ball down with a drift punch and slide the correct shaft into housing and shift fork. Install the capscrew to secure shaft on fork and secure with a lockwire. Install other shaft and fork in same manner. Install expansion plug at each end of each shaft.

Steering Column Shift (Parcel Delivery): Slide plunger into position in housing and install plunger plug. Install shifter shaft spring, shifter shaft inner lever and shifter shaft into housing. Press spring away from inner lever and insert key in inner lever, then force lever over key. Install one snap ring at each side of inner lever. Drop a shifter shaft lock plunger spring and ball through one of the housing holes, then place proper shift shaft in position. Move the ball down with a drift and slide correct shifter shaft into housing and shift fork. Install a shifter fork lockscrew, and secure screw with lockwire. Install remaining shaft in same manner. Install expansion plugs at each end of

CONTINUED ON NEXT PA E

FORD TRUCK 3-SPEED (HEAVY DUTY) TRANSMISSION



1948-55 FORD TRUCK 3-SPEED (HEAVY DUTY) (Cont.)

each shaft. Place selector lever assembly on stud in housing, then install spacer, lock washer, and nut. Position shifter shaft outer lever on shifter shaft, then install flat washer, lock washer and nut.

Steering Column Shift (F-1, F-100 Truck): Place one shifting cam in position in gear shift housing. Assemble interlock spring and balls in retainer and install interlock assembly in housing. Install oil seals in housing, then install gearshift levers on camshafts, install retaining pin. Assemble shifter forks.

Transmission: Lubricate all parts with transmission lubricant. Position reverse idler gear in case and install idler shaft, driving it into case until edge of lockplate notch in shaft is flush with rear face of case. Install countershaft gear front thrust washer with tip on washer hooked to groove on side of case. Position cluster gear assembly in case with larger gear toward front. Make sure thrust washer and plates remain in position. Coat synchronizer blocker ring with grease, and place on rear end of main drive gear, and install main drive gear in case. Install snap ring in groove, making sure that ring is flush with case. Position gasket on case, and install main drive gear retainer. Tighten capscrews securely. Place main shaft assembly in case, and install oil baffle or spacer on main shaft. Install snap ring in groove on rear bearing, then drive bearing on shaft until bearing snap ring is flush with side of case. Make sure synchronizer rings are free in synchronizer assembly. Raise cluster gear assembly until bore of gear is aligned with holes in case. Make sure thrust washers are in alignment, then insert end of countershaft through hole in rear end of case, pushing shaft forward until edge of notch in shaft is flush with case and notch is aligned with notch in idler gear shaft. Install locking plate and gasket, and parking brake assembly. Position new gasket on case, then place shifter forks in neutral. Place gearshift housing assembly on case, making sure shift forks are in proper channels on sliding gear and synchronizer sleeve.

CAUTION—Position low and reverse fork with smooth side of fork toward gear, or transmission will not shift into first speed. Install capscrews and lockwashers, securing gearshift housing to case. Install drain plug. Rotate main drive gear by hand to make sure gears free and shift forks properly installed.

3-SPEED (HEAVY DUTY) SHIFT ASSEMBLY

1941-52 FORD TRUCK 4-SPEED (SPUR GEAR)

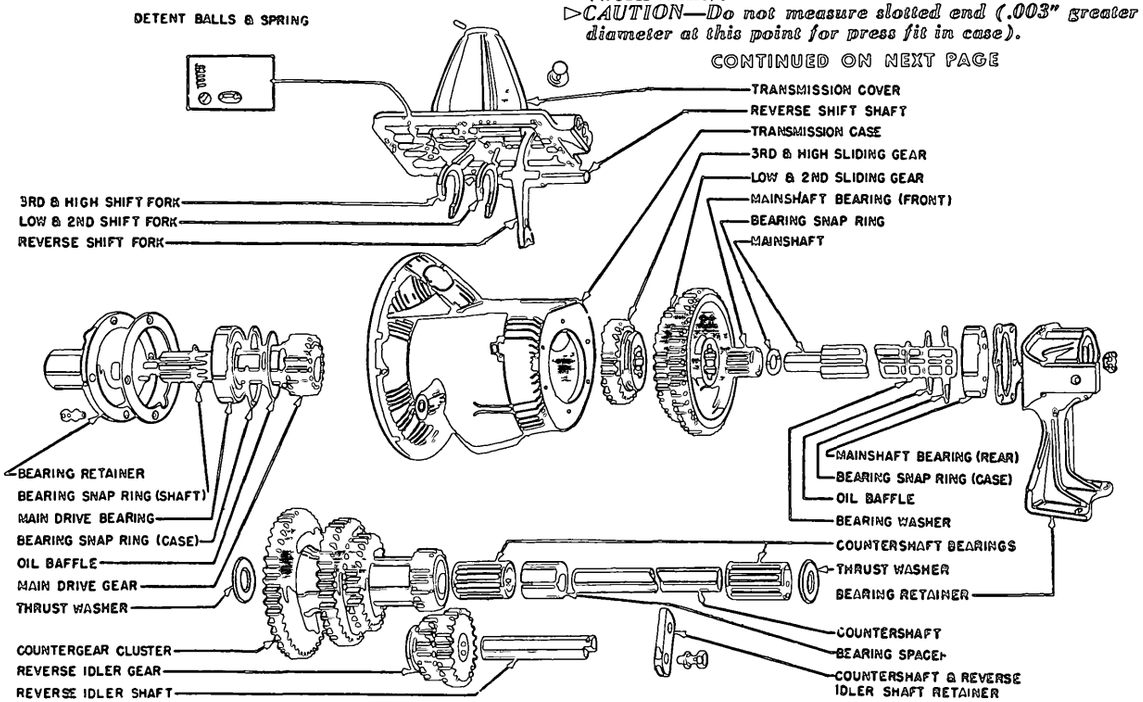
Standard Equipment
1941-51—All Trucks (Exc. ½ & ¾ Ton Models)
1952—F-4, F-5, F-6 (Exc. F-5 Parcel Del. & F-6 Truck with 6 Cyl. "M" Engine)

Optional Equipment
1941-51—½ & ¾ Ton Models
1952—F-1, F-2, F-3 (Exc. Parcel Del.)

DESCRIPTION: Four-speed, sliding spur gear type.

REMOVAL OF TRANSMISSION: *See "Transmission" on car model page.*

DISASSEMBLY: Remove gearshift housing (transmission cover) assembly and gasket. Remove the clutch release bearing spring, release bearing, and retainer. Take out screws in bearing retainer on front end of case, remove retainer, withdraw clutch shaft main dive gear and bearing assembly (tap main drive gear with a brass hammer if required). Remove mainshaft front (roller) bearing and spacer from mainshaft. Take off nut on rear end of main shaft and remove universal joint flange and brake drum. Take out screws in bearing retainer on rear end of case, remove retainer, withdraw speedometer gear and spacer from shaft. Remove speedometer driven gear bearing and gear from retainer. Withdraw mainshaft and bearing out through rear of case (use brass hammer and tap on front end of shaft until bearing free of case) and remove sliding gears out through top of case. Take out cotter pin from front end of reverse idler, shifter shaft on left side of transmission and drive shaft out through rear of case and lift out shifter fork. Take off reverse idler retainer (lock plate) on rear of case and pry out reverse idler shaft with screwdriver engaging slot in end of shaft, lift out reverse idler gear. Drive countershaft out through rear of case, lift out cluster gear. Remove bearings and spacer from cluster gear.



CLEARANCES & PARTS CHECK: Replace gears if worn excessively or teeth chipped or broken. Replace bearings discolored by overheating or if binding or looseness noted when rotating bearing on shaft by hand. Replace parts worn beyond the following limits:

Countergear Cluster: Endplay .009-.021" (new), .025" (worn limit). Measure between gear and case. Inside diameter 1.6255-1.6265" (new), 1.630" (worn).

Countershaft: Diameter .9995-1.0000" (new), .9945" (worn limit).

▷*CAUTION—Do not measure slotted end (.003" greater diameter at this point for press fit in case).*

CONTINUED ON NEXT PAGE

1941-52 FORD TRUCK 4-SPEED (SPUR GEAR) TRANSMISSION

1941-52 FORD TRUCK 4-SPEED (SPUR GEAR) (Cont.)

Reverse Idler Gear: Inside diameter .9890-.9900" (new), .991" (worn limit). If bushing worn, replace gear. Do not remove bushing from gear (gear furnished with bushing installed).

Reverse Idler Shaft: Diameter .9872-.9877" (new), .986" (worn limit).

Mainshaft Assembly: 3rd & High Gear—Fit to shaft correct if gear holds own weight on shaft splines.

First & Second Gear—Backlash limit .003".

Mainshaft—Pilot (front) end diameter .8110-.8115" (new), .806" (worn limit).

Main Drive Gear Assembly: Gear end inside diameter 1.312-1.313" (new), 1.316" (worn limit).

REASSEMBLY: Assemble in reverse order of disassembly (above) and note following points:

Mainshaft Assembly: Install first and second gear and third and fourth gear with shifter fork channels facing each other (first and second facing toward front, 3rd & 4th channel facing rear).

1951-55 FORD TRUCK 4-SPEED (SYNCHRO-MESH)

►**F-6 Note**—With 8 Cyl. "R" or 6 Cyl. "H" Engine.

►CHANGES & CORRECTIONS

►***1953 GEAR SHIFTER SHAFT LOCK PLUNGER SPRING PRODUCTION CHANGE: Spring Part No. 8D-7234 with pressure of 8-9 lbs. against plunger balls has been replaced by spring Part No. BB-7234 with pressure of 22-26 lbs. Change provides additional security against transmission jumping out of gear.***

►***1953 DIFFICULT SHIFTING TO REVERSE CORRECTION***—May be caused by distortion of reverse gear shifter arm causing upper end of arm to not engage notch in reverse gear shifter shaft. To correct this condition, drain transmission and remove gear shift housing. Insert reverse gear shoe, installed in lower end of reverse gear shifter arm, in slot in reverse idler gear. Hold shifter arm against pivot shoulder in case and check distance between upper end of shifter arm and left side of case. Distance should be 4.42" to 4.45". If not correct, insert ¼" brass rod (not steel) shifter arm and gear teeth (to steady arm), and bend arm with crescent wrench until correct dimension obtained. When replacing shifter arm, make sure it enters slot in shifter shaft.

DESCRIPTION: Four-speed constant-mesh, synchro-mesh, helical gears (Second, Third & Fourth). Sliding spur gears (First & Reverse). Synchronizer assemblies are friction ring-and-sleeve type.

TRANSMISSION REMOVAL: *See "Transmission" on truck model page.*

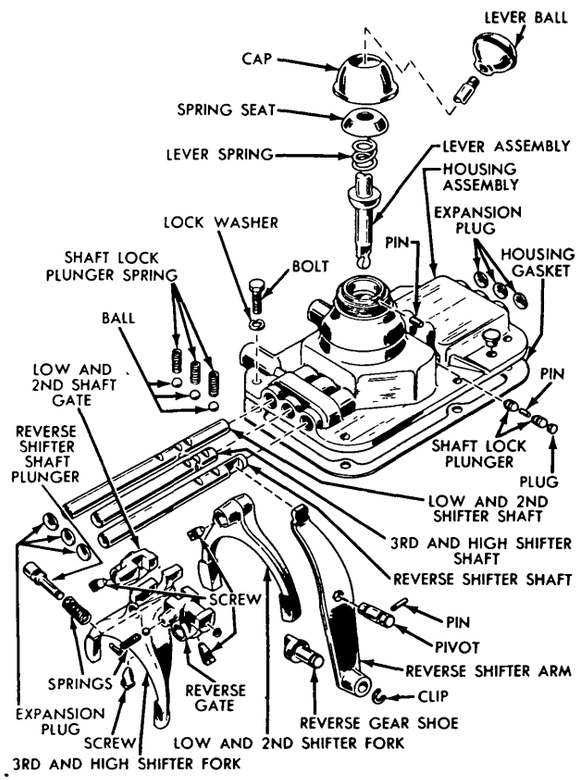
TRANSMISSION DISASSEMBLY: Remove parking brake assembly. Remove speedometer driven gear retaining nut and the driven gear. Remove rear bearing retainer and gasket (noting location of longest retainer-to-case bolt). Remove reverse idler shaft and countershaft retainer plate from rear of case. Slide speedometer drive gear and spacer off main shaft. Remove gear shift housing assembly and gasket. Unhook clutch release bearing return spring and remove release bearing and hub assembly. Remove capscrews from front bearing retainer and the nuts from clutch housing-to-case attaching bolts then remove clutch housing and retainer from case. Remove snap ring from main drive gear bearing and from main drive gear and then remove the bearing using Tool 7025-C (Puller). Remove oil baffle and the snap ring from rear main shaft bearing and pull the bearing with Tool 7025-C. Drive countershaft from case, working from the front, using dummy shaft, Tool 7111-A. *(CAUTION*—Keep dummy shaft in contact with countershaft to avoid dropping needle bearings). Allow cluster to remain in bottom of case. Remove main drive gear through the front end of case, then remove synchronizer blocker ring and needle bearings from gear. Pull reverse idler shaft out of case, using Tool 7140. Slide reverse shifter fork off shaft and remove from case. Tilt main shaft assembly and remove through top of case. Take out reverse idler gear. Position case with power take-off side next to bench. Roll cluster gear assembly toward top of case until cluster gear small end can be pushed through main shaft bearing bore in case. Using extreme care not to disturb needle bearings, remove gear assembly out of case.

DISASSEMBLY OF COMPONENT PARTS:

Main Shaft: Remove third and high synchronizer snap ring from main shaft, then slide third and high speed synchronizer assembly and third speed gear off shaft. Remove second speed synchronizer snap ring and slide second speed synchronizer hub gear off synchronizer, using care not to lose balls, springs and plates. Pull synchronizer hub off shaft. Remove snap ring at rear of second speed gear and remove gear, spacer, rollers, and thrust washers.

Cluster Gear: Remove dummy shaft, 88 bearing rollers, bearing spacer washers and bearing spacer.

Reverse Idler Gear: Install reverse idler gear on shaft, check gear for smooth, free rotation on shaft. If any roughness noted, disassemble gear as follows: Remove snap ring from one end of gear, then remove idler gear bearing rollers, thrust washers, bearing spacer, and idler gear bushing from gear. Remove remaining snap ring from gear.



Gearshift Housing: Remove gearshift lever cap, then lift lever out of cover. Remove lock wires and lock screws, shifter forks and shifter shaft gates. Remove expansion plugs from front end of housing and tap shifter shafts out of housing while holding one hand over holes in housing to prevent loosing springs and steel balls. Remove two lock plungers.

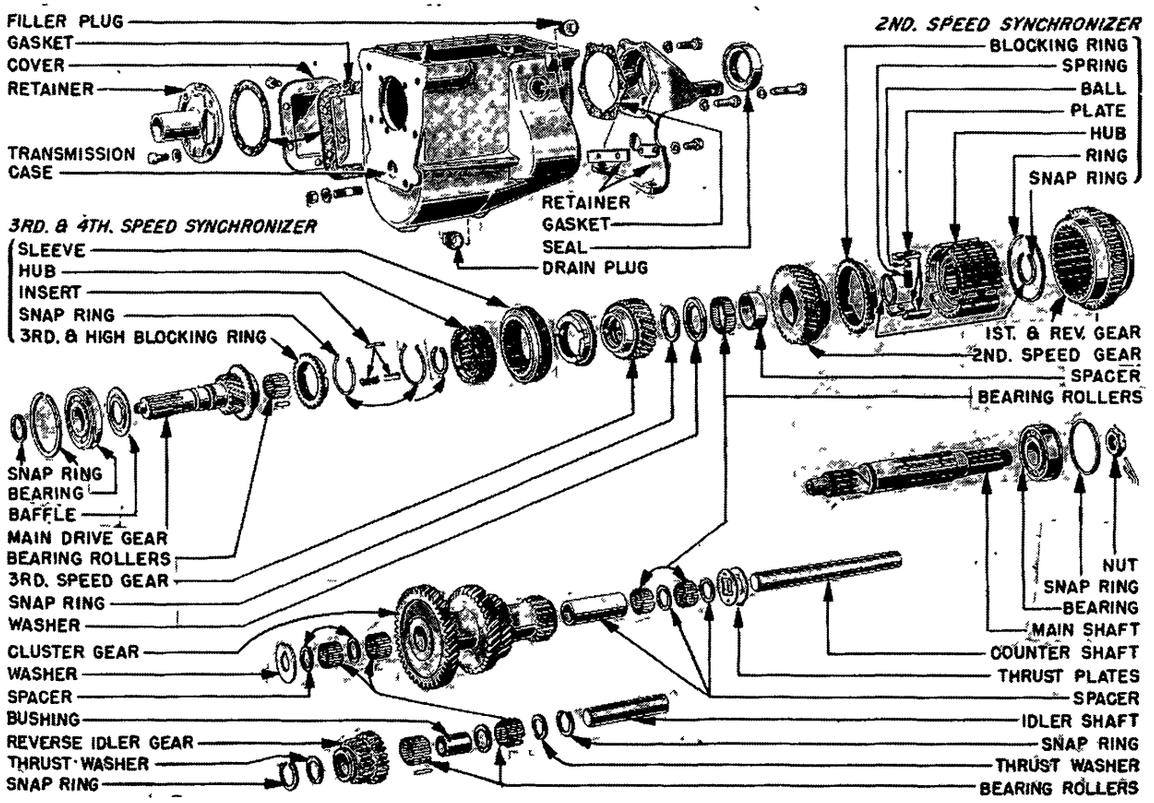
REASSEMBLY OF COMPONENT PARTS:

Cluster Gear: Slide the long spacer into cluster gear and then insert dummy shaft into spacer. Hold cluster gear in a vertical position and install 22 bearing rollers. Install spacer washer on top of rollers and then install 22 bearing rollers and a spacer washer on top of rollers. Hold a large thrust washer against end of cluster gear to keep rollers from falling out, and invert the gear assembly. Install bearing rollers in opposite end (above).

Main Shaft: Install second speed gear thrust washer on main shaft. Hold shaft in vertical position and slide second speed gear on main shaft. Insert second speed gear bearing rollers in gear, then slide spacer into gear hub. Install spacer snap ring in groove of main shaft. *(CAUTION*—Do not invert shaft. Rollers will slide out of shaft). Press second speed synchronizer hub on shaft and install snap ring. Place main shaft in vertical position in a vice. Position synchronizer springs and plates in hub and place second speed synchronizer ring on hub. Hold ring above hub spring and ball holes and position one ball at a time in hub. Push down to depress ball into hole and slide ring down to retain ball in hub, then repeat the foregoing procedure and install remaining two balls. Remove main shaft from vice and install the third speed gear, and sychronizer

CONTINUED ON NEXT PAGE

4-SPEED SHIFT ASSEMBLY



1951-55 FORD TRUCK 4-SPEED (SYNCHRO-MESH) (C nt.)

blocking ring on shaft. Install a snap ring at each end of hub with spring openings staggered. Place synchronizer inserts on sleeve and slide the assembly onto main shaft, making sure slots in blocker ring in line with inserts. Install front snap ring.

Reverse Idler Gear: Install snap ring in one end of reverse idler gear. Set gear on end with snap ring on bottom. Position a bearing roller thrust washer in gear on top of snap ring, then install idler gear bushing. Insert a row (37) of bearing rollers between bushing and bore of gear. Install bearing spacer, then install second row (37) bearing rollers. Position remaining thrust washer on rollers, install snap ring.

Gearshift Housing: Place spring on reverse gate plunger and install plunger and spring in reverse gate. Press plunger through the gate and secure it with the clip. Place reverse gate plunger ball and spring in poppet hole. Compress the spring and install cotter pin. Place shifter shaft lock plunger spring and steel ball into reverse shifter shaft hole in housing. Press down on ball with a long, narrow drift, then position reverse shifter shaft so reverse arm notch does not slide over the ball, and insert shaft part way into housing. Slide reverse shaft gate onto shaft, and drive shaft into housing until ball snaps into groove of shaft. Install lock screw and lock wire to secure gate to shaft. Insert the two interlock plungers into pockets between shifter shaft holes. Place the spring and a steel ball into the first and second shifter shaft hole. Press down on steel ball, then insert shifter shaft part way into housing. Slide first and second gear shifter fork onto shaft so the offset of fork is toward rear of housing. Push shaft all the way into housing until ball snaps into place in groove. Install lock screw and wire to secure fork. Install third and high shifter shaft in same manner, then install expansion plugs in shaft bores.

TRANSMISSION REASSEMBLY: Lubricate all parts with transmission lubricant. Enter countershaft into hole in rear of case and tap shaft until forward end is flush with inside of case. Slot in end of shaft must be at rear and faced toward idler gear shaft. Position case with power take-off plate downward. Hold the two thrust washers at each end of cluster gear and install gear in bottom of case, then install the third thrust washer between case and rear washer. Position idler gear shaft into case with slot at rear and faced toward countershaft and while holding reverse idler gear in position, tap shaft until slot is aligned with rear face of case. Align cluster gear with holes in case and push the dummy shaft out through front of case with countershaft. (*CAUTION*—Be sure to keep cluster gear in contact with dummy shaft to prevent bearing from dropping into gear). Align slot in countershaft with rear edge of case. Install main shaft pilot bearing rollers in main drive gear, and position gear in front bearing bore, working from inside the case. Position the stop yoke Tool No. 2025-D to prevent jamming synchronizer rings. Install oil baffle and main shaft bearing on shaft and drive bearing into position with Tool 7065-A, install snap ring. Using same tool, drive rear bearing on shaft and into rear bearing bore, then install rear bearing snap ring. Install main drive gear snap ring on shaft. Install front bearing retainer and clutch housing on front of transmission. Install gear shift housing and gasket. Install idler and countershaft retainer plate, securing with two capscrews. Install rear bearing retainer and new gasket making sure the longest screw is installed in correct hole. Install speedometer drive gear and spacer on end of main shaft and install driven gear and retaining nut. Install flange and parking brake drum and tighten nut, locking in place with cotter pin.

1951-55 FORD TRUCK 4-SPEED SYNCHRO-MESH TRANSMISSION

1941-47 HUDSON

Hudson 6 & 8, All Models (1941 to 1947)

DESCRIPTION: New constant-mesh, synchro-mesh (Second & High), sliding gear (Low & Reverse), all-helical gear type. Main drive gear is integral with clutch shaft and is mounted on ball bearing in front of case.

Transmission Controls—Steering column mounted gearshift is standard on all models. *Refer to separate Hudson Transmission Control article for adjustment and servicing data.*

Drive-master Transmission—Optional on all models. Consists of a special automatic gearshift mechanism mounted on the transmission case. Refer to separate Drive-Master article (preceding) for all data on this equipment.

REMOVAL OF TRANSMISSION: *See "Transmission" on car model page.*

OVERDRIVE DISASSEMBLY: On car models with overdrive, overdrive unit can be disassembled and serviced without disturbing transmission providing that adapter plate is not disturbed (must not be allowed to separate from transmission case). *See "Warner Type R9 Overdrive."*

DISASSEMBLY OF TRANSMISSION: On Vacumotive Drive cars unscrew the Governor from housing. Remove transmission cover screws, lift cover off carefully to prevent detent ball spring flying out, tilt transmission case to one side and remove spring and detent ball. Remove front universal joint companion flange nut, lockwasher, plain washer. Use puller J-820 to remove companion flange. Take out screws in speedometer gear housing (rear bearing retainer), remove housing and speedometer gear using care not to damage oil seal in housing. Remove low & reverse shift fork lockscrew and shifter lockscrew, slide low & reverse shift rail out through front of case, remove shift fork and reverse shifter from case. Tilt case and remove interlock plunger from hole in side of case. Remove second & high shift fork lockscrew and lock bolt and washer on left side (1942 on), slide shift rail out, lift fork out of case, tilt case and remove detent ball and spring. Slide mainshaft and

CONTINUED ON NEXT PAGE

1941-47 HUDSON (Cont.)

gear assembly back so that rear bearing is free of case, tilt front end of shaft up, remove snap ring in shaft directly in front of synchronizer inner clutch sleeve (use special pliers J-1575). Slide synchronizer unit, second speed gear, low speed gear, off shaft and remove through top of case, then withdraw mainshaft and bearing through rear of case. Remove countershaft lockplate screw on rear of case, drive out plate with a drift, drive countershaft out through rear of case using Driver J-1574, remove countergear cluster and thrust washers. Pull main drive gear out through front of case (use driver J-1574 if necessary—gear will be free with clutch housing and bearing retainer removed). Use driver J-1574 inserted through main drive gear bearing hole to drive out reverse idler gear shaft.

REASSEMBLY OF TRANSMISSION: Reverse disassembly directions given above and note following special instructions: Install sliding low speed gear on mainshaft with shift fork flange toward front and make certain that four oil holes in flange groove line up with grooves in shaft. Install second speed gear with tapered side of hub toward front, install synchronizer unit with tapered side of shift sleeve toward front, select lock ring of correct thickness (furnished .087", .090", .093", .097" thick) so that synchronizer has no appreciable endplay when lock ring installed. See that detent balls and springs correctly installed (low & reverse spring at top is heavier than second & high spring at bottom and springs must not be interchanged). Install second and high shift rail stop screw making certain that lockwasher in place under screw head (stopscrew used on 1942 and later cars only).

CAUTION—If lockwasher not used on stopscrew, screw will bottom on shift rail preventing gear engagement.

Mainshaft & Rear Bearing Assembly:—Use special puller J-1134H to remove bearing from shaft. To install bearing, see that locking ring on bearing is toward rear of shaft, use replacer tool J-1570 to drive bearing in place.

Main Drive Gear & Bearing Assembly:—To remove bearing, remove lock ring in groove in shaft with J1575 pliers, use puller J-1134-H to remove bearing from shaft (bearing will be damaged if driven off). When installing bearing, see that shielded side is toward gear (to rear when installed), use replacer tool J-1570 to drive bearing in place. Use lock ring of correct thickness (furnished in thicknesses of .090", .093", .096") so that lock ring is snug fit in groove and there is no appreciable endplay. Use grease to retain mainshaft bearing rollers in drive gear hub until mainshaft installed. If oil seal in bearing retainer being replaced, use remover J-1576 to tap old seal out, press new seal in place with J-1569 seal replacer tool. Use new gasket when installing retainer on case. NOTE—Retainer locating pin engages hole in clutch housing so that retainer can only be installed with throw-out bearing oil holes lined up properly.

Synchronizer Unit:—If synchronizer unit being dismantled, mark inner and outer clutch sleeves and rings to insure reassembly in same positions. Install struts with open face toward inner clutch sleeve, install springs with hooked end of each spring in same strut with free ends running in opposite directions. See that undercut on inner sleeve points toward rear of transmission and install synchronizer on mainshaft with tapered side of outer sleeve toward front.

IMPORTANT NOTE—Two types of synchronizer rings and sleeves used in production and must not be interchanged. Rings with 110° chamfer on face of teeth are marked '110' on flange face and must be used with 110° clutch sleeves which are marked by groove on outside face. 90° chamfer rings and sleeves not marked. CAUTION—90° parts must not be used with 110° parts.

Countergear Assembly: Countergear bushings can be renewed by using J-1573 puller to remove old bushings, J-1572 replacer to install new bushings, and then reaming bushing with KMO-338 bushing reamer (pilot reamer on guide installed in other end of gear cluster while reaming each bushing). When installing countergears in transmission, coat bronze thrust washers with chassis lubricant, install washers in case so that they engage retaining pins in case, install steel thrust washer between gear cluster and rear thrust washer. See that both countershaft and reverse idler shaft are locked in place by lockplate and that lockplate screw tightened securely.

Shifter Shafts & Levers:—Selector shaft can be removed from within case after taking off nut, washers, and lever on outer end of shaft. Bushing is withdrawn from outside after bushing setscrew has been loosened. When removing shift shaft, first punchmark inner lever and shaft to insure correct reassembly (if position lost, use indexing tool J-1571 to re-install inner lever). Remove nut on outer end of shaft, remove lever. Drive out pin in shaft boss on side of case, remove inner lever, withdraw shaft and felt seal. Install levers in same manner.

REASSEMBLY: Reverse the disassembly procedure in installing all units in transmission case.

HUDSON SUPER-MATIC DRIVE

Pacemaker, Model 500 (1950), 4A (1951) Optl.
Super Six, Model 501 (1950), 5A (1951) Optl.

DESCRIPTION: Super-Matic Drive consists of a three-speed transmission and overdrive unit with automatic shift mechanism and automatic clutch control. With this installation, whenever Super-Matic "On" button is pushed in, and Automatic 4th-Speed Button pushed in, operation is entirely automatic and controlled by the accelerator pedal (shifts up-and-down through 2nd-3rd-4th automatically and dependent on accelerator pedal position and car speed). An ultra-low gear is also provided and is engaged manually when required.

Upshift Speeds

2nd-to-3rd①	Above 14 MPH.
3rd-to-4th①	Above 22 MPH.

Downshift Speeds

4th-to-3rd (Normal)	18 MPH.
4th-to-3rd (Kick-down)	②
3rd-to-2nd	12 MPH.

①—Engaged by releasing accelerator pedal momentarily.

②—At any speed above 18 MPH. by fully depressing accelerator pedal.

DISASSEMBLY & OVERHAUL: Super-Matic Drive units can be serviced separately as follows:

Clutch Control: *See "Hudson Vacumotive Drive" in Clutch Section for data.*

Automatic Shift Control: *See "Hudson Drive-Master" for data.*

Transmission: *See "1948-Early 1952 Hudson Transmission" for data.*

Overdrive: *See "Warner Type R10" Overdrive for data.*

1948-EARLY 1952 HUDSON

Hudson 6 & 8, All Models (1948-Early 1952)—See Notes.

►*LATE 1952 TRANSMISSION PRODUCTION CHANGE: Warner Transmission used beginning in Late 1952. See "Warner" Transmissions for complete data.*

►**OVERDRIVE TRANSMISSION NOTE:** Optl. on all models. Consists of Warner Type R10D Overdrive used with Hudson transmission for which data is given below. *See Warner Type R10 Overdrive article*

►**HYDRA-MATIC DRIVE TRANSMISSION NOTE:** Optl. on 1950-52 models (except Pacemaker). *See "Hydra-Matic Transmission" for data.*

►CHANGES, CAUTIONS, CORRECTIONS

►**SLIPPING OUT OF GEAR CORRECTION (Second & High Shift Rail Production Change):** New type Shift Rail, Hudson No. 303832, and Lock Ball Spring, Hudson No. 303847, should be installed when overhauling transmission to correct slipping out of gear *NOTE*—These parts used in production beginning with Serial No. 500-26338.

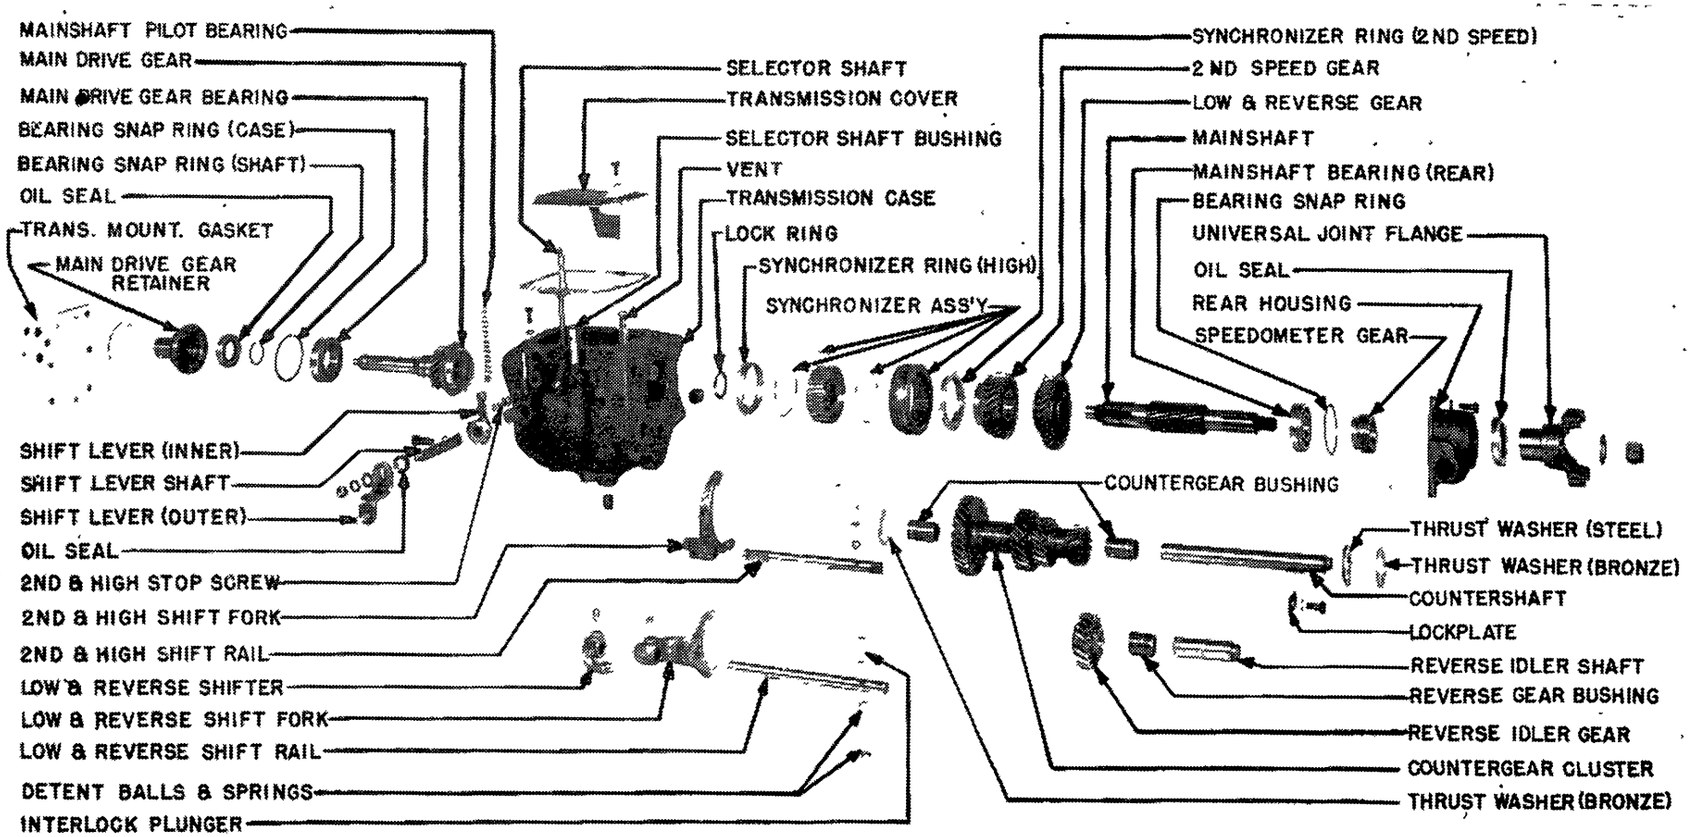
►**INSTALLATION OF 1951 TYPE OVERDRIVE TRANSMISSION COVER ON 1948-50 CARS (to correct insufficient lubrication of Overdrive):** If insufficient lubrication noted in overdrive case, 1951 type Transmission Case Cover, Hudson No. 305424, should be used to replace original cover. This 1951 type has oil trough located so as to catch maximum oil spray from transmission gears and conducts lubricant to overdrive case opening.

DESCRIPTION: Three-speed, all helical gear type. Constant-mesh, synchro-mesh (Second & High), sliding gear (Low & Reverse). Transmission is similar to design used on previous Hudson models.

OVERDRIVE SERVICING NOTE: On transmissions with Overdrive, overdrive unit can be disassembled and serviced separately without disturbing transmission.
See "Warner R10 Overdrive."

REMOVAL OF TRANSMISSION: *See "Transmission" on car model page.*

CONTINUED ON NEXT PAGE



1948-EARLY 1952 HUDSON (Continued)

TRANSMISSION DISASSEMBLY: On cars with Governor (for Vacumotive Drive, Drive-Master, or Overdrive Control), remove governor from rear bearing retainer. Remove nut on end of driveshaft, pull universal joint flange. Take out capscrews in transmission cover, lift cover off carefully to prevent loss of shift rail spring (tip cover up on left side, remove spring and lock ball, lift cover off). Take out retaining capscrews and remove rear bearing retainer, slide speedometer drive gear off shaft. Remove 2nd & High shift rail stopscrew on left side of case. Remove lockscrew from Low Speed Shifter Fork and from Low Speed Shifter (use straight blade screwdriver which bottoms in screw slot—do not use taper blade screwdriver), slide shift rail out at front of case, lift out shift fork and shifter. Remove interlock plunger. Remove setscrew from 2nd & High Shift Fork, slide shift rail out through front of case. Remove spring and lock ball from case (tip case up). Take out retaining screw on rear of case, remove lock plate to free countershaft and reverse idler shaft. Drive countershaft out through rear of case, using bronze Driver J-1574, lower countergear cluster to bottom of case. Pull mainshaft rearward by hand until puller can be engaged behind bearing or snap ring (if necessary, re-install universal flange, tap on flange to move shaft). Remove bearing from shaft with Puller J-1134-H. Pull mainshaft to rear until forward end clears pilot bearing in main drive gear, then tilt forward end up, move synchronizer and sliding gear to rear as far as possible, remove mainshaft assembly through top of case. Pull main drive gear forward until bearing retainer snap ring is free, remove snap ring, tap drive gear into case and remove through top of case. Remove shift shaft inner lever, lift countergear cluster and thrustwashers out. Drive out reverse idler shaft (use driver J-1574 inserted through mainshaft bearing hole in front of case), lift reverse idler gear out. Remove nut and washer on upper end of shift selector shaft, lift off lever, take out setscrew in side of shaft, remove shaft from within case, pull bushing straight up and out. Remove nut and washers on outer end of shifter shaft, remove outer lever, drive out tapered lockpin in side of shaft (use pin punch, withdraw shifter shaft and seal. Disassemble all sub-assemblies as follows:

Mainshaft Assembly: Remove sliding gear, take out lock ring in groove ahead of synchronizer hub, slide synchronizer assembly and 2nd speed gear off shaft. When reassembling, make certain that oil holes in gear hub register with shaft spline oil channels (four splines have oil channel at front end). Install 2nd speed gear with the ground tapered hub end toward front of shaft, see that synchronizer struts engage slots in synchronizer rings, use new lock ring in shaft groove and carefully fit ring in groove. Check 2nd speed gear endplay which should be .003-.016".

Synchronizer Assembly: Need not be disassembled (can be removed as a unit by sliding it off front end of mainshaft). To disassemble, lift out synchronizer rings, slide outer sleeve off inner hub, lift out three synchronizer struts or plates and springs. When reassembling, place three struts in position in hub slots, install synchronizer springs with one end of each spring engaging same groove in strut and with springs extending around hub in opposite directions. Install outer sleeve with shifter fork groove toward undercut on hub, and install assembly on mainshaft with this end toward rear of transmission.

CONTINUED ON NEXT PAGE

HUDS N 6 & 8 TRANSMISSION (N VERDRIVE)

1948-EARLY 1952 HUDSON (Continued)

Countergear Cluster: Examine bushings for wear and replace if clearance greater than .005". Install new bushings with Replacer J-1572 (position bushings with annular groove nearest end of shaft, draw both bushings in until end .015" beyond thrust face of gears). Ream bushings to .865" using KMO-338 Reamer (pilot reamer in bushing at opposite end of gear and ream each bushing in succession). When installing assembly in case, place thin thrust washer in case at each end (bronze surface out toward gear, washers engaging retaining pins in case), place steel washer on rear face of cluster gear with tongue engaging slot in end of gear. Check end-play which should be .006-.016".

Reverse Idler Gear: Replace bushing if clearance exceeds .005". Install bushing with Replacer J-1572. Ream to inside diameter of .865" using Reamer KMO-338 and pilot. Clearance should be .001-.0025".

Main Drive Gear: To remove bearing, take out lock ring in shaft groove, use Puller J-1134-H. Install bearing with Replacer J-1570, install lock ring in shaft groove but do not install retainer ring in bearing groove until after assembly installed in transmission case.

TRANSMISSION REASSEMBLY: After all sub-assemblies completed, reassemble transmission by reversing disassembly directions except as noted below:

Main Drive Gear Installation: Insert gear and bearing assembly through cover opening in case, push through hole in front of case until retaining ring groove in bearing exposed at front of case, install retainer ring. Install pilot bearing rollers in recess in gear hub (use viscous grease to hold rollers until mainshaft installed).

Mainshaft Assembly Installation: With shaft in place in case, place rear bearing and bearing retainer on end of the shaft, use three special bolts ½" longer than regular capscrews to pull retainer up against housing and push bearing on shaft (draw bolts up evenly). Remove bearing retainer, use regular capscrews when retainer finally installed (after speedometer gear installed).

Countershaft Installation: After mainshaft installed, lift countergear cluster up in case (use care not to dislodge thrustwashers), insert beveled end of countershaft at rear of case, drive countershaft in with a soft hammer (coat last 1½" section with red lead for sealing) making certain that shaft turned so that locking plate can be engaged. Install locking plate to lock countershaft and reverse idler shaft.

Reverse Idler Shaft Installation: Make certain that shaft turned to proper position for lock plate engagement, tap shaft into case, coating outer section with red lead or other sealer, drive shaft into place with a soft hammer. Install locking plate (see Countershaft Installation).

Shifter Shaft: Two types of oil seal used—correct type must be used with each type case (see below). To install shift shaft, lubricate shaft with engine oil, insert shaft in case, lock in place by driving lock pin in hole in case (pin engages groove in shaft). Install rubber sealing washer, outer shift lever, plain washer, shakeproof washer, tighten nut securely. Check by rotating shaft. If more than slight drag noted, check oil seal for interference.

►**Oil Seal Change**—*Two types used. Not interchangeable. Correct type must be used as follows:*

	Shift Shaft Seal	Transmission Case
First Type①	163251	300423③, 300917④
Second Type②	301495	301841③, 301838④

①—(Cars without Overdrive with 15x7.10 Tires)—Before Serial No. 7354 & No. 7498 to 7603 incl. (Cars without Overdrive with 15x7.60 Tires)—Before Serial No. 6324. (Cars with Overdrive)—Before Serial No. 21666 & No. 21910 to 22052 incl.
②—Cars after above serial numbers.
③—Without Overdrive. ④—With Overdrive.

Shifter Rail Lock Balls & Springs: 2nd & High spring and lock ball should be inserted in case first, install 2nd & High shift rail, then insert interlock plunger, install Low & Reverse shift rail, finally insert Low & Reverse lock ball and spring. See spring data below.

►***CAUTION—Different type springs used in each type transmission—correct type spring must be used to insure transmission not jumping out of gear.***

Shift Rail Springs

	Low & Reverse	Second & High
Std. Trans.	9 lbs. (41151)	9 lbs. (41151)
With O.D.	30 lbs. (41236)	19 lbs. (163442)
With HDM	19 lbs. (163442)	19 lbs. (163442)
With O.D. & HDM	30 lbs. (41236)	19 lbs. (163442)

O.D.—Overdrive. **HDM**—Hudson Drive-Master.

1954-55 METROPOLITAN

Metropolitan, Nash & Hudson Models (1954-55)

DESCRIPTION: Three speed constant mesh, synchro-mesh (second & high), sliding gear (reverse).

REMOVAL OF TRANSMISSION: *See "Transmission" on car model pages.*

TRANSMISSION DISASSEMBLY: 1) Drain transmission and remove the clutch release bearing by prying the two retaining springs off bearing fork shaft. Lift bearing away from fork and slide it off shaft. Remove nut and lockwasher from throwout bearing fork taper pin and remove pin. Remove snap ring and flat washer from right side of clutch operating shaft and remove shaft from left side of case.

2) Remove nuts and lockwashers retaining front transmission cover to case (cover can be removed at this time, however, it is advisable to remove the cover when countershaft is removed). Remove capscrews from side cover and remove cover and shifter shafts as an assembly. Remove capscrews retaining rear cover to tap transmission main shaft with a plastic hammer to release rear cover from rear bearing retainer).

3) Tap countershaft slightly forward to release front cover and remove cover from case. Remove snap ring from second and high shifter rod located in front of fork. Tap the two shifter rods from front of case toward rear to release lock keys which keep rods from turning. Install dummy shaft (described below) into shifter rod forks from the rear, keeping dummy shaft tight against shifter rods as rods are being removed. This will retain the loaded ball and spring in the shifter fork (NOTE—When removing the second and third speed shifter rod, remove the spacer sleeve located on rod behind shifter fork). With the rods removed, forks can be lifted out of case.

►**Shifter Rod Dummy Shaft:** Use ½" round stock and cut to 3½" lengths (2 required). Chamfer one end 3/32" by grinding or filing.

4) Remove reverse idler gear and bracket (bracket is fastened to case by a hex head screw which also locks shaft in position). Bend lip on lockwasher, remove bolt and bracket, then tap reverse idler shaft out toward rear of case and remove gear. With a soft metal drift and hammer, tap countershaft forward. After countershaft is removed, the countershaft gears and two thrust washers will drop to bottom of case. The countershaft gears cannot be removed from case until mainshaft and clutch shaft assemblies are removed.

5) Remove mainshaft and gear assembly out of case, tipping the rear of the mainshaft down slightly to pass over countershaft gears. Before removing clutch shaft, tilt countershaft gear so it clears gear teeth on clutch shaft. With a soft metal drift and hammer, drive shaft forward and out of case. Remove countershaft gear and thrust washers out through rear of case, (the larger diameter thrust washer is located at front of case. The smaller thrust washer is located at rear of case and is supplied in various thicknesses to obtain proper end play).

Mainshaft Disassembly: Slide second and third speed synchro-clutch gear off main shaft. Depress the spring loaded thrust washer lock pin with a pointed tool. Then turn retaining thrust washer lock ring in line with the splines on mainshaft and remove washer, lock pin and spring. Remove second speed gear, bronze bushing, and bronze thrust washer from mainshaft. Remove first speed gear and bronze bushing and reverse speed sliding gear. The rear transmission ball bearing and speedometer drive gear are secured to main shaft by means of a nut and lockwasher. To remove these, place mainshaft in a vise after protecting the splines and finished surface with copper vise jaws. Remove nut and lockwasher and reposition shaft assembly in vise so bear-

CONTINUED ON NEXT PAGE

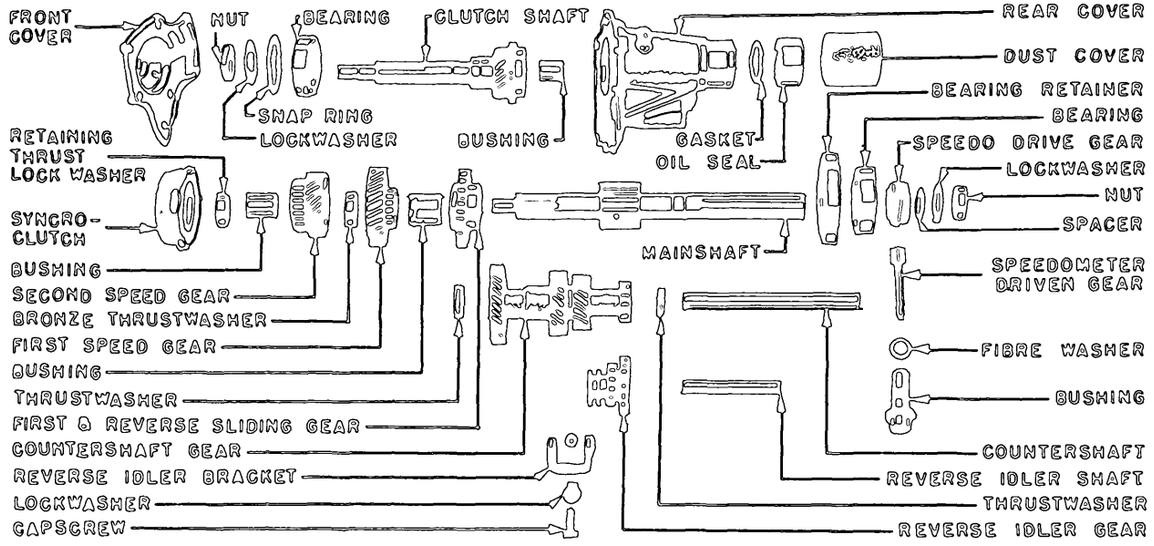
METROPOLITAN SYNCHRO-MESH (Continued)

ing retainer is supporting the assembly. Tap the long splined end of shaft with a soft hammer to release shaft from ball bearing and speedometer drive gear.

Clutch Shaft Disassembly: To remove bearing from shaft, bend lip lockwasher away from nut and place shaft assembly upright in a copper jawed vise. Remove nut *(CAUTION–NUT HAS A LEFT HAND THREAD).* Place bearing on the jaws of an open vise, rest the assembly on the snap ring, and tap shaft downward. *CAUTION–Use only a s ft hammer to prevent end of shaft from spreading.*

Rear Cover Disassembly: Remove dust shield by carefully hacksawing the three indentations in the shield and tapping it off cover. The oil seal is also indented but it can be driven off without removing indentations, Remove the oil seal gasket. Remove speedometer driven gear and breather.

Synchro-Clutch Gear Disassembly: Clutch contains five springs and balls located in inner gear and when disassembling, place assembly on a clean cloth to retain these parts when assem'ly is pulled apart.



▷*ASSEMBLY NOTE–Lubricate all parts with engine oil before assembly.*

Synchro-Clutch Gear Reassembly: Install aligning sleeve J-5568 over inner gear and install each spring and ball through the drilled hole in the aligning sleeve, using a punch to depress the spring. Rotate tool until all five springs and balls are inserted. Slide outer gear over inner gear and snap into place.

Rear Cover Reassembly: Install speedometer driven gear, using a new fibre washer. Install breather assembly. Install cork gasket in end of cover and place new oil seal in position. Use extreme care when indenting the seal in three places to insure proper seating of seal against rear cover. Install a new dust seal locating it evenly to eliminate interference with propeller shaft. Indent it in three places to retain it in place.

Clutch Shaft Reassembly: Install new bearing with tool J-2995 and tighten left hand nut securely. Bend the lock washer lips on two sides of nut. Check main shaft fit in bushing in clutch shaft. This clearance should not exceed .003". If greater, replace bushing.

Main Shaft Reassembly: Install rear bearing retainer, bearing, speedometer drive gear, drive gear spacer, lockwasher, and nut on rear end of main shaft. Tighten nut securely and bend lips of lockwashers on two sides of nut. Install the low and reverse sliding gear on front end of mainshaft, positioning it against shoulder on shaft. Then install first speed gear bushing, first speed gear, bronze thrust washer, second speed gear, and second speed gear bushing. Place spring and plunger into hole in mainshaft and slide the retaining thrust lock washer into position. Depress plunger and slide

METROPOLITAN SYNCHRO-MESH TRANSMISSION ASSEMBLY

thrust lock washer over plunger. Rotate thrust washer to lock it in position with plunger engaged in groove in washer. At this point, measure the clearance between the second speed gear and the bronze thrust washer (located between first speed gear and second speed gear). This clearance should be .003-.006". Adjust by selecting a retaining thrust lock washer of correct thickness to provide this clearance. These washers are furnished in three sizes as follows: .2035-.2045" (Part No. 8110447), .2055-.2065" (Part No. 8110448), .2075-.2085" (Part No. 8110448). Install synchro-clutch gear assembly on mainshaft.

TRANSMISSION REASSEMBLY: 1) Install countershaft gear, countershaft and front and rear thrust washers (larger washer to the front and smaller one to rear). Countershaft gear endplay should be .001-.003". If not correct, replace rear thrust washer with one of correct thickness to obtain specified endplay. These washers are furnished in the following thicknesses: .156-.157", .163-.164"; .1585-.1595"; .1605-.1615" for selective fitting.

2) Remove countershaft and insert a thin rod so that countergears and thrust washers will be positioned in assembly sequence in bottom of transmission (this will allow clearance for replacing mainshaft gear assembly).

3) Install clutch shaft and front bearing assembly into case, driving it into place with tool J-2170 and an outer three inch Timken bearing race. The bearing snap ring must fit flush with recess in end of case. Insert clutch and mainshaft bushing in clutch shaft.

4) Install mainshaft gear assembly through rear of case and start forward end of shaft into clutch shaft bushing. Tap rear end of shaft with a plastic hammer until rear bearing retainer is flush with recess in the case Check for freeness of entire assembly. If binding occurs, tap clutch shaft slightly.

5) Install the countershaft with the lipped end to the front, and with the rear end flush with the case. The lipped end will fit into a recess in front cover when cover is installed. Install reverse idler gear, shaft and bracket securing bracket with the hex head capscrew and lock washer. Bend lip of lock washer against head of screw and case.

6) Insert the dummy shift rods in each shifter fork to retain preloaded spring and ball in place in fork until they are installed. Install second and third speed shifter fork in case, placing the fork in the synchro-clutch gear groove, place first and second fork over the teeth of the first and reverse sliding gear. Start the second and third speed shifter rod into case from the rear and place the limit sleeve on the rod. Push rod into the fork keeping the rod tight against the dummy shaft. Hold the shifter fork toward the rear and slide the rod through the fork, and remove the dummy shaft. Install snap ring in groove at front end of shifter fork on rod. Install first and reverse shifter fork in the same manner. Check to make sure ball in forks engage grooves in rods. Insert locks in slots at rear of case.

7) Align the dowel pin in the rear bearing retainer with the rear cover and install rear cover, gasket, and speedometer driven gear. Install front cover and gasket. Install side cover assembly and gasket aligning shifter shafts with shifter forks. Install shift levers. Install clutch operating shaft and bearing assembly, securing bearing assembly to yoke with a snap ring on each stub shaft.

NASH "600" STATESMAN & RAMBLER SYNCHRO-MESH

"600", All Series (1946-49)
Statesman, All Series (1950-55)
Rambler, All Series (Late 1953-55)

►CHANGES, CAUTIONS, CORRECTIONS

►*1953 NASH RAMBLER TRANSMISSION PRODUCTION CHANGE*—At 1953 Car Serial No. D-150580, "Warner Type" Transmission replaced by "Statesman" Series Standard Transmission.

►*1953 TRANSMISSION SYNCHRONIZER PRODUCTION CHANGE*—"Nash Type" Synchronizer Clutch replaced "Warner Type" temporarily between Car Serial Numbers K-611840 & K-613887 (Statesman); D-152241 & D-172945 (Rambler). **"Nash Type" & "Warner Type" synchronizer clutch parts are not interchangeable.** If it is necessary to change from one type to the other, it will be necessary to also change the following parts: Clutch Shaft, Second Speed Gear, Shifter Fork (Second & High), Shifter Fork Shoe, and the complete synchronizer clutch.

►**1946-47 TRANSMISSION SHIFT SHAFT & FORK CHANGE (To correct gear disengagement caused by distortion of Fork or Quadrant):** On cars before Serial No. K-140220, check clearance between rear face of synchronizer shift collar and front face of 2nd. speed gear with transmission 2nd. speed gear fully engaged. If clearance less than .028" (use feeler gauge), install new type Shifter Fork and Shaft Assemblies (forged quadrants pressed on steel shafts with larger pivots on forks and larger holes in shafts). New type parts replace original design (quadrants brazed on shafts).

►*NOTE—Only new type parts furnished for service. Install complete unit package (High & Second and Low & Reverse Shafts and Forks).*

►**1949 SYNCHRONIZER PRODUCTION CHANGE:** Beginning with Serial No. K-298081 on 1949 "600," Synchronizer Assy. changed to same type as used on Ambassador Six. *This new synchronizer requires different disassembly procedure (see below).*

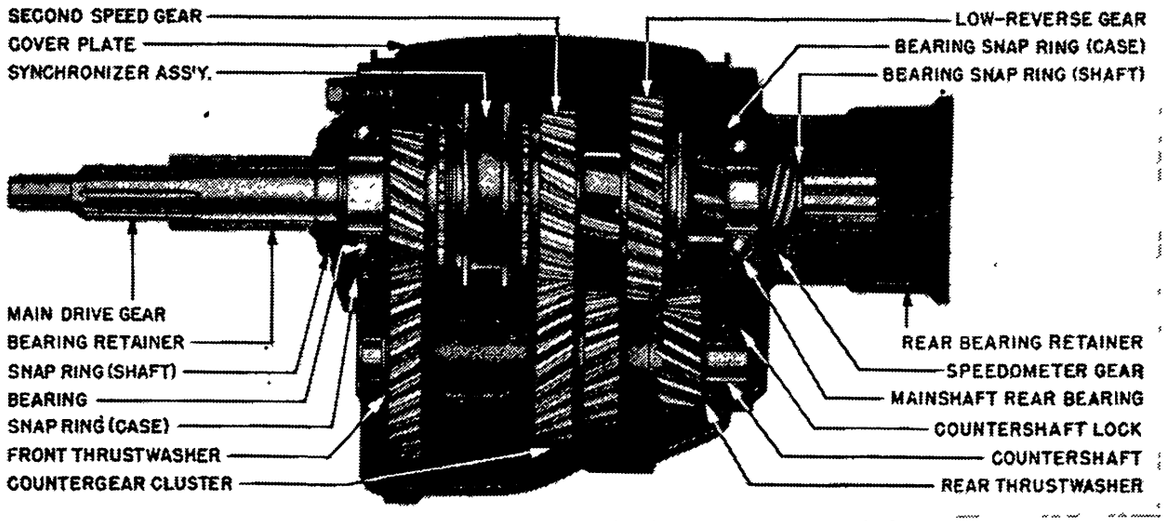
►**1950 TRANSMISSION NOISE CORRECTION:** Noise in transmission or overdrive may be due to the following conditions caused by incorrect adjustment of the torque tube trunnion:
(1) Transmission rear bearing snap ring wrong size or incorrectly installed (furnished in four thicknesses and must be firmly seated in groove to control mainshaft endplay).
(2) Above snap ring broken by excessive loading due to incorrect torque tube trunnion adjustment causing propeller shaft to protrude more than ⅛-¼".
(3) Dust shield on propeller shaft scraping on trunnion bracket due to incorrect torque tube trunnion bracket adjustment.
See "Nash Hypoid (with Torque Tube Drive) Rear Axle" in Rear Axle Section for Torque Tube Trunnion adjustment.

OVERDRIVE TRANSMISSION NOTE: These transmissions serviced in same manner as standard type (below) except for Overdrive (Warner R10B). *See "Warner R10 Overdrive."*

DESCRIPTION: Three-speed, all helical gear type with constant-mesh, synchro-mesh (Second & High), sliding gear (Low & Reverse).

REMOVAL OF TRANSMISSION: *See "Transmission" on car model page.*

TRANSMISSION DISASSEMBLY: Remove transmission case cover and gasket. Remove shifter shaft nut, washer, and lever from Low & Reverse shifter shaft, drive lockpin out to free shaft (drive pin up), drive shaft out of case as far as possible (use brass drift on inner end) to provide clearance for gear removal (NOTE—Not necessary to drive out Second & High shifter shaft). Remove capscrews in rear bearing retainer, move retainer, mainshaft and gear assembly to rear until synchronizer unit completely disengaged from shaft, remove low & reverse shifter fork, then withdraw retainer and shaft through rear of case (on overdrive transmissions, lower left stud must be removed to permit complete assembly to be withdrawn). Drive the countershaft lock out to free shaft. Use Countershaft Aligning Tool J-2632 to drive countershaft out through rear of case allowing countergear cluster to drop down on small diameter of aligning tool. Take out capscrews in bearing retainer on front of case, remove retainer, withdraw main drive gear assembly through front of case, lift out front synchronizer ring through top opening of case. Turn synchronizer assembly at right angles and lift it from case (CAUTION—Shifter shoes will drop out as synchronizer removed from fork—remove shoes from case). If reverse idler gear being removed, drive shaft out through rear of case using a long punch (CAUTION—do not damage shaft or gear), lift gear out. Remove forks from shifter shaft quadrants. Remove lever on outer end of Second & High shift shaft, drive out lockpin. Remove both shifter shaft assemblies from within case. Remove Second & High speed finder poppet (plunger & spring) from within case, Low & Reverse speed finder poppet from plug hole at bottom of case. Remove Interlock poppet from boss in case between shifter shaft holes. Lift out countergear cluster and thrustwashers. Dismantle and service sub-assemblies as follows:



Main Drive Gear: Remove snap ring from shaft groove in front of bearing, press bearing off shaft. Check mainshaft pilot bearing rollers in gear recess for wear (jar gear lightly on block of wood, if rollers fall out, install new rollers and make certain that retainer ring installed in recess). Press bearing on shaft with snap ring groove toward front, install ring in this groove (.076-.0785" thick, not variable). Install snap ring in shaft groove making certain that snap ring is snug fit in groove (selective fit—this ring furnished .092", .095", .098" thick).

Mainshaft & Gears: Remove clutch ring driver from front end of shaft, rotate 2nd. speed gear thrust washer until tongues on washer line up with spline grooves, remove washer, slide synchronizer ring, 2nd. speed gear, and low-reverse sliding gear off shaft. Remove snap ring from rear bearing retainer (in front of bearing), tap shaft and bearing out of retainer toward front using a brass drift. To remove bearing, remove snap ring from shaft at rear of speedometer gear, remove gear, lift out gear woodruff key, press bearing off. Inspect all parts for wear.

Mainshaft Rear Bearing—Press bearing on shaft with closed end forward and tight against shoulder on shaft. Install speedometer gear (and woodruff key) install snap ring in shaft groove, selecting ring for snug fit (this ring furnished .087", .090", .093" thick). Install shaft and bearing assembly in rear bearing retainer with bearing seated firmly in retainer recess, install snap ring in retainer groove, selecting ring for snug fit so that shaft has no endplay (furnished .062", .065", .068", .071" thick).

Low-reverse Sliding Gear—Shift collar must be toward rear and gear must slide freely on splines.

Second Speed Gear—Gear synchronizer cone must be forward and gear turn freely on shaft. Push thrust washer on shaft against gear, revolve washer until tongues engage groove in shaft splines so that washer is locked in place (washer will be held in place by clutch ring driver). Check gear endplay

NASH '600" & STATESMAN TRANSMISSION (N OVERDRIVE)

CONTINUED ON NEXT PAGE

NASH "600" STATESMAN RAMBLER (Continued)

with feeler between rear face of gear and shoulder on shaft. Endplay should be .002-.010".

Synchronizer Assembly (1946-49): If these parts to be dismantled, mark the hub and sleeve to insure reassembly in same position, slide sleeve off hub being careful not to lose poppet balls and springs which will fly out of hub holes. When reassembling, use piston ring compressor to retain springs and balls in hub, slide sleeve on hub with chamfered side of sleeve toward long end of hub.

Synchronizer Ring & Driver—Engage synchronizer ring in gear cone (prongs forward), engage Clutch Ring Driver on shaft splines with short lugs toward 2nd. speed gear and in line with notches in gear thrust washer. Turn synchronizer ring so that prongs line up with notches in driver, push driver in place against gear (locks thrustwasher in place).

Synchronizer Assembly (1949 & Later): Hub and sleeve are marked by etched line to insure correct reassembly. If disassembled, install struts with open face toward inner clutch sleeve and with hooked end of each spring wire engaged in the same strut (free end of spring will be between this strut and next strut in a clockwise direction).

Rear Bearing Retainer Mainshaft Bushing & Oil Seal: Bushing and oil seal installed in rear end of retainer extension housing. Oilite bushing can be replaced with oil seal out as follows:

Bushing Replacement—Remove old bushing through rear of housing. Assemble felt oil ring on new bushing, press bushing in housing until shoulder on bushing is ¼" from shoulder in housing.

▷*CAUTION*—Felt oil ring must not be compressed.

Oil Seal Installation—Use driver J-1556 to install oil seal in recess at rear of housing.

▷*CAUTION*—Seal must be inserted with lip on leather toward front.

TRANSMISSION REASSEMBLY: After all sub-assemblies serviced as above, reassemble transmission by reversing disassembly directions and note the following important points:

Reverse Idler Gear: Beveled side of gear teeth must be forward. Drive the shaft in from rear until lock slot is flush with rear face of case (slot should face countershaft).

▷*CAUTION*—Low & Reverse Shifter Shaft must be installed before reverse idler gear installed.

Countergear Cluster: Use heavy lubricant on thrustwashers, insert gear cluster and front thrustwasher in case (lip on washer lined up with slot in case), install rear thrustwasher through hole in case, insert J-2632 aligning tool to retain parts while remainder of transmission assembled. After all parts installed, tap countershaft in through rear of case (take care not to damage thrustwashers) until lock slot flush with rear face of case, install lock plate in slots in countershaft and reverse idler shaft.

Shifter Shaft Assemblies: Inspect needle bearings in case before installing second-high shifter shaft, replace nedle bearings, if necessary, with special driver. After installing speed finder poppets and springs, and interlock poppet, insert shaft from inside case but do not install lock pins and levers until transmission completely reassembled. Install synchronizer assembly in second-high fork (use heavy grease to retain fork shoes).

Main Shaft & Rear Bearing Retainer: Place standard .010" shim (with gasket on each side) on face of rear bearing retainer, insert assembly through rear of case and work shaft through synchronizer assembly hanging in shift fork, being careful to line up clutch hub recesses with clutch ring driver prongs. Line up low & reverse shift fork with collar on low-reverse gear. After main drive gear installed, check mainshaft endplay (synchronizer ring clearance) and adjust as follows:

Mainshaft Endplay Adjustment—Controlled by shim thickness under rear bearing retainer. Check and adjust as directed below. *CAUTION—Each type synchronizer requires special gauge and different setting:*

With 1946-49 First Type Synchronizer—To check synchronizer ring clearance, insert special clearance gauge, Tool J-1542, at each end of synchronizer sleeve while holding rear bearing retainer tight against case. If clearance not equal to gauge thickness (.105"), adjust by increasing or decreasing shim thickness at rear bearing retainer. Rear bearing retainer capscrews can be installed after this adjustment completed. *CAUTION*—Gasket must be installed on each side of this bearing retainer shim.

With 1949 & Later Type Synchronizer—Use special clearance gauge, Tool J-1410 (.075"). Clearance should be .060-.080". Checking and adjusting procedure same as for first type synchroinzer (above).

Main Drive Gear: When installing gear in case, line up synchronizer ring prongs with slots in clutch ring driver. Install bearing retainer with new gasket and line up oil return holes in retainer and case. When tightening capscrews, note whether retainer contacts bearing before contacting case and correct this condition by installing additional gaskets under retainer. Main drive gear endplay must not exceed .005" and should preferably be .000".

Shifter Fork Alignment: After assembly completed, shift transmission into Second Gear and make certain that gear fully engaged. Measure clearance between rear face of synchronizer clutch shift collar and front face of second speed gear which must not be less than .028". If less, shifter fork or quadrant has been distorted and should be replaced.

Transmission Cover Plate: Install gasket on case with vent hole to rear (mark FRONT forward), install cover with vent hole forward and see that this vent is clean and open.

1941-49 NASH AMBASSADOR

Ambassador Six, All Series (1941 to 1948)
Ambassador Six, Series 4960 (Early 1949)
Ambassador Eight, All Series (1941-42)

▷CHANGES, CAUTIONS, CORRECTIONS

▷1949 TRANSMISSION CHANGE: This Nash transmission (with Optl. Warner Overdrive) used only on Early 1949 cars. Later cars have Warner Transmission.

See Warner Transmission data for later 1949 cars.

▷1947 TRANSMISSION SHIFTER SHAFT & FORK CHANGE After Serial No. R-444510 (Std. Trans), R-443972 (Overdrive Trans.): New type heavier Shifter Shafts, Forks, and Sleeves used beginning with above serial numbers. These new parts furnished for service on earlier cars and entire group of new parts must be installed as an assembly (cannot be installed singly on earlier cars).

▷*IDENTIFICATION NOTE*—New design parts have forged quadrants which are pressed on machined steel shafts.

▷1947 TRANSMISSION MAIN DRIVE GEAR, BEARING RETAINER & LOCK RING CHANGE (Starting Serial No. R-432468 Std. Trans., R-432167 Overdrive Trans.): Lock ring in bearing changed from .065" thick to .077" and new type main drive gear and bearing retainer used.

▷*CAUTION—New and previous design parts must not be interchanged and each type must be installed differently (see Transmission Asembly direction).*

OVERDRIVE TRANSMISSION NOTE: These transmissions serviced in same manner as standard type (below) except for Overdrive Unit which is Warner Type R7C (1941-46), Type R10 (1946-48).

See "Warner R6 & R7 Overdrive (With Kick-down)" and "Warner R10 Overdrive."

DESCRIPTION: Three-speed, all helical gear type. Constant-mesh, synchro-mesh (Second & High), sliding gear (Low & Reverse). Main drive gear mounted on ball bearing in front of transmission case (see Production Change above). Mainshaft is mounted on roller bearing in main drive gear (front), ball bearing in retainer cap on case (rear).

REMOVAL OF TRANSMISSION: *See "Transmission" on car model page.*

TRANSMISSION DISASSEMBLY: Remove cover capscrews, lift off cover and baffle, remove mounting capscrew and lift oil trough out. Move both shifter shaft levers away from each other slightly so that speed finder plungers move out of notches in quadrants, tighten speed finder lockscrew (on outside of case between lever shafts) to hold plungers away from quadrants. Mark shift levers and shafts to insure correct reassembly, remove levers, drive shaft lockpins up and out of bosses in case. Use soft drift to drive shifter shafts toward outside of case as far as possible, lift off oil seals, retainers, and shaft sleeves which will be pushed out of case. Remove low-reverse shifter fork, remove interlock, remove second-high shifter fork (work pivot end toward rear as fork slips out of collar). Remove low-reverse shifter shaft (move sliding gear toward rear of case for clearance) and second-high shifter shaft (slide clutch sleeve to rear for clearance, turn shifter shaft so that pivot hole is downward, pass quadrant under synchronizer until end of shaft free from hole in case). Remove capscrew and washer on rear end of mainshaft, pull companion flange (Puller J-1412). Remove capscrews in rear bearing retainer and rotate retainer to expose countershaft hole in rear face of case (on Overdrive Transmissions, merely take out pipe plug at rear of overdrive case). Use Countershaft Aligning Tool J-1415-A to drive countershaft out at front of case so that countergear cluster drops down on small diameter of tool. Remove capscrews and nuts retaining rear bearing retainer cap (or adapter plate on overdrive transmissions), withdraw mainshaft and gears through rear of case as an assembly (CAUTION—On over-

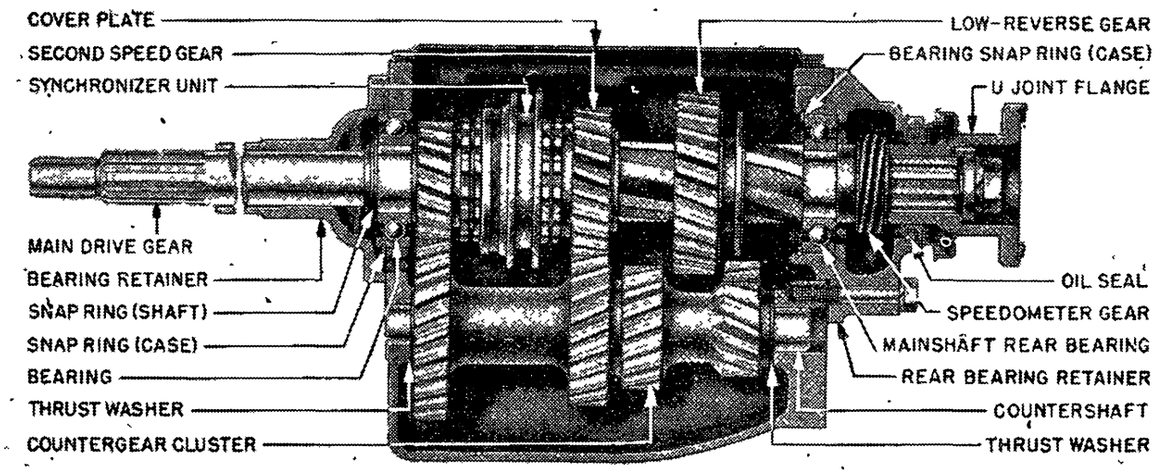
CONTINUED ON NEXT PAGE

1941-49 NASH AMBASSADOR (C ntinued)

drive models, use extreme care that adapter plate does not separate from overdrive case which would require dismantling of overdrive to reassemble freewheel rollers—install one screw to hold adapter plate and overdrive case together while off transmission). To remove main drive gear, take out screws in bearing retainer on front of case, withdraw gear and bearing as assembly. Lift countergear cluster and thrust washers out of case. To remove reverse idler gear, use long brass drift inserted through front of case to drive shaft out toward rear. Dismantle and service sub-assemblies as follows:

Main Drive Gear: Remove snap ring from shaft, press bearing off in arbor plate using J-1298-N bearing plate. Check mainshaft pilot bearing rollers in recess for wear (jar gear lightly on block of wood, if roller falls out, install new rollers and make certain that retainer ring installed in recess). Press bearing on shaft with snap ring groove toward front, use tool J-1416 to install snap ring in shaft groove making certain ring is snug fit in groove (selective fit—furnished .087", .090", .092", .093", .096" thick). Large snap ring installed in bearing groove should be .065" thick (first type gear with oil hole in shaft), .077" (later type gear without oil hole).

See Production Change Note above for data on this parts change.



Synchronizer & Second Speed Gear:—To dismantle assembly, depress locking plunger under lock ring in front of synchronizer inner clutch sleeve with a sharp pointed tool, revolve lock ring one spline so that it is free and withdraw from shaft, remove synchronizer, bronze thrustwasher, second speed gear, steel thrustwasher. Sliding gear can then be removed from shaft. Install assembly in same manner selecting retainer washer of correct thickness so that second gear endplay is .002-.004" with retainer installed. See that retainer turned so that it is locked in place in mainshaft splines and that locking plunger prevents retainer from turning.

►*CAUTION*—Install second speed gear steel thrustwasher with chamfer toward rear end and tongue in line with notch on spline shaft, install bronze thrustwasher with tongues toward front of shaft and **rotate washer so that tongues engage notches in splines** (see that washer does not slip out of place when installing synchronizer).

Synchronizer Unit—Inner and outer clutch sleeves and rings should be marked before disassembly to insure reassembly in same positions. Install struts with open face toward inner clutch sleeve and hooked end of each spring wire engaged in the same strut (free end of this spring will be between this strut and next strut in clockwise direction).

Mainshaft Rear Bearing: Remove snap ring from recess in rear bearing retainer (in front of bearing), tap shaft and bearing out of retainer toward front using a brass drift. To remove bearing, slide speedometer gear off shaft, press bearing off. Install bearing with closed side forward. On overdrive cars, overdrive unit must be dismantled and snap ring on shaft behind overdrive sun gear removed, then press shaft out (will not disturb sun gear assembly).

Reverse Idler Gear:—Idler gear should be removed by driving shaft out toward rear. When installing idler gear, see that chamfered edge of gear teeth is toward front of case.

NASH AMB. 6 TRANSMISSION (NO OVERDRIVE)

Countergear Assembly:—When installing countergear cluster, install thrust washer at each end with tongue in line with slot in case (washers may be held by grease while installing gears. Allow gears to hang down on small diameter of tool J-1415-A while main drive gear and mainshaft are being assembled then push out tool by inserting countershaft at forward end of case. CAUTION—Use care not to damage thrust washers.

TRANSMISSION REASSEMBLY: After all sub-assemblies serviced as directed above, reassemble transmission by reversing disassembly directions and note the following important points:

Mainshaft Rear Bearing Retainer Installation: Install same number and thickness of shims (as removed when transmission disassembled) on face of retainer with new gasket on each side of shim pack. Bolt retainer in place and after assembly completed, check and adjust mainshaft endplay as follows:

Mainshaft Endplay—Controlled by thickness of shims between rear of transmission case and rear main bearing cap or overdrive adapter. With transmission assembled, install shift collar centering gauge tool J-1410 (.075" thick) between front face of high speed synchronizer ring and rear face of main drive gear, place second gauge similarly between second speed synchronizer ring and second speed gear. Gauges should slip into position freely and will center the synchronizer sleeve. Front gauge should be from a tight fit to .015" clearance (corresponding to .000-.015" endplay). Adjust by adding or removing shims from between rear bearing retainer and face of transmission case (above).

Main Drive Gear & Bearing Retainer Installation: ►*CAUTION—Make certain that correct type parts used together (see Production Change Note above).* Check thickness of snap ring in bearing groove (.065" thick for first type gear with oil hole in shaft, .077" thick for later type gear without oil hole), and make certain that correct type bearing retainer used for each type gear. Install main drive gear in front end of case, install each type bearing retainer exactly as follows:

First Type Retainer (with .078" deep lock ring counterbore)—This type retainer must be fitted when installed on case (inner face of counterbore contacts front face of bearing and forces lock ring against case). Press retainer firmly in place against bearing, use feeler gauge to measure clearance between face of retainer and transmission case, **install sufficient gasket thickness at this point to take up clearance** (gaskets furnished in various thicknesses). With retainer bolted in place, drive gear endplay must not exceed .015" (.000" preferred).

Later Type Retainer (with .064-.067" deep lock ring counterbore)—With this type retainer, lock ring is clamped between counterbore and face of transmission case. Use a new gasket under the retainer and make certain that oil return hole is at bottom with retainer installed on case. Drive gear endplay must not exceed .015" (.000" preferred).

Shifter Shafts: When installing shifter shaft forks, see that low and reverse fork installed with longer segment at top. Cork oil seals and retainers are installed on outer ends of shafts and shaft bushing retaining pins should be installed from the top.

NOTE—Use tool J-2633 to install oil seals.

Speed Finder Locating Screw—Located on side of transmission case between shifter shafts. Need not be disturbed to remove detent plungers but if removed, screw should be adjusted so that inner end engages flattened portion of plungers to prevent plungers turning but must not cause plungers to bind. Lock adjustment with locknut.

►*CAUTION*—After transmission assembly completed, screw should be backed off just enough so that speed finder plungers operate freely, lock adjustment by tightening locknut.

Transmission Cover: With oil trough installed in case and mounting capscrew tight, install baffle with vent louvre at rear of case, install cover with vent on right side. NOTE—Use gasket on each side of baffle.

PACKARD SYNCHRO-MESH

Packard (1946-55)

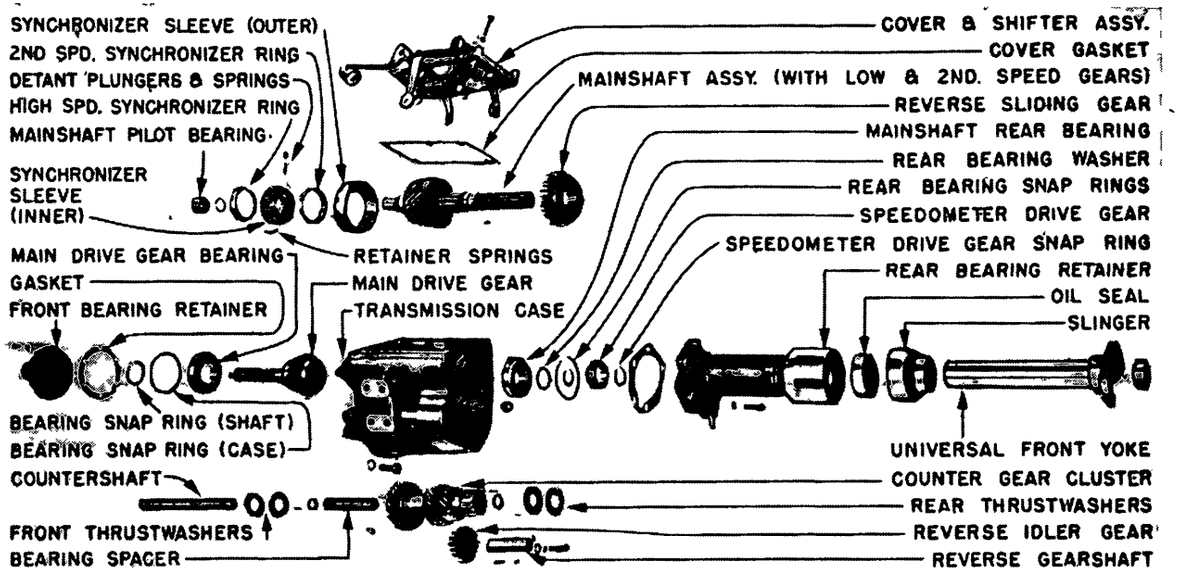
►*AUTOMATIC TRANSMISSION NOTE: See "Packard Ultramatic Drive" and "Packard Twin Ultramatic Drive."*

►**OVERDRIVE NOTE:** *Various Overdrive units used with this transmission as follows:*

1941-48 Warner Type R9—*See "Warner R9 Overdrive" for data.*
1949-55 Warner Type R11—*See "Warner R11 Overdrive" for data.*

DESCRIPTION: Constant-mesh, synchro-mesh (2nd. & High), constant-mesh (Low) helical gears, sliding spur gear (Reverse). Second-speed & Low-speed gears are mounted on special double-row ball bearings on mainshaft (furnished as assembly with shaft). Second and high are engeged by synchronizer unit on mainshaft, low speed gear by clutch teeth in sliding reverse gear which engage clutch teeth on low gear hub.

►**OVERDRIVE TRANSMISSION DISASSEMBLY:** *See Warner Overdrive data for disassembly of overdrive and note following important points:*



REMOVAL OF TRANSMISSION: *See "Transmission" on car model page.*

DISASSEMBLY OF TRANSMISSION: Take out mounting screws and lift off cover and shifter assembly. Remove nut on rear end of mainshaft at universal joint yoke and remove yoke from shaft (nut not used on later cars where yoke is free on mainshaft splines). Remove rear bearing retainer, take out snap ring and slide speedometer gear off Take out mounting screws and remove front bearing retainer. Drive countershaft out (see Note below), remove main drive gear and bearing through front of case. Move mainshaft assembly to rear until rear bearing free of case, tap bearing off shaft, then remove mainshaft through top of case. Lift counter gear cluster and thrustwashers out through top of case. To remove reverse idler gear, remove retaining capscrew and washers on rear end of shaft, drive shaft out through rear of case (use drift inserted through front of case), lift out reverse gear. Remove two countershaft thrust springs, use small punch to drive out thrust spring plugs.

C untershaft Note—Shaft must be driven out toward front (key in forward end of shaft engages slot in front end of transmission case). Use J-2559 countershaft assembly bar to drive shaft out and leave tool in counter gear cluster to retain bearing rollers until re-installed. Overdrive Model—Remove overdrive case drain plug (on rear end of case at bottom) and insert J-2559 tool through this hole to drive countershaft out.

OVERHAUL: Disassemble and overhaul all sub-assemblies as follows:

Synchronizer Unit: To disassemble, press outer sleeve off inner clutch hub by hand (CAUTION—use care not to lose detent plungers and springs which will fly out). Remove three retainer springs, lift out synchronizer rings. When reassembling, use Clamp J-2563 to hold plungers and springs in place, install synchronizer sleeve with wider shoulder of external groove on opposite end from extended hub of inner sleeve.

PACKARD TRANSMISSION

REASSEMBLY: After overhaul of sub-assemblies:

Synchronizer Travel Adjustment—Check clearance between lug on second-high shifter fork and stop on cover with shift lever in High Gear position. Clearance should be .005" min., .010" max. Adjust by bending lug. CAUTION—If clearance greater than .010", outer clutch sleeve may move too far forward which will allow synchronizer balls and springs to fly out (requiring removing cover & reassembling).

Mainshaft, Low & Second Speed Gear Assembly:—Both low and second speed gears are furnished as an assembly with the mainshaft and should not be removed. These gears are constant-mesh type and are mounted on double row ball bearings on shaft

Mainshaft Assembly: Install synchronizer on forward end of shaft with wider shoulder of external groove toward second speed gear, then install front bearing spacer on shaft. Install reverse gear on rear end of shaft with shifter groove toward rear or away from low speed gear.

Reverse Idler Gear: Align woodruff key in shaft with slot in case, tap shaft into case until it engages gear, install gear, drive shaft in until key is seated, secure shaft with plain washer, lockwasher, and capscrew.

Countergear Assembly: If roller bearings removed, first install assembly bar J-2559 in gear cluster, install bearing spacer, assemble 25 rollers in each end (use grease to retain rollers), install end plate and thrustwasher on each end of gear cluster. Install assembly in bottom of transmission case. **After main drive gear installed,** raise assembly up and insert countershaft through front of case aligning woodruff key with slot in case, drive shaft into place which will push assembly bar out at rear. Install two countershaft thrust springs in openings in case and install thrust spring plugs.

►*CAUTION*—Lips on countershaft thrustwashers must point upward and engage grooves in case.

Main Drive Gear Assembly: Install bearing and retaining ring on drive gear shaft, install snap ring. Install mainshaft pilot bearing in recess in rear end of gear.

Main Drive Gear & Mainshaft Installation: Place mainshaft assembly in case with rear end of shaft extending out through bearing hole, install rear bearing and retaining ring on shaft and tap bearing into place in case. Install main drive gear in case and enter mainshaft in front bearing. Install main drive gear bearing retainer using new gasket and aligning drain passage in cover with hole in case, tighten retainer capscrews. Install rear bearing plain washer, snap ring, speedometer drive gear (CAUTION—see that gear key in place), and gear snap ring.

►**Endplay Note**—Rear bearing and speedometer gear snap rings furnished in various thicknesses and should be selected to eliminate endplay.

Shifter Mechanism:—Yokes on horizontal shafts in cover engage synchronizer clutch sleeve (front shaft), low speed gear clutch and reverse gear (rear shaft) directly without intermediate linkage. Spring-loaded ball type detents are located in bracket on side of cover and engage sectors on shafts. Entire shifter mechanism located in cover and need not be dismantled when cover removed.

Interlock Assembly—If bracket removed, install parts as follows: Place interlock ball spacer and detent ball spring in bracket (interlock spacer toward center, detent ball spring toward outer edge of cover). Place cover on bench with top down, position forks so that center neutral grooves are in line, install bracket (CAUTION—hold detent and interlock balls in position in bracket, pull shoe ends of both forks together and push down on bracket at the same time so that balls engage center grooves. Install bracket retaining screw.

1948-52 BUICK DYNAFLOW

Series 40 & 50 (1949-52)—Optional
Series 70 (1948-52)—Standard

►CHANGES, CAUTIONS, CORRECTIONS

►**TRANSMISSION IDENTIFICATION (For Production Change & Parts Interchangeability Data):** Serial No. (first cars) or Identification No. (later cars) stamped on bottom face of transmission case on left side directly to rear of High Accumulator.

IDENTIFICATION NO. CAUTION—Where identification number used instead of serial number (prefix C, D, E and later), **the number following this letter (1, 2, 3, etc.) indicates manufacturing date and production changes** and is not a serial number.

1948 & Early 1949 Serial Numbers

Series 70	A-1 to A-98355
Series 50	B-1 to B-52325

Late 1949-52 Identification Numbers

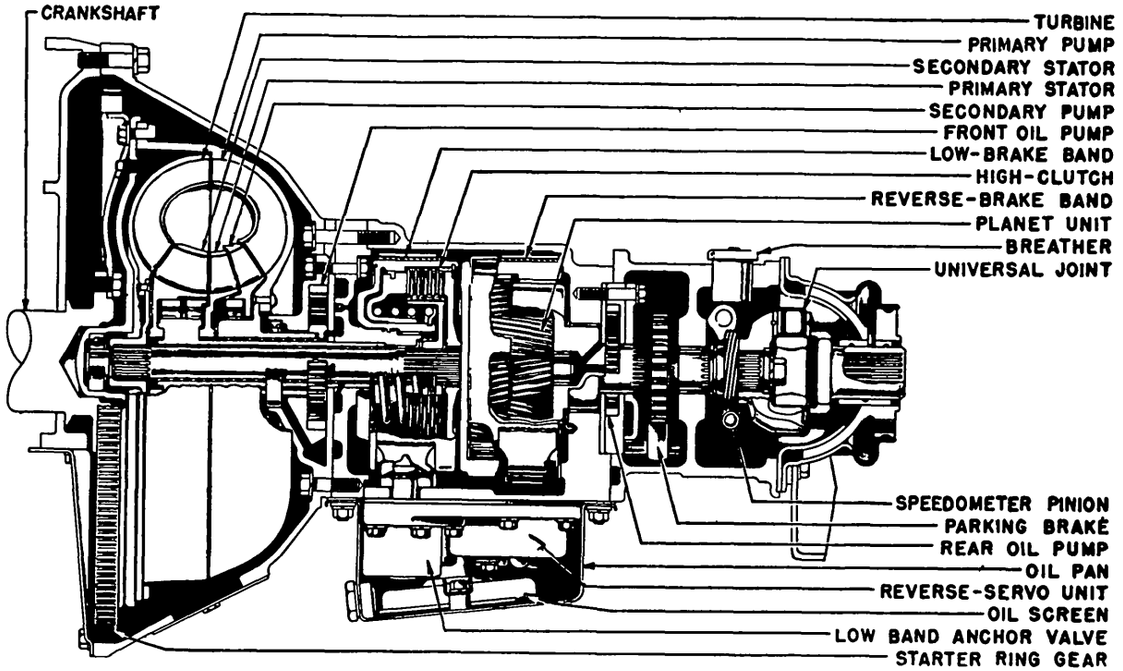
Series 50 (Late 1949)	D-1, 2, 3, etc.
Series 70 (Late 1949-50)	C-1, 2, 3, etc.
Series 40 & 50 (1950)	E-1, 2, 3, etc.
Series 40 & 50 (1951-52)	F-1—F-999 & H-1—H-999
Series 70 (1951-52)	G-1—F-999 & J-1—J-999

►*1951 & LATER BAND ADJUSTMENT CAUTION*—Floor pan openings not provided and bands cannot be adjusted on the car (transmission must be out of the car for access to band adjustment screws). *CAUTION—Bands on these cars must be properly adjusted BEFORE transmission is installed in car.*

►**ENGINE & TRANSMISSION VIBRATION CORRECTION (When Repl. Crankshaft or Flywheel Installed):** If vibration due to change in balance by installation of new parts, correct by installing balance weights on primary pump cover *See instructions at end of TRANSMISSION INSTALLATION data.*

►**STARTING ENGINE BY TOWING OR PUSHING CAR:** On Dynaflow cars, place control lever in neutral "N" position until car reaches a speed of 15 MPH., then shift to Low "L" position and continue to increase speed until engine cranks (at approximately 25 MPH.). After engine starts, return lever to Neutral "N" position for engine warm-up

►**USE OF EMERGENCY LOW FOR ADDITIONAL BRAKING ON GRADES:** Car speed should be reduced to below 40 MPH before control lever is moved from Drive "D" to Low "L"



►**TOWING DYNAFLOW CARS:** If Dynaflow Drive disabled, **car must not be towed with control lever in any driving range.** Car can be towed with lever in Neutral "N" position only at speeds **under 30 MPH.** but long distance tows not recommended

Neutral Safety Strap Installation—Can be installed over shift lever to lock transmission in neutral for towing when neutral position cannot be obtained or held by means of regular transmission control.

►**FRONT OIL PUMP & RELATED CHANGES (Beginning Trans. No. A-56000 & B1):** New cast iron type pump cover (and shorter heavier pump body with two locating dowels) supersedes previous type with recessed steel cover. **When installing this new cast iron pump cover to replace recessed steel cover, install all related parts as follows:**

Converter Primary Pump—New shorter primary pump must be used with cast iron pump cover. Can be identified by length of 1 13/16" from FLAT face of flange to end (first type 1⅞" from STEP on flange to end).

Reaction Shaft Flange—New ⅛" longer studs must be used with cast iron pump cover. These longer studs can be used with recessed steel cover (added length will not cause interference). First type Reaction Shaft Flange can be used by installing new square head bolts. See Reaction Shaft Bolt change.

1948-52 BUICK DYNAFLOW DRIVE

►**FRONT PUMP INTERCHANGEABILITY:** Only new heavier pump body (see above) furnished for service in two types for all installations:

1) Without Dowels and Dowel Holes—Use with first type recessed steel pump cover.

2) With Dowels—Use with new cast iron pump cover.

►**REACTION SHAFT FLANGE BOLT CHANGE (Beginning Trans. No. A-86000 & B-29000):** First type pump mounting studs with welded nuts superseded by square head bolts. Bolts can be installed to replace studs by running a 5/16" drill through the tapped stud holes, reaming holes to 21/64", and pressing in new square head bolts.

CAUTION—Holes must not be reamed oversize and flange must be supported when pressing bolts in. **Bolts must be press fit in flange.**

►**REAR OIL PUMP CHANGE (Beginning Trans. No. A-36000 & B-1):** Pump changed from separate body-and-cover design to one-piece integral type. **This new one-piece pump can be used to replace original type.**

►**VALVE & SERVO BODY CHANGES:** ***Three types used in production and for leakage corrections:***

1) Trans. No. A-1 to A-2999—Has been replaced by second type (following) as service correction for oil leaks. **Install second type Valve & Servo Body with second type Anchor Piston whenever this first type removed for any reason.**

CAUTION—Change transmission number by adding "-3" to number when above parts installed.

2) Trans. No. A-3000 to A-41999—May be identified by added ribs, change of left center bolt to a stud, adding of stud at center lower flange, and adding of boss and screw on lower flange. These changes require change in spacer plate and gaskets, and longer bolts where ribbing added. Low Band Anchor Piston changed from servo body spacer plate to transmission case (diameter of holes in spacer plate and gasket increased) and width of piston top land increased.

3) Trans. No. A-42000 & B-1 Up—New type which can not be installed in earlier transmissions due to changes in transmission case. May be identified by change of left center stud back to a bolt (same as 1), addition of bolt and copper washer in center, and Allen head screw added between low band anchor and reverse servo pistons.

NOTE—Beginning Trans. No. C-5, D-5, E-5; servo body spacer plate upper gasket changed due to change in case at reverse band anchor (see Reverse Ring Gear and Reverse Anchor Change Note).

►**OIL PAN & OIL SCREEN CHANGES:** First type oil screen and integral suction pipe superseded by separate screen and suction pipe beginning Trans. No. C-1 & D-1. **New type screen can be used to replace earlier type** and has rubber grommet at center for

CONTINUED ON NEXT PAGE

BUICK DYNAFLOW DRIVE (Cont.)

snug fit on suction pipe. New type suction pipe has cork gasket and coil spring for sealing.

New Oil Pan & Filler Pipe (Beginning Trans. No. C-2 & D-2): Pan has filler pipe extending forward on right side of car so that oil level can be checked and oil added from under-hood. This pan and oil filler can be installed on early cars if second type oil screen and separate suction pipe also used.

CAUTION—Filler pipe connecting hose is neoprene type marked by red stripe to prevent confusion with regular hose used between thermostat housing and water pump.

▷TRANSMISSION CASE CHANGES: *Various types used which are interchangeable only when other changes made as follows:*

1) Beginning Trans. No. A-42000 & B-1—Two tapped holes added for additional valve and servo body bolts (see 3rd. type Valve & Servo Body data above).

2) Beginning Trans. No. C-2 & D-2—Oil filler base removed (used with new oil pan having extended under-hood filler pipe). See Oil Pan Changes.

3) Beginning Trans. No. C-5, D-5, E-5—Transmission case openings changed to fit new forged type reverse band anchor. See Reverse Band Anchor Changes (following).

▷*TRANSMISSION CASE REPLACEMENT CAUTION*—Only latest type case (3 above) furnished for service. May be used with either 2nd. or 3rd. type Valve & Servo Body but must be used with new type Oil Pan & Under-hood Filler Pipe and forged type Reverse Band Anchor.

▷REVERSE RING GEAR CHANGE (Beginning Trans. No. A-42275 & B-1): Separate front thrustwasher eliminated and reverse ring gear width increased 1/16" to compensate for this thickness. First type Narrow Ring Gear (2 11/16" overall) must never be used without thrustwasher. Later type Wider Ring Gear (2 3/4" overall) can be used in earlier transmissions by discarding original thrustwasher but thrustwasher must never be used with this wider ring gear.

▷REVERSE BAND ANCHOR CHANGE (Beginning Trans. No. C-5, D-5, E-5): New one-piece forged anchor superseded previous two-piece type and is used with new band which has full width ends. These new parts require use of new transmission case with enlarged opening and new servo body spacer plate upper gasket (see Transmission Case Changes above).

▷*REVERSE ANCHOR REPLACEMENT CAUTION—It is recommended that forged type anchor be used to replace earlier type whenever transmission disassembled for any reason.* Forged type anchor may be used with early type narrow-end reverse band but transmission case must be altered as directed below. NOTE—web by tapping on center with hammer. File all only forged type Reverse Anchor and corresponding type Reverse Band and Transmission Case furnished for service.

Transmission Case Alteration (for installation of Forged Reverse Band Anchor)—Remove solid web between two reverse anchor openings in case by cutting grooves approximately 1/32" deep with a chisel (leave semi-circular area around hole near edge of new opening—anchor has notch to clear this area) between the openings and then knocking out edges to remove burrs and ridges. (CAUTION—keep chips and filings out of case). Check to see that operating lever works freely between ears on anchor and that servo body spacer plate screws are securely tightened.

CAUTION—On Trans. No. A-1 to A-2999, install second type Valve & Servo Body when making above changes.

▷LOW ACCUMULATOR SPRING & CAP CHANGE (Beginning Trans. No. C-5, D-5, E-5): See illustration for latest type springs and cap used to provide softer engagement of Low Band and smoother Low Range Shift. These new parts can be used to replace earlier type parts.

▷PRIMARY PUMP COVER & FLYWHEEL BOLT CHANGE: Various types used as listed below and all primary pump-to-cover bolts must be of same length and installed in same locations as originally to maintain converter balance.

1) Trans. before No. C-3, D-3, E-3—Short bolts (15/16") used without balance weights and where balance weights thin enough to allow full thread engagement, longer bolts (1 5/32") used with thick balance weights.

2) Trans. beginning No. C-3, D-3, E-3—All bolts 1 5/32" (same bolts as used to attach converter to flywheel).

3) Trans. beginning No. C-4, D-4, E-4—New nuts 21/64" thick used (supersedes 17/64" nuts). Only these new thicker nuts furnished for service.

CAUTION—New 21/64" nuts cannot be installed individually. If one nut used to replace earlier 17/64" type, REPLACE ALL NUTS.

4) Trans. F-261 through F-265 & G-261 through G-265. Special nuts used on these transmissions (trial run) can be identified by the slotted portion being turned down leaving hexagonal portion below the slots.

CAUTION—If any of these nuts replaced by regular production type nut, the nut diametrically opposite should also be replaced to maintain proper balance.

▷LOW BAND ANCHOR PISTON PRODUCTION CHANGE (Beginning Trans. No. E-9 & C-9): Anchor piston not used on these and later transmissions and band strut is anchored by a shaft in the transmission case. *Disregard all Low Servo Anchor Piston data (in Valve & Servo Body Disassembly & Assembly section) when working on these later transmissions.*

▷HIGH CLUTCH PISTON PRODUCTION CHANGE (Beginning Trans. No. F-164 & G-164): New High Clutch Piston with redesigned ball check valve (ball changed to opposite side of piston, relief hole enlarged, relieved area provided on face of piston for oil discharge). This later type piston, Part No. 1343578, is interchangeable with previous type and will be furnished for service for all transmissions.

▷SECONDARY PUMP PRODUCTION CHANGE (Beginning Trans. No. F-168 & G-176): New secondary pump assembly with cast boss which bears directly on primary pump hub (eliminates thrust washer used at this point with previous type pump). This new Secondary Pump, Part No. 1341727 (40, 50), 1341725 (70), is interchangeable with previous type

▷PRIMARY PUMP PRODUCTION CHANGE (Beginning Trans. No. F-341 & G-341): New design Converter Primary Pump and Cover assemblies (has "O" sealing ring in place of flat gasket and chamfer on inside corner of cover mounting flange for this ring) provides more positive seal against oil leakage. New and previous type covers are not interchangeable and new type can be identified by having only 15 assembly bolts.

▷*PRIMARY PUMP REPLACEMENT CAUTION*—New type Primary Pump only will be furnished for service replacement and whenever pump replaced, new type Cover, Seal, and related parts must be installed also. First type Cover will be furnished and can be replaced separately on cars having previous type primary pump. New type Primary Pump and Cover require different installation instructions and clearance shimming data (see Reassembly data).

▷HIGH CLUTCH PLATE PRODUCTION CHANGE (Series 70 Trans. Beginning No. G-310): New internally splined clutch plates used which are not interchangeable singly with previous type plates. These new plates may be identified by facing material (on one side, outer diameter faced with cork, inner diameter with "Krafelt"; on opposite side, outer diameter faced with "Krafelt", inner diameter with cork).

▷*REPLACEMENT CLUTCH PLATE CAUTION*—Above type plates not furnished for service at this time. If replacement of plates required, install entire pack of regular service internally and externally splined clutch plates.

▷PARKING LOCK APPLY SPRING CHANGE (Beginning Trans. No. A-11064 & B-1): New 3-coil type spring used (supersedes earlier 2-coil type). New spring requires new parking lock operating lever assembly with 1/16" longer spring step. Only the new 3-coil spring is furnished for service.

▷*PARKING LOCK REPLACEMENT CAUTION*—Manufacturer recommends that new 3-coil spring be installed on early cars whenever it is necessary to repair parking lock pawl. New Parking Lock Operating Lever (with 1/16" longer spring step) must also be installed when spring changed.

DESCRIPTION

The Dynaflow Drive consists of: (1) Torque Converter Assembly mounted directly on the flywheel in the bell housing, and (2) Planetary Gear Unit mounted in the transmission case directly behind the torque converter. Torque Converter action is entirely automatic while the Planetary Unit is controlled by the driver through a Control Lever on the steering wheel (provides Emergency Low, Reverse, Neutral, and Parking. Transmission controlled by hydraulic system for which oil pressure is supplied by two oil pumps built in the transmission (forward pump in recess in rear face of bell housing, rear pump in recess at rear of transmission case). An oil cooler on the side of the transmission case maintains oil at operating temperature.

Torque Converter Description: Torque converter consists of the five independent rotating members listed and the operation of the unit varies in accordance with car speed and load conditions as described below (transition from one type of operation to another is gradual so these phases should not be considered as distinct "steps").

(1) Primary Pump (Driving Member). Integral with rear half of case bolted directly on flywheel. Pump is positively driven by the crankshaft at engine speed at all times.

(2) Turbine (Driven Member). Splined on converter shaft and transmits drive to transmission.

CONTINUED ON NEXT PAGE

BUICK DYNAFLOW DRIVE (Cont.)

(3) Secondary Pump. Mounted on primary pump hub with overrunning "free-wheel" clutch which allows this pump to rotate faster than primary pump when unit is operating as a torque converter.

(4 & 5) Primary & Secondary Stators. Mounted on stationary "reaction" shaft (tubular shaft fixed in transmission case) with overrunning "free-wheeling" clutch in each stator hub. Stators are locked or held stationary when unit is operating as a torque converter (reaction members) but free-wheel when torque multiplication not required.

Planetary Unit Description: Planetary unit consists of parts listed below. Operation of unit depends on the position of the Shift Control Valve (linked to control lever on steering column) which directs application of hydraulic pressure in the planetary unit hydraulic mechanism as described below.

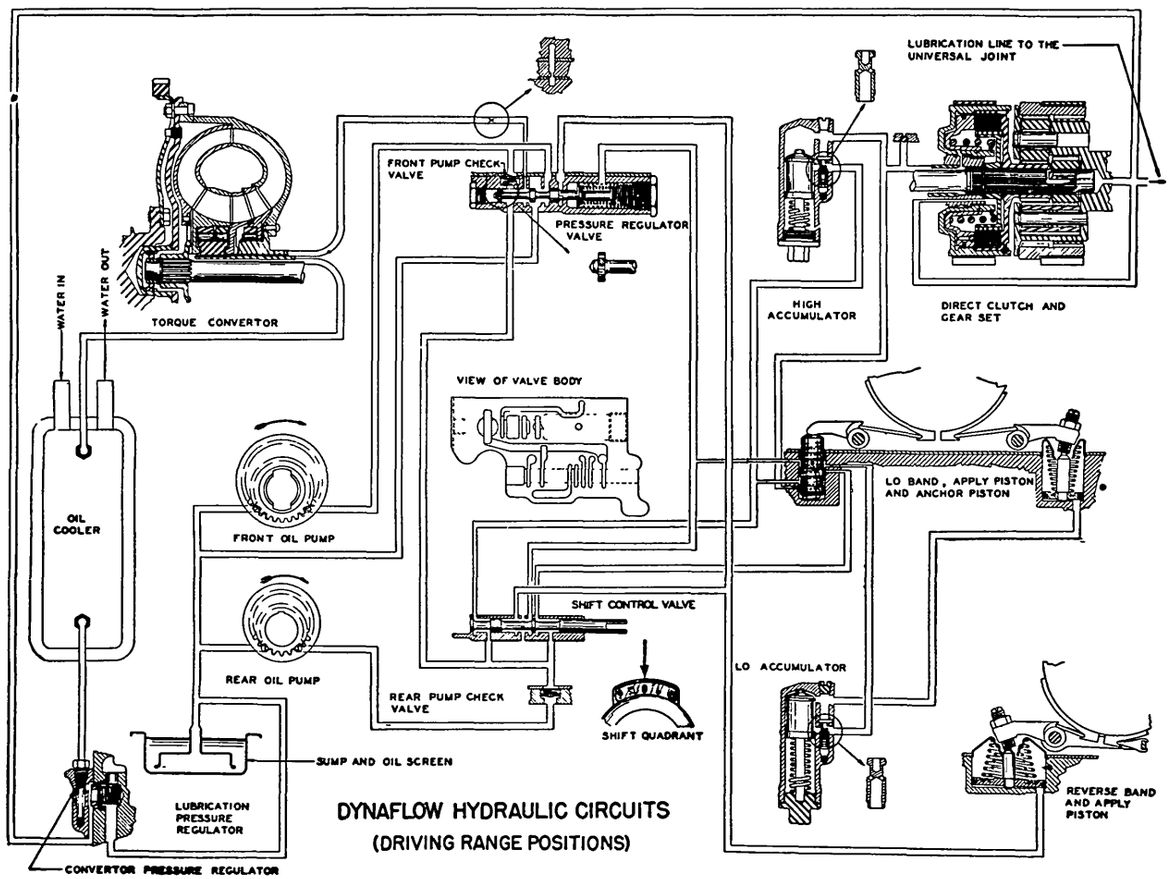
(1) Sun Gears—Consist of two gears in tandem on drive (input) shaft. Front Sun Gear (Low Range Reaction Gear) is integral with the Direct Drive Clutch (locked to shaft when clutch engaged) and meshes with the Reverse Planet Pinions. Rear Sun Gear (Reverse Sun Gear) is splined on the drive shaft (acts as driving gear for Low & Reverse) and meshes with the Low Planet Pinions.

(2) Planetary Pinions—Consist of three Reverse Planet Pinions (larger short gears) and three Low Planet Pinions (smaller long gears) mounted alternately on the Planet Carrier and all meshing together. The Reverse Planet Pinions mesh with the forward sun gear (Low Range Reaction Gear) and with the Reverse Gear (large internal gear controlled by the Reverse Brake Band). The Low Planet Pinions mesh with the rear sun gear (Reverse Sun Gear). The Planet Carrier is integral with the output shaft.

(3) Low Range Drum & Clutch—Mounted on drive shaft in front of the planetary pinion. Inner clutch member is splined on drive shaft and rotates with the shaft. Outer clutch member incorporates the Low Range drum and front sun gear (Low Range Reaction Gear) as well as the clutch engaging hydraulic piston and disengaging spring. Clutch engagement is controlled by the High Accumulator which permits rapid initial movement and smooth final engagement. A ball check valve is built in the clutch piston to insure complete draining of oil from the chamber when clutch disengaged for Reverse and Neutral. Check valve is positively closed by contact between ball and steel clutch plate when clutch engaged.

(4) Low Range Brake Band & Engaging Mechanism—Band holds Low Range Drum and front sun gear (Low Reaction Gear) stationary when it is applied by the servo "apply" piston acting through the lever and strut engaging one end of the band (servo action is controlled by the Anchor Piston and "Lo" Accumulator). This action requires a boosted oil pressure of 180 lbs. (normal pressure 90 lbs.) which is secured by boosting the Pressure Regulator Valve spring pressure hydraulically. Low Range operation also requires that the clutch be disengaged and this disengagement is secured by opening the clutch pressure line (Anchor Piston acts in conjunction with Shift Control Valve).

(5) Reverse Brake Band & Engaging Mechanism—Band holds Reverse Gear (internal gear) stationary when it is applied by the servo "apply" piston acting through the lever and struts engaging both ends of the band.



Oil Pumps & Hydraulic Control System: See the Hydraulic Circuit illustration for details of Dynaflow control units. These units operate as follows:

Front Oil Pump—This pump is driven by the engine and is of large capacity to provide necessary pressure and volume of oil for starting, low speed, and reverse operation. At car speeds above 45 MPH., rear pump takes over and front pump idles (oil bypassed back to suction side through oil pressure regulator). A check valve in the pump delivery line prevents oil bleeding back through the idling pump.

Rear Oil Pump—This pump driven from output shaft (driven by rear wheels when car pushed or towed) to operate direct drive clutch and fill torque converter when front pump not operating. Acts in conjunction with front pump at speeds below 45 MPH. and supplies all oil at speeds above 45 MPH. when front pump idles.

Pressure Regulator Valve—Controls pressure in main oil supply line (see Converter & Lubrication Pressure Regulator below) and limits pressure to 90 lbs. (80-90 lbs.) except when pressure boosted for Low Range operation. This boost is effected by supplementing regulator spring pressure with hydraulic pressure (acting on regulator stem piston) which increases pressure in system to 180 lbs. (160-180 lbs.).

Converter & Lubrication Pressure Regulator—Converter is filled with oil from metering orifice in Pressure Regulator Valve and returns to the oil sump through the Oil Cooler and Converter Pressure Regulator which maintains pressure in this circuit at 50 lbs. Oil is bled from this circuit at regulator for lubrication of transmission units (front oil line for Low Range Drum Bushing and Clutch Plates, rear oil line for Transmission Rear Bushing, Planetary Gears, Rear Bearing Retainer Bushing, and Universal Joint). Pressure in the lubrication circuits is maintained at 15 lbs. by the regulator.

1948-52 BUICK DYNAFLOW HYDRAULIC CIRCUIT—DRIVING RANGE POSITION

CONTINUED ON NEXT PAGE

BUICK DYNAFLOW DRIVE (C nt.)

Shift Control Valve—This valve is controlled by the lever on steering wheel and directs flow of oil for planetary unit operation (see Planetary Unit Operation above).

OPERATION

Dynaflow Drive Torque Converter automatically provides a torque multiplication ranging from an equivalent gear reduction of 2.24-2.4 to 1 (for Starting, Heavy Loads, and Acceleration) to an equivalent "High" 1 to 1 ratio (for Light Loads and Steady Driving when torque converter acts as a simple Fluid Coupling). The Planetary unit is controlled by the driver and provides definite gear ratios (in addition to the varying ratio of the torque converter) depending on the control lever position as follows:

Drive Range ("D" Lever Position)—Bands are released and clutch is engaged. This locks the front sun gear to the drive shaft, and as rear sun gear is splined on the drive shaft, no rotation of the gears is possible (both gears meshed with reverse pinions and tend to rotate pinions at two different speeds). The entire planetary gear assembly turns as a unit and the output shaft rotates at the same speed as the input shaft with resultant gear ratio of 1-1.

Low Range ("L" Lever Position)—Low Range Band is applied and clutch is disengaged (band holds front sun gear stationary). Drive shaft turns rear sun gear which meshes with Low Planet Pinions, and as these pinions also mesh with the Reverse Pinions which mesh with the stationary front sun gear, the reverse pinions "walk" around the sun gear rotating the Planet Carrier and output shaft in the same direction as input shaft but at slower speed to provide a gear reduction of 1.82-1.

Reverse ("R" Lever Position)—Reverse Band is applied and clutch is disengaged (band holds internal Reverse Gear stationary). Drive shaft turns rear sun gear which meshes with Low Planet Pinions, and as these pinions also mesh with the Reverse Pinions which mesh with the stationary internal gear, these Reverse Pinions move around the gear in a direction opposite to their direction of rotation, rotating the Planet Carrier and output shaft in opposite direction to input shaft and at slower speed to provide a gear reduction of 1.82-1.

Neutral ("N" Lever Position)—Both bands are released and clutch is disengaged. With all gears free to spin, no power is transmitted through the planetary unit and output shaft is stationary.

Parking Mechanism Operation: Control lever is linked to a stationary pawl anchored in the transmission case. Moving lever to park "P" position, engages pawl with ratchet wheel splined on output shaft in bearing retainer housing at rear of transmission and locks the drive shaft.

LUBRICATION

Check oil level at 1000 mile intervals and add oil as required. Drain and refill at 25000 mile intervals.

►***CAUTION—Oil must be warm and engine must be idling when checking oil level, warm up oil before draining.***

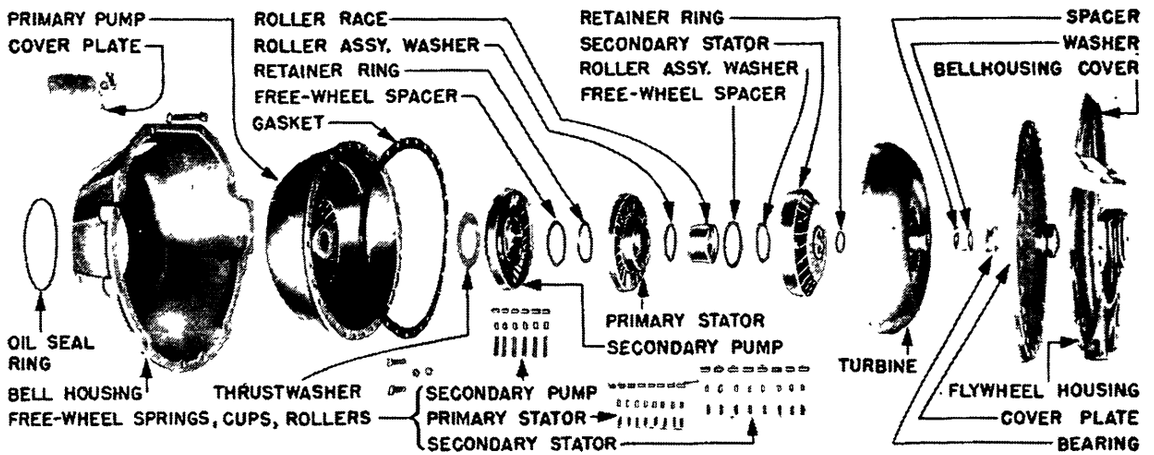
Checking Oil Level: With oil warm and engine idling with control lever in Parking "P" position, check oil level as indicated on dipstick in filler tube in engine compartment (on right side between battery and engine). If level more than 1" below FULL mark on rod, add recommended oil to bring level up to FULL mark *(CAUTION*—do not fill above the FULL mark). Distance between ADD OIL and FULL marks on rod is 1" or equal to approximately 1 pint of oil.

►***CAUTION—If oil level is consistently low when checked (indicating loss of 1 pint or more per 1000 miles), check transmission thoroughly for oil leaks.***

Oil Gauge Rod Location—Changed during 1949:

1948 & Early 1949 Cars—On right side of transmission case under floor, accessible by removing front floor pan cover.

Beginning 1949 Cars—In engine compartment, accessible by raising hood.



►***CAUTION—Do not confuse Dynaflow Oil Gauge Rod with Engine Oil Gauge Rod located near this same point.***

Draining & Refilling: With oil warm, drain transmission case by removing drain plug in oil pan, drain torque converter, after removing bell housing cover for access to drain plugs, by loosening one plug and turning converter until second plug is downward and removing this plug. Re-install and tighten all drain plugs. Install 3 quarts of recommended oil through filler opening in case. Start engine and allow it to idle with control lever in Parking "P" position, add additional oil to bring level up to point 1¾" below "FULL" mark on oil gauge rod. Recheck oil level after transmission warmed up. Oil level should then be at full mark on rod.

►***CAUTION—DO NOT FLUSH transmission when changing oil.***

Capacity—(40, 50) 8½ qts. (70) 10 qts. *NOTE*—1¾ pints additional required if transmission completely dry (after overhaul etc.).

Recommended Oil—Use only "Special Buick Oil for Dynaflow Drive" or "Automatic Transmission Fluid, Type A" with AQ-ATF number embossed on can.

DYNAFLOW DRIVE TORQUE CONVERTER & BELL HOUSING

LINKAGE ADJUSTMENT

LINKAGE ADJUSTMENT: Adjust all units in order and exactly as follows:

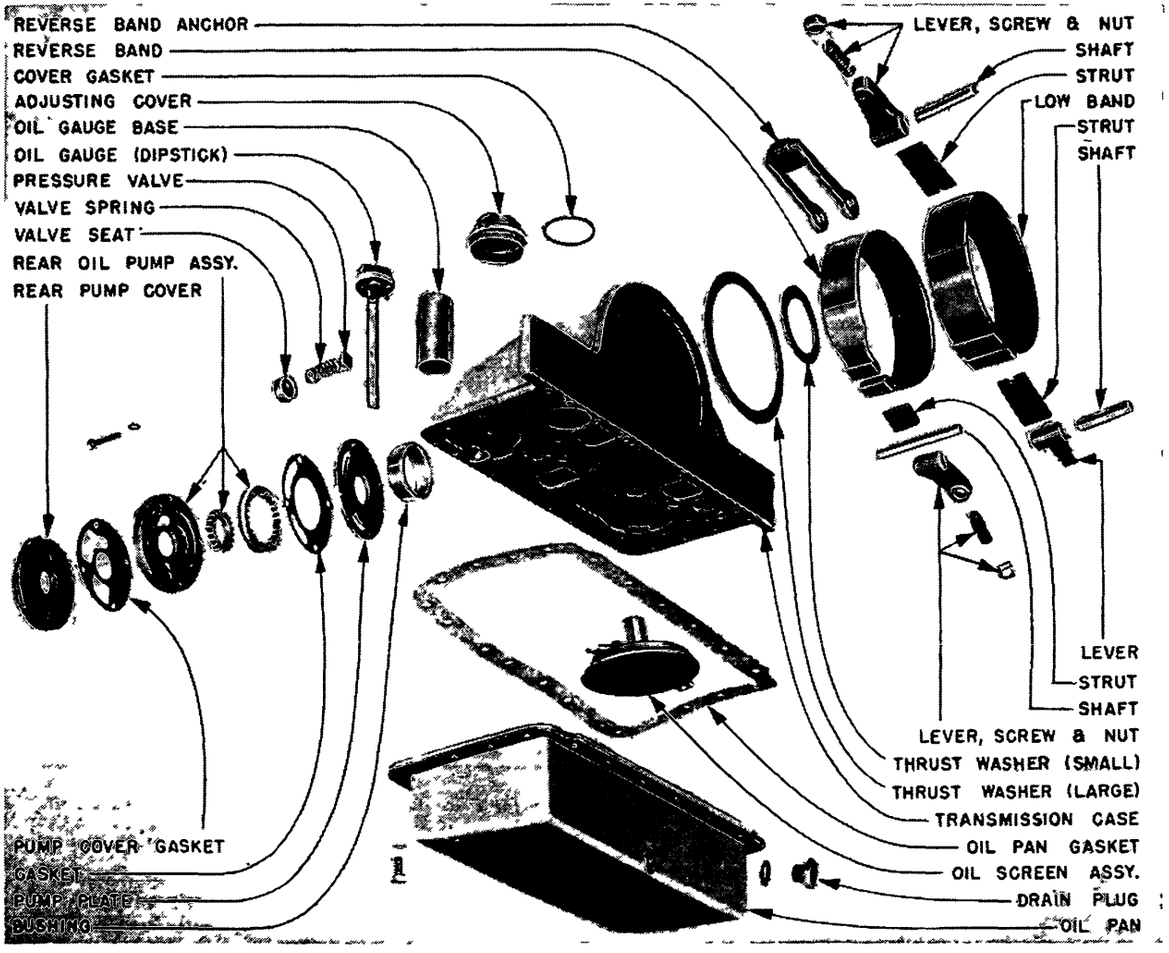
Manual Control Linkage: Transmission must be thoroughly warmed up (driven approximately 20 miles under traffic conditions with frequent starts and stops) and oil level must be correct. Then proceed as follows:

(1) Place shift control level in Neutral "N" with detent plunger centered in detent notch, move lever until stop pin is against stop in dial housing, note movement of dial pointer. Repeat this operation in Low "L" position. Dial pointer movement should be approximately equal in both positions. If not, loosen control detent mounting bolts on steering column jacket, shift detent until dial pointer travel is equal. Place lever in Low "L" position, carefully bend dial pointer, if necessary, so pointer is in line with "L" on dial.

(2) Check parking mechanism by placing car on ramp or steep grade with control lever in Parking "P". Parking lock should hold securely. Place control lever in Neutral "N" and allow car to roll. If "clicking" ratchet noise heard, or if parking lock did not hold car on grade, adjust as follows: Place control lever in Parking "P" position, disconnect shift rod from shift idler lever on steering column, pull forward on rod and move car slightly to make certain locking pawl fully engaged (CAUTION—do not jerk on rod). Check movement at lower end of shift lever on left side of transmission case by pressing forward on lever (against spring tension) until definite stop is felt. This movement should be 1/8-3/16" beyond the parking "P" position. If spring travel not within these limits, control valve is out of adjustment (requires removal of torque ball). If spring travel correct, pull shift rod forward against stop, adjust shift rod clevis until clevis pin can just be entered in hole in idler lever with control detent engaged in

CONTINUED N NEXT PAGE

BUICK DYNAFLOW DRIVE (C nt.)



Parking "P" position, then lengthen rod by unscrewing clevis 3 full turns, connect rod temporarily (may require readjustment in next step).

(3) Place shift control lever in Neutral "N" position with detent fully engaged, install Shift Control Linkage Adjustment Gauge No. J3085 on dial housing with line under "N" centered on dial pointer. With transmission warm and engine idling at 600 RPM., move control lever from Neutral "N" to Drive "D" position slowly. Clutch should engage (noted by immediate decrease in engine speed) when tip of dial pointer is behind long gauge mark midway between "N" and "D" on speed ratio dial (width of mark is allowable variation in shift point). Move control lever from Drive "D" to Neutral "N" position slowly. Clutch should disengage (noted by immediate increase in engine speed) when tip of pointer is behind midway mark on gauge. If clutch engagement and disengagement points not correct, readjust clevis on shift rod at shift lever (see (2) above), being careful not to disturb Parking adjustment. Do not connect shift rod permanently until adjustment (4) completed.

►*CAUTION—When making above adjustment, do not change shift rod length so much that parking lock fails to hold or pawl contacts ratchet wheel in Neutral (check as directed in (2) above).*

(4) Check operation in Low "L" and Reverse "R" positions. Detents should be engaged and shift points should occur when tip of dial pointer is directly behind mark midway between "D" & "L" (Low), midway between "L" & "R" (Reverse). If shifts do not occur at correct points, check for bent transmission shift lever, bent valve operating upper lever, or lever loose or incorrectly seated on shaft.

(5) After above adjustments completed, tighten clevis nut on shift rod clevis and permanently install clevis pin with plain washer and spring washer on each side of clevis.

TRANSMISSION CASE, REAR OIL PUMP, & SERV BAND ASSYS.

►*CAUTION—Neutral Safety Switch and Back-up Light Switch must be checked after changing control detent and shift rod adjustments.*

Throttle Linkage & Dash Pot—Must work freely and smoothly. *See adjustment data under "Carburetor" on Buick car model pages.*

Starter Vacuum Switch: If operation not correct after carburetor linkage and dash pot adjustments made, *See "Stromberg Starter Switch" and "Carter Car Starter" in Electrical Equipment Section for checking and adjustment of these switches.*

Neutral Safety Switch: Located on control lever linkage at lower end of steering column and connected in starter control circuit so that starter operative only with Dynaflow control lever in Neutral "N" or park "P" position. Switch should be closed in neutral and should remain closed until lever moved toward Drive position enough to move outer end of control lever pointer 5/32" (if switch opens with less than ⅛" pointer travel, starter may not operate in neutral; if more than 3/16" pointer travel required to open switch, starter may operate in Drive "D" position and cause starter to move car). Check and adjust switch as follows:

Checking Neutral Switch—Ground coil terminal on distributor so that engine can be cranked without starting. Firmly set parking brake. Place Dynaflow control lever in neutral "N" position (check to see that detent firmly engaged). Install Shift Control Linkage Adjustment Gauge J3085 on dial housing so that short line under "N" is centered on dial pointer. Move control lever to Driving "D" position, turn ignition on, depress accelerator pedal to close starter vacuum switch. Move control lever slowly from "D" toward "N", note position of center of dial pointer at instant starter begins to operate, release accelerator pedal. Center of dial pointer should be within limits of short line to right of "N" mark on gauge (provides required limits of 1/8-3/16" out of neutral). If not within these limits, adjust as directed below.

Adjust Neutral Switch—Place control lever so dial pointer centered on short line to right of "N" mark on gauge J3085 and hold the lever in this position while adjusting. Loosen the two mounting bolts on switch bracket at lower end of steering column, raise switch up as far as possible. With ignition switch turned on and accelerator pedal depressed, tap switch down until starter just begins to operate, then tighten switch mounting bolts being careful not to change switch position. Recheck switch adjustment.

Back-up Light Switch: Check and adjust after transmission control detent adjusted as follows:

1948 Switch—Place control lever in Reverse "R" position, check clearance between switch operating arm and nearest edge of switch mounting bracket. If this clearance not 15/32", loosen two switch mounting screws and shift switch on bracket (screw holes are slotted).

1949 & Later—Place control lever in Low "L" position, check clearance between switch operating arm and lower edge of control shaft lower lever. If this clearance not 0" to 1/16", loosen two switch mounting screws and shift switch on bracket (screw holes slotted).

C NTINUED N NEXT PAGE

BUICK DYNAFLOW DRIVE (Cont.)

BAND ADJUSTMENT

▷*BAND ADJUSTMENT CAUTION—Floor pan openings are not provided and Bands cannot be adjusted with transmission in car (bands must be correctly adjusted before transmission installed).*

LOW & REVERSE BAND ADJUSTMENT: Adjust only if chatter or slip in low and reverse severe or objectionable, (slight chatter as car starts in reverse, disappearing when car in motion, is normal). Adjust bands as follows:

(1) Remove front floor mat, insulation pad, and transmission opening cover from floor pan.

(2) Use tool J2655 to remove band adjusting cover and gasket (Covers are shallow sheet metal cups on upper right (Low), left (Reverse) of transmission case.

(3) Loosen locknut and turn adjusting screw clockwise until considerable resistance felt indicating that band in full contact with drum or ring gear.

(4) Back off screw until trace of endplay noted when prying up on locknut with screwdriver, then back off screw additional six complete turns, hold screw from turning and tighten locknut snug.

(5) Note position of adjusting screw slot, use torque wrench to tighten locknut to 20-25 ft. lbs., check screw slot to make certain that screw position not changed.

(6) Install band adjusting cover using new gasket.

NOTE—Both Low and Reverse Bands adjusted alike as directed above.

TESTING HYDRAULIC UNITS

If performance not satisfactory, make following tests with transmission thoroughly warmed up and at operating temperature:

Oil Level: Check oil level, add fluid as necessary to bring level up to FULL mark on dipstick, recheck performance with correct oil level. If car has been losing oil at rate of 1 pint or more each 1000 miles, make thorough check for oil leaks.

Manual Control Linkage: Check and adjust manual control linkage. See Linkage Adjustment.

Hydraulic Control System Pressures: Use Transmission Oil Pressure Gauge J-2575. Support rear end of car solidly with wheels off floor so that transmission can be operated. Remove transmission cover in floor pan for access to pressure take-off points. Connect gauge and make tests as follows:

Front Oil Pump—Connect pressure gauge at pipe plug opening on left side of reaction shaft flange. Run engine at 500 RPM., check pressure with selector lever in Low, Drive, and Reverse range. Repeat tests at 1000 RPM. and at 1800 RPM. in Low and Drive Range only. See table below for correct pressures. Low or erratic pump pressure indicates air leaks in suction line, improper pressure regulator valve action, or excessive pump clearances.

Front Oil Pump Pressures

Selector Lever—	Low	Drive	Reverse
500 RPM.	100 lbs.	90 lbs.	100 lbs.
1000 RPM.	160 lbs.	90 lbs.	
1800 RPM.	180 lbs.	90 lbs.	

Rear Oil Pump—Connect pressure gauge at pipe plug opening in lower flange at front end of rear bearing retainer. Run engine at 500 RPM., check pressure with selector in Low & Drive Range. Repeat test at 1000 RPM. and 1800 RPM. See table below for correct pressures. Low or erratic pump pressure indicates air leaks in suction line (this will affect both pumps), improper pressure regulator valve action, excessive pump clearances, or leak in valve and servo body passages between pump and regulator valve.

Rear Oil Pump Pressures

Selector Lever—	Low	Drive
500 RPM.	75 lbs.	90 lbs.
1000 RPM.	125 lbs.	90 lbs.
1800 RPM.	175 lbs.	90 lbs.

High Accumulator—Connect pressure gauge at pipe plug opening on top of accumulator body (left side of car). Place selector lever in Drive range. Run engine and check pressure at 500 RPM. (should be 80 lbs.), and at 1000 RPM. and 1800 RPM. (should be 85 lbs.). Low accumulator pressures may be caused by leakage past accumulator body gasket. If accumulator pressure more than 10 lbs. lower than front oil pump pressure, check for leakage between accumulator and multiple disc clutch and for restricted or plugged metering orifice in accumulator dump valve.

Low Accumulator—Connect pressure gauge at pipe plug opening on top of accumulator body (right side of car). Place selector lever in Low range. Run engine and check pressure at 500 RPM. (should be 90 lbs.), at 1000 RPM. (should be 150 lbs.), and at 1800 RPM. (should be 170 lbs.). Low accumulator pressures may be caused by leakage past accumulator body gasket. If accumulator pressure more than 10 lbs. lower than rear oil pump pressure, check for leakage between accumulator and low servo and for restricted or plugged metering orifice in accumulator dump valve.

TROUBLE SHOOTING

CAR WILL NOT MOVE (Rear wheels may be locked or free).

1) With selector in any Range (rear wheels free).

If car will not move for 1-8 minutes after standing over night—Check front pump oil pressure (see Testing) after allowing car to stand for several hours. If zero pressure noted, check pump for excessive clearances allowing pump to lose its prime. Check alignment of bell housing and converter primary pump hub.

▷*CAUTION—If this condition found, inspect Clutch and Bands for excessive wear due to slippage caused by low oil pressure.*

If car will not move after extended operation in Reverse—Check for air leaks in pump suction line (at rear oil pump gaskets), or excessive clearance in front pump (at pump gears and cover). Check alignment of bell housing and converter primary pump hub.

2) With selector in any Range (rear wheels locked). Parking lock engaged. Broken parts in transmission or rear axle. Parking brake applied.

3) With selector in Drive Range. Check front oil pump pressure and High Accumulator pressure. If OK, check for sticking Low Band Anchor Piston, remove and inspect Clutch for worn or sticking clutch plates, leaking clutch seal rings. If High Accumulator pressure low, also check rear pump Check Valve for correct installation and proper seating, check for leaks at accumulator body gasket, reaction flange gasket, clutch piston outer seal and clutch ball check valve, and leaks at sealing rings on reaction shaft flange and low drum.

4) With selector in Reverse Range. Check reverse band for displaced operating strut caused by too loose adjustment, improper installation, or broken band anchor (indicated by free up and down movement of band operating lever). If band assembly OK (no free movement of lever), check servo operation by running engine and shifting into Reverse. Remove Valve & Servo Body and check for reverse servo piston seal leaks.

EXCESSIVE SLIPPAGE (High engine speed in relation to car speed, or poor acceleration).

1) In all Speed Ranges. Low oil level. Incorrect manual control linkage adjustment. Air leak in oil pump suction pipe at oil screen sealing ring. Low front oil pump pressure caused by wear or excessive clearances in pump. Leaks at front pump cover or reaction shaft flange, pressure regulator valve, Valve & Servo Body gasket. Pressure regulator valve defective.

2) In Drive Range. Incorrect manual control linkage adjustment. If High Accumulator pressure low, check for leak at accumulator body gasket; if gasket OK, check for leaking clutch sealing rings, sticking clutch piston, worn or sticking clutch plates.

3) In Low Range. Incorrect manual control linkage adjustment. Incorrect low band adjustment. Low band and drum worn or scored. If Low Accumulator pressure low, check for leak at accumulator body gasket; if gasket OK, remove Valve & Servo Body and check for gasket leaks or leaks at low servo piston seal.

4) In Reverse Range. Incorrect manual control linkage adjustment. Reverse band out of adjustment, strut out of place, or anchor broken. If front oil pump pressure low, remove Valve & Servo Body and check for gasket leaks and leaking reverse servo piston seal.

CAR CREEPS (Forward or Backward).

1) Creeps forward with selector in Neutral. Incorrect manual control linkage adjusment. Sticking low servo piston (check by removing low band adjustment cover). Sticking clutch caused by warped, binding, or incorrectly assembled clutch plates (not stacked properly with "dish" in same direction).

If Car Creeps only when engine accelerated to 2500 RPM—Check clutch vent ball checks in clutch piston and reaction shaft flange.

2) Creeps forward with selector in Reverse or backward with selector in Low. Incorrect manual control linkage adjustment.

SHIFTS ARE ROUGH.

1) Low-to-Drive Shift. Incorrect Low Band adjustment. If High Accumulator pressure low, check for leak at accumulator body gasket and for dump valve or accumulator piston sticking down (top land of piston should be visible through top port in body). Sticking low band anchor piston (remove Valve & Servo Body to check), or incorrect piston location (see piston shimming data in Valve & Servo Body Reassembly). Valve & Servo Body gasket leaks. Clutch plates worn or binding.

CONTINUED ON NEXT PAGE

BUICK DYNAFLOW DRIVE (C nt.)

EXCESSIVE CHATTER OR CLUNK WHEN STARTING

►*CAUTION—Slight "clunk" when shifting into Low or Reverse is normal, and slight chatter when car starting to move in reverse (disappearing as soon as car in motion) is also normal.*

1) In Low & Reverse Range. Incorrect Low or Reverse Band adjustment. Engine and transmission mountings loose or incorrectly adjusted, thrust pad at transmission mounting broken (see Engine Mountings in Buick Special Data). Clutch plates warped, sticking, or incorrectly assembled (not stacked properly with "dish" in same direction). Reverse ring gear bushing worn. Planet pinion needle bearing rough.

NOISE IN TRANSMISSION.

►*CAUTION—Hum or low whine in Neutral or Parking is normal (due to free rotation of all planetary gears) and slight hum in Low and Reverse may be expected.*

1) Buzzing Noise. Low oil level. Front pump check valve hanging up on edge of gasket between valve and servo bodies. If noise noticed in Parking or Neutral, pressure regulator valve clearance in body may be excessive or orifice in valve land oversize (correct by replacing valve and body).

2) Clicking Noise. If noticed in all ranges, may be caused by foreign material in converter. If noticed only when car in motion, may be caused by parking lock pawl contacting ratchet wheel due to incorrect manual control linkage adjustment.

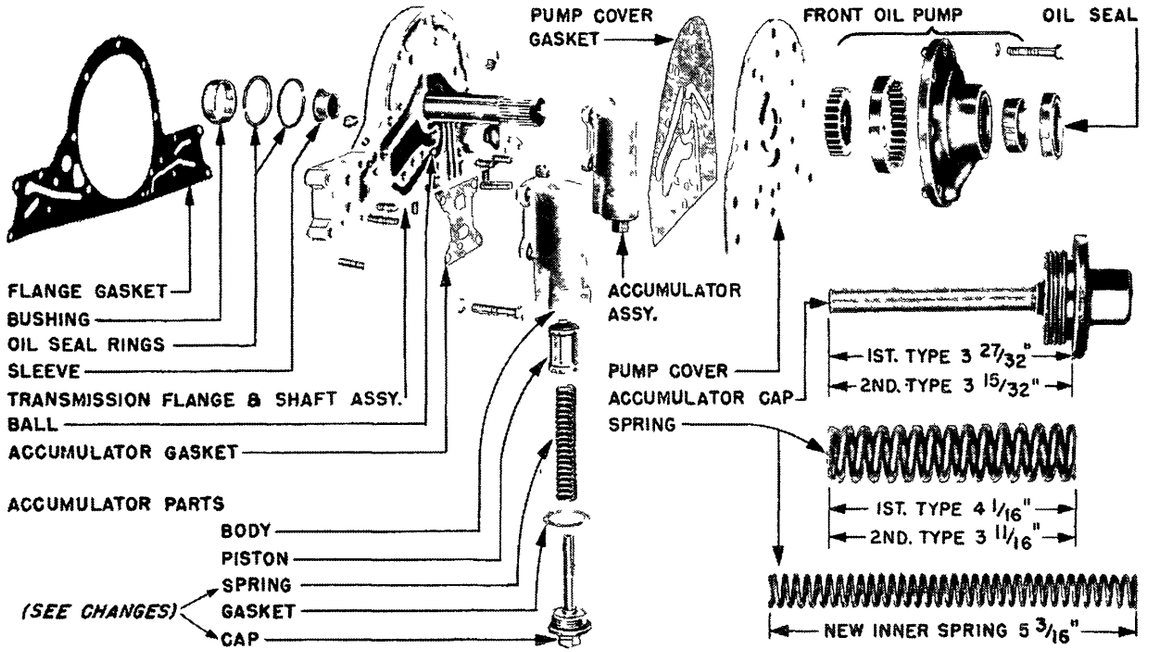
3) Abnormal Hum or Whine (see Caution above). If noted in all ranges, may be caused by worn parts or excessive front pump clearances (front pump noise will increase in Low and decrease at car speeds above 45 MPH. in Direct Drive). Check front pump for excessive clearances by testing for low pump pressure. If noise noted in all ranges except Direct Drive, may be caused by trouble in planetary gears (gears locked out in Direct Drive).

4) Squealing or Screeching following installation of Front Oil Pump. Pump driving gear installed backward. On transmissions before Serial No. A-56000, may be caused by installation of thick front pump cover **without changing** converter primary pump (see Production Change note on Front Oil Pump & Related Changes).

►*CAUTION—Above condition must be corrected WITHOUT FURTHER OPERATION OF TRANSMISSION or severe damage will result.*

REMOVAL FROM CAR

Transmission and Torque Converter are removed as a unit as follows:



1) Remove bell housing dowel bolt to rear of starter solenoid using an offset brass drift and working from under the hood on the right side (this bolt cannot be removed from beneath car).

2) Support car securely on stands under frame with frame rails at least 20" above floor.

3) Disconnect torque tube at torque tube ball and move rear axle back to disengage propeller shaft from universal joint.

4) Remove bell housing cover and bell housing hand hole cover.

5) Drain converter and transmission oil pan (see draining data under LUBRICATION).

REACTION SHAFT FLANGE, ACCUMULATOR, & FRONT OIL PUMP ASSY. (SHOWING LOW ACCUMULATOR SPRING CHANGE)

6) Disconnect oil cooler pipes at transmission case connectors, free oil cooler bracket from transmission and tie oil cooler up to frame out of the way.

NOTE—Oil cooler can be removed by disconnecting water hose connections.

7) Disconnect oil filler pipe (later under-hood type) at hose connector. Disconnect transmission control rod at both ends and remove rod. Disconnect speedometer cable.

8) Disconnect thrust pad from transmission support by removing three nuts and taking out plate and adjusting shims. Remove two bolts and plate attaching mounting pad to transmission support.

9) Install engine support bar under rear end of engine oil pan, adjust support snugly under pan.

NOTE—Support bar can be made up of piece of 2x4 straight grain hardwood with 5/8" bolt at each end (bolts 25" center-to-center). Bolts should have 2½" hook at upper end to engage frame side rail and sufficient threaded length at lower end to allow support bar to be adjusted under oil pan.

10) Install hoist in front compartment (will require removal of floor pan opening cover) or transmission jack to support transmission weight.

11) Raise engine and transmission with engine support bar (9) and jack or hoist (10) to relieve load on transmission support. Remove support by taking out bolts in frame X-member, remove thrust pad from thrust plate on transmission.

12) Mark flywheel, converter primary pump, and cover with paint to insure reassembly in exact same relative positions.

CAUTION—This is necessary to maintain balance.

13) Disconnect converter from flywheel by taking off nuts on mounting bolts (nuts on front face of flywheel and are accessible through housing cover opening on front of bell housing).

14) Lower engine and transmission just enough so that top bolts in bell housing are accessible (can be removed from above if floor pan cover removed), disconnect bell housing by taking out all attaching bolts.

►*CAUTION—Make certain that both engine and transmission securely supported before loosening these bolts.*

15) Move transmission straight back to disengage converter pump cover from crankshaft, then lower transmission and remove from beneath car.

DISASSEMBLY

►**DISASSEMBLY CAUTION:** *CLEANLINESS IS EXTREMELY IMPORTANT when disassembling and working on transmission. Thoroughly clean exterior before disassembling, use CLEAN tools on a CLEAN workbench, provide CLEAN storage space for all parts, and separate parts to avoid nicking or burring of ground and polished surfaces.*

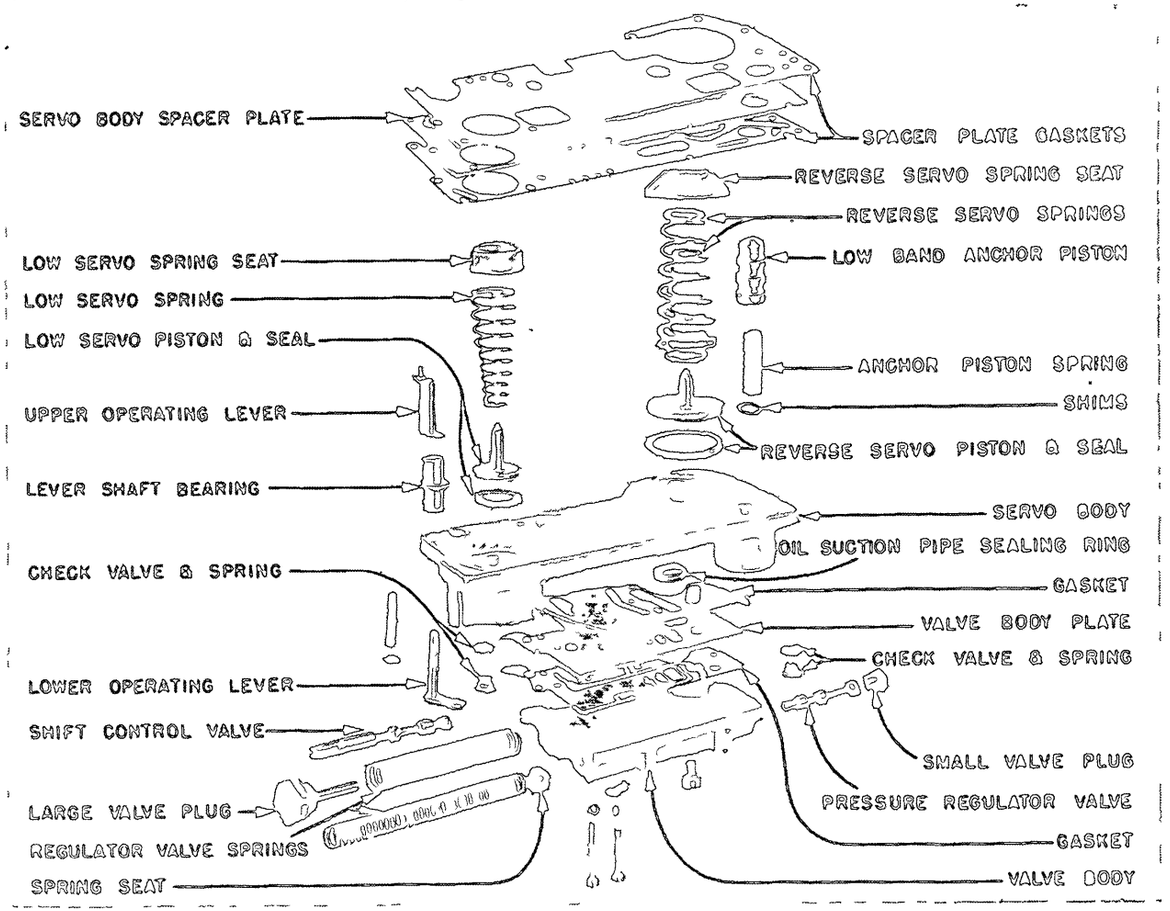
DISASSEMBLY OF TRANSMISSION (into Major Components): With transmission on bench, first remove shift lever by taking off retaining nut and lockwasher on shaft while holding lever forward (to avoid strain on linkage), remove oil cooler and pipes if this unit removed with transmission, remove both band adjustment covers and gaskets using Remover Tool J-2655, remove oil gauge rod (first

CONTINUED ON NEXT PAGE

BUICK DYNAFLOW DRIVE (Cont.)

type transmission). Remove both pipe plugs in primary cover to completely drain converter. Then place transmission on bench with oil pan upward and remove various sub-assemblies as follows:

Converter & Bell Housing Removal—Take out all primary pump cover nuts and bolts (CAUTION—insert punch in drive bolt holes through bell housing hand hole to keep cover from turning), screw three 5/16"-18 capscrews into tapped holes in pump cover to loosen cover, remove cover. Remove converter spacer and shim washers (on input shaft or in bearing recess in pump cover). Press on end of input shaft (to prevent shaft coming out) and withdraw converter turbine. Check stators for freewheel clutch slippage before removing these parts (stators should rotate freely in clockwise direction but lock when turned in opposite direction), use narrow pointed tool to remove retaining ring from reaction shaft, remove both stators as a single unit (CAUTION—separating stators will allow clutch parts to fly out). Check secondary pump for freewheel clutch slippage (pump should rotate freely in clockwise direction but lock when turned in opposite direction). Pull primary and secondary pumps off reaction shaft and immediately check for evidence of oil leakage (streaks of fresh oil on back of primary pump and fresh oil running down face of front oil pump indicate leakage past oil pump seal—if leakage noted, check for loose bell housing bolts) Take out bell housing attaching bolts, remove bell housing, check rubber oil seal for uniform compression (if seal not compressed uniformly, check around oil pump and in bell housing opening for burrs or foreign material preventing uniform seal compression). *See Overhaul data for disassembly of converter stators and pump.*



Oil Pan and Valve & Servo Body Removal—*Not necessary to remove other parts prior to this operation.* Remove oil pan and gasket. On transmissions with first type oil screen, examine oil screen suction pipe impression on sealing ring in servo body recess (ring should show full impression of end of suction pipe indicating no air leakage at this point), remove sealing ring. On transmissions with second type oil screen, lift screen away from suction pipe, remove suction pipe spring support and retaining spring, remove suction pipe and cork gasket from recess in servo body. Disconnect valve operating rod from upper valve operating lever by inserting screwdriver blade through hole in case and pressing rod away from lever (ball stud on lever engages spring socket in rod). Loosen all valve & servo body attaching screws slightly but do not loosen slotted safety nuts on valve-to-servo body studs, turn all screws out evenly to relieve anchor piston spring tension, (not necessary on C-9, E-9 and later transmissions), pry assembly upward lightly to free gasket, push shift control valve and lower operating lever inward to align lever with transmission case opening, lift assembly off while supporting anchor piston to prevent it falling out (piston not used on C-9, E-9 and later models). Use care to avoid slotted end of shift control valve which has sharp edges when lifting on assembly. Remove gasket and check for evidence of oil leaks. Remove reverse band operating strut (support strut with finger extended through adjustment hole to prevent it falling into case, release strut by raising operating lever). *See Overhaul data for disassembly of valve & servo body.*

Reaction Shaft Flange, Front Oil Pump, and Accumulator Removal—*Converter & Bell Housing and Oil pan must be removed first but Valve & Servo Body need not be disturbed.* Loosen but do not remove both accumulator body caps (will facilitate removal later). Remove three attaching capscrews from each accumulator body but do not disturb stud nut. Remove capscrews extending through front oil pump cover but do not remove stud nuts (first type has one capscrew and two stud nuts, later type has two capscrews and one stud nut). Tap lightly on rear of accumulator bodies with fiber hammer to loosen reaction shaft flange, remove assembly and gasket from case leaving input shaft in transmission. Examine gasket for uneven impression or other evidence of oil leaks.

Input Shaft, Clutch, & Low Range Band Removal: *All parts listed in preceding removal sections must be removed first.* Pull input shaft and clutch hub front thrustwasher out of transmission (thrustwasher will come out on shaft), then lift out clutch assembly. Use screwdriver to block low band anchor lever (transmissions C-8 & E-8 and earlier), compress the low band with the operating lever (later transmissions), install Band Installing Clip J-2595 across band strut flanges to keep band compressed, release the lever and lift band out of case, lift out band struts (will drop down in case when band removed). Remove the low band anchor lever and operating lever by threading a ¼-20 capscrew in end of each lever shaft and pulling shafts out of case. *See Overhaul data for clutch disassembly.*

Torque Ball & Universal Joint Removal: *Does not require removal of any other parts first.* Remove torque ball rubber boot. Take out attaching bolts in thrust plate, remove thrust plate and gasket, torque ball inner and outer retainers, and paper adjusting shims. Remove speedometer driven gear and sleeve assembly. Lock drive shaft by engaging parking lock pawl (use shift lever to press forward on shift lever shaft while turning universal joint until pawl engages), remove universal joint bolt, lockwasher, and flat washer, pull universal joint using puller J-882A (40, 50), J-859A (70).

CONTINUED ON NEXT PAGE

VALVE & SERVO BODY ASSY.
(ANCHOR PISTON NOT USED ON C9, E9, & LATER TRANSMISSIONS)

BUICK DYNAFLOW DRIVE (C nt.)

Rear Bearing Retainer & Parking Lock Ratchet Whe l Removal: ***Torque Ball, Universal Joint, and Oil Pan must be removed first.*** Disconnect valve operating rod from upper operating lever by inserting screwdriver through hole in case and pressing rod away from lever (ball stud on lever engages spring socket in rod). Remove universal joint retaining ring from slot in output shaft (use screwdriver and hammer to free ends of this lock ring). Take out retaining bolts and remove rear bearing retainer and gasket, check gasket for evidence of oil leakage. Take out ratchet wheel outer retaining ring (use snap ring pliers to free ring), slide ratchet wheel off output shaft, remove inner retaining ring. *See Overhaul data for disassembly of rear bearing retainer.*

Rear Oil Pump and Lubrication Oil Pressure Regulator Valve Removal: ***Rear Bearing Retainer (preceding) must be removed first.*** Take out retaining bolts and remove pump body and gears as an assembly (on first transmissions, separate cover and gasket used). Check gaskets for evidence of oil leakage. Remove pump drive key from shaft recess, remove rubber cushion located under drive key with a pointed tool. If possible, lift off rear pump plate and gasket (if plate sticks, tap plate out **after planetary gear set removed**). Check gasket for evidence of oil leakage. Remove lubrication pressure oil regulator valve seat from rear face of transmission case (use special drag link socket to turn valve seat out), remove valve and spring.

Planetary Gear Set, Reverse Ring Gear, and Reverse Brake Band Removal: ***All parts listed in preceding removal sections must be removed first.*** Pull planetary gear set out through front of transmission case. Lift out reverse ring gear and two planet carrier thrust washers (if these parts did not come out with planetary gear set). If rear oil pump plate and gasket not removed previously (see above), tap out with hammer handle inserted through front of case. Remove reverse band operating lever by threading a ¼"-20 capscrew into tapped hole in anchor shaft and pulling shaft out, then lift out lever. Rotate reverse band toward adjusting hole until anchor accessible, disengage and lift out anchor. Compress reverse band and install Band Installing Clip J-2595 across strut flanges to hold band compressed, lift band out. Remove reverse ring gear thrust washer from case. *See Overhaul data for disassembly of Planetary Gear Set.*

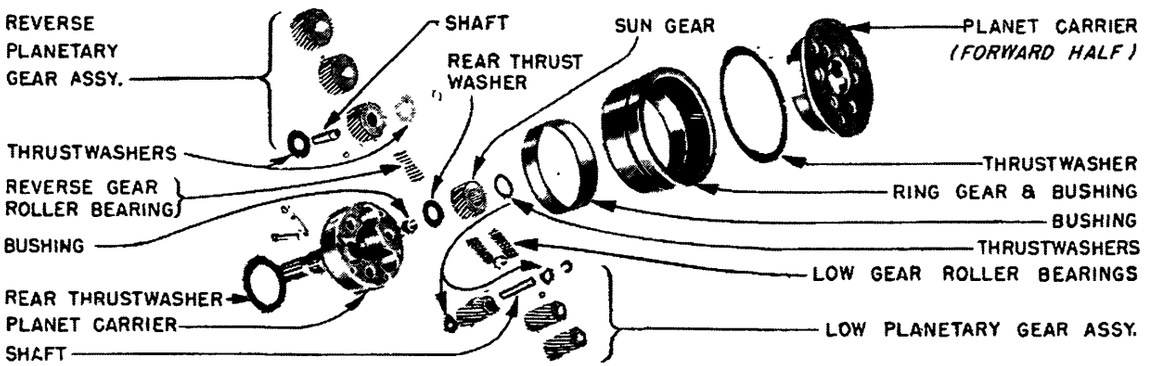
OVERHAUL

After all Converter and Transmission Major Components removed from transmission case, disassemble and overhaul these units as follows:

Converter Stators & Pump: Disassembly. Rotate primary and secondary stators in opposite directions while slowly pulling them apart (CAUTION—do not allow free-wheeling rollers and springs to fly out). Remove free-wheel race (may remain in either stator), remove roller spacer from secondary stator, remove all free-wheel rollers, springs, and spring cups, remove roller assembling washer from primary stator. Take out secondary pump retaining ring and free-wheel roller spacer, withdraw secondary pump from primary pump (rotate in clockwise direction to free the free-wheel rollers), remove free-wheel rollers, springs, and spring cups, lift out secondary pump thrust washer (see Note) which may be found in the primary pump or on the secondary pump.

►**Secondary Pump Thrustwasher Note**—This thrustwasher used only with first type Secondary Pump, not used with later type pump which has cast hub bearing directly against primary pump hub.

►*CAUTION—This thrustwasher must be used with first type pump but should be DISCARDED WHEN LATER TYPE SECONDARY PUMP INSTALLED AS REPLACEMENT.*



Inspection—Wash all parts in clean solvent and dry with air. Examine all parts for wear, scoring, nicks, or other damage. Replace input shaft pilot bearing if worn or rough. Remove small nicks on free-wheel rollers and race by stoning and polishing with crocus cloth. Remove nicks on pump and stator blades with a fine file.

Reassembly—Install secondary pump thrustwasher over primary pump hub (CAUTION—use this thrustwasher only with first type secondary pump, see Note under Disassembly above), insert free wheel springs and spring cups in secondary pump, install secondary pump over primary pump hub with springs outward (rotate pump clockwise to facilitate installation), compress springs with thin narrow tool and insert all free-wheel rollers. Install roller spacer and retaining ring to hold secondary pump in place. Check installation by rotating secondary pump (should turn freely in clockwise direction but lock in opposite direction). Install free-wheel springs, cups, and race in secondary stator (old race in same direction as before as indicated by wear pattern, new race either end first). Depress springs and cups with thin tool and install long rollers, then install roller spacer around race and over rollers. Install free-wheel springs and cups in primary stator, install Primary Stator Assembly Tool J-3081 (40, 50), J-2592 (70) in stator with three tool points between roller recesses, place roller assembly washer flat on tool. Depress springs and cups with thin tool, install **short** rollers (first roller next to one tool leg, next roller diametrically opposite, then alternate rollers until all installed). Remove assembly tool by turning tool until one end can be pushed into roller recess which will free other tool legs without disturbing assembling washer. Install primary stator on secondary stator by placing secondary stator on bench with rollers facing upwards, lower primary stator (rollers downward) squarely on secondary stator while twisting it in counter-clockwise direction.

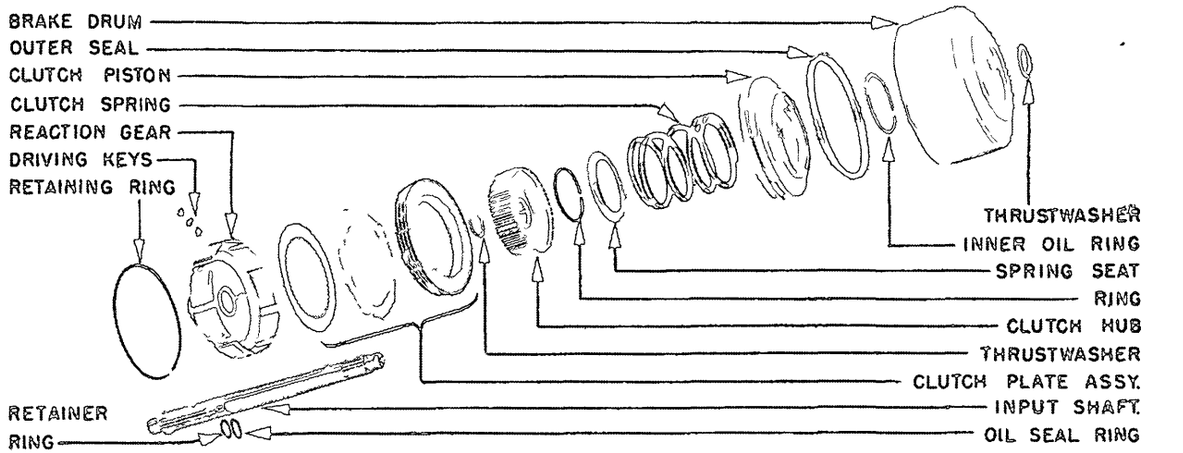
Valve & Servo Bodies: Disassembly. ***On Trans. A-2999 and earlier, replace Valve & Servo Body with 2nd. type and install later type Anchor Piston also as described in Production Change notes.*** Lift low band anchor piston, spring and shims from servo body (not used on C-9, E-9 and later transmissions). Remove safety nuts and washers from body studs, lift off valve body and gasket, examine gasket for evidence of oil leakage. Remove shift control valve from valve body and rear pump delivery check valve and spring from servo body. Remove large pressure regulator valve plug from valve body (CAUTION—hold plug to prevent it flying off due to heavy spring pressure), remove springs and spring seat. Remove small valve plug and lift out pressure regulator valve. Remove valve body plate and gasket, examine gasket for evidence of oil leakage. Lift out front pump delivery check valve and spring. Take off nut and lockwasher attaching upper and lower valve operating levers in servo body and remove levers. Use wooden block placed across low and reverse servo spring seats to hold them in place with springs compressed while taking out spacer plate attaching screws, carefully relieve spring pressure (CAUTION—use care not to spring spacer plate or allow servo springs to fly out), lift off spacer plate and gasket, examine gasket for evidence of oil leakage. Lift out low and reverse servo spring seats, springs, and pistons. On early transmissions with low band anchor pistons which is retained by spacer plate, remove the piston, springs, and shims at this point. *NOTE*—On C-9 & E-9 and later transmissions, anchor piston not used and low band anchored to shaft in transmission case.

Inspection—Wash valve and servo bodies and parts with clean solvent, blow out all passages and dry parts with air. Inspect bodies for cracks, damaged gasket surfaces, and scored piston and valve cylinders. Inspect valves and pistons for nicks, scores, scratches, or rounded shoulders (edges must be sharp to keep out foreign material which might cause sticking). Replace worn or damaged piston seals.

►**Piston Seal Installation Caution—Lip on seal must fit over SMALLER diameter land on piston.**

PLANETARY UNIT ASSY.

C NTINUED N NEXT PAGE



BUICK DYNAFLOW DRIVE (Cont.)

Reassembly—Install low and reverse servo pistons in servo body (CAUTION—use care not to damage seals), check to see that pistons move freely in body. Install piston springs and spring seats (small end of low servo spring in groove in piston, large end of both reverse servo springs in grooves in piston). Place check ball in the reverse servo feed channel. Use new spacer plate gasket, compress servo springs and tighten all spacer plate attaching screws uniformly. Check anchor piston for free movement (on C-8 & E-8 and earlier transmissions only) and if spacer plate or gasket interfere, loosen all spacer plate screws and tap plate to provide uniform clearance around piston, retighten screws uniformly). Check Anchor Piston Height (Trans. C-8 & E-8 and earlier models—see Anchor Piston Height Note below for data). Install both upper and lower operating levers with lower lever pointing to low servo cylinder and upper lever to reverse servo piston spring seat, tighten lever shaft nut to 5-7 ft. lbs. torque. Install front pump delivery check valve spring (large end down), and valve (ridged side up), then install valve body plate using new gasket and making sure that valve seats against plate (must not hang on gasket). Install pressure regulator spring seat, inner and outer springs, and valve plug in valve body, tighten plug to 20-25 ft. lbs. torque. Install pressure regulator valve (see that oil orifice in end land is clear and place this land outward), tighten valve plug to 20-25 ft. lbs. torque. Install shift control valve with slotted end of valve pointing toward large pressure regulator plug. Install rear pump delivery check valve (ridged face inward), and spring (large end upward). Install valve body on servo body using new gasket (CAUTION—see that pump delivery check valve spring below gasket), tighten all stud nuts to 11-15 ft. lbs. torque.

▷Anchor Piston Height Note (C-8 & E-8 & Earlier): Check anchor piston height with Anchor Piston Gauge J-2657 and a .010" feeler gauge (gauge made for first type pistons and is .010" too high). Distance from top face of spacer plate to top edge of top land on piston should be .080-.090" (equal to "Go" and "No Go" legs of gauge with .010" feeler between gauge and piston land). Adjust height by adding or removing shims between spring and piston (if height too great with all shims removed, grind off the end of the spring).

Oil Screen & Oil Pan: Mark first type screen (mounted in oil pan) to insure re-installation in same position. Clean screen and pan thoroughly, check for cracks or holes in screen and for bent pan flanges. When re-installing screen in pan, check oil suction pipe height by placing straightedge (Gauge J-2596 can be used) across pan flanges and measuring from lower edge of straightedge to top of pipe. If this distance not 17/32", adjust by bending screen mounting brackets.

Reaction Shaft Flange & Oil Pump: Disassembly. Remove high and low accumulators and gaskets using care not to drop retaining pin and check ball out of High Accumulator (not used in Low unit) Check gaskets for oil leakage. Check oil pump mounting nuts for tightness (loose nuts may have been causing oil leakage), remove nuts, take out pump body and gears (tap body lightly with soft hammer if necessary). Lift off pump cover and gasket, check gasket for evidence of oil leakage. Remove check ball from clutch feed passage in reaction flange if ball free to fall out (do not remove ball if retained by peened edges of hole).

DIRECT DRIVE CLUTCH ASSY.

Oil Pump Inspection & Repair—Clean pump parts with solvent and dry with air. Check pump gears and mounting faces of body and cover for excessive wear. Check front pump bushing for excessive wear or looseness which will require replacement of pump assembly (NOTE—Check flywheel and primary pump hub run-out and bell housing misalignment if bushing worn or loose). Check front oil pump seal and replace if damaged or any evidence of leakage noted. Drive out old seal, coat outside of new seal with Permatex #3, start seal in place with deep groove in retainer outward, tap seal into place with wood block and mallet. Check following clearances and replace pump parts if excessive:

Pump Gear Side Clearance—Place straightedge across face of pump body and gears. Clearance between face of gears and straightedge should be .001-.0025" (front pump), .001-.002" (rear pump).

Pump Gear Clearances—Check pump gears with feeler gauge between gear teeth and crescent while pressing gear away from crescent. Clearance should be .005-.009" (front pump driven gear), .0045-.007" (rear pump driven gear), .010-.016" (front pump driving gear), .006-.012" (rear pump driving gear).

Pump Cover Gear Wear—Replace cover if gear bearing area scored or worn to depth of more than .001".

Reaction Shaft Flange Inspection—Clean flange in solvent, blow out all passages and dry with air. Check mounting surface of flange for low spots with straightedge (Gauge J-2596) and feeler gauge, replace if out more than .002". Inspect mating face of transmission case similarly and replace case if it cannot be trued up within .002". Check both surfaces for nicks and burrs, remove these with a mill file. Check bronze bushing on reaction flange rear hub and cast iron sleeve within hub, replace reaction shaft flange if these parts scored or worn excessively. Check oil sealing rings and replace if damaged (rings have interlocked ends and are released by compressing ring and depressing one end while raising the other). Check all studs for tightness, replace if threads damaged or stripped (step studs furnished—can be installed by tapping out hole). When replacing oil pump attaching studs on transmission before No. A-86000 and B-29000, install later type square head bolts.

Reassembly—Install pump cover on reaction flange using new gasket (make certain that check ball in clutch feed passage first). Lubricate pump gears and install in pump body with beveled side of driving gear outward so that it will be against cover when pump installed (CAUTION—reversal of gear will cause severe damage to transmission). Install oil pump on reaction shaft flange, seating pump body squarely in recess in cover (first type) or engaging locating dowels in dowel holes (second type), use lockwashers under nuts, tighten nuts (or new type bolts) to 5 ft. lbs. torque in correct sequence (see note below), then fully tighten nuts to 25-30 ft. lbs. torque in same sequence, finally tighten cover attaching stud nut to 25-30 ft. lbs. torque.

▷Front Pump Tightening Sequence—Tighten nuts in following order: Top, Bottom, Right Center, Left Upper Center, Right Lower Center, Left Lower Center, Right Upper Center.

High & Low Accumulators: Disassembly. *See illustration and Production Change Notes for various types of Accumulator Springs and Caps used.* Remove retaining pin and check ball from High Accumulator body (not used in Low Accumulator). Remove the pipe plug, cap, gasket, spring and piston from each accumulator body keeping these parts separated so that same parts will be re-installed in same body.

Inspection—Clean all parts with solvent, blow out all passages and dry with air. Check parts for excessive wear, scoring, nicks, burrs, and other damage. Remove nicks and burrs from pistons and valves by stoning but do not round off sharp edges of pistons and valves (edges must be sharp to keep out foreign material which might cause sticking). Check mounting face of acumulator body for flatness with

CONTINUED ON NEXT PAGE

BUICK DYNAFLOW DRIVE (C nt.)

a straightedge (face can be trued up by using emery cloth on a surface plate but all traces of emery must be removed). Replace accumulator assembly if body, or piston worn (these parts not furnished separately). Check piston for wear by placing it in cylinder (all parts clean and dry). Piston should slide freely as body is tilted back and forth.

Reassembly—Lubricate all parts before installation. Install each piston in same cylinder from which removed, install springs (see illustration and Spring Note below), use new gasket on cap and tighten cap finger tight—DO NOT attempt to tighten caps fully at this time (caps will be tightened to 40-50 ft. lbs. torque **after** reaction flange assembly re-installed in transmission).

►**Accumulator Spring Note**—Springs can be identified by free lengths as listed below (early transmissions have single spring only in Low Accumulator).

Low Accumulator Springs

	Free Length	Part No.
Trans. before C-6, D-6, E-6	4 1/16"	1333426
After above Nos. (Inner)	5 3/16"	1339495
(Outer)	3 11/16"	1339496

High Accumulator Spring

All Transmissions	4 5/16"	1331461

Multiple Disc Clutch & Input Shaft: Disassembly. Remove retainer ring from reaction gear flange, use pointed tool to remove three flange driving keys. Lift out Low Range Reaction Gear, Thrustwasher, Clutch Hub, and all 10 Clutch Plates. Install Clutch Spring Compressor J-2590 in clutch drum placing slot in compressor ring over ends of spring seat retainer ring, compress spring sufficiently to remove retainer ring, release clutch spring pressure (CAUTION—use care that spring seat does not hang up in retainer ring groove in drum). Remove compressor, lift out spring seat and spring. Tap drum, open end down, on block of wood to dislodge clutch piston (CAUTION—if check ball in piston unseated during this operation, snap ball back in place).

Inspection—Wash parts in solvent and dry with air (CAUTION—use only gasoline or kerosene on clutch bands and plates—do not use chemical degreasers or commercial solvents). Inspect and replace all clutch plates which are worn, scored, burred, or warped (CAUTION—new plates must slide freely on clutch hub—tight plates will prevent full disengagement). Inspect oil seal ring on clutch hub and replace if damaged (ring has interlocked ends and is released by compressing ring and depressing one end while raising the other). Replace clutch piston outer seal if hardened, broken, or with turned lip (install new seal with lip extending over smaller diameter piston land). **See Piston Seal Note below.** Inspect Low Range Band and replace if worn smooth without visible grooves. Inspect oil seal ring and replace if damaged (same type ring with interlocked ends as used on clutch hub). Check to make sure retaining ring in place in shaft groove. See that small bleed hole in piston is open and that check ball is staked in place (CAUTION—ball must be free to move in recess).

TORQUE BALL ASSY.

►**Piston Seal Note**—When replacing piston seal on transmission below No. A-3000, it will be necessary to **replace piston also** since only later type wider seal furnished for service (seal width increased from .104" to .113" and piston groove increased from .112" to .116").

Reassembly—Lubricate piston seal and inner surface of drum with light oil, install piston using extreme care not to distort or turn lip of seal. Top of piston should be approximately even with shoulder in drum when installed. Install clutch spring, use Compressor J-2590 to compress spring, install spring retaining ring in groove in drum, remove compressor. Place reaction gear on bench with flange upward and install all clutch parts in following order: Clutch Hub Thrustwasher, Clutch Hub (open end upward), and all clutch plates (see Clutch Plate Caution below). Bottom clutch plate should be internally splined (faced) type and top clutch plate externally splined (plain steel) type with the two types alternating in the assembly. Install drum and clutch piston assembly over reaction gear and clutch assembly with driving key recesses in drum and gear flange aligned. After drum pressed evenly in place, fully align driving key recesses by tapping reaction gear flange, install three driving keys and flange retainer ring.

Clutch Plate Caution—Externally splined (plain steel) clutch plates are concave or "dished" and **these plates must all be installed with "dished" face in same direction** (either up or down). Check each plate with a straightedge and stack plates with dished faces in the same direction before beginning installation. *NOTE*—Internally splined clutch plates are flat and can be installed in either direction.

►**Clutch Plate Caution (Series 70 Trans. No. G-310 & Later)**—New type clutch plates used (see Production Change Note). Until these type plates furnished for service, it will be **necessary to install entire pack of regular service internally and externally splined clutch plates** if any replacement required.

Rear Bearing Retainer, Universal Joint, & Torque Ball: Disassembly. Disconnect valve operating rod clevis from valve operating cross-shaft inside retainer housing (clevis pin on transmissions before No. C-1 & D-1, snap fastener on later cars), withdraw rod through forward end of housing. Disconnect parking lock operating rod from cross-shaft by unscrewing rod end from lever. Remove cross-shaft bearing using a box wrench (CAUTION—loose fitting socket or end wrench will distort bearing), remove cross-shaft. Remove parking lock pawl shaft by screwing ¼"-20 capscrew into shaft and pulling shaft out. Tap parking lock operating lever toward front of retainer (use long punch), remove operating lever shaft, operating lever, lever and pawl assembly, and apply spring from the retainer.

Rear Bearing Retainer Inspection—Wash parts in solvent and dry with air. Check parking brake pawl, pawl locking link, and ratchet wheel for worn teeth, cracks, or other damage preventing positive locking. Check valve operating cross-shaft and bearing for wear, remove and discard rubber seal in bearing. Inspect ouput shaft bushing in retainer for wear scoring, check clearance by inserting output shaft in bushing. Clearance should be .001-.006". Replace bushing with Bushing Remover & Replacer Tool J-2997 (not necessary to ream new bushing).

Universal Joint Inspection—Check for wear and excessive play between spider pins and bushings (should be .002-.004"). Check yokes for wear on shaft splines. Front yoke must be tight fit on output shaft (play will allow "snap" between forward and reverse), rear yoke backlash on propeller shaft should be .0005-.0045". Rear yoke clearance in torque ball bushing should be .004-.006" and bearing surfaces must not be scored.

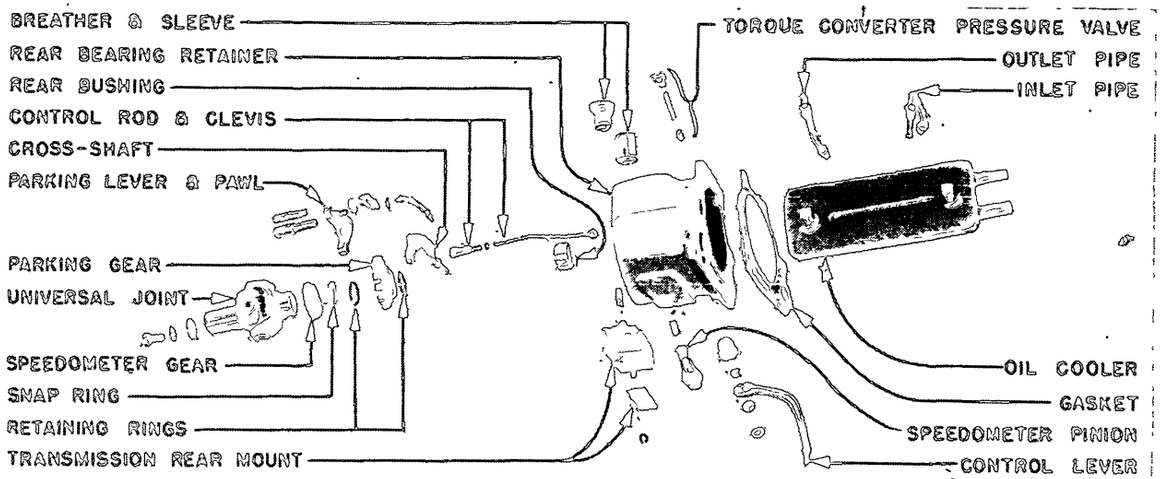
Torque Ball Inspection—Replace torque ball and retainers if bearing surfaces scored or pitted. Inspect oil seal and replace if worn (use seal which has been soaked in neatsfoot oil, press seal squarely into place until flush with torque ball flange and with feather edge of seal pointing into torque ball. Check universal rear yoke for excessive wear at point where seal bears.

Reassembly—Assemble locking pawl and lever, apply spring, and parking lock operating lever & rod using a dummy shaft for this purpose (dummy shaft can be made up of 7/16" round stock, 1½" long, with ⅛" chamfer on one end), place this assembly in position in bearing retainer and install operating shaft through retainer and lever. Install parking lock pawl shaft through bearing retainer and lock

C NTINUED N NEXT PAGE

BUICK DYNAFLOW DRIVE (Cont.)

pawl with tapped end outward. Install valve operating cross-shaft and cross-shaft bearing with new rubber seal in bearing (grooved side inward). Connect parking lock operating rod to cross-shaft lever (use lockwasher on threaded rod end) but do not connect valve operating rod and lever to cross-shaft until rear bearing retainer being assembled to transmission case.



Planetary Gear Set: Disassembly. Remove reverse ring front thrustwasher (not used on later transmissions beginning with No. A-42475 & B-1—see Production Change Notes for interchangeability of first and later type reverse gears). Take out three planet carrier screws and special lockwashers (use 7/32" Allen wrench), separate front and rear halves of planet carrier (hold carrier by output shaft, tap down on flange on front end). Lift out sun gear rear thrustwasher and reverse sun gear. Remove all planet pinion assemblies (three long low pinions, three short reverse pinions) by tapping shaft out of front half of carrier using care not to lose steel ball imbedded in end of each shaft to prevent shaft rotating in carrier. Disassemble pinion assemblies by removing thrustwashers and shafts from pinions and then taking out bearing rollers (long pinions have two sets of rollers separated by spacer, short pinions have one set of rollers).

Inspection: Wash all parts in solvent and dry with air. Inspect planet pinion shaft and rollers, replace if worn. Inspect all gear teeth for wear, remove all nicks and burrs by stoning. Replace bushing in rear end of planet carrier if worn or scored (use Bushing Remover J-3197, Bushing Replacer J-2996—new bushing may be installed either end first and need not be reamed). Inspect reverse band anchor for cracks. If anchor is first two-piece type, rework transmission case and install later forged type anchor (see Production Change notes). Replace reverse band if cracked or the lining worn smooth.

Reassembly—Assemble each planet pinion with its bearing rollers, thrust washers, and shaft (24 rollers in each reverse pinion, 20 rollers at each end of low pinion and separated by a spacer). Make certain that thrustwasher installed at each end of each pinion (lower washer against retaining ring on shaft, upper washer on outer end of shaft). Install planet pinion assemblies in carrier making certain that steel ball imbedded in lower end of each shaft (necessary to prevent shafts turning). Install reverse sun gear with bronze thrustwasher on top of gear, align assembly marks on both planet carrier halves when installing upper half (numbers stamped on dividing line during production), make certain that special lockwasher used on each carrier screw, tighten screws evenly to 25-30 ft. lbs. torque. Install reverse ring gear thrustwasher (first transmissions only—see Production Change notes for gears on which thrustwasher must be used), install reverse ring gear.

Transmission Case (Cleaning & Inspection): Wash case and blow out all passages. Inspect for cracks, and stripped bolt threads. Check machined surfaces for nicks and burrs and clean these up with a mill file. Check bushing in case for wear by inserting planet carrier in bushing and checking clearance with a feeler gauge. Clearance should be .002-.004". Replace bushing if clearance excessive or if scored.

Bushing Replacement—To remove old bushing, support case with rear end down, drive bushing out with tool J-3175-1 (part of replacer set). To install new bushing, place pilot J-3175-2 (part of replacer set) in rear oil pump recess in case, slip bushing over J-3175-1 and drive bushing into case from front side until bushing is flush with front surface of case wall which supports the bushing. Bushing must be installed with wide deep ends of oil grooves toward rear of case.

REAR BEARING RETAINER ASSY.

Flywheel & Primary Pump Run-out and Bell Housing Alignment Check: *Make this check if front oil pump noisy, bushing and oil seal worn, or if oil leakage noted at Converter or Front Oil Pump Body.*

Flywheel Run-out—Remove all burrs from around drilled holes in face of flywheel, mount dial indicator on flywheel housing with strip of .005" shim stock between dial indicator and face of flywheel (clamp shim stock under a flywheel housing bolt so that it covers bolt holes and provides smooth surface for dial indicator pick-up. Turn flywheel holding end thrust in one direction. Run-out should not exceed .008". If excessive run-out cannot be corrected by tapping high side with mallet or by removing flywheel and cleaning up burrs at crankshaft flange mounting holes, install new flywheel and re-check run-out.

Primary Pump Hub Run-out—With converter primary pump and bell housing installed, mount dial indicator on bell housing so that it bears against primary pump hub. If run-out exceeds .012" when flywheel turned, mark flywheel and primary pump, remove and re-install pump at point 180° from first position. If pump run-out still exceeds .012", install new primary pump and recheck run-out. When position found where run-out is less than .012", mark flywheel and pump with paint and align these marks when transmission is finally re-installed.

Bell Housing Alignment—Mount dial indicator on oil pump driving lug on rear end of converter primary pump hub (CAUTION—do not clamp indicator on bearing surface) so that it bears against rear face of bell housing at 3¾" radius. Rotate flywheel holding end thrust in one direction. Run-out should not exceed .005". Mount dial indicator so as to bear against inner edge of pilot hole in bell housing and repeat test. Run-out should not exceed .004". Correct by installing paper shims of correct thickness between flywheel housing and engine crankcase (use shellac to hold shims in place).

REASSEMBLY

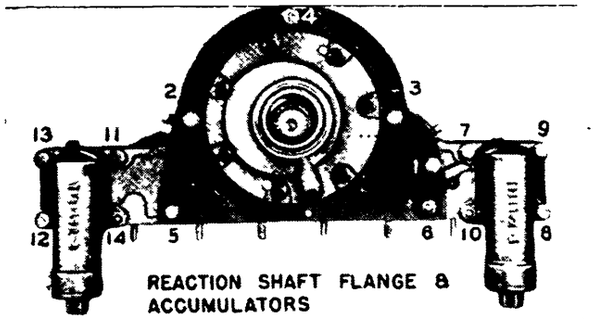
After overhaul of Major Components, make certain that all parts absolutely clean, oil moving parts with 10-W engine oil before installation, use ALL NEW GASKETS & SEALS. Tighten all parts evenly to specified torque and in correct sequence (see illustrations). Proceed in reverse order of disassembly directions and note all of following points:

Planetary Gear Set Installation: After reverse ring gear thrustwasher and reverse band installed in case (with Installing Clip J-2595 on band), rotate band 45° toward servo opening, insert anchor and engage hooked end of band, then rotate assembly back into position. Position band operating lever in place with strut shoulder toward inside of case, install anchor shaft with tapped end outward. If installation correctly made, adjustment screw will be centered in servo opening (lever has offset end). See that planet carrier front (steel) thrustwasher installed on carrier with three tangs engaging holes in carrier, install rear (bronze) thrustwasher in case with three tangs engaging holes in case, then install planet carrier. If correctly installed, chamfer on output shaft journal will be flush with rear end of transmission case bushing.

Rear Oil Pump & Lubrication Oil Pressure Regulator Valve Installation: Install rear gasket (gasket with LARGER hole—do not confuse with cover gasket) and plate on transmission case with bolt holes aligned, install drive key cushion and key in output shaft, then install driving gear to engage key (old gear should face in same direction as before, new gear with either face in). On first transmissions with

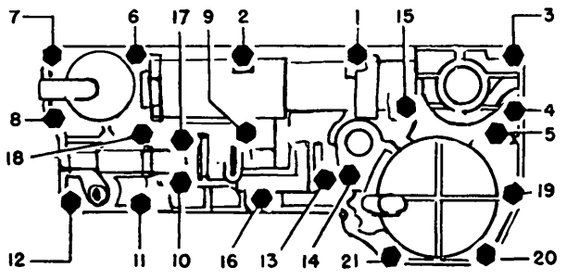
CONTINUED ON NEXT PAGE

BUICK DYNAFLOW DRIVE (C nt.)



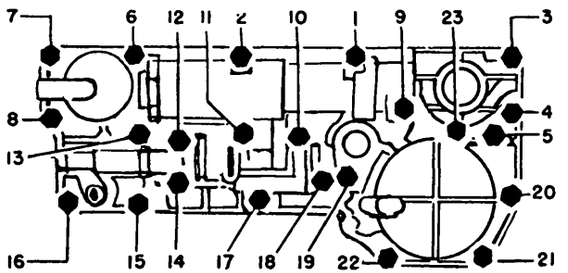
separate cover, use cover gasket (with SMALLER hole) under cover. Tighten attaching bolts to 5 ft. lbs. torque in following sequence: Top, Bottom, Right, Left; then retighten bolts to 25-30 ft.lbs. torque in same sequence. Check pump for free operation by rotating output shaft. Install lubrication oil check valve assembly in case.

►*CAUTION—On first transmissions with separate pump cover, cover must be centered on body to allow rear bearing retainer to be installed.*



Parking Lock Ratchet Wheel & Rear Bearing Retainer: Make certain that retaining ring installed on each side of ratchet wheel on output shaft, insert valve operating rod through square hole in front face of bearing retainer and connect rod to cross-shaft lever, then install rear bearing retainer and gasket, tighten attaching bolts evenly to 35-40 ft.lbs.

Low Brake Band, Clutch, & Input Shaft Installation: Install low band operating lever and anchor lever with strut shoulders of levers toward inside of case and tapped ends of shaft outward (operating lever on side of case having large servo opening, anchor lever on opposite side). Install low band struts in ends of levers with notched ends together using two wooden blocks (1" x 2" x 3½") to support struts and band while assembling. Install low band with J-2595 band installing clip holding band compressed (CAUTION—used band must be installed in original position with point of heavier wear at anchor end, new band can be installed either way). With struts engaging ends of band (notches on struts must straddle pins on band), apply operating lever and remove clip. Place bronze reaction gear thrust-washer on sun gear, install clutch assembly (use wire hook to lift low band if clutch does not go down fully), place bronze thrustwasher on front face of clutch hub. Install input shaft (make certain that oil seal ring ends properly locked and that retaining ring installed in shaft groove). If shaft does not go down into place, make certain all four thrust-washers are properly centered.



Reaction Shaft Flange, Front Oil Pump, & Accumulator Installation: Install special guide pin (see Guide Pin Note below) in accumulator bolt hole at each end of flange on transmission case. Install new gasket over guide pins so that **all holes in gasket and case aligned** (CAUTION—gasket can be installed incorrectly). Check oil seal rings on reaction shaft flange for correct installation with ends locked, install flange using care not to damage these seal rings. Install low accumulator (on same side as low band operating lever), and high accumulator (opposite side) making certain that **holes in gasket and flange match.** Coat accumulator bolt threads lightly with Permatex #3, install bolts and nuts with lockwashers but **do not tighten,** remove guide pins. Install three special bolts (⅜"-16 x 2") with plain washers in #2, 3, 4 positions (see Tightening Sequence illustration) for assembly purposes (these bolts removed after assembly completed), install regular pump cover bolts, nuts, and lockwashers at positions #1, 5, 6 (CAUTION—Coat #5 bolt threads with Permatex #3). Tighten all bolts and nuts (1-14) to 5 ft.lbs. torque in sequence shown in the illustration, then tighten #1 through #4 to 35-40 ft.lbs. and all remaining nuts and bolts to 20-25 ft.lbs. torque in the same sequence. Remove the three special bolts (#2, 3, 4). Tighten accumulator body caps to 40-50 ft.lbs. torque. Check flange gasket and trim lower edge flush with bottom face of transmission case if it projects.

REACTION SHAFT FLANGE & ACCUMULATORS

SECOND TYPE VALVE & SERVO BODY

THIRD TYPE VALVE & SERVO BODY

BOLT TIGHTENING SEQUENCES

►**Guide Pin Note**—These 5/16" guide pins can be made up from 5/16" round stock, 2½" long, with 5/16"-18 thread-½" long on one end and screwdriver slot on opposite end (chamfer this end slightly).

Valve & Servo Body Installation: With transmission inverted on bench, raise reverse band operating lever and insert strut between lever and end of band (CAUTION—rounded ends of strut must be against band and lever). After strut installed, **do not raise lever while installing valve and servo body** (will allow strut to fall into case). Install two 5/16" guide pins (same pins as used for reaction shaft flange—see above) in case to guide each end of servo body, install spacer plate gasket over guide pins. Install valve and servo body on case (hold anchor piston from falling out and move shift control valve and lower operating lever inward to align upper lever with opening in case). Engage control valve pin in slot in operating lever. Install correct length bolts and lockwashers in all mounting holes *using copper washer on #10 bolt on 3rd type body* (see Tightening Sequence illustration for **ach type** valve & servo body), remove guide pins. Install operating lever stop (used only with first type oil screen). Tighten all attaching bolts and nuts to 5 ft.lbs. torque in **correct sequence for particular type valve & servo body used** (see illustration), then fully tighten all ¼" bolts and nuts to 11-15 ft.lbs. and all 5/16" bolts to 15-20 ft.lbs. torque in same sequence (CAUTION—when tightening nuts and bolts adjacent to shift control valve, operate valve to make sure that it does not bind—if necessary, readjust bolts to lower torque limit to correct binding). On transmissions with second type oil screen, remove bolt #18 and stud nut #9, install cork gasket, oil suction pipe, retaining spring and spring support, tighten this #18 bolt and #9 nut to 11-15 ft. lbs. Connect valve operating rod to upper operating lever by reaching into case with Linkage Hook-up Finger J-2591 and pulling upward on rod to engage ball in socket. Install shift lever on cross-shaft temporarily to check and adjust linkage. Valve linkage must operate freely. Move lever toward front of transmission to engage parking lock. Pawl must fully engage ratchet wheel and pawl lock must be in full contact with pawl in this position. Push shift control valve away from stop pin until all play in linkage is just taken up, check clearance between end of valve and stop pin with feeler gauge. Clearance should be .030-.040" and spring travel at end of shift lever should be 1/8-3/16". Adjust by turning clevis on end of valve operating rod. After adjusting, make certain clevis locknut tightened and that clevis pin secured with cotter pin (first type—snap fastener used on later transmissions).

Oil Pan Installation: If first type oil screen used, check suction pipe fit in servo body (see below). Coat area on transmission case where case cut away under oil pan gasket thinly with Permatex #3. Install 5/16" guide pin at each end (same pins as used for reaction shaft flange—see note above), install new oil pan gasket over guide pins. Install oil pan (use heavy-duty internal tooth lockwashers on bolts and stud nuts), tighten all bolts and nuts evenly to 15-18 ft. lbs. torque.

Oil Screen Suction Pipe Check—*Required for first type oil screen only.* Install new sealing ring in servo body recess, coat upper edge of suction pipe with red lead, install oil pan with new gasket using two 5/16" guide pins (same pins used for reaction shaft flange installation—see above) in case to guide each end of pan. Install two oil pan bolts and two stud nuts, tighten securely. Remove pan and check pipe contact impression on sealing ring. Pipe must have full 100% contact to prevent air leaks at this point. Adjust by adjusting screen mounting brackets.

►*CAUTION—Do not change oil pip height setting (17/32" below top edge of pan flange) when making above adjustments.*

Universal Joint Installation: Make certain that joint retaining ring fully seated in groove in output shaft before installing universal joint. If universal cannot

CONTINUED ON NEXT PAGE

BUICK DYNAFLOW (C nt.)

be seated firmly against retaining ring by hand, use Replacer J-865 (40, 50), J-855 (70) to press universal on shaft. Tighten universal joint bolt to 30-35 ft.lbs.

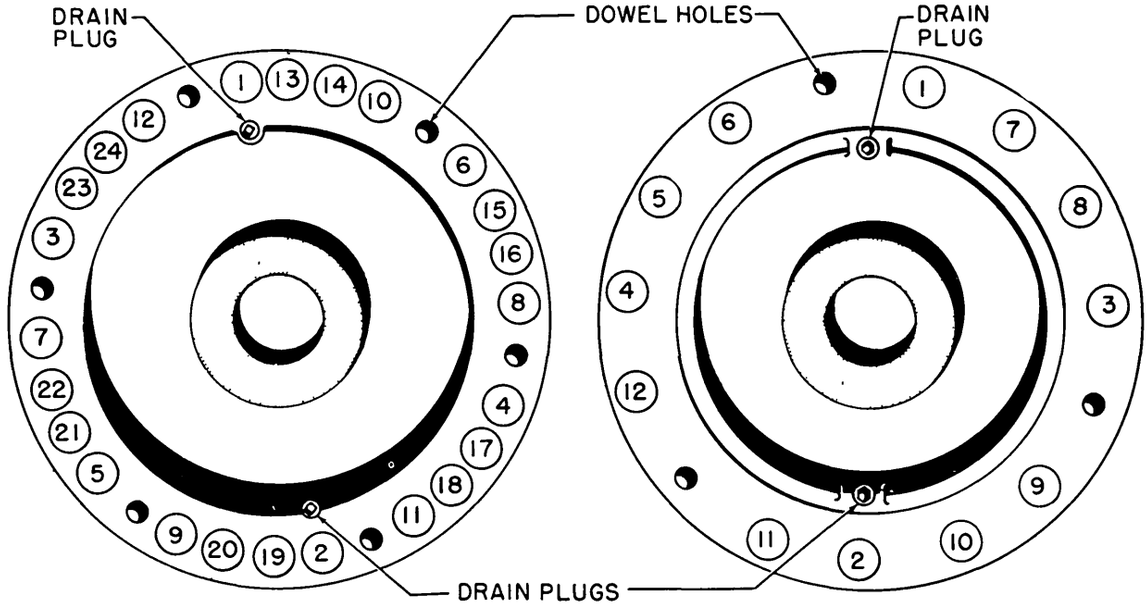
►*CAUTION—Oil passage in bolt must be clear (for universal joint lubrication).*

Torque Ball Installation & Adjustment: *See "Torque Ball Adjustment" in Buick Special Data in Car Model Section for complete data and also note:*

Bell Housing & Torque Converter Assy. Installation:

►*CAUTION—Different converter clearance checking procedure required for transmissions beginning with Nos. F-341 & G-341 (requires reworked gauges and different shimming chart as listed below).*

►**Checking Tool Note**—Converter Clearance Gauges J-3045 (40, 50), J-2596 (70) as designed for early transmissions must be reworked for use on transmissions F-341 & G-341 and later (with redesigned primary pump and cover) by having a cut-out made at each end of the tool immediately inside the stepped ends so that the tool will clear the bulge on the inside of the cover adjacent to the mounting flange face.
Install parts (and check and adjust converter clearance) exactly as follows:



1) See that front oil pump seal ring installed around pump body on pump cover. Install bell housing (use lockwashers on bolts & stud) coating threads of lower right bolt lightly with Permatex #3 (this bolt hole opens into transmission), tighten all bolts evenly to 35-40 ft.lbs. torque.

2) Support primary pump cover firmly on blocks, install bearing plug of Converter Clearance Gauge (see Checking Tool Note above) in pump cover ball bearing, place gauge bar on cover with stepped ends resting on flat surface of cover flange between bolt holes but **do not exert pressure on bar,** carefully measure clearance between gauging step at center of bar and top of plug with a feeler gauge. Rotate gauge bar 90° around pump cover and repeat clearance check. **Averag** these two clearances and **make a record of this figure** for use in step (5) below.

3) Place stators and turbine in position in primary pump, place assembly on bench with turbine hub up. Place gauge bar on assembly with stepped ends resting on flat surface of pump flange between bolt holes, measure clearance between gauge step at center of bar and top edge of turbine hub, **make a record of this figure** for use in step (5) below.

4) Install primary and secondary pump assembly on transmission reaction shaft (rock pump to engage pump hub lugs with oil pump driving gear slots), install primary and secondary stator assembly on shaft, install retaining ring in shaft groove. Install converter turbine on input shaft.

5) **Add the two clearance figures** obtained in steps (2) and (3) above and note this "total clearance" in the **correct** Converter Clearance Shimming Chart below (CAUTION—different chart required for earlier and later transmissions as noted). Select the correct .018" Shim Washer and .060" Spacer combination as listed for this total clearance and use this in step (6) below.

①—With FLAT type Pump Cover Gasket.
②—With "O" RING type Pump Cover Gasket.
③—.060" Spacer & .018" Washer.

6) Install the correct shim washer and spacer combination as selected in 5 (above) on the input shaft.

7) **On transmission before No. F-341 & G-341** (with FLAT type pump cover gasket), install primary pump cover with **new** gasket. Insert pump cover bolts beginning with the two holes directly in line with the drain plugs and **omit the bolt in every fifth hole** clockwise around the cover (see Tightening Sequence diagram). Install bolts from primary pump side with plain washers and safety nuts on cover side but do not tighten bolts until cover has been aligned.

On Transmissions beginning F-341 & G-341 (with "O" RING type pump cover gasket), install primary pump cover with **new** "O" sealing ring, making certain that ring has not been twisted. Insert bolts in following order: With drain plug which is between two bolt holes upward, insert first bolt in hole to right of drain plug, install bolts in clockwise direction around cover **omitting the bolt in every fifth hole** (see Tightening Sequence diagram). Install bolts from primary pump side with plain washers

CONTINUED ON NEXT PAGE

BUICK DYNAFLOW DRIVE (C nt.)

and safety nuts on cover side but do not tighten bolts until cover has been aligned.

►*CAUTION—All bolts must be same length and have bolt heads of same length. See Primary Pump Cover & Flywheel Bolt Production Change Note.*

8) After cover bolts have been installed, align cover by inserting shank of 11/32" drill through one bolt hole to align all bolt holes, then tighten all bolts to approximately 5 ft. lbs. in correct sequence (see Tightening Sequence diagram for each type pump and cover assembly) **using a wide screwdriver inserted between flat side of bolt head and primary pump to prevent bolt digging into pump,** finally tighten all bolts in same sequence to 30-35 ft. lbs. torque. Install converter drain plugs.

Band Adjustment: Adjust Low and Reverse Bands. *See Band Adjustment.*

Shift Lever Installation: Hold lever forward while tightening nut on cross-shaft to prevent damaging internal linkage.

Oil Cooler Installation: Install oil cooler on right side flange of transmission case, install oil pipes and tighten securely.

Transmission Breather Installation: Make certain that "U" shaped steel baffle is correctly installed in breather body (baffle legs should be aligned with centerline of transmission when breather installed), install breather with tube extending over right rear end of rear bearing retainer, tap breather firmly into opening in bearing retainer.

INSTALLATION IN CAR

After transmission and torque converter completely assembled, install unit in reverse order of removal procedure and note following important points:

Alignment of Parts—See that flywheel, converter primary pump, and converter cover positioned so that paint marks (as made for removal) will be aligned when transmission installed.

►*CAUTION—This alignment necessary to maintain converter assembly balance.*

Bell Housing Mounting Bolt Installation—Install the two bell housing dowel bolts first, then install remaining bolts and tighten evenly to 45-55 ft. lbs. torque tightening the lower right hand bolt last (CAUTION—tightening this bolt first may cause misalignment of the bell housing). Install lockwasher and nut on right hand bell housing dowel bolt from under the engine hood after the car has been lowered to the floor (oil pipe spring bracket is also retained by dowel bolt nut).

NOTE—Crankcase ventilator outlet pipe support is attached to lower right bolt. On cars where exhaust pipe hanger attached to lower left bolts, install and tighten regular bolt nuts, then use additional nuts to attach exhaust pipe hanger.

Transmission Support & Thrust Pad Installation & Adjustment—*See ENGINE MOUNTING in Buick Special Data.*

Converter Mounting Bolt Installation—Use correct type bolts and nuts (see Primary Pump Cover & Flywheel Bolt Change) and make certain that balance weights (if used) correctly located under bolt heads, use shank of 11/32" drill to align bolt holes in flywheel and converter, install bolts and tighten evenly to 25-30 ft.lbs. torque.

Final Road Test—After transmission installed and all adjustments made, road test car by driving approximately 20 miles with frequent starts and stops to duplicate heavy traffic conditions. After transmission thoroughly warmed up, check transmission and all oil lines and connections for leaks. If vibration noted due to unbalance of replacement parts, correct this condition as follows:

►**ENGINE & TRANSMISSION VIBRATION CORRECTION:** Remove bell housing cover and bell housing hand hole cover for access to converter primary pump-to-cover bolts, determine location and weight of necessary balance weights as follows:

1) Place car solidly on work stands for access to underneath of car.

2) Connect tachometer to engine. Start engine, place selector lever in Park "P" position, increase speed gradually until speed reached at which vibration is definite. Note this speed for later rechecking, then stop engine.

3) Install one .060" balance weight (see table below) under the head of one primary pump cover bolt and tighten bolt to 25-30 ft.lbs. torque. *CAUTION*—DO NOT place weight at flywheel-to-converter driving bolt since these bolts are not long enough to take the balance weight. Run engine at critical speed as noted in (2) above with selector lever in Parking "P" position and compare performance. Stop engine, remove balance weight, retighten bolt to 25-30 ft.lbs. torque.

4) Repeat entire procedure (3 above) with balance weight installed at other primary pump cover bolts equally spaced around cover and compare performance at critical speed for greater or lesser vibration.

5) At the location where the least vibration noted in above tests, install balance weights of correct thickness to eliminate objectionable vibration.

Part No.	Balance Weights	Thickness
1341420		.0345"
1341419		.060"
1341418		.120"

6) After balance weights finally installed and cover bolts tightened to correct 25-30 ft. lbs. torque, spot the center of hole in each weight with 5/32" drill, then use No. 32 (.116") drill to drill hole ⅜" deep in pump flange. Install drive screw (No. 145067—⅜" long or No. 450543—½" long depending on weight thickness) in this hole to permanently attach weight to pump flange.

►*IF VIBRATION CAN NOT BE ELIMINATED by above procedure, replace new part which caused the unbalance and repeat balancing procedure.*

Shift Rod Installation—Check and adjust linkage when installing shift rod. **See LINKAGE ADJUSTMENT.**

Filling Transmission—See LUBRICATION.

Road Testing Car—After installation completed, road test car by driving approximately 20 MPH. with frequent starts and stops (heavy traffic conditions) to thoroughly warm up transmission. Check transmission carefully for oil leaks, recheck oil level.

1953-54 BUICK "TWIN TURBINE" DYNAFLOW DRIVE

Buick, Series 40 & 50 (1953-54)—Optl.
Buick, Series 60 (1954)—Optl.
Buick Series 70 (1953-54)—Std.
Cadillac, Series 63, 60S, & 86 (1953)—Std.
Oldsmobile, All Series (1953)—Optl.

▷CHANGES, CAUTIONS, CORRECTIONS

▷*STARTING ENGINE BY PUSHING CAR:* Place shift control lever in Neutral "N" position until car reaches a speed of 15 MPH., then move control lever to Low "L" position and continue to increase speed until engine starts (at approximately 25 MPH.). After engine starts, return lever to "N" position for engine warm-up.

▷*DYNAFLOW INTERCHANGEABLE PARTS CAUTION (Between Buick Type and Cadillac, Oldsmobile Type)*—Dynaflow parts (Converter & Transmission) are the same for all cars EXCEPT AS NOTED BELOW:

Converter Pump Cover Assembly—Cadillac & Oldsmobile are the same, and are interchangeable. Buick Converter Front Cover has a higher hub and cannot be interchanged with Cadillac & Oldsmobile.

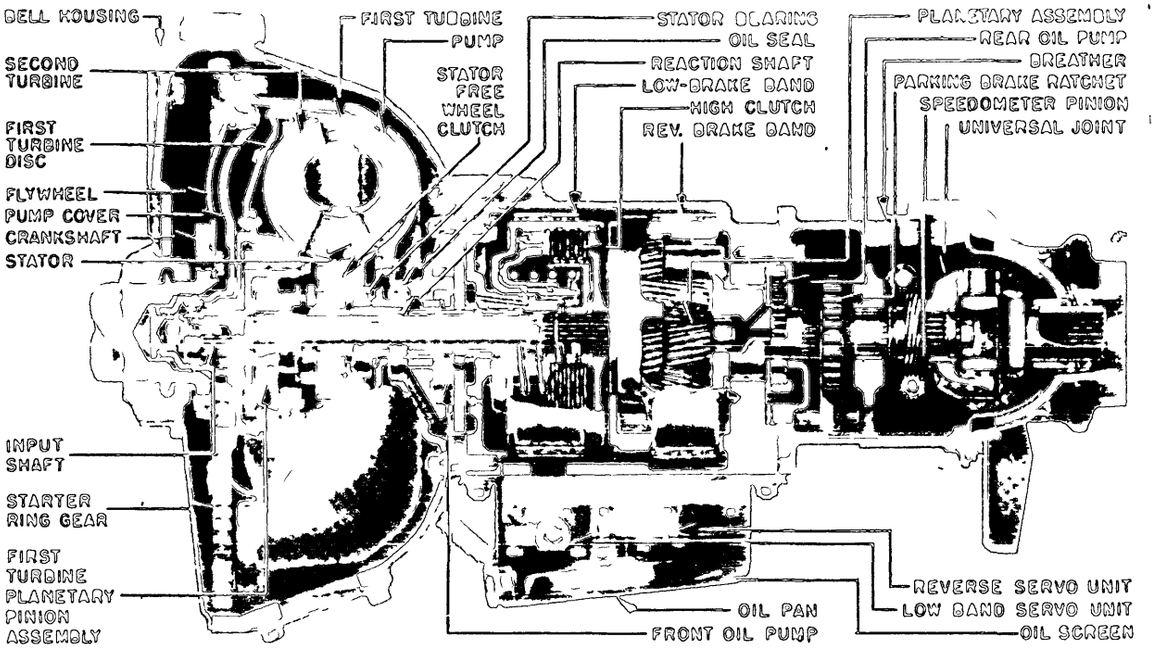
Converter Pump Cover Plug, Main Shaft Pilot Bearing Retainer Bolt, Retainer & Bearing—Buick parts are DIFFERENT and cannot be used on Cadillac & Oldsmobile. Cadillac & Oldsmobile parts can be interchanged between the two. NOTE—There is not a lockwasher under Main Shaft Pilot Bearing Retainer Bolt on Cadillac & Oldsmobile as in the Buick Assembly.

Twin Turbine Assembly—Twin Turbine Gears used on Buick & Oldsmobile are the same, and are NOT INTERCHANGEABLE with turbine gears used on Cadillac.

Bell Housing—Cadillac & Oldsmobile housings are the same, and are NOT INTERCHANGEABLE with housing used on Buick. Cadillac & Oldsmobile housing is about one-half the length of the Buick housing.

Transmission Case Oil Pan Assembly—Not interchangeable between cars due to differences in oil pan lower pipe.

Rear Bearing Retainer—Oldsmobile bearing retainer is same as used on Buick Series 50 & 70. Cadillac bearing retainer is different and is not interchangeable with Buick & Oldsmobile.



▷*CAUTION—Rear Bearing Retainer internal parts for all cars are different and are not interchangeable.*

DESCRIPTION

"Twin Turbine" Dynaflow Drive has a completely new Torque Converter unit used with a planetary gear transmission of same design as used with previous Dynaflow Drive Transmission (except for modifications on Buick Series 50 & 70 with V8 engine, and the adaption to Cadillac & Oldsmobile, as described below).

Torque Converter Description: Converters used on all models are identical except for the Stator (see Stator below). Converter consists of a Pump (similar to type used previously), First Turbine, Second Turbine, and Single Stator (replacing previous Primary and Secondary Stators and Secondary Pump).

First Turbine—Located directly forward of the converter pump and has narrow band of vanes which receive all oil flow from pump. This turbine is mounted on a disk and hub assembly bearing on the turbine carrier hub and is geared to the second turbine (internal gear of planetary gear set is mounted on the disk hub).

DYNAFLOW SECTIONAL VIEW

Second Turbine—Located within first turbine case with broad band of vanes which receive all oil flow from first turbine and directs the oil flow back into the stator. This turbine is bolted to a turbine carrier which is splined on the input shaft. The planet pinions of the turbine gears are mounted on carrier and mesh with the internal gear on the first turbine disk hub and with the sun gear which is mounted on a bearing on the input shaft and coupled to stator free-wheel cam (gears are always in mesh but operate only when sun gear and stator are held stationary for torque converter action). With the stator unlocked and free-wheeling (when torque converter operating as a fluid coupling, sun gear is likewise free to rotate which allows all units to rotate at nearly the same speed as the converter pump.

Stator—Located directly behind inner end of second turbine vanes. Receives oil from second turbine and redirects oil back into pump. Stator is mounted on reaction shaft by means of a free-wheeling unit similar to that used with previous stators. The free-wheeling cam is coupled to the sun gear of the turbine planetary gear set and controls the geared action of the first and second turbines (see Second Turbine above). Different stators used for each type engine as follows:

Buick, Series 40 Stator No. 1318718 with 12 broad vanes.

Buick, Series 50, 60, 70 Stator No. 1318759 with 20 narrow vanes.

OPERATION

OPERATION: Planetary unit and controls operate in exactly same manner as on previous Dynaflow Drive. New Torque Converter operates as follows: Torque Converter Operation—When the car is started up, the stator and turbine sun gear will be locked and held stationary. This results in First and Second turbine operation as a geared unit with a ratio of 1.6-1 (first turbine rotating faster). This provides a maximum torque multiplication of 2.54-1 under stall conditions. As the car speed increases, the torque reaction against the sun gear and the back pressure on the stator decreases and when this ceases, the stator free-wheels and the sun gear is released. With the sun gear free, the speed of the second turbine increases until both turbines and the stator are rotating at approximately converter pump speed. At this point the torque converter operates as a fluid coupling with a 1-1 torque ratio. The car speed at which this change occurs depends entirely on the torque requirements and is determined by the car operating conditions.

LUBRICATION

Check oil level at 1000 mile intervals and add oil as required. Drain and refill at 25,000 mile intervals.

▷*CAUTION—Oil must be warm and engine must be idling when checking oil level, warm up oil before draining.*

Checking Oil Level: With oil warm and engine idling with control lever in Parking "P" position, check oil level as indicated on dipstick in filler tube in engine compartment (on right side between battery and engine). If level more than 1" below FULL mark on rod, add recommended oil to bring level up to FULL

CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (C nt.)

mark *(CAUTION*—do not fill above the FULL mark). Distance between ADD OIL and FULL marks on rod is equal to approximately 1 pint of oil.

►***CAUTION—If oil level is consistently low when checked (indicating loss of 1 pint or more per 1000 miles), check transmission thoroughly for oil leaks.***

Draining & Refilling: With oil warm, drain transmission case by removing drain plug in oil pan, drain torque converter, after removing bell housing cover for access to drain plugs, by loosening one plug and turning converter until second plug is downward and removing this plug. Re-install and tighten all drain plugs. Install 3 quarts of recommended oil through filler opening in case. Start engine and allow it to idle with control lever in Parking "P" position, add additional oil to bring level up to point 1¾" below "FULL" mark on oil gauge rod. Recheck oil level after transmission warmed up. Oil level should then be at full mark on rod.

►***CAUTION—DO NOT FLUSH transmission when changing oil.***

Capacity—10 qts. *NOTE*—1¾ pints additional required if transmission completely dry (after overhaul, etc.).

Recommended Oil—Use only "Special Buick Oil for Dynaflow Drive" or "Automatic Transmission Fluid, Type A" with AQ-ATF number embossed on can.

LINKAGE ADJUSTMENT

BUICK LINKAGE ADJUSTMENT: ***Make adjustments in order and exactly as follows:***

Manual Control Linkage: Transmission must be thoroughly warmed up (driven approximately 20 miles under traffic conditions with frequent starts and stops) and oil level must be correct. Then proceed as follows:

(1) Place shift control lever in Neutral "N" with detent plunger centered in detent notch, move lever until stop pin is against stop in dial housing, note movement of dial pointer. Repeat this operation in Low "L" position. Dial pointer movement should be approximately equal in both positions. If not, loosen control detent mounting bolts on steering column jacket, shift detent until dial pointer travel is equal. Place lever in Low "L" position, carefully bend dial pointer, if necessary, so pointer is in line with "L" on dial.

(2) Check parking mechanism by placing car on ramp or steep grade with control lever in Parking "P". Parking lock should hold securely. Place control lever in Neutral "N" and allow car to roll. If "clicking" ratchet noise heard, or if parking lock did not hold car on grade, adjust as follows: Place control lever in Parking "P" position, disconnect shift rod from shift idler lever on steering column, pull forward on rod and move car slightly to make certain locking pawl fully engaged (CAUTION—do not jerk on rod). Check movement at lower end of shift lever on left side of transmission case by pressing forward on lever (against spring tension) until definite stop is felt. This movement should be 1/8-3/16" beyond the parking "P" position. If spring travel not within these limits, control valve is out of adjustment (requires removal of torque ball). If spring travel correct, pull shift rod forward against stop, adjust shift rod clevis until clevis pin can just be entered in hole in idler lever with control detent engaged in Parking "P" position, then **lengthen rod by unscrewing clevis 3 full turns,** connect rod temporarily (may require readjustment in next step).

(3) Place shift control lever in Neutral "N" position with detent fully engaged. With transmission warm and engine idling at 600 RPM., move control lever from Neutral "N" to Drive "D" position slowly. Clutch should engage (noted by immediate decrease in engine speed) when tip of dial pointer is midway between "N" and "D" on speed ratio dial. Move control lever from Drive "D" to Neutral "N" position slowly. Clutch should disengage (noted by immediate increase in engine speed when tip of pointer is midway between "D" and "N" on dial. If clutch engagement and disengagement points not correct, readjust clevis on shift rod at shift lever (see (2) above), being careful not to disturb Parking adjustment. Do not connect shift rod permanently until adjustment (4) completed.

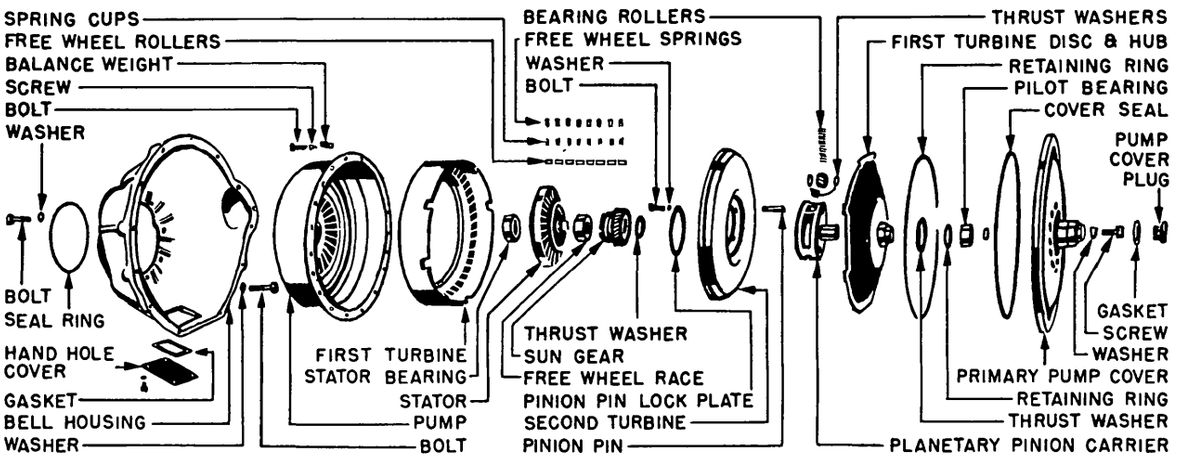
►***CAUTION—When making above adjustment, do not change shift rod length so much that parking lock fails to hold or pawl contacts ratchet wheel in Neutral (check as directed in (2) above).***

(4) Check operation in Low "L" and Reverse "R" positions. Detents should be engaged and shift points should occur when tip of dial pointer is midway between "D" & "L" (Low), midway between "L" & "R" (Reverse). If shifts do not occur at correct points, check for bent transmission shift lever, bent valve operating upper lever ,or lever loose or incorrectly seated on shaft.

(5) After above adjustments completed, tighten clevis nut on shift rod clevis and permanently install clevis pin with plain washer and spring washer on each side of clevis.

►***CAUTION—Neutral Safety Switch and Back-up Light Switch must be checked after changing control detent and shift rod adjustments.***

Throttle Linkage: Make sure accelerator pedal is in good condition and that floor mat is properly installed, then tighten pedal mounting screws. Check throttle linkage for proper lubrication, make sure pedal rod does not bind in its seal, and make sure that return spring is strong enough to fully close throttle valve. Adjust throttle stop screw for proper HOT idling speed of 450 RPM. With engine shut off and throttle closed to hot idling position check clearance between rear leg of accelerator lever (bell crank) and front face of stop lug on lever mounting bracket. Clearance should be .040 (3/64") to permit proper closing of throttle valves to hot idle position. Disconnect upper end of vertical throttle operating rod and adjust rod as required to obtain specified clearance. Make sure throttle is fully open with accelerator striking floor mat rather than having stop on throttle lever strike against boss on throttle body. Check linkage for smooth operation.



Dashpot Adjustment (1953): Adjust after the throttle linkage is adjusted and engine is at normal operating temperature. With throttle valve closed to hot idling position, back off dash pot until it is clear of lever and equalizer shaft, then adjust it down to touch lever. With transmission in Direct Drive and brakes firmly applied, speed engine up to about 1400 RPM and immediately release accelerator pedal. If engine stalls from too rapid closing of throttle, move dash pot down until its action prevents engine stalling, then lock it in position with the lock nut.

Dashpot Adjustment (1954): Adjust after the throttle linkage has been adjusted and engine is at normal operating temperature. Rotate fast idle cam to extreme cold idle position (choke closed), hold throttle lever closed against a .030" feeler gauge placed between stop screw and highest step of fast idle cam. Adjust dashpot until it just clears arm of throttle lever, tighten locknut. Final setting of dashpot should result in engine returning to idle promptly without engine stalling. If engine stalls when returning to idle, dashpot should be moved forward. Rearward movement will reduce time required to idle engine. Tighten locknut after each adjustment. If proper control cannot be obtained by adjustment. replace dashpot.

Starter Vacuum Switch: If operation not correct after carburetor linkage and dash pot adjustments made,

See Carburetor Equipment Section for complete data.

CONTINUED N NEXT PAGE

DYNAFLOW TORQUE CONVERTER & BELL HOUSING (TYPICAL)

DYNAFLOW DRIVE (Cont.)

Neutral Safety Switch & Back-up Light Switch (1953 Series 40): Separate switches used. Both switches are mounted on lower end of steering column. Switch should be closed in neutral and should remain closed until lever moved toward Drive position enough to move outer end of control lever pointer 5/32" (if switch opens with less than ⅛" pointer travel, starter may not operate in Neutral; if more than 3/16" pointer travel required to open switch, starter may operate in Drive "D" position and cause starter to move car). Check and adjust switch as follows:

Checking Neutral Switch—Ground coil terminal on distributor so that engine can be cranked without starting. Firmly set parking brake. Place Dynaflow control lever in neutral "N" position (check to see that detent firmly engaged). Install Shift Control Linkage Adjustment Gauge J3085 on dial housing so that short line under "N" is centered on dial pointer. Move control lever to Driving "D" position, turn ignition on, depress accelerator pedal to close starter vacuum switch. Move control lever slowly from "D" toward "N", note position of center of dial pointer at instant starter begins to operate, release accelerator pedal. Center of dial pointer should be within limits of short line to right of "N" mark on gauge (provides required limits of 1/8-3/16" out of neutral). If not within these limits, adjust as directed below.

Adjust Neutral Switch—Place control lever so dial pointer centered on short line to right of "N" mark on gauge J3085 and hold the lever in this position while adjusting. Loosen the two mounting bolts on switch bracket at lower end of steering column, raise switch up as far as possible. With ignition switch turned on and accelerator pedal depressed, tap switch down until starter just begins to operate, then tighten switch mounting bolts, being careful not to change switch position. Recheck switch adjustment.

Back-up Light Switch (1953 Series 40)—Check and adjust after transmission control detent has been adjusted. Place control lever in Low "L" position, check clearance between switch operating arm and lower edge of control shaft lower lever. If this clearance not 0" to 1/16", loosen two switch mounting screws and shift switch on bracket (screw holes slotted).

Neutral Safety Switch & Backup Light Switch (1953 Series 50 & 70, and 1954-55 All Series): Located on steering column jacket under instrument panel.

▷*CAUTION: Switch must be wired correctly and control lever stop plate must be correctly positioned for correct switch operation as follows:*

Neutral Safety Switch Adjustment: With manual control linkage properly adjusted, ground primary terminal of distributor so that engine can be cranked without firing. Fully apply parking brake and place transmission control lever in "N" (Neutral) position. Place a narrow strip of masking tape on speed ratio dial so that upper end of dial pointer is visible. Make two marks on masking tape at ⅛" and 3/16" from center of pointer. Move control lever to "D" (Driving) position, turn ignition on and depress accelerator pedal to close accelerator vacuum switch. Slowly move dial pointer from "D" to "N" and note position of center of pointer at instant cranking motor just starts to operate. Release accelerator pedal. The center of the pointer should be between the two marks made on masking tape. If switch does not cut in within the specified limits, loosen switch mounting screws and move switch sideways as required for proper timing. Tighten mounting screws.

▷*BACKING SWITCH NOTE*—No separate adjustment required (switch operation will be correct when neutral safety switch properly adjusted).

Switch Wiring—Check wire connections on switch terminals for correct wiring (incorrect wiring may allow starter to crank with lever in other positions than Neutral or Park—may engage when shifting from Low to Drive during heavy pull), or backing lights may operate with shift lever in other than Reverse. Switch connections from Right to Left (viewed from driver's seat) should be:

No. 1 (Right)—Black wire (to Backing Lights).
No. 2—Brown wire (to #1 terminal on fuse block).
No. 3—Natural wire with Red Cross Tracer (to Ignition Switch).
No. 4 (Left)—Natural wire with Red Parallel Tracer (to starter switch on carburetor).

Control Lever Stop Plate Checking & Adjustment: Stop plate is mounted on column jacket directly below control shaft lower lever and engages a tongue on the lever to limit lever movement (lever must be raised against return spring pressure to free lever tongue from stop plate slot for shift into Reverse, Neutral, Parking). Two clearance checks are required as follows: .010-.020" clearance between tongue on lever and nearest edge of large hole in stop plate with control lever in "Drive" position, .120-.130" (⅛") between lower face of lower lever and upper face of stop plate with control lever in "Drive" position. Adjust by loosening stop plate clamp bolt and shifting the plate as required for above clearances. *Make certain that lower lever does not ride over the top of the stop (switch lever will then act as the stop and will be damaged or broken. REPLACE STOP PLATE IF CORRECT ADJUSTMENT CANNOT BE SECURED.*

▷*CAUTION—Excessive bending of the stop plate or lever tongue may cause breakage of these parts.*

CADILLAC LINKAGE ADJUSTMENT: *Make adjustments in order and exactly as follows:*

Manual Control Linkage: (1) Place selector lever in "Park" (P) position. Disconnect manual rod at shift lever.

(2) Shift lever on transmission should be in the "Park" position. Make sure that parking pawl is completely engaged in ratchet wheel (this can be done by raising rear of car and rotating propeller shaft by hand until a definite "click" can be heard as the pawl is engaged).

(3) Loosen mounting screw on detent roller bracket and position bracket so that the roller is in parking notch on quadrant. From this position it should be possible to move shift lever forward 1/8" to 3/16" as measured at clevis pin hole. Hole in manual rod trunnion should line up with hole in shift lever. If not, adjust trunnion on the manual rod to assure correct alignment. Connect manual rod to shift lever.

(4) Place selector lever in "Reverse" (R) position and note position of roller on detent quadrant. Roller should be in reverse notch of quadrant.

Throttle Return Check Adjustment (Carter & Rochester): Check alignment of throttle return check adjusting screw with contact on secondary throttle lever. If necessary, bend the return check bracket to center adjusting screw on radius of the contact lever. Place selector lever in "Drive" (Dr.) or "Low" (L) range and apply hand and foot brakes to prevent car movement. With throttle valves in hot idle position, adjust throttle return check by turning adjusting screw until ⅛" (Rochester Carburetor); .047" (Carter Carburetor) is obtained between throttle lever and plunger when plunger diaphragm is fully compressed. *(CAUTION—To prevent diaphragm damage, hold flats on screw shaft with 5/16" wrench while adjusting screw is being turned).* Open throttle half way (DO NOT STALL TEST), then quickly release accelerator pedal. If engine does not stall, the adjustment is correct.

Neutral Safety & Back-up Light Switch: *Switches are combined, and mounted on steering column directly below floor.*

Adjustment—Adjust switch by loosening mounting bolt and rotating switch in bracket so that engine will start when shift lever is in "Park" (P), and "Neutral" (N) positions only, and the Back-up Lights operate only in "Reverse" (R) position.

▷Backing Switch Note—No separate adjustment required (switch operation will be correct when neutral safety switch properly adjusted).

OLDSMOBILE MANUAL LINKAGE ADJUSTMENT:

(1) Place selector lever in "Park" (P) position. Disconnect relay rod clevis from relay bell crank. Place adjusting tool J-5615 on relay bell crank, then adjust shift rod clevis until tool just touches rear face of engine mount. Install clevis pin and wave washer in shift rod clevis, then tighten jam nut.

▷*CAUTION—Shift rod and relay rod clevis pin heads must face each other.*

(2) Hold transmission shift lever forward and rotate propeller shaft until parking pawl engages (It will be possible to pull the lever forward ⅛" to 3/16" beyond this point which winds up a spring on parking pawl).

(3) With a light tension forward on relay rod, so that parking pawl spring is not wound up, adjust the rod length to obtain a free fit. Then shorten relay rod clevis 1½ turns.

(4) Finally check, with wheels moving, hold shift lever firmly against Neutral stop and listen for ratchet noise. If noise exists, lengthen clevis by ½ turn.

Stop Plate Adjustment—Stop plate is located on lower end of mast jacket in a position to engage a lug on shifter tube lower lever. With selector lever in Reverse, Neutral ,or Parking positions, lug on shifter lever must be flush with bottom surface of stop plate. Stop plate can be adjusted after loosening the clamp bolt.

Throttle Return Check: With throttle valve in hot idle position, adjust throttle return check by turning adjusting screw until 1/16" clearance between throttle lever and plunger when plunger diaphram is fully compressed.

Neutral Safety & Back-up Light Switch: If Back-up Lights used, Back-up Light Switch is combined with Neutral Safety Switch.

CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (C nt.)

Adjustment—Place selector lever in "Drive" (Dr) position Hold ignition key in start position and then slowly move selector lever toward "Neutral" until starter operates With selector held in this position, engine should be free to rev-up without producing drive through transmission If car moves, adjust switch as follows Place selector lever in "Neutral" (N) position Loosen switch mounting bolt and move switch until 3/32" drill shank inserted in lever hole indexes with hole in switch bracket Tighten mounting bolt and recheck switch operation as outlined above.

BAND ADJUSTMENT

►*BAND ADJUSTMENT CAUTION—Bands cannot be adjusted with transmission in car and adjustment ordinarily required only when transmission overhauled. BANDS MUST BE CORRECTLY ADJUSTED BEFORE TRANSMISSION INSTALLED IN CAR.*

LOW & REVERSE BAND ADJUSTMENT: Both bands are adjusted alike as follows

(1) Remove band adjusting covers and gaskets from upper right (Low), and left (Reverse) of transmission case

(2) Loosen locknut and turn adjusting screw clockwise until considerable resistance felt indicating that band in full contact with drum or ring gear

(3) Back off screw until trace of endplay noted when prying up on locknut with screwdriver, **then back off screw additional six turns,** hold screw from turning and tighten locknut snug

(4) Note position of adjusting screw slot, use torque wrench to tighten locknut to 20-25 ft lbs, check screw slot to make certain that screw position not changed

(5) Install band adjusting cover **using new gasket.**

TESTING

If performance not satisfactory, make following tests **with transmission thoroughly warmed up and at operating temperature:**

Oil Level: Check oil level, add fluid as necessary to bring level up to FULL mark on dipstick, recheck performance with correct oil level If car has been losing oil at rate of 1 pint or more each 1000 miles, make thorough check for oil leaks

Manual Control Linkage Check and adjust manual control linkage See Linkage Adjustment.

Hydraulic Control System Pressures: Use Transmission Oil Pressure Gauge J-2575 Support rear end of car solidly with wheels off floor so that transmission can be operated Remove transmission cover in floor pan for access to pressure take-off points

Connect gauge and make tests as follows:

Front Oil Pump—Connect pressure gauge at pipe plug opening on left side of reaction shaft flange Run engine at 500 RPM, check pressure with selector lever in **Low, Drive, and Reverse range.** Repeat tests at 1000 RPM and at 1800 RPM in **Low and**

Drive Range only See table below for correct pressures Low or erratic pump pressure indicates air leaks in suction line, improper pressure regulator valve action ,or excessive pump clearances

1953 Buick Front Oil Pump Pressures

Selector Lever—	Low	Drive	Reverse
500 RPM	100 lbs	90 lbs	100 lbs
1000 RPM	160 lbs	90 lbs	
1800 RPM	180 lbs	90 lbs	

1954 Buick Front Oil Pump Pressures

Selector Lever—	Low	Drive	Reverse
500 RPM	120 lbs	90 lbs	100 lbs
1000 RPM	180 lbs.	90 lbs	
1800 RPM	180 lbs	90 lbs.	

Cadillac Front Oil Pump Pressures

Selector Lever—	Low	Drive	Reverse
500 RPM	110 lbs	100 lbs	110 lbs
1000 RPM	180 lbs	100 lbs	
1800 RPM	200 lbs	100 lbs	

Oldsmobile Front Oil Pump Pressure

Selector Lever—	Low	Drive	Reverse
500 RPM	110 lbs	100 lbs	110 lbs
1000 RPM	175 lbs	100 lbs	
1800 RPM	200 lbs	100 lbs	

Rear Oil Pump—Connect pressure gauge at pipe plug opening in lower flange at front end of rear bearing retainer Run engine at 500 RPM, check pressure with selector lever in **Low & Drive Range.** Repeat test 1000 RPM and 1800 RPM See table below for correct pressures Low or erattic pump pressures indicate air leaks in suction line (this will affect both pumps), improper pressure regulator valve action, excessive pump clearances or leaks in valve and servo body passages between pump and regulator valve.

1953 Buick Rear Oil Pump Pressures

Selector Lever—	Low	Drive
500 RPM	75 lbs.	90 lbs
1000 RPM	125 lbs	90 lbs.
1800 RPM	175 lbs	90 lbs.

1954 Buick Rear Oil Pump Pressures

Selector Lever—	Low	Drive
500 RPM	90 lbs	90 lbs
1000 RPM	180 lbs	90 lbs.
1800 RPM	180 lbs	90 lbs

Cadillac Rear Oil Pump Pressures

Selector Lever—	Low	Drive
500 RPM	85 lbs	100 lbs
1000 RPM	140 lbs	100 lbs
1800 RPM	190 lbs	100 lbs

Oldsmobile Rear Oil Pump Pressures

Selector Lever—	Low	Drive
500 RPM	80 lbs	100 lbs
1000 RPM	135 lbs	100 lbs.
1800 RPM	190 lbs	100 lbs

High & Low Accumulator—Connect pressure gauge at pipe plug opening on top of accumulator body (**High**—left side of car); (**Low**—right side of car). Place selector lever in **Drive Range** (High Accumulator Test); **Low Range** (Low Accumulator Test). Run engine and check pressures at speeds indicated in tables below. Low accumulator pressure may be caused by leakage past accumulator body gasket If accumulator pressure more than 10 lbs lower than front pump pressure, check for leakage between accumulator and multiple disc clutch and for restricted or plugged metering orifice in accumulator dump valve

1953 Buick Accumulator Pressures

Selector Lever—	Low	Drive
500 RPM	90 lbs	80 lbs
1000 RPM	150 lbs	85 lbs
1800 RPM	170 lbs	85 lbs.

500 RPM	100 lbs	90 lbs.
1000 RPM	165 lbs.	95 lbs.
1800 RPM	185 lbs	95 lbs

Oldsmobile Accumulator Pressures

Selector Lever—	Low	Drive
500 RPM	100 lbs	85 lbs.
1000 RPM	165 lbs	90 lbs.
1800 RPM	185 lbs	90 lbs.

TROUBLE SHOOTING

CAR WILL NOT MOVE (Rear wheels may be locked or free).

1) With selector in any Range (rear wheels free). If car will not move for 1-8 minutes after standing over night—Check front pump oil pressure (see Testing) after allowing car to stand for several hours If zero pressure noted, check pump for excessive clearances allowing pump to lose its prime Check alignment of bell housing and converter primary pump hub.

►*CAUTION—If this condition found, inspect Clutch and Bands for excessive wear due to slippage caused by low oil pressure.*

If car will not move after extended operation in Reverse—Check for air leaks in pump suction line (at rear oil pump gaskets), or excessive clearance in front pump (at pump gears and covers). Check alignment of bell housing and converter primary pump hub

2) With selector in any Range (rear wheels locked). Parking lock engaged Broken parts in transmission or rear axle Parking brake applied

3) With selector in Drive Range. Check front oil pump pressure and High Accumulator pressure If OK, check for sticking Low Band Anchor Piston, remove and inspect Clutch for worn or sticking clutch plates, leaking clutch seal rings If High Accumulator pressure low, also check rear pump Check Valve for correct installation and proper seating, check for leaks at accumulator body gasket, reaction flange gasket, clutch piston outer seal and clutch ball check valve, and leaks at sealing rings on reaction shaft flange and low drum

4) With selector in Reverse Range. Check reverse band for displaced operating strut caused by too loose adjustment, improper installation, or broken band anchor (indicated by free up and down movement of band operating lever) If band assembly OK (no free movement of lever), check servo operation by running engine and shifting into Reverse Remove Valve & Servo Body and check for reverse servo piston seal leaks

CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (Cont.)

EXCESSIVE SLIPPAGE (High engine speed in relation to car speed, or poor acceleration).

1) In all Speed Ranges. Low oil level. Incorrect manual control linkage adjustment. Air leak in oil pump suction pipe at oil screen sealing ring. Low front oil pump pressure caused by wear or excessive clearances in pump. Leaks at front pump cover or reaction shaft flange, pressure regulator valve, Valve & Servo Body gasket. Pressure regulator valve defective.

2) In Drive Range. Incorrect manual control linkage adjustment. If High Accumulator pressure low, check for leak at accumulator body gasket; if gasket OK, check for leaking clutch sealing rings, sticking clutch piston, worn or sticking clutch plates.

3) In Low Range. Incorrect manual control linkage adjustment. Incorrect low band adjustment. Low band and drum worn or scored. If Low Accumulator pressure low, check for leak at accumulator body gasket; if gasket OK, remove Valve & Servo Body and check for gasket leaks or leaks at low servo piston seal.

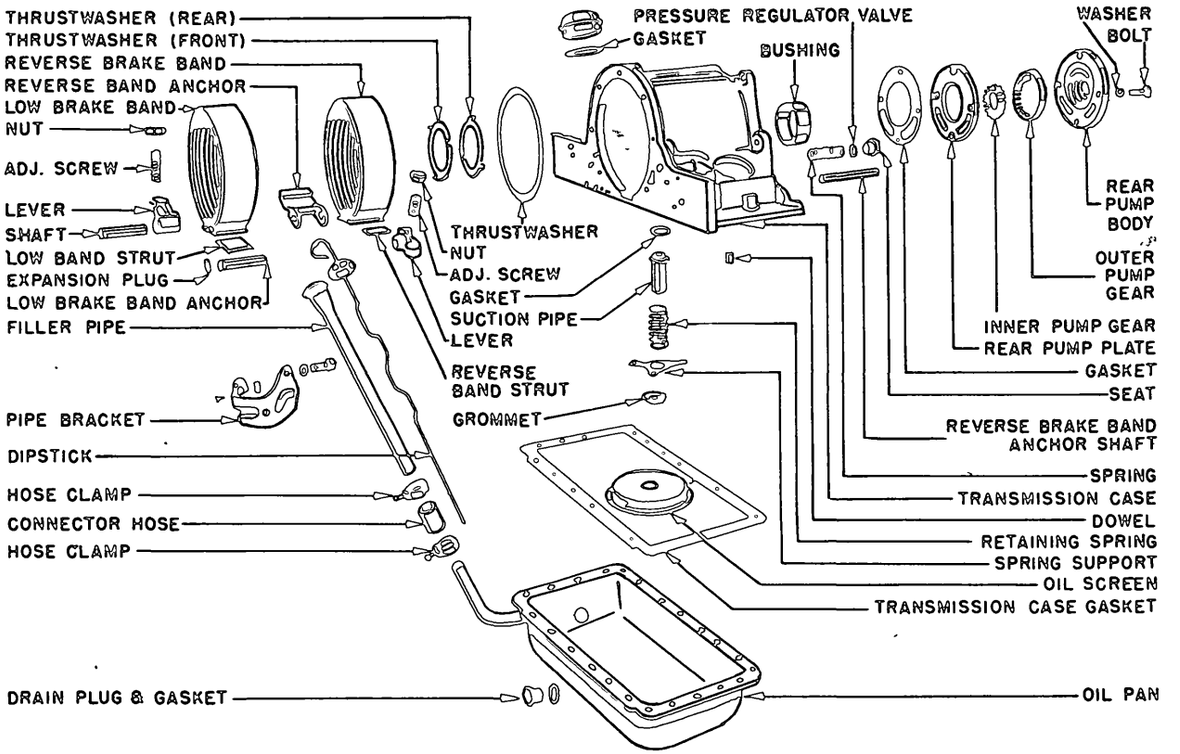
4) In Reverse Range. Incorrect manual control linkage adjustment. Reverse band out of adjustment, strut out of place, or anchor broken. If front oil pump pressure low, remove Valve & Servo Body and check for gasket leaks and leaking reverse servo piston seal.

CAR CREEPS (Forward or Backward).

1) Creeps forward with selector in Neutral. Incorrect manual control linkage adjustment. Sticking low servo piston (check by removing low band adjustment cover). Sticking clutch caused by warped, binding, or incorrectly assembled clutch plates (not stacked properly with "dish" in same direction).

If Car Creeps only when engine accelerated to 2500 RPM—Check clutch vent ball checks in clutch piston and reaction shaft flange.

2) Creeps forward with selector in Reverse or backward with selector in Low. Incorrect manual control linkage adjustment.



SHIFTS ARE ROUGH.

1) Low-to-Drive Shift. Incorrect Low Band adjustment. If High Accumulator pressure low, check for leak at accumulator body gasket and for dump valve or accumulator piston sticking down (top land of piston should be visible through top port in body). Sticking low band anchor piston (remove Valve & Servo Body to check), or incorrect piston location (see piston shimming data in Valve & Servo Body Reassembly). Valve & Servo Body gasket leaks. Clutch plates worn or binding.

EXCESSIVE CHATTER OR CLUNK WHEN STARTING

▷*CAUTION—Slight "clunk" when shifting into Low or Reverse is normal, and slight chatter when car starting to move in reverse (disappearing as soon as car in motion) is also normal.*

1) In Low & Reverse Range. Incorrect Low or Reverse Band adjustment. Engine and transmission mountings loose or incorrectly adjusted, thrust pad at transmission mounting broken (see Engine Mountings in Buick Special Data). Clutch plates warped, sticking, or incorrectly assembled (not stacked properly with "dish" in same direction). Reverse ring gear bushing worn. Planet pinion needle bearing rough.

DYNAFLOW TRANSMISSION CASE, OIL PUMP, & SERVO BAND ASSYS.

NOISE IN TRANSMISSION.

▷*CAUTION—Hum or low whine in Neutral or Parking is normal (due to free rotation of all planetary gears) and slight hum in Low and Reverse may be expected.*

1) Buzzing Noise. Low oil level. Front pump check valve hanging up on edge of gasket between valve and servo bodies. If noise noticed in Parking or Neutral, pressure regulator valve clearance in body may be excessive or orifice in valve land oversize (correct by replacing valve and body).

2) Clicking Noise. If noticed in all ranges, may be caused by foreign material in converter. If noticed only when car in motion, may be caused by parking lock pawl contacting ratchet wheel due to incorrect manual control linkage adjustment.

3) Abnormal Hum or Whine (see Caution above). If noted in all ranges, may be caused by worn parts or excessive front pump clearances (front pump noise will increase in Low and decrease at car speeds above 45 MPH. in Direct Drive). Check front pump for excessive clearances by testing for low pump pressure. If noise noted in all ranges except Direct Drive, may be caused by trouble in planetary gears (gears locked out in Direct Drive).

4) Squealing or Screeching following installation of Front Oil Pump. Pump driving gear installed backward.

▷*CAUTION—Above condition must be corrected WITHOUT FURTHER OPERATION OF TRANSMISSION or severe damage will result.*

REMOVAL FROM CAR
BUICK

Transmission and torque converter are removed as an assembly as follows:

1) Raise car so that frame side rail is at least 20" off floor and place stands at front and rear to support car.

2) Disconnect torque tube from torque ball and move rear axle back to disengage propeller shaft from universal joint. Remove cranking motor splash pan, bell housing cover and bell housing hand hole cover.

3) Drain converter and transmission. Mark position of converter on flywheel to assure installation in same position and remove bolts attaching converter to flywheel. Disconnect pipes from oil cooler and disconnect cooler from transmission from rear mounting thrust plate. Remove cooler. Disconnect oil filler pipe at rubber hose and disconnect exhaust pipe hanger at right accumulator. Disconnect shift rod and speedometer cable at transmission.

4) Support transmission with a jack or hoist and remove four bolts attaching thrust plate to rear bearing retainer, then remove two nuts and plate which attach mounting pad to transmission support.

5) Raise engine and transmission just enough to relieve load on transmission support. Remove bolts attaching both ends of support to frame, then re-

CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (C nt.)

move support and thrust plate as an assembly. *CAUTION*—If shims are found at this point, note their number and location so they can be reinstalled in the same position.

6) Support engine at rear end of lower crankcase so it will be supported while transmission is removed. ***CAUTION—Do not use bar with hooks placed over frame side rail. Brake lines will be damaged.***

7) On cars with air-conditioning, disconnect discharge and suction lines at compressor. This will avoid damaging flexible couplings when engine is raised and lowered.

8) Lower the transmission just enough so that bell housing bolts can be reached, then remove bell housing to crankcase bolts. Move transmission rearward to disengage hub of converter pump from crankshaft, lower transmission and remove it from beneath car.

CADILLAC

Transmission and Torque Converter are removed as a unit as follows:

1) Place car on stands with all four wheels approximately 12" above floor. Disconnect propeller shaft at rear universal joint flange and remove shaft with front universal and yoke.

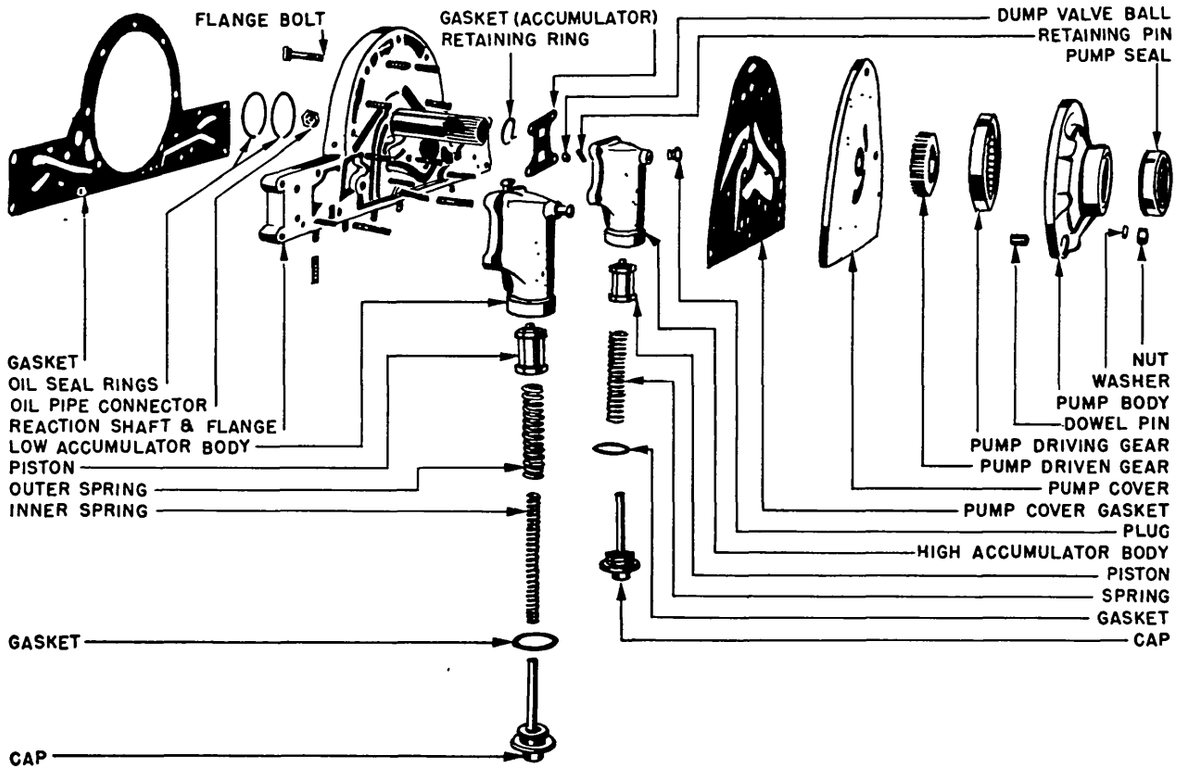
2) Disconnect battery and remove starter motor from lower flywheel housing. Remove lower flywheel housing cover and upper portion of oil filler pipe with dipstick at rubber connector.

3) Turn flywheel until one converter drain plug can be loosened sufficiently to provide air vent. Then turn flywheel until opposite drain plug is straight down. Remove this plug and allow oil to drain from converter. Remove plug from oil pan and drain oil from transmission.

4) Drain radiator and remove two hoses from oil cooler. Disconnect transmission manual shift rod and speedometer cable.

5) Place jack under engine at rear of oil pan using a wood block to prevent damage to oil pan, or use special engine support stand (J-3068). Place Hydra-Lift under car and raise transmission just enough to take strain off rear engine support.

6) Disconnect engine rear support at transmission rear bearing retainer. Remove bracket cross member that carries support.



7) Mark flywheel, converter primary pump, and cover, with daubs of paint so pump can be reinstalled in same position on flywheel. Disconnect converter from flywheel by removing three attaching screws.

8) Lower jack or engine support stand (J-3068), under engine pan until top of bell housing clears floor pan. Remove screws holding bell housing to engine crankcase. Remove transmission and bell housing as a unit by moving assembly back toward rear of car, and at same time lowering assembly to floor.

OLDSMOBILE

Transmission and Torque Converter are removed as a unit as follows:

1) Disconnect positive battery cable from battery, then hoist car. Remove engine filler plates and disconnect battery cable and lead wires from starting motor. Remove lower flywheel housing and starting motor.

DYNAFLOW REACTION SHAFT FLANGE, ACCUMULATORS, & FRONT OIL PUMP ASSY.

2) Turn flywheel until one converter plug can be loosened to provide air vent, then turn flywheel until opposite plug is straight down. Remove this plug and drain oil from converter. Remove plug from oil pan and drain oil from transmission.

3) Remove right hand exhaust pipe and loosen hose clamp on oil filler tube, then push tube up out of the way. Place drain pan under extension housing and remove propeller shaft.

4) Place a drain pan under oil cooler and disconnect external lines from cooler, then remove two cooler attaching nuts at rear bearing retainer and permit oil to drain from cooler. Place cooler to left side of frame with hoses attached.

5) Disconnect speedometer cable and remove relay rod from relay bell crank and shift lever, at side of transmission. Remove frame cross member.

6) Mark flywheel, converter pump and cover with daubs of paint so they can be reinstalled in the same position. Remove three flywheel to converter attaching bolts.

7) Support transmission with Hydro-Lift and Dynaflow adapter. Remove left rear engine mount and disconnect the right rear mount at frame support.

Lower transmission ½", then install engine support bar.

8) Remove six bell housing-to-cylinder block attaching bolts, then place adapter chain over top of transmission and secure.

9) Pull transmission assembly back until converter pump is against flywheel housing and turn flywheel until converter cover hub will clear flywheel-to-crankshaft bolts, then lower transmission assembly.

DISASSEMBLY

►**DISASSEMBLY CAUTION:** ***CLEANLINESS IS EXTREMELY IMPORTANT when disassembling and working on transmission. Thoroughly clean exterior before disassembling, use CLEAN tools on CLEAN workbench, provide CLEAN storage space for all parts, and separate parts to avoid nicking or burring of ground and polished surfaces.***

DISASSEMBLY OF TRANSMISSION (into Major Components): With transmission on bench, first remove shift lever by taking off retaining nut and washer on shaft while holding lever forward (to avoid strain on linkage), remove oil cooler and pipes if this unit removed with transmission, remove both band adjusting covers and gaskets using Remover Tool J-2655. Remove both pipe plugs in primary cover to completely drain converter, then place transmission on bench with oil pan upward and remove various sub-assemblies as follows:

Converter & Bell Housing Removal: (1) Remove large hex plug and gasket from hub of converter pump cover, then remove the socket head set screw and lockwasher located in hub, using a hex wrench 5/16" across flats).

C NTINUED N NEXT PAGE

DYNAFLOW DRIVE (Cont.)

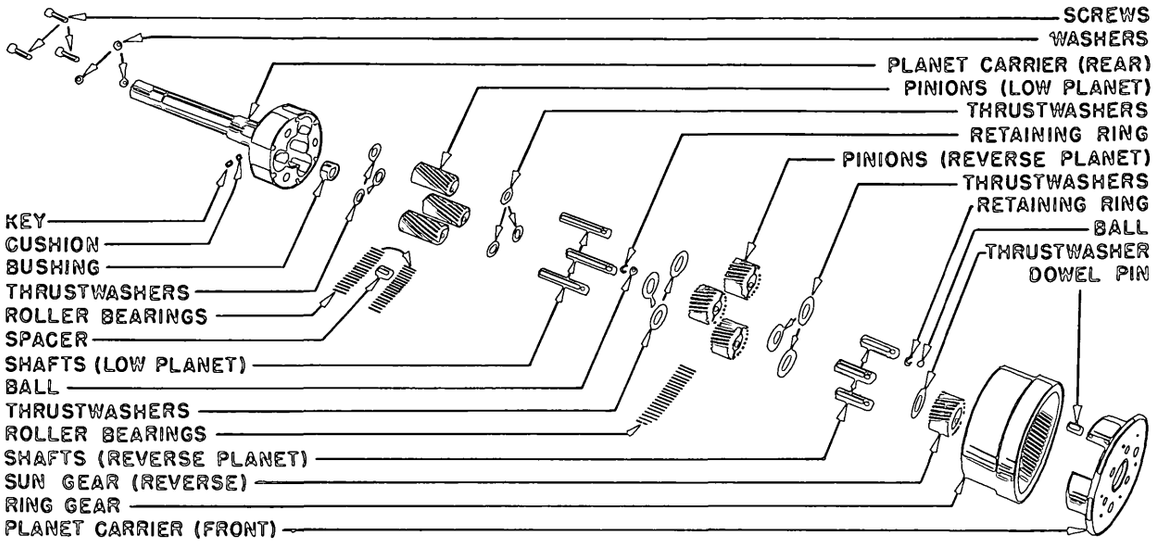
2) Remove all nuts, plain washers, and bolts attaching cover to converter pump. Insert a punch through bell housing hand hole and into a drive bolt hole to hold pump from turning.

3) Remove cover from pump, tapping or prying against edge to loosen it. Check seal for damage or evidence of oil leakage before removing cover.

4) Insert a screw driver into a hole in the first turbine disk to aid in removing the twin turbine assembly from input shaft. Push inward on shaft to avoid withdrawing it. Remove bronze thrust washer from turbine hub.

5) Remove retaining ring from groove in input shaft, using snap ring pliers, then remove bronze thrust washer and the sun gear.

6) Remove retaining ring from groove in reaction shaft and slide converter stator and free wheel roller race from reaction shaft. Remove stator bearing from reaction shaft if it did not come out with stator.



7) Pull converter pump forward from reaction shaft and immediately check for evidence of leakage.

Radial streaks of fresh oil on back of pump and fresh oil streaks on face of pump body indicate leakage past oil pump seal. Before removing bell housing, check to see that all attaching bolts are tight. Loose bolts may be cause of oil leakage at this point.

8) Place transmission so that bell housing is over edge of bench. Take out bell housing attaching bolts, remove bell housing, check rubber oil seal for uniform compression (if seal not compressed uniformly, check around oil pump and in bell housing opening for burrs or foreign material preventing uniform seal compression). *See Overhaul data for disassembly of converter stators and pump.*

Oil Pan and Valve & Servo Body Removal: *Not necessary to remove other parts prior to this operation.* Remove oil pan and gasket. Lift oil screen away from suction pipe to which it is held by a rubber grommet snapped into hole in screen body. Remove suction pipe spring support, retaining spring, suction pipe, and cork gasket which seats in recess in servo body. Disconnect valve operating rod from valve operating lever (upper) by placing screw driver on rod close to lever and exerting slight pressure, (spring loaded socket on rod engages a ball stud on lever). Loosen all valve and servo body attaching screws slightly but do not loosen slotted safety nuts on valve-to-servo body studs, pry assembly upward slightly to free gasket, push shift control valve and lower operating lever inward to align lever with transmission case opening, lift assembly off. Use care to avoid slotted end of shaft control valve which has sharp edges, when lifting on assembly. Remove gasket and check for evidence of oil leaks. Remove reverse band operating strut (support strut with finger extended through adjusting hole to prevent it falling into case, release strut by lifting on operating lever). *See Overhaul data for disassembly of valve and servo body.*

Reaction Shaft Flange, Front Oil Pump, and Accumulator Removal—*Converter & Bell Housing and Oil pan must be removed first but Valve & Servo Body need not be disturbed.* Loosen but do not remove both accumulator body caps (will facilitate removal later). Remove three attaching capscrews from each accumulator body but do not disturb stud nut. Remove capscrews extending through front oil pump cover but do not remove stud nuts. Tap lightly on rear of accumulator bodies with fiber hammer to loosen reaction shaft flange, remove assembly and gasket from case leaving input shaft in transmission. Examine gasket for uneven impression or other evidence of oil leaks.

DYNAFLOW TRANSMISSION PLANETARY ASSEMBLY

Input Shaft, Clutch, & Low Band Removal: *All parts listed in preceding removal sections must be removed first.* Pull input shaft and clutch hub front thrustwasher out of transmission (thrustwasher will come out on shaft), then lift out clutch assembly. Compress low band with the operating lever, install Band Installing Clip J-2595 across band strut flanges to keep band compressed, release the lever and lift band out of case, lift out band struts, (will drop down in case when band removed). Remove the low band anchor lever and operating lever by threading a ¼"-20 capscrew in end of each lever shaft and pulling shafts out of case. *See Overhaul data for clutch disassembly.*

Torque Ball & Universal Joint Removal (Buick): *Does not require removal of any other parts first.* Remove torque ball rubber boot. Take out attaching bolts in thrust plate, remove thrust plate and gasket, torque ball inner and outer retainers, and paper adjusting shims. Remove speedometer driven gear and sleeve assembly. Lock drive shaft by engaging parking pawl (use shift lever to press forward on shift lever shaft while turning universal joint, until pawl engages), remove universal joint bolt, lockwasher and flat washer, pull universal joint using puller J-682A (40, 50), J-859A (70).

Extension Housing & Shaft Removal (Cadillac & Oldsmobile): Remove six screws attaching extension housing to rear bearing retainer flange. Remove extension housing and discard gasket.

Rear Bearing Retainer & Parking Lock Ratchet Wheel Removal: Universal Joint, Oil Pan, and (Buick) Torque Ball must be removed first. Disconnect valve operating rod from upper operating lever by inserting screw driver through hole in case and pressing rod away from lever (ball stud on lever engages socket in rod). (On Buick, remove universal joint retaining ring from slot in output shaft, using a screw driver and hammer to free ends of this lock ring). Take out retaining bolts and remove rear bearing retainer and gasket, check gasket for evidence of oil leakage. Take out ratchet wheel outer retaining ring (use snap ring pliers to free ring). *See Overhaul data for disassembly of rear bearing retainer.*

Rear Oil Pump and Lubrication Oil Pressure Regulator Valve Removal: *Rear Bearing Retainer (preceding) must be removed first.* Take out retaining bolts and remove pump body and gears as an assembly. Check gaskets for evidence of oil leakage. Remove pump drive key from shaft recess, remove rubber cushion located under drive key with a pointed tool. If possible, lift off rear pump plate and gasket (if plate sticks, tap plate out after planetary gear set removed). Check gasket for evidence of oil leakage. Remove lubrication pressure oil regulator valve seat from rear face of transmission case (use special drag link socket to turn valve seat out), remove valve and spring.

Planetary Gear Set, Reverse Ring Gear, and Reverse Brake Band Removal: *All parts listed in preceding removal sections must be removed first.* Pull planetary gear set out through front of transmission case. Lift out reverse ring gear and two planet carrier thrust washers (if these parts did not come out with planetary gear set). If rear oil pump plate and gasket not removed previously (see above), tap out with hammer handle inserted through front of case. Remove reverse band operating lever by threading a ¼"-20 capscrew into tapped hole in anchor shaft and pulling shaft out, then lift out lever. Rotate reverse band toward adjusting hole until anchor accessible, disengage and lift out anchor. Compress

CONTINUED ON NEXT PAGE

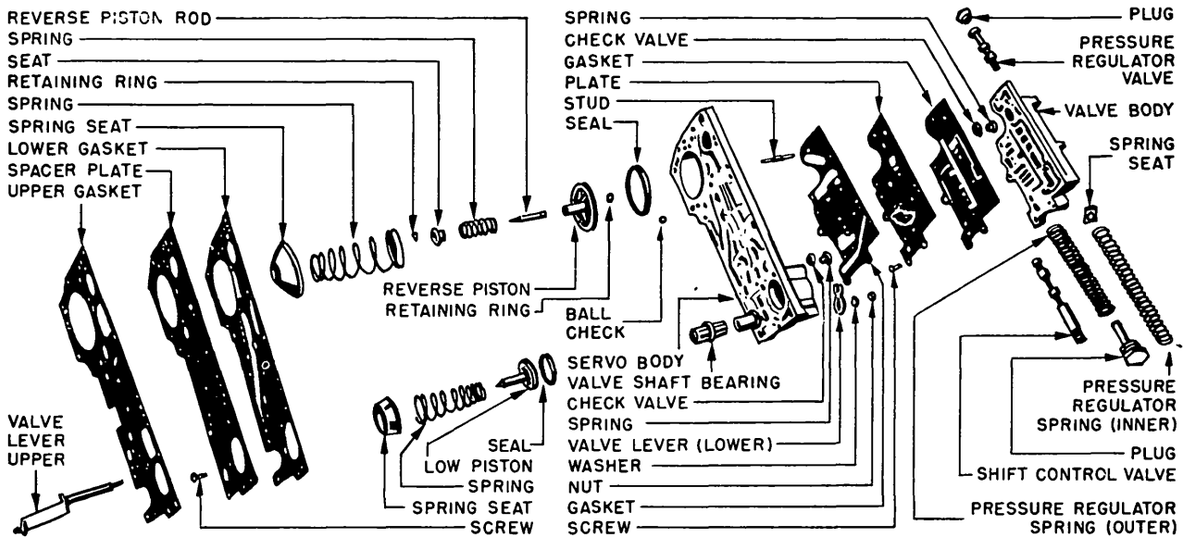
DYNAFLOW DRIVE (C nt.)

reverse band and install Band Installing Clip J-2595 across strut flanges to hold band compressed, lift band out. *See Overhaul data for disassembly of Planetary Gear Set.*

OVERHAUL

►***PARTS INTERCHANGE CAUTION: The following parts are NOT interchangeable between 1953 and 1954 torque converters. 1st Turbine Disc & Hub Assembly, 2nd Turbine, Planet Carrier, Planet Pinions, and Sun Gear and Yoke***

►*1954 FRONT PUMP PRODUCTION CHANGE:* A new oil pump, Part No. 1391884, with blind bolt holes (bolt holes not drilled all the way through flange), entered production with Dynaflow Transmission No. .070. **This later type pump is not interchangeable with previous pump.**



►***REACTION FLANGE TO FRONT PUMP BOLT PRODUCTION CHANGE:*** A longer mounting bolt is now being supplied for service replacement on both early and late type front oil pumps. Later type bolt is ⅛" longer (1½") than early type and can be used with both type pumps. *CAUTION*—When installing this longer bolt on early pumps it will be necessary to use a bottoming tap so that depth of threads will be .562" (approximately one full turn of tap past the old thread depth).

►***OIL COOLER & RETAINING BOLT PRODUCTION CHANGE***—A new type oil cooler and oil cooler retaining bolt (attaching oil cooler to rear bearing retainer) will be used making it unnecessary to remove the two lower bolts holding transmission rear bearing retainer to transmission. New bolt is "stud bolt" type having a threaded section on both sides of hex head.

After all Converter and Transmission Major Components removed from transmission case, disassemble and overhaul these units as follows:

Converter Stators & Pump: Disassembly—Pry retaining ring out of groove in first turbine, insert screw driver in hole in disc and lift disc and hub assembly out of first turbine. Lift second turbine and carrier assembly out of first turbine. Remove four bolts with lockwasher and pinion pin lock plate from second turbine. It is not necessary to lift turbine from carrier at this time. Remove pins, then remove the four planet pinions and thrust washers from turbine carrier. Remove bearing rollers (22) from each pinion. Remove ball bearing from rear side of converter stator, push the free wheel roller race out of free wheel cam in front side of stator, then remove all rollers, cups, and springs from the cam. Pry the pilot bearing retaining ring out of its groove in hub of converter pump cover, then push pilot bearing and bearing retainer out of the hub.

Inspection—Wash all parts in clean solvent and dry with air. Inspect all planetary gear teeth, thrust washers, bushings, and related bearing surfaces for excessive wear, scoring or other damage. Inspect free wheel roller springs for distortion and check rollers and race for nicks or burrs. Small nicks or burrs should be removed with an Arkansas stone and polished with crocus cloth. Inspect converter pump, turbines, and stator for damaged or cracked vanes. Inspect rear edge of first turbine hub (at ring gear) and the mating thrust surface

DYNAFLOW VALVE & SERVO BODY ASSEMBLY

on second turbine (around carrier) for wear, scoring or other damage. Inspect turbine carrier for excessive wear or other damage. ***(If second turbine or the carrier must be replaced, use care in separating them to avoid damage to the good part).*** Inspect converter pump hub for scores and for wear caused by the front pump seal.

►*INSPECTION CAUTION*—Converter oil leaks, oil pump body leaks, front oil pump noise, and excessive wear of front pump bushing and oil seal may be caused by (1) Excessive runout of converter pump hub; (2) Excessive runout of flywheel face; (3) Misalignment of bell housing. When any of these conditions are encountered and there is any doubt as to their true cause see Alignment of Converter and Bell Housing (below).

Assembly—***(CAUTION—If stator was replaced, make certain that new stator has correct number of vanes—12 vanes, Buick 40; 20 vanes, all others).***

1) Place input shaft pilot bearing retainer in hub of converter pump cover with shouldered side upward, push the pilot bearing into hub of cover until outer race bears against shoulder in hub, then install retaining ring.

2) Install springs and cups on free-wheel roller race in cam on front side of converter stator, then use a suitable thin blade to depress the cup and spring while inserting each of the free wheel rollers.

3) Install the ball bearing in rear side of stator, using care to start it squarely into place. The bearing must be fully seated in counter-bored recess and outer race must be free to turn.

4) If second turbine was separated from carrier, make sure that counter-bored recess in turbine and mating surfaces of carrier are free of burrs and clean, then apply a thin film of oil to these surfaces.

5) Support carrier on suitable blocks, install several pinion pins to serve as pilots, then place turbines in position so that carrier is started squarely into recess in turbine. Use a hammer and hardwood dowel or other soft punch to tap turbine down over carrier. ***Avoid distortion of turbine by using light blows applied midway between holes and alternated from side to side to keep parts square with each other.***

►***CAUTION—If turbine cannot be assembled on carrier with moderate force, remove it and check for burrs in counter-bored recess.***

6) With turbine and carrier supported on wood blocks, hub side down, assemble and install the four pinions as follows: Place planet pinion on thrust washer, install 22 needle bearing rollers in pinion and place a thrust washer on top of pinion. ***(NOTE—A loading tool can be made by using a piece of steel rod ⅜" in diameter by 11/16" long. Place tool in center of pinion and install needle bearings around tool).*** Place assembled pinion in carrier and install a pinion pin with notched end up. After loading tool is pushed out of carrier, slide block under pinion pin to hold it in place. Turn all pins so that notch faces center of carrier.

7) Install pinion pin lock plate so that it enters notches in all pins, then install the four turbine-to-carrier bolts with lockwashers. Place second turbine and carrier assembly in first turbine, then install first turbine disc and hub assembly over second turbine.

8) Rotate disc until ring gear meshes with carrier pinions, then align driving lugs on disc with notches in first turbine and push the assembly all the way into turbine.

9) *CAUTION—Turbine disc retaining ring is installed exactly as follows:* Place the ring in position with "dished" side upward so that the inner edge will bear firmly against disc when ring is engaged in groove in first turbine. Start one end of ring into grove in turbine, then twist ring upward in order to lay ring flat on disc so that it can be progressively entered into groove all the way around.

10) Make certain that ring is fully seated in groove and that inner edge bears against turbine disc. Tap inner edge down against disc if it has raised up.

CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (Cont.)

Valve & Servo Bodies: Disassembly—Remove safety nuts and washers from body studs, lift off valve body and gasket, examine gasket for evidence of oil leakage. Remove shift control valve from valve body and rear pump delivery check valve and spring from servo body. Remove large pressure regulator valve plug from valve body *(CAUTION*—hold plug to prevent it flying off due to heavy spring pressure), remove springs and spring seat. Remove small valve plug and lift out pressure regulator valve. Remove valve body plate and gasket, examine gasket for evidence of oil leakage. Lift out front pump delivery check valve and spring. Take off nut and lockwasher attaching upper and lower valve operating levers in servo body and remove levers. Use wooden block placed across low and reverse servo spring seats to hold them in place with springs compressed while taking out spacer plate attaching screws, carefully relieve spring pressure *(CAUTION*—use care not to spring spacer plate or allow servo springs to fly out), lift off spacer plate and gasket, examine gasket for evidence of oil leakage. Lift out low and reverse servo spring seats, springs and pistons. Remove check valve from reverse servo feed channel.

Inspection—Wash valve and servo bodies and parts with clean solvent, blow out all passages and dry parts with air. Inspect bodies for cracks, damaged gasket surfaces, and scored piston and valve cylinders. Inspect valves and pistons for nicks, scores, scratches, or rounded shoulders (edges must be sharp to keep out foreign material which might cause sticking). Replace worn or damaged piston seals.

▷Piston Seal Installation Caution—Lip on seal must fit over SMALLER diameter land on piston.

Reassembly—Install low and reverse servo pistons in servo body (CAUTION—use care not to damage seals), check to see that pistons move freely in body. Install piston springs and spring seats (small end of low servo spring in groove in piston, large end of both reverse servo springs in grooves in piston). Place check ball in reverse servo feed channel. Use new spacer plate gasket, compress servo springs and tighten all spacer plate attaching screws uniformly. Install both upper and lower operating levers with lower lever pointing to low servo cylinder and upper lever to reverse piston spring seat, tighten lever shaft nut to 15-20 ft. lbs. torque. Install front pump delivery check valve spring (large end down), and valve (ridged side up), then install valve body plate using new gasket and making sure that valve seats against plate (must not hang on gasket). Install pressure regulator spring seat, inner and outer springs, and valve plug in valve body, tighten plug to 20-25 ft. lbs. torque. Install pressure regulator valve (see that oil orifice in end land is clear and place this land outward), tighten valve plug to 20-25 ft. lbs. torque. Install shift control valve with slotted end of valve pointing toward large pressure regulator plug. Install rear pump delivery check valve (ridged face inward), and spring (large end upward). Install valve body on servo body using new gasket *(CAUTION*—see that pump delivery check valve spring below gasket), tighten all stud nuts to 11-15 ft. lbs. torque.

High & Low Accumulators: Disassembly—Remove retaining pin and check ball from High Accumulator body (not used in Low Accumulator). Remove the pipe plug, cap, gasket, spring and piston from each accumulator body keeping these parts separated so that same parts will be re-installed in same body.

Inspection—Clean all parts with solvent, blow out all passages and dry with air. Check parts for excessive wear, scoring, nicks, burrs, and other damage. Remove nicks and burrs from pistons and valves by stoning but do not round off sharp edges of pistons and valves (edges must be sharp to keep out foreign material which might cause sticking). Check mounting face of accumulator body for flatness with a straightedge (face can be trued up by using emery cloth on a surface plate but all traces of emery must be removed). Replace accumulator assembly if body, or piston worn (these parts not furnished separately). Check piston for wear by placing it in cylinder (all parts clean and dry). Piston should slide freely as body is tilted back and forth.

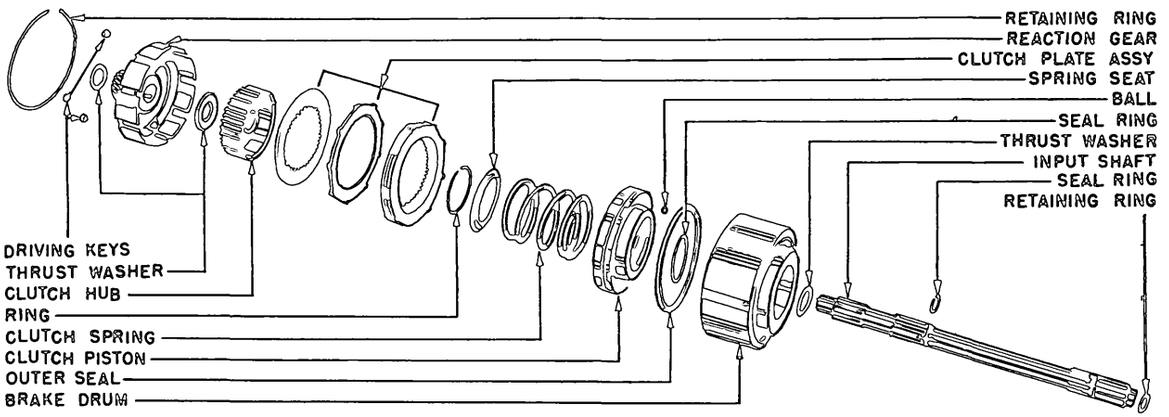
Reassembly—Lubricate all parts before installation. Install each piston in same cylinder from which removed, install springs (see illustration and Spring Note below), use new gasket on cap and tighten cap finger tight—DO NOT attempt to tighten caps fully at this time (caps will be tightened to 40-50 ft. lbs. torque after reaction flange assembly re-installed in transmission).

Reaction Shaft Flange & Oil Pump: Disassembly. Remove high and low accumulators and gaskets using care not to drop retaining pin and check ball out of High Accumulator (not used in Low unit). Check gaskets for oil leakage. Check oil pump mounting nuts for tightness (loose nuts may have been causing oil leakage), remove nuts, take out pump body and gears (tap body lightly with soft hammer if necessary). Lift off pump cover and gasket, check gasket for evidence of oil leakage. Remove check ball from clutch feed passage in reaction flange if ball free to fall out (do not remove ball if retained by peened edges of hole).

Oil Pump Inspection & Repair—Clean pump parts with solvent and dry with air. Check pump gears and mounting faces of body and cover for excessive wear. Check front pump bushing for excessive wear or looseness which will require replacement of pump assembly *(NOTE*—Check flywheel and primary pump hub run-out and bell housing misalignment if bushing worn or loose). Check front oil pump seal and replace if damaged or any evidence of leakage noted. Drive out old seal, coat outside of new seal with Permatex #3, start seal in place with deep groove in retainer outward, tap seal into place with wood block and mallet. Check following clearances and replace pump parts if excessive:

Reassembly—Install pump cover on reaction flange using new gasket (make certain that check ball in clutch feed passage first). Lubricate pump gears and install in pump body with beveled side of driving gear outward so that it will be against cover when pump installed *(CAUTION*—reversal of gear will cause severe damage to transmission). Install oil pump on reaction shaft flange, engaging locating dowels in dowel holes in flange, then install nuts with lock washers. Tighten nuts to 5 ft. lbs. in correct sequence (see note below), then fully tighten nuts to 25-30 ft. lbs. torque in same sequence, finally tighten cover attaching stud nut to 25-30 ft. lbs. torque.

▷Front Pump Tightening Sequence—Tighten nuts in following order: Top, Bottom, Right Center, Left Upper Center, Right Lower Center, Left Lower Center, Right Upper Center.



Pump Gear Side Clearance—Place straightedge across face of pump body and gears. Clearance between face of gears and straightedge should be .001-.0025" (front pump), .001-.002" (rear pump).

Pump Gear Clearances—Check pump gears with feeler gauge between gear teeth and crescent while pressing gear away from crescent. Clearance should be .005-.009" (front pump driven gear), .0045-.007" (rear pump driven gear), .010-.016" (front pump driving gear), .006-.012" (rear pump driving gear).

Pump Cover Gear Wear—Replace cover if gear bearing area scored or worn to depth of more than .001".

Reaction Shaft Flange Inspection—Clean flange in solvent, blow out all passages and dry with air. Check mounting surface of flange for low spots with straightedge (Gauge J-2596) and feeler gauge, replace if out more than .002". Inspect mating face of transmission case similarly and replace case if it

CONTINUED ON NEXT PAGE

DYNAFLOW DIRECT DRIVE CLUTCH ASSEMBLY

DYNAFLOW DRIVE (C nt.)

cannot be trued up within .002". Check both surfaces for nicks and burrs, remove these with a mill file. Check bronze bushing on reaction flange rear hub and cast iron sleeve within hub, replace reaction shaft flange if these parts scored or worn excessively. Check oil sealing rings and replace if damaged (rings have interlocked ends and are released by compressing ring and depressing one end while raising the other). Check all studs for tightness, replace if threads damaged or stripped (step studs furnished—can be installed by tapping out hole).

Accumulator Spring Note—Springs can be identified by free lengths as listed below.

Low Accumulator Springs

	Free Length	Part No.
Inner Spring	5 3/16"	1339495
Outer Spring	3 11/16"	1339496

High Accumulator Spring—Part No. 1331461. Length 4 15/16".

Multiple Disc Clutch & Input Shaft: Disassembly. Remove retainer ring from reaction gear flange, use pointed tool to remove three flange driving keys. Lift out Low Range Reaction Gear, Thrustwasher, Clutch Hub, and all 10 Clutch Plates. Install Clutch Spring Compressor J-2590 in clutch drum placing slot in compressor ring over ends of spring seat retainer ring, compress spring sufficiently to remove retainer ring, release clutch spring pressure *(CAUTION*—use care that spring seat does not hang up in retainer ring groove in drum). Remove compressor, lift out spring seat and spring. Tap drum, open end down, on block of wood to dislodge clutch piston *(CAUTION*—if check ball in piston unseated during this operation, snap ball back in place).

Inspection—Wash parts in solvent and dry with air *(CAUTION*—use only gasoline or kerosene on clutch bands and plates—do not use chemical degreasers or commercial solvents). Inspect and replace all clutch plates which are worn, scored, burred, or warped *(CAUTION*—new plates must slide freely on clutch hub—tight plates will prevent full disengagement). Inspect oil seal ring on clutch hub and replace if damaged (ring has interlocked ends and is released by compressing ring and depressing one end while raising the other). Replace clutch piston outer seal if hardened, broken, or with turned lip (install new seal with lip extending over smaller diameter piston land). Inspect Low Range Band and replace if worn smooth without visible grooves. Inspect oil seal ring and replace if damaged (same type ring with interlocked ends as used on clutch hub). Check to make sure retaining ring in place in shaft groove. See that small bleed hole in piston is open and that check ball is staked in place *(CAUTION*—ball must be free to move in recess).

Reassembly—Lubricate piston seal and inner surface of drum with light oil, install piston using extreme care not to distort or turn lip of seal. Top of piston should be approximately even with shoulder in drum when installed. Install clutch spring, use Compressor J-2590 to compress spring, install spring retaining ring in groove in drum, remove compressor. Place reaction gear on bench with flange upward and install all clutch parts in following order: Clutch Hub Thrustwasher, Clutch Hub (open end upward), and all clutch plates (see Clutch Plate Caution below). Bottom clutch plate should be internally splined (faced) type and top clutch plate externally splined (plain steel) type with the two types alternating in the assembly. Install drum and clutch piston assembly over reaction gear and clutch assembly with driving key recesses in drum and gear flange aligned. After drum pressed evenly in place, fully align driving key recesses by tapping reaction gear flange, install three driving keys and flange retainer ring.

BUICK REAR BEARING RETAINER & TORQUE BALL ASSEMBLY

►**Clutch Plate Caution**—Externally splined (plain steel) clutch plates are concave or "dished" and these plates must be installed with "dished" face in same direction (either up or down). Check each plate with straightedge and stack plates with dished faces in same direction before beginning installation. *NOTE*—Internally splined clutch plates are flat and can be installed in either direction.

Rear Bearing Retainer: Disassembly—Disconnect valve operating rod clevis from valve operating cross-shaft inside retainer housing, withdraw rod through forward end of housing. Disconnect parking lock operating rod from cross-shaft by unscrewing rod end from lever. Remove cross-shaft bearing using a box wrench *(CAUTION*—loose fitting socket or end wrench will distort bearing), remove cross-shaft. Remove parking lock pawl shaft by screwing ¼"-20 capscrew into shaft and pulling shaft out. Tap parking lock operating lever toward front of shaft, operating lever, lever & pawl assembly, and apply spring from retainer.

Rear Bearing Retainer Inspection—Wash parts in solvent and dry with air. Check parking brake pawl, pawl locking link, and ratchet wheel for worn teeth, cracks, or other damage preventing positive locking. Check valve operating cross-shaft and bearing for wear, remove and discard rubber seal in bearing. Inspect output shaft bushing in retainer for wear scoring, check clearance by inserting output shaft in bushing. Clearance should be .001-.006". Replace bushing with Bushing Remover & Replacer Tool J-2997 (not necessary to ream new bushing).

Universal Joint Inspection—Check for wear and excessive play between spider pins and bushings (should be .002-.004"). Check yokes for wear on shaft splines. Front yoke must be tight fit on output shaft (play will allow "snap" between forward and reverse), rear yoke backlash on propeller shaft should be .0005-.0045". Rear yoke clearance in torque ball bushing should be .004-.006" and bearing surfaces must not be scored.

Torque Ball Inspection—Replace torque ball and retainers if bearing surfaces scored or pitted. Inspect oil seal and replace if worn (use seal which has been soaked in neatsfoot oil), press seal squarely into place until flush with torque ball flange and with feather edge of seal pointing into torque ball. Check universal rear yoke for excessive wear at point where seal bears.

Reassembly—Assemble locking pawl and lever, apply spring, and parking lock operating lever & rod using a dummy shaft for this purpose (dummy shaft can be made up of 7/16" round stock, 1½" long, with ⅛" chamfer on one end), place this assembly in position in bearing retainer and install operating shaft through retainer and lever. Install parking lock pawl shaft through bearing retainer and lock pawl **with tapped end outward**. Install valve operating cross-shaft and cross-shaft bearing with **new rubber seal** in bearing (grooved side inward). Connect parking lock operating rod to cross-shaft lever (use lockwasher on threaded rod end) but do not connect valve operating rod and lever to cross-shaft until rear bearing retainer being assembled to transmission case.

Extension Case: Disassembly—(Cadillac) Remove large extension shaft bearing retainer ring from front end of housing. Carefully remove extension shaft, with speedometer drive gear, sleeve, oil pipe, and bearing. Using an arbor press, remove speedometer gear and sleeve from extension shaft. Remove small bearing retainer from extension shaft and press bearing off of shaft. Remove small oil pipe from extension shaft, and remove oil seal from extension housing.

Oldsmobile—Remove seal from rear of housing, and remove inner snap ring from extension shaft through seal end of housing. Tap extension shaft with soft hammer until bearing free on extension

CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (Cont.)

shaft, then remove extension shaft assembly from front of housing. Remove large snap ring from bearing housing using Tool J-5172, then remove bearing. Remove snap ring from shaft. Press off sleeve using Tools J-358-1, J-4390, J-1184; then remove speedometer gear from sleeve by pressing sleeve out of gear.

Inspection—Wash all parts in cleaning solvent, and inspect extension shaft for excessive wear and nicks or burrs on splines. Check bearing for pitting or galling. Inspect extension housing for cracks.

Reassembly—Reverse the Disassembly instructions given above.

Planetary Gear Set: Disassembly—Take out three planet carrier screws and special lockwashers (use 7/32"Allen wrench), separate front and rear halves of planet carrier (hold carrier by output shaft, tap down on flange on front end). Lift out sun gear rear thrustwasher and reverse sun gear. Remove all planet pinion assemblies (three long low pinions, three short reverse pinions) by tapping shaft out of front half of carrier using care not to lose steel ball imbedded in end of each shaft to prevent shaft rotating in carrier. Disassemble pinion assemblies by removing thrustwashers and shafts from pinions and then taking out bearing rollers (long pinions have two sets of rollers separated by spacer, short pinions have one set of rollers).

Inspection: Wash all parts in solvent and dry with air. Inspect planet pinion shaft and rollers, replace if worn. Inspect all gear teeth for wear, remove all nicks and burrs by stoning. Replace bushing in rear end of planet carrier if worn or scored (use Bushing Remover J-3197, Bushing Replacer J-2996—new bushing may be installed either end first and need not be reamed). Inspect reverse band anchor for cracks. Replace reverse band if cracked or the lining worn smooth.

Reassembly—Assemble each planet pinion with its bearing rollers, thrust washers, and shaft (24 rollers in each reverse pinion, 20 rollers at each end of low pinion and separated by a spacer). Make certain that thrustwasher installed at each end of each pinion (lower washer against retaining ring on shaft, upper washer on outer end of shaft). Install planet pinion assemblies in carrier making certain that steel ball imbedded in lower end of each shaft (necessary to prevent shafts turning). Install reverse sun gear with bronze thrustwasher on top of gear, align assembly marks on both planet carrier halves when installing upper half (numbers stamped on dividing line during production), make certain that special lockwasher used on each carrier screw, tighten screws evenly to 25-30 ft. lbs. torque. Install reverse ring gear thrustwasher.

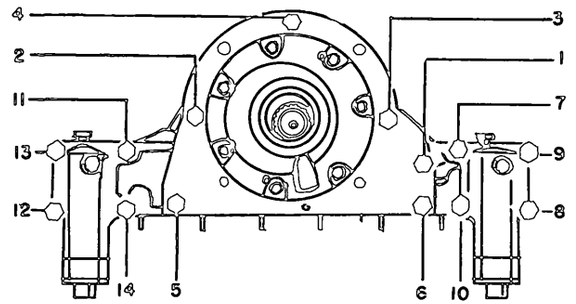
Transmission Case (Cleaning & Inspection): Wash case and blow out all passages. Inspect for cracks, and stripped bolt threads. Check machined surfaces for nicks and burrs and clean these up with a mill file. Check bushing in case for wear by inserting planet carrier in bushing and checking clearance with a feeler gauge. Clearance should be .002-.004". Replace bushing if clearance excessive or if scored.

Bushing Replacement—To remove old bushing, support case with rear end down, drive bushing out with tool J-3175-1 (part of replacer set). To install new bushing, place pilot J-3175-2 (part of replacer set) in rear oil pump recess in case, slip bushing over J-3175-1 and drive bushing into case from front side until bushing is flush with front surface of case wall which supports the bushing. Bushing must be installed with wide deep ends of oil grooves toward rear of case.

Flywheel & Primary Pump Run-out and Bell Housing Alignment Check: *Make this check if front oil pump noisy, bushing and oil seal worn, or if oil leakage noted at Converter or Front Oil Pump Body.*

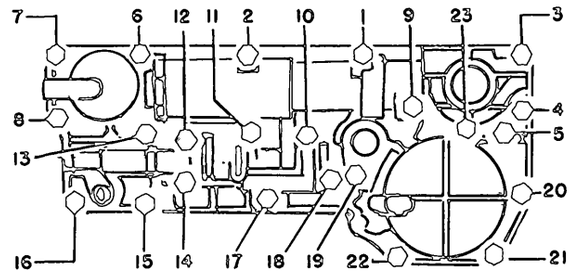
Flywheel Run-out—Remove all burrs from around drilled holes in face of flywheel, mount dial indicator on flywheel housing with strip of .005" shim stock between dial indicator and face of flywheel (clamp shim stock under a flywheel housing bolt so that it covers bolt holes and provides smooth surface for dial indicator pick-up). Turn flywheel holding end thrust in one direction. Run-out should not exceed .008". If excessive run-out cannot be corrected by tapping high side with mallet or by removing flywheel and cleaning up burrs at crankshaft flange mounting holes, install new flywheel and re-check run-out.

Primary Pump Hub Run-out—With converter primary pump and bell housing installed, mount dial indicator on bell housing so that it bears against primary pump hub. If run-out exceeds .012" when flywheel turned, mark flywheel and primary pump, remove and re-install pump at point 180° from first position. If pump run-out still exceeds .012", install new primary pump and recheck run-out. When position found where run-out is less than .012", mark flywheel and pump with paint and align these marks when transmission is finally re-installed.



Bell Housing Alignment—Mount dial indicator on oil pump driving lug on rear end of converter primary pump hub (*CAUTION*—do not clamp indicator on bearing surface) so that it bears against rear face of bell housing at 3¾"" radius. Rotate flywheel holding end thrust in one direction. Run-out should not exceed .005". Mount dial indicator so as to bear against inner edge of pilot hole in bell housing and repeat test. Run-out should not exceed .004". Correct by installing paper shims of correct thickness between flywheel housing and engine crankcase (use shellac to hold shims in place).

REASSEMBLY



After overhaul of Major Components, make certain that all parts absolutely clean, oil moving parts with 10-W engine oil before installation, use ALL NEW GASKETS & SEALS. Tighten all parts evenly to specified torque and in correct sequence (see illustrations). Proceed in reverse order of disassembly directions and note all of following points:

Planetary Gear Set Installation: After reverse ring gear thrustwasher and reverse band installed in case (with Installing Clip J-2595 on band), rotate band 45° toward servo opening, insert anchor and engage hooked end of band, then rotate assembly back into position. Position band operating lever in place with strut shoulder toward inside of case, install anchor shaft with tapped end outward. If installation correctly made, adjustment screw will be centered in servo opening (lever has offset end). See that planet carrier front (steel) thrustwasher installed on carrier with three tangs engaging holes in carrier, install rear (bronze) thrustwasher in case with three tangs engaging holes in case, then install planet carrier. If correctly installed, chamfer on output shaft journal will be flush with rear end of transmission case bushing.

Rear Oil Pump & Lubrication Oil Pressure Regulator Valve Installation: Install rear gasket (gasket with LARGER hole—do not confuse with cover gasket) and plate on transmission case with bolt holes aligned, install drive key cushion and key in output shaft, then install driving gear to engage key (old gear should face in same direction as before, new gear with either face in). Tighten attaching bolts to 5 ft. lbs. torque in following sequence: Top, Bottom, Right, Left; then retighten bolts to 25-30 ft. lbs. torque in same sequence. Check pump for free operation by rotating output shaft. Install lubrication oil check valve assembly in case.

REACTION SHAFT FLANGE & ACCUMULATOR BOLT TIGHTENING SEQUENCE

VALVE & SERVO BODY BOLT TIGHTENING SEQUENCE

Parking Lock Ratchet Wheel & Rear Bearing Retainer: Make certain that retaining ring installed on each side of ratchet wheel on output shaft, insert valve operating rod through square hole in front face of bearing retainer and connect rod to cross-shaft lever, then install rear bearing retainer and gasket, tighten attaching bolts evenly to 35-40 ft. lbs.

Low Brake Band, Clutch, & Input Shaft Installation: Install low band operating lever and anchor lever with strut shoulders of levers toward inside of case and tapped ends of shaft outward (operating lever on side of case having large servo opening, anchor lever on opposite side). Install low band struts in ends of levers with notched ends together using two wooden blocks (1" x 2" x 3½") to support struts and band while assembling. Install low band with J-2595 band installing clip holding band compressed (*CAUTION*—used band must be installed in original position with point of heavier wear at anchor end,

CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (C nt.)

(new band can be installed either way). With struts engaging ends of band (notches on struts must straddle pins on band), apply operating lever and remove clip. Place bronze reaction gear thrustwasher on sun gear, install clutch assembly (use wire hook to lift low band if clutch does not go down fully), place bronze thrustwasher on front face of clutch hub. Install input shaft (make certain that oil seal ring ends properly locked and that retaining ring installed in shaft groove). If shaft does not go down into place, make certain all four thrustwashers are properly centered.

Reaction Shaft Flange, Front Oil Pump, & Accumulator Installation: Install special guide pin (see Guide Pin Note below) in accumulator bolt hole at each end of flange on transmission case. Install new gasket over guide pins so that **all holes in gasket and case aligned** *(CAUTION*—gasket can be installed incorrectly). Check oil seal rings on reaction shaft flange for correct installation with ends locked, install flange using care not to damage these seal rings. Install low accumulator (on same side as low band operating lever), and high accumulator (opposite side) making certain that **holes in gasket and flange match.** Coat accumulator bolt threads lightly with Permatex #3, install bolts and nuts with lockwashers but **do not tighten,** remove guide pins. Install three special bolts (⅜"-16 x 2") with plain washers in #2, 3, 4 positions (see Tightening Sequence illustration) for assembly purposes (these bolts removed after assembly completed), install regular pump cover bolts, nuts, and lockwashers at positions #1, 5, 6 *(CAUTION*—Coat #5 bolt threads with Permatex #3). Tighten all bolts and nuts (1-14) to 5 ft. lbs. torque in sequence shown in the illustration, then tighten #1 through #4 to 35-40 ft. lbs. and all remaining nuts and bolts to 20-25 ft. lbs. torque in the same sequence. Remove the three special bolts (#2, 3, 4). Tighten accumulator body caps to 40-50 ft. lbs. torque. Check flange gasket and trim lower edge flush with bottom face of transmission case if it projects.

►**Guide Pin Note**—These 5/16" guide pins can be made up from 5/16" round stock, 2½" long, with 5/16"-18 thread ½" long on one end and screwdriver slot on opposite end (chamfer this end slightly).

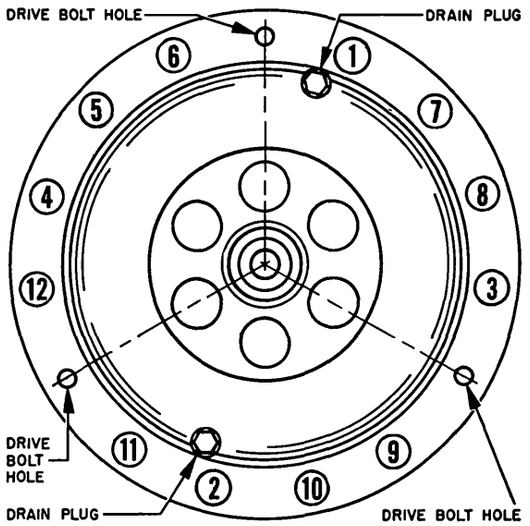
Valve & Servo Body Installation: With transmission inverted on bench, raise reverse band operating lever and insert strut between lever and end of band *(CAUTION*—rounded ends of strut must be against band and lever). After strut installed, **do not raise lever while installing valve and servo body** (will allow strut to fall into case). Install two 5/16" guide pins (same pins as used for reaction shaft flange—see above) in case to guide each end of servo body. Install spacer plate gasket over guide pins. Install valve and servo body on case (hold anchor piston from falling out and move shift control valve and lower operating lever inward to align upper level with opening in case). Engage control valve pin in slot in operating lever. Install correct length bolts and lockwashers in all mounting holes using copper washer on #10 bolt (see Tightening Sequence illustration), remove guide pins. Tighten all attaching bolts and nuts to 5 ft. lbs. torque in **correct sequence** (see illustration), then fully tighten all ¼" bolts and nuts to 11-15 ft. lbs. and all 5/16" bolts to 15-20 ft. lbs. torque in same sequence *(CAUTION*—When tightening nuts and bolts adjacent to shift control valve, operate valve to make sure that it does not bind—if necessary, readjust bolts to lower torque limit to correct binding). Remove #18 and stud nut #9, install cork gasket, oil suction pipe, retaining spring and spring support, tighten this #18 bolt and stud nut #9 to 11-15 ft. lbs. Connect valve operating rod to upper operating lever by reaching into case with Linkage Hook-up Finger J-2591 and pulling upward on rod to engage ball in socket. Install shift lever on cross-shaft temporarily to check and adjust linkage. Valve linkage must operate freely. Move lever toward front of transmission to engage parking lock. Pawl must fully engage ratchet wheel and pawl lock must be in full contact with pawl in this position. Push shift control valve away from stop pin until all play in linkage is just taken up, check clearance between end of valve and stop pin with feeler gauge. Clearance should be .030-.040" and spring travel at end of shift lever should be 1/8-3/16". Adjust by turning clevis on end of valve operating rod. After adjusting, make certain clevis locknut tightened and that clevis pin secured with snap fastener.

Oil Pan Installation: Coat area on transmission case where case cut away under oil pan gasket thinly with Permatex #3. Install 5/16" guide pin at each end (same pin as used for reaction shaft flange—see note above), install new oil pan gasket over guide pins. Install oil pan (use heavy-duty internal tooth lockwashers on bolts and stud nuts), tighten all bolts and nuts evenly to 15-18 ft. lbs. torque.

Buick Universal Joint Installation: Make certain that joint retaining ring fully seated in groove in output shaft before installing universal joint. If universal cannot be seated firmly against retaining ring by hand, use Replacer J-865 (40, 50), J-855 (70) to press universal joint on shaft. Tighten universal joint bolt to 30-35 ft. lbs. torque.

►***CAUTION—Oil passage in bolt must be clear (for universal joint lubrication).***

Buick Torque Ball Installation & Adjustment: *See "Torque Ball Adjustment" in Buick Special Data in Car Model Section for complete data.*



Bell Housing & Torque Converter Assembly Installation:

1) Install front oil pump seal ring around pump body against pump body. Install bell housing, using lockwashers on bolts and stud. Sparingly coat threads of lower right side bolt with Permatex #3 (bolt hole opens into transmission case). Tighten bolts and stud nut evenly to 35-40 ft. lbs. torque.

2) Install converter pump on reaction shaft, turning it until lugs on pump hub enter the slots in front oil pump driving gear. Make sure that the ball bearing is properly seated in converter stator, then install this unit on reaction shaft while pushing against the roller race to keep it from sliding out of place. Install stator retaining ring in groove in reaction shaft.

3) Install sun gear on input shaft and mesh it with free wheel cam in stator, then install bronze thrust washer on shaft. Place second retaining ring in groove in shaft, using Expander J-5338-2 on end of input shaft, and Driver J-5338-1 to push retaining ring over end of shaft.

4) Support twin turbine assembly so that all weight rests on a block placed under center of second turbine.

PUMP COVER TIGHTENING SEQUENCE

5) Attach Extension J-5339 to plunger of Dial Indicator KMO-30-B, then mount indicator on Support J-1013 with Sleeve KMO-30-K. Place indicator support on the protruding hub of turbine carrier, adjust dial indicator so that extension bears against ground surface on first turbine hub, then SET DIAL INDICATOR AT ZERO.

6) Support converter pump cover on blocks in a horizontal position, lightly tap the input pilot bearing down against shoulder in hub of cover, and place a bronze thrust washer in recess at center of pump cover.

7) Remove dial indicator and support from turbine assembly and set it firmly on the thrust washer on pump cover so that indicator plunger extension bears against inner race of pilot bearing. *CAUTION —use care to avoid changing the zero setting of dial indicator.*

8) The dial indicator should read between .002" and .010" CLOCKWISE from ZERO because the distance measured in Step 7 must be .002" to .010" LESS than the distance measured in Step 5. This difference is required to give the first turbine proper endplay or operating clearance in its position between the pump cover and second turbine.

9) If indicator does not read within specified limits, select another washer of proper thickness, which are furnished in the following sizes:

Thrust Washers

Part No.	Thickness	①Marked
1318799	.052-.055"	5
1318458	.060-.063"	6
1161654	.068-.071"	7

①—Thrust washer marked on flat surface.

CONTINUED N NEXT PAGE

DYNAFLOW DRIVE (C nt.)

10) Install twin turbine assembly on output shaft, turning it as required to mesh planet pinions with sun gear.

11) Looking at front face of converter pump cover, select the three bolt holes that are aligned with the center of the hub and one of the counterbored recesses adjacent to hub (see illustration). Mark these holes for later installation of flywheel-to-pump driving bolts.

12) Install a new O-ring seal on pump cover, making sure that surfaces are clean and that seal has even tension all around and is not twisted.

13) Grease the selected thrust washer so it will adhere and place it in recess in cover, then install cover on pump so that the three marked driving bolt holes are not aligned with any hole in pump rim at which a balance weight is located.

14) Install bolts with plain washers and special nuts in all but the three driving bolt holes, insert shank of a 11/32" drill through one bolt hole to align all holes, then tighten bolts approximately 5 ft. lbs. torque in numerical sequence shown in illustration. Finally tighten bolts in same sequence to 25-30 ft. lbs. torque.

►*CAUTION—When tightening bolts, insert a wide screwdriver blade between flat side of bolt head and pump to prevent a corner of bolt from digging into pump casting.*

15) Screw the socket setscrew with lockwasher into input shaft through opening in pump cover hub.

16) Remove reverse band adjustment cover and shift into "P" (Parking). Pry up on reverse band operating lever with screwdriver to lock input shaft then tighten socket setscrew to 25-30 ft. lbs. torque. Install large hex plug with gasket in hub of pump cover and tighten securely. Install adjustment cover and gasket.

INSTALLATION IN CAR

After transmission and torque converter completely assembled, install unit in reverse order of removal procedure and note following important points:

Alignment of Parts—See that flywheel, converter primary pump, and converter cover positioned so that paint marks (as made for removal) will be aligned when transmission installed.

►*CAUTION—This alignment necessary to maintain converter assembly balance.*

Bell Housing Mounting Bolt Installation—Adjust lifting equipment so that bell housing meets engine crankcase squarely and engages the two dowels, then install all bell housing bolts with lockwashers. Tighten all bolts to 45-55 ft. lbs. torque.

Transmission Support & Thrust Pad Installation & Adjustment—*See ENGINE MOUNTING in Buick Special Data.*

Converter Mounting Bolt Installation—Use the shank of a 11/32" drill to align bolt holes in flywheel and converter, install bolts and tighten to 25-30 ft. lbs. torque.

Final Road Test—After transmission installed and all adjustments made, road test car by driving approximately 20 miles with frequent starts and stops to duplicate heavy traffic conditions. After transmission thoroughly warmed up, check transmission and all oil lines and connections for leaks. If vibration noted due to unbalance of replacement parts, correct this condition as follows:

Shift Rod Installation—Check and adjust linkage when installing shift rod. *See LINKAGE ADJUSTMENT.*

Filling Transmission—*See LUBRICATION.*

Road Testing Car—After installation completed, road test car by driving approximately 20 MPH. with frequent starts and stops (heavy traffic conditions) to thoroughly warm up transmission. Check transmission carefully for oil leaks, recheck oil level.

ENGINE BALANCING

►*IF VIBRATION NOTED AFTER INSTALLATION OF CRANKSHAFT, FLYWHEEL, AND OTHER ROTATING PARTS, CORRECT THIS UNBALANCED CONDITION AS FOLLOWS:*

►*CAUTION:* Procedure below will correct minor unbalance caused by replacement of individually balanced parts. Extreme vibration caused by parts abnormally out of balance, or different in weight from corresponding parts, should be corrected by replacement of these parts.

Critical Speed of Vibration—Determine speed at which vibration is most evident (use tachometer) and operate engine at this speed to check results from the following corrective procedures.

1)—Remove bell housing cover and bell housing hand hole cover for access to flywheel.

2)—Install one .060" balance weight of correct type (see Balance Weight Note following step 5 below) under the head of one of the primary pump cover bolts, tighten bolt to 25-30 ft.lbs. torque.

►*CAUTION—DO NOT install weight at flywheel-to-converter driving bolt (bolts are too short for addition of weights).*

3)—Operate engine and check for vibration. Mark location of balance weight on converter pump, then remove weight and tighten cover bolt to 25-30 ft.lbs. torque.

4) Repeat entire procedure (3 above) with balance weight installed at other primary pump cover bolts equally spaced around cover and compare performance at critical speed for greater or lesser vibration.

5) At the location where the least vibration noted in above tests, install balance weights of correct thickness to eliminate objectionable vibration.

Part No.	Balance Weights	Thickness
1341420		.0345"
1341419		.060"
1341418		.120"

6) After balance weights finally installed and cover bolts tightened to correct 25-30 ft. lbs. torque, spot the center of hole in each weight with 5/32" drill, then use No. 32 (.116") drill to drill hole 3/8" deep in pump flange. Install drive screw (No. 145067—3/8" long or No. 450543—1/2" long depending on weight thickness) in this hole to permanently attach weight to pump flange.

►*IF VIBRATION CAN NOT BE ELIMINATED by above procedure, replace new part which caused the unbalance and repeat balancing procedure.*

Shift Rod Installation—Check and adjust linkage when installing shift rod. See LINKAGE ADJUSTMENT.

Filling Transmission—See LUBRICATION.

Road Testing Car—After installation completed, road test car by driving approximately 20 MPH. with frequent start and stops (heavy traffic conditions) to thoroughly warm up transmission. Check transmission carefully for oil leaks, recheck oil level.

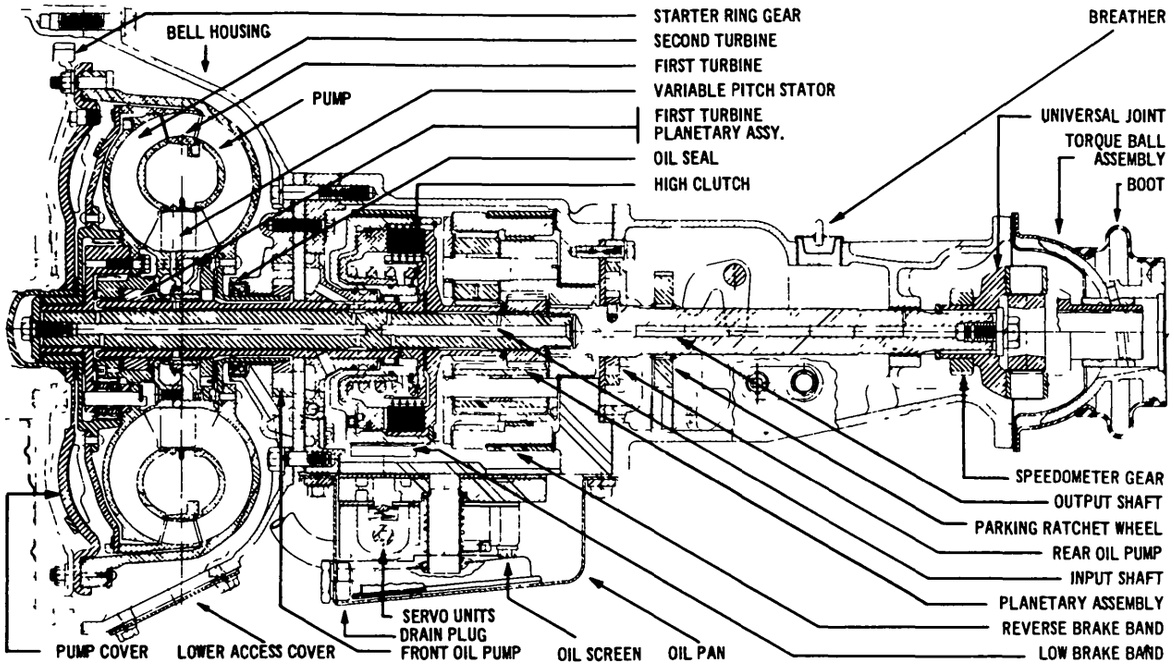
1955 BUICK "VARIABLE PITCH" DYNAFLOW DRIVE

Buick, Series 40, 50, 60 (1955)—Optional.
Buick, Series 70 (1955)—Standard.

►CHANGES, CAUTIONS, CORRECTIONS

►*STARTING ENGINE BY PUSHING CAR:* Place shift control lever in Neutral "N" position until car reaches a speed of 15 MPH., then move control lever to Low "L" position and continue to increase speed until engine starts (at approximately 25 MPH.). After engine starts, return lever to "N" position for engine warm-up.

DESCRIPTION



"Variable Pitch" twin-turbine torque converter of a new design, and a hydraulically operated planetary transmission similar in design to previous models.

Torque Converter Description: Converter consists of a first turbine, second turbine, pump, and "variable pitch" stator. The converter used on all models is identical.

First Turbine—Located directly forward of the converter pump and has narrow band of vanes which receive all oil flow from pump. This turbine is mounted on a disk and hub assembly bearing on the turbine carrier hub and is geared to the second turbine (internal gear of planetary gear set is mounted on the disk hub).

Second Turbine—Located within first turbine case with broad band of vanes which receive all oil flow from first turbine and directs the oil flow back into the stator. This turbine is bolted to a turbine carrier which is splined on the input shaft. The planet pinions of the turbine gears are mounted on carrier and mesh with the internal gear on the first turbine disk hub and with the sun gear which is mounted on a bearing on the input shaft and coupled to stator free-wheel cam (gears are always in mesh but operate only when sun gear and stator are held stationary for torque converter action). With the stator unlocked and free-wheeling (when torque converter operating as a fluid coupling, sun gear is likewise free to rotate which allows all units to rotate at nearly the same speed as the converter pump.

"Variable Pitch" Stator—The single variable pitch stator is located directly behind inner end of second turbine vanes and receives oil from second turbine and redirects it back into pump. Stator is mounted on a reaction shaft by means of a free wheeling unit similar to that used on previous models. Each of the twenty stator blades is mounted on an individual control crank which is supported at its outer end by the carrier ring and which is free to turn in its bearing in the stator carrier. The carrier contains a piston which actuates all blades through the control cranks when oil pressure is applied to one or both sides of piston. It is by this means that stator can be set at "high" or "low" angle as desired for rapid acceleration or for normal cruising.

VARIABLE PITCH DYNAFLOW SECTIONAL VIEW

OPERATION

OPERATION: Planetary units and controls operate in same manner as on previous Dynaflow Drive. The Torque Converter operates as follows:

Torque Converter Operation—When car is started up, the stator (in "low" angle) and turbine sun gear will be locked and held stationary. This results in First Turbine and Second Turbine as a geared unit with a ratio of 1.6-1 (first turbine rotating faster). This provides a maximum torque multiplication of 2.10-1 under stall conditions. As car speed increases, the torque reaction against the sun gear and the back pressure on the stator decreases and when this ceases, the stator free wheels and the sun gear is released. With sun gear released, the speed of the second turbine increases until both turbines and the stator are rotating at approximately converter pump speed. At this point the torque converter operates as a fluid coupling with a 1.0-1 torque ratio. The operation described has occurred without reaching wide open throttle operation, therefore the stator blades have remained in the "low" angle cruising position. If accelerator pedal is pressed to floor mat at any time in "D" range, the stator blades will be shifted to "high" angle performance position. In this position, the stall speed and torque multiplication of converter are increased.

LUBRICATION

Check oil level at 1000 mile intervals and add oil as required. Drain and refill at 25,000 mile intervals.

►***CAUTION—Oil must be warm and engine must be idling when checking oil level, warm up oil before draining.***

Checking Oil Level: With oil warm and engine idling with control lever in Parking "P" position, check oil level as indicated on dipstick in filler tube in engine compartment (on right side between battery and engine). If level more than 1" below FULL mark on rod, add recommended oil to bring level up to FULL mark *(CAUTION*—do not fill above the FULL mark). Distance between ADD OIL and FULL marks on rod is equal to approximately 1 pint of oil.

►***CAUTION—If oil level is consistently low when checked (indicating loss of 1 pint or more per 1000 miles), check transmission thoroughly for oil leaks.***

Draining & Refilling: With oil warm, drain transmission case by removing drain plug in oil pan, drain torque converter, after removing bell housing cover for access to drain plugs, by loosening one plug and turning converter until second plug is downward and removing this plug. Re-install and tighten all drain plugs. Install 3 quarts of recommended oil through filler opening in case. Start engine and allow it to idle with control lever in Parking "P" position, add additional oil to bring level up to point 1¾" below "FULL" mark on oil gauge rod. Recheck oil level after transmission warmed up. Oil level should then be at full mark on rod.

►***CAUTION—DO NOT FLUSH transmission when changing oil.***

Capacity—10 qts. *NOTE*—1¾ pints additional required if transmission completely dry (after overhaul, etc.).

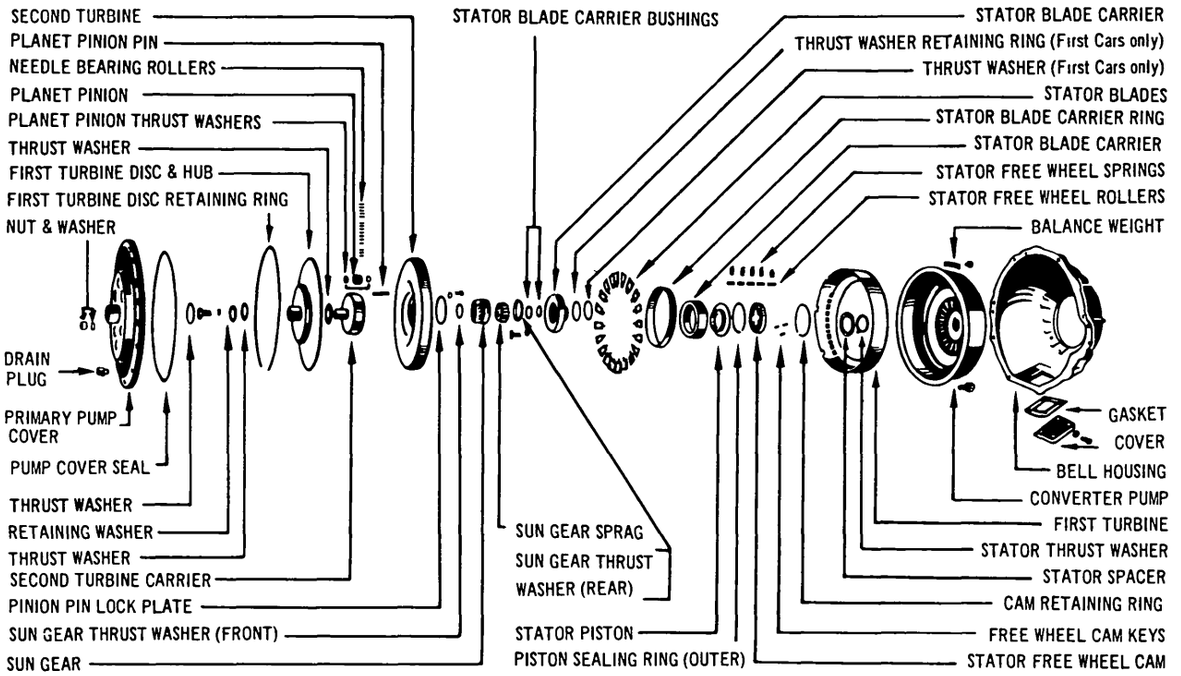
Recommended Oil—Use only "Special Buick Oil for Dynaflow Drive" or "Automatic Transmission Fluid, Type A" with AQ-ATF number embossed on can.

CONTINUED N NEXT PAGE

DYNAFLOW DRIVE (Cont.)

LINKAGE ADJUSTMENT

►*THROTTLE LINKAGE ADJUSTMENT NOTE:* The throttle operating rod contains an adjustable spring loaded stretch link which may be optionally adjusted to provide "overtravel" for delayed action of the variable pitch stator In production the stretch link is locked solid to eliminate overtravel and the throttle linkage is adjusted so the stator shifts to high angle performance position just as wide open throttle is reached If car is operated consistently at high speed it may be preferred to have the high angle shift occur after wide open throttle is reached In this case, "overtravel" may be obtained as outlined in "Adjustment with Overtravel" below ***CAUTION—Adjust throttle linkage WITHOUT overtravel on all Synchro-mesh cars.***



►*SHIFT CONTROL VALVE ADJUSTMENT CHANGE* The method of adjusting the shift control valve has been changed *See "Reaction Shaft Flange, Front Pump & Accumulator Installation" under Reassembly.*

►*STEERING COLUMN (SHIFT CONTROL) RATTLE CORRECTION*· Adjust manual shift control linkage EXACTLY as indicated in "Manual Shift Control Linkage Adjustment" below, to obtain a clearance of 035- 050" between stop screw and upper edge of large opening in stop plate If a "buzzing" sound or rattle continues to persist it may be caused by control shaft return spring vibrating and can be detected by moving transmission control lever toward steering wheel If this stops the "buzzing" or rattle, while lever is raised the trouble is in the spring and can be corrected by coating the spring with underbody sealer using a stiff bristle brush

BUICK LINKAGE ADJUSTMENT: ***Make adjustments in order and exactly as follows:***

Manual Shift Control Linkage Adjustment: 1) With shift control lever released, the stop screw in control shaft lower lever must be flush (± 010") with upper surface of stop plate Adjust as required
2) With shift control lever in "D" (drive) position, 035- 050" clearance must exist between lower lever stop screw and upper edge of large opening in stop plate (since this clearance cannot be readily checked, because of location, it may be assured by carefully performing the following adjustment)
(a) Disconnect lower shift rod clevis from idler lever and make sure that transmission shift lever is firmly held by detent in "D" position
(b) With shift control lever on steering column in "D" position, push upward on the lever to hold stop screw in contact with stop plate, then adjust clevis in shift rod so that clevis pin will freely enter clevis and lever
(c) Shorten length of rod by turning clevis 2 to 3 turns up on rod, then install clevis pin with anti-rattle washers and tighten clevis locknut The number of turns at the clevis provides a specified clearance at the stop pin
3) Park car on ramp or other slight grade with the control lever in "P" (parking) position to determine whether parking lock holds securely Then let car roll with control lever in "N" (neutral) position and listen for a clicking or ratchet noise which indicates that the parking lock pawl is contacting the parking lock ratchet wheel If parking lock fails to hold or ratchet noise exists, jack car up so that a wheel may be turned to rotate propeller shaft
4) Loosen linkage adjusting lever lock bolt on side of rear bearing retainer With transmission in "N" (neutral), tap rear end of lever upward until a slight ratchet noise is heard when propeller shaft is turned, then tap lever down just enough to eliminate the noise Tighten lock bolt securely making certain that lever does not change position
5) Set parking brake to prevent rear wheels from turning then start engine, with car still safely jacked up
6) With transmission warmed up and engine idling at approximately 600 RPM, slowly move control lever from "N" to "D" position The clutch should engage, as indicated by an immediate decrease in engine speed when center of dial pointer is midway between "N" and "D" on dial
7) Slowly move control lever from "D" to "N" position Clutch should disengage, as indicated by an immediate increase in engine speed, when center of dial pointer is midway between "D" and "N" on dial
8) If points of clutch engagement and disengagement are not as specified, and all preceding linkage adjustments have been made correctly, it will be necessary to remove transmission oil pan, suction screen, and adjust position of shift control valve as described in "Valve & Servo Body Installation" under "Reassembly" below

Throttle Linkage Adjustment: With floor mat properly installed and all throttle linkage well lubricated and operating freely, adjust throttle stopscrew for proper HOT idling speed of 450 RPM Turn engine off and check operation of unloader (adjust if necessary), proceed as follows
1) Disconnect throttle return spring and throttle operating rod from lever on equalizer shaft Back off stator pick-up lever adjusting screw until screw end is flush with lever surface
2) Adjust throttle operating rod in rod end at carburetor so that approximately ⅝" of thread is exposed, then tighten locknut
3) **For Adjustment Without Over-travel**—Turn rear end of throttle operating rod until stretch link is locked While another person presses accelerator pedal firmly against the floor mat, hold throttle lever in wide open position and hold rear end of operating rod at hole in throttle lever Rod must be approximately 1/16" **short** of entering hole in lever Change position of lever on shaft as required to obtain this condition, then tighten clamp bolt securely
4) **For Adjustment With Over-travel**—Turn rear end of throttle operating rod until rod can be stretched approximately 7/16" against tension of stretch link spring, measured at forward end of link While another person holds throttle UPWARD as far as possible, hold throttle lever closed to HOT idle position and hold rear end of throttle operating rod at hole in throttle operating lever Rod must extend 1/16" BEYOND hole in lever Change position of lever on shaft as required to obtain this condition, then tighten clamp bolt securely
5) Connect operating rod to operating lever, snap retaining clip over rod and connect return spring

VARIABLE PITCH DYNAFLOW TORQUE CONVERTER & BELL HOUSING

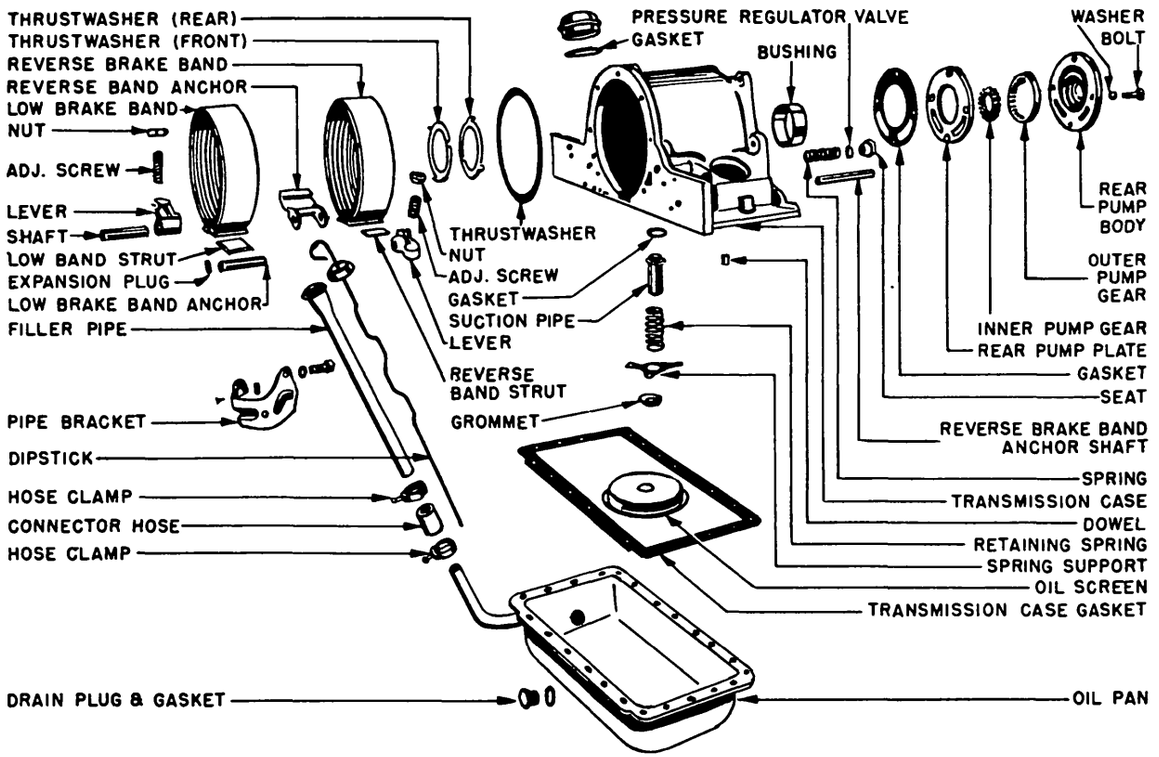
CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (C nt.)

With throttle closed to HOT idle position, check clearance between equalizer shaft lower lever and the stop lug in the shaft-to-cowl mounting bracket. A minimum clearance of 1/16" must exist at this point.

6) Hold choke valve closed while accelerator pedal is pressed to floor mat to check operation of unloader. If clearance between lower lever and stop lug is less than 1/16", or choke unloader does not operate properly, readjust the operating rod length at rod end on throttle lever or change position of upper lever on equalizer shaft one serration at a time until proper settings are obtained.

7) Depress accelerator pedal firmly against floor mat, then turn stator pick-up lever adjusting screw against stator operating lever, raising lever until all vertical play is removed from stator operating control rod. Turn screw back ½ turn to provide a slight clearance between stator control valve operating lever and its stop on high accumulator.



8) Finally check for smooth operation of linkage from fully closed to wide open position of throttle valve. Make sure that throttle closes firmly against stop screw. ***NOTE—On Dynaflow Cars (Without Over-travel), and on Synchro-mesh Cars, throttle valve should be wide open when accelerator pedal strikes floor mat. On Dynaflow Cars (With Over-travel), the stop on throttle lever must strike boss on throttle body before accelerator pedal can be pressed to floor against tension of stretch spring.***

Dashpot Adjustment: Adjust dash pot only after throttle linkage has been adjusted and engine is at normal operating temperature. Rotate fast idle cam to extreme cold idle position (choke closed), hold throttle lever against a .030" feeler gauge placed between stop screw and highest step of fast idle cam. Adjust dash pot until it just clears arm of throttle lever, tighten lock nut. With transmission in Direct Drive and brakes firmly applied speed engine up to about 1500 RPM and immediately release throttle, noting engine operation as throttle valves close. If engine stalls from too rapid closing of throttle valves, move dash pot forward until its action prevents engine stalling. If excessive time is required for throttle valves to reach closed position, move dash pot rearward. Tighten lock nut after each adjustment. If proper control cannot be obtained by adjustment, replace dash pot.

Starter Vacuum Switch: If operation not correct after carburetor linkage and dash pot adjustments made, *See Carburetor Equipment Section for complete data.*

N utral Safety Switch & Back-Up Light Switch: Located on steering column jacket under cowl and is actuated by transmission control shaft.

N utral Safety Switch Adjustment: With manual control linkage properly adjusted, ground primary terminal of distributor so that engine can be cranked without firing. Fully apply parking brake and place transmission control lever in "N" (Neutral) position. Place a narrow strip of masking tape on speed ratio dial so that upper end of dial pointer is visible. Make two marks on masking tape at ⅛" and 3/16" from center of pointer. Move control lever to "D" (Driving) position, turn ignition on and depress accelerator pedal to close accelerator vacuum switch. Slowly move dial pointer from "D" to "N" and note position of **center** of pointer at instant cranking motor just starts to operate. Release accelerator pedal. The **center** of the pointer should be between the two marks made on masking tape. If switch does not cut in within the specified limits, loosen switch mounting screws and move switch sideways as required for proper timing. Tighten mounting screws.

VARIABLE PITCH DYNAFLOW TRANSMISSION CASE, OIL PUMP, & SERVO BAND ASSY.

►***BACKING SWITCH NOTE***—No separate adjustment required (switch operation will be correct when neutral safety switch properly adjusted).

Switch Wiring—Check wire connections on switch terminals for correct wiring (incorrect wiring may allow starter to crank with lever in other positions than Neutral or Park—may engage when shifting from Low to Drive during heavy pull), or backing lights may operate with shift lever in other than Reverse. Switch connections from Right to Left (viewed from driver's seat) should be:

►***SWITCH WIRING CAUTION: Switch must be wired correctly and control lever stop plate must be correctly positioned for correct switch operation as follows:***

No. 1 (Right)—Black wire (to backing lights).

No. 2—Light Blue wire (to #1 terminal on fuse block).

No. 3—Pink wire (to Ignition Switch).

No. 4 (Left)—Yellow (to starter switch on carburetor).

BAND ADJUSTMENT

►***BAND ADJUSTMENT CAUTION—Bands cannot be adjusted with transmission in car and adjustment ordinarily required only when transmission overhauled. BANDS MUST BE CORRECTLY ADJUSTED BEFORE TRANSMISSION INSTALLED IN CAR.***

LOW & REVERSE BAND ADJUSTMENT: Both bands are adjusted alike as follows:

(1) Remove band adjusting covers and gaskets from upper right (Low), and left (Reverse) of transmission case.

(2) Loosen locknut and turn adjusting screw clockwise until considerable resistance felt indicating that band in full contact with drum or ring gear.

(3) Back off screw until trace of endplay noted when prying up on locknut with screwdriver, **then back off screw additional six turns,** hold screw from turning and tighten locknut snug.

(4) Note position of adjusting screw slot, use torque wrench to tighten locknut to 20-25 ft. lbs., check screw slot to make certain that screw position not changed.

(5) Install band adjusting cover **using new gasket.**

CONTINUED N NEXT PA E

DYNAFLOW DRIVE (Cont.)

TESTING

If performance not satisfactory, make following tests with transmission thoroughly warmed up and at operating temperature:

Oil Level: Check oil level, add fluid as necessary to bring level up to FULL mark on dipstick, recheck performance with correct oil level. If car has been losing oil at rate of 1 pint or more each 1000 miles, make thorough check for oil leaks.

Manual Control Linkage: Check and adjust manual control linkage. See Linkage Adjustment.

Hydraulic Control System Pressures: Use Transmission Oil Pressure Gauge J-2575. Support rear end of car solidly with wheels off floor so that transmission can be operated. Remove transmission cover in floor pan for access to pressure take-off points.

Connect gauge and make tests as follows:

Front Oil Pump—Connect pressure gauge at pipe plug opening on left side of reaction shaft flange. Run engine at 500 RPM., check pressure with selector lever in Low, Drive, and Reverse range. Repeat tests at 1000 RPM. and at 1800 RPM. in Low and Drive Range only. See table below for correct pressures. Low or erratic pump pressure indicates air leaks in suction line, improper pressure regulator valve action ,or excessive pump clearances.

Front Oil Pump Pressures

Selector Lever—	Low	Drive	Reverse
500 RPM	120 lbs.	90 lbs.	120 lbs.
1000 RPM	180 lbs.	90 lbs.	
1800 RPM	180 lbs.	90 lbs.	

Rear Oil Pump—Connect pressure gauge at pipe plug opening in lower flange at front end of rear bearing retainer. Run engine at 500 RPM., check pressure with selector lever in Low & Drive Range. Repeat test 1000 RPM. and 1800 RPM. See table below for correct pressures. Low or erattic pump pressures indicate air leaks in suction line (this will affect both pumps), improper pressure regulator valve action, excessive pump clearances or leaks in valve and servo body passages between pump and regulator valve.

Rear Oil Pump Pressures

Selector Lever—	Low	Drive
500 RPM	90 lbs.	90 lbs.
1000 RPM	180 lbs.	90 lbs.
1800 RPM	180 lbs.	90 lbs.

High & Low Accumulator—Connect pressure gauge at pipe plug opening on top of accumulator body (High—left side of car); (Low—right side of car). Place selector lever in Drive Range (High Accumulator Test); Low Range (Low Accumulator Test). Run engine and check pressures at speeds indicated in tables below. Low accumulator pressure may be caused by leakage past accumulator body gasket. If accumulator pressure more than 10 lbs. lower than front pump pressure, check for leakage between accumulator and multiple disc clutch and for restricted or plugged metering orifice in accumulator dump valve.

Accumulator Pressures

Selector Lever—	Low	Drive
500 RPM	115 lbs.	80 lbs.
1000 RPM	175 lbs.	85 lbs.
1800 RPM	175 lbs.	85 lbs.

Stator—Connect pressure gauge at pipe plug opening on left end of reaction shaft flange. Test pressure in Drive range at 500 RPM, 1000 RPM, and 1800 RPM.

Stator Pressures

Selector Lever—	Drive
500 RPM	70 lbs.
1000 RPM	75 lbs.
1800 RPM	75 lbs.

TROUBLE SHOOTING

▷*EXCESSIVE DYNAFLOW WHINE CORRECTION: (This condition is usually the result of excessive clearance between input shaft and bearing in the reaction shaft).* If transmission is to be disassembled to correct whine, perform the following:

1) Remove converter cover, twin turbine assembly, and sun gear, then mount dial indicator on end of input shaft with indicator button contacting reaction shaft. Position indicator button 90° to left of top center (facing end of shaft) then move input shaft away from and toward indicator while noting the gauge reading. Repeat this check at 45° to left of top center. If dial reading exceeds .005", excessive clearance exists between input shaft and bearing in reaction flange.
2) Before replacing bearing, remove reaction flange assembly and input shaft and observe the following: (a) Inspect bearing surface on input shaft. If surface appears abnormally rough or scored, replace input shaft; if not, polish journal area with crocus cloth. (b) Inspect the two oil seal rings toward rear of input shaft and the mating surface in the reaction shaft for scoring or other damage. If reaction shaft or input shaft shows evidence of scoring or other damage, replace worn or damaged parts.
3) If inspection reveals that condition of reaction shaft and input shaft are satisfactory, replace only the input shaft bearing (see Overhaul data).
4) If input shaft, reaction flange, or the bearing requires replacement, it will be necessary to replace the converter sun gear and planet pinions. *NOTE*—When installing reaction flange service bushing, be sure the assembly is supported on rear end of reaction shaft to prevent distortion of aluminum reaction flange.

CAR WILL NOT MOVE (Rear wheels may be locked or free).

1) With selector in any Range (rear wheels free). If car will not move for 1-5 minutes after standing over night—Check front pump oil pressure (see Testing) after allowing car to stand for several hours. If zero pressure noted, check pump for excessive clearances allowing pump to lose its prime. Check alignment of bell housing and converter primary pump hub.

▷*CAUTION—If this condition found, inspect Clutch and Bands for excessive wear due to slippage caused by low oil pressure.*

If car will not move after extended operation in Reverse—Check for air leaks in pump suction line (at rear oil pump gaskets), or excessive clearance in front pump (at pump gears and covers). Check alignment of bell housing and converter primary pump hub.
2) With selector in any Range (rear wheels locked). Parking lock engaged. Broken parts in transmission or rear axle. Parking brake applied.
3) With selector in Drive Range. Check front oil pump pressure and High Accumulator pressure. If OK, check for sticking Low Band Anchor Piston, remove and inspect Clutch for worn or sticking clutch plates, leaking clutch seal rings. If High Accumulator pressure low, also check rear pump Check Valve for correct installation and proper seating, check for leaks at accumulator body gasket, reaction flange gasket, clutch piston outer seal and clutch ball check valve, and leaks at sealing rings on reaction shaft flange and low drum.
4) With selector in Reverse Range. Check reverse band for displaced operating strut caused by too loose adjustment, improper installation, or broken band anchor (indicated by free up and down movement of band operating lever). If band assembly OK (no free movement of lever), check servo operation by running engine and shifting into Reverse. Remove Valve & Servo Body and check for reverse servo piston seal leaks.

EXCESSIVE SLIPPAGE (High engine speed in relation to car speed, or poor acceleration).
1) In all Speed Ranges. Low oil level. Incorrect manual control linkage adjustment. Air leak in oil pump suction pipe at oil screen sealing ring. Low front oil pump pressure caused by wear or excessive clearances in pump. Leaks at front pump cover or reaction shaft flange, pressure regulator valve, Valve & Servo Body gasket. Pressure regulator valve defective.
2) In Drive Range. Incorrect manual control linkage adjustment. If High Accumulator pressure low, check for leak at accumulator body gasket; if gasket OK, check for leaking clutch sealing rings, sticking clutch piston, worn or sticking clutch plates.
3) In Low Range. Incorrect manual control linkage adjustment. Incorrect low band adjustment. Low band and drum worn or scored. If Low Accumulator pressure low, check for leak at accumulator body gasket; if gasket OK, remove Valve & Servo Body and check for gasket leaks or leaks at low servo piston seal.
4) In Reverse Range. Incorrect manual control linkage adjustment. Reverse band out of adjustment, strut out of place, or anchor broken. If front oil pump pressure low, remove Valve & Servo Body and check for gasket leaks and leaking reverse servo piston seal.

CAR CREEPS (Forward or Backward).
1) Creeps forward with selector in Neutral. Incorrect manual control linkage adjustment. Sticking low servo piston (check by removing low band adjustment cover). Sticking clutch caused by warped, binding, or incorrectly assembled clutch plates (not stacked properly with "dish" in same direction).
If Car Creeps only when engine accelerated to 2500 RPM—Check clutch vent ball checks in clutch piston and reaction shaft flange.
2) Creeps forward with selector in Reverse or backward with selector in Low. Incorrect manual control linkage adjustment.

CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (C nt.)

SHIFTS ARE ROUGH.

1) Low-to-Drive Shift. Incorrect Low Band adjustment. If High Accumulator pressure low, check for leak at accumulator body gasket and for dump valve or accumulator piston sticking down (top land of piston should be visible through top port in body). Sticking low band anchor piston (remove Valve & Servo Body to check), or incorrect piston location (see piston shimming data in Valve & Servo Body Reassembly). Valve & Servo Body gasket leaks. Clutch plates worn or binding.

EXCESSIVE CHATTER OR CLUNK WHEN STARTING

►*CAUTION—Slight "clunk" when shifting into Low or Reverse is normal, and slight chatter when car starting to move in reverse (disappearing as soon as car in motion) is also normal.*

1) In Low & Reverse Range. Incorrect Low or Reverse Band adjustment. Engine and transmission mountings loose or incorrectly adjusted, thrust pad at transmission mounting broken (see Engine Mountings in Buick Special Data). Clutch plates warped, sticking, or incorrectly assembled (not stacked properly with "dish" in same direction). Reverse ring gear bushing worn. Planet pinion needle bearing rough.

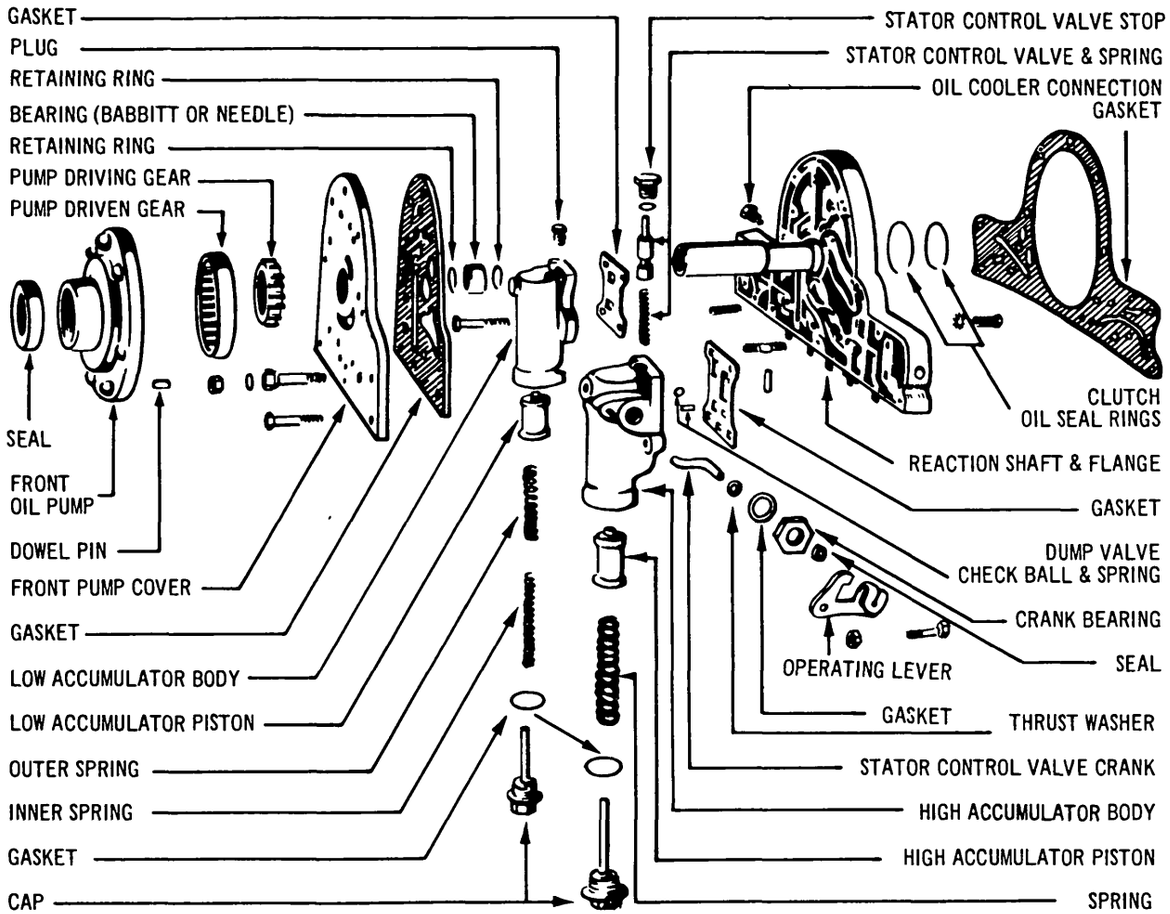
NOISE IN TRANSMISSION.

►*CAUTION—Hum or low whine in Neutral or Parking is normal (due to free rotation of all planetary gears) and slight hum in Low and Reverse may be expected.*

1) Buzzing Noise. Low oil level. Front pump check valve hanging up on edge of gasket between valve and servo bodies. If noise noticed in Parking or Neutral, pressure regulator valve clearance in body may be excessive or orifice in valve land oversize (correct by replacing valve and body).

2) Clicking Noise. If noticed in all ranges, may be caused by foreign material in converter. If noticed only when car in motion, may be caused by parking lock pawl contacting ratchet wheel due to incorrect manual control linkage adjustment.

3) Abnormal Hum or Whine (see Caution above). If noted in all ranges, may be caused by worn parts or excessive front pump clearances (front pump noise will increase in Low and decrease at car speeds above 45 MPH. in Direct Drive). Check front pump for excessive clearances by testing for low pump pressure. If noise noted in all ranges except Direct Drive, may be caused by trouble in planetary gears (gears locked out in Direct Drive).



4) Squealing or Screeching following installation of Front Oil Pump. Pump driving gear installed backward.

►*CAUTION—Above condition must be corrected WITHOUT FURTHER OPERATION OF TRANSMISSION or severe damage will result.*

REMOVAL FROM CAR

Transmission and torque converter are removed as an assembly as follows:

1) Raise car so that frame side rail is at least 20" off floor and place stands at front and rear to support car.

VARIABLE PITCH DYNAFLOW REACTION SHAFT FLANGE, ACCUMULATORS, & FRONT OIL PUMP ASSY.

2) Disconnect torque tube from torque ball and move rear axle back to disengage propeller shaft from universal joint. Remove cranking motor splash pan, bell housing cover and bell housing hand hole cover.

3) Drain converter and transmission. Mark position of converter on flywheel to assure installation in same position and remove bolts attaching converter to flywheel. Disconnect pipes from oil cooler and disconnect cooler from transmission from rear mounting thrust plate. Remove cooler. Disconnect oil filler pipe at rubber hose and disconnect exhaust pipe hanger at right accumulator. Disconnect shift rod and speedometer cable at transmission.

4) Support transmission with a jack or hoist and remove four bolts attaching thrust plate to rear bearing retainer, then remove two nuts and plate which attach mounting pad to transmission support.

5) Raise engine and transmission just enough to relieve load on transmission support. Remove bolts attaching both ends of support to frame, then remove support and thrust plate as an assembly. *CAUTION*—If shims are found at this point, note their number and location so they can be reinstalled in the same position.

6) Support engine at rear end of lower crankcase so it will be supported while transmission is removed. *CAUTION—Do not use bar with hooks placed over frame side rail. Brake lines will be damaged.*

7) On cars with air-conditioning, disconnect discharge and suction lines at compressor. This will avoid damaging flexible couplings when engine is raised and lowered.

8) Lower the transmission just enough so that bell housing bolts can be reached, then remove bell housing to crankcase bolts. Move transmission rearward to disengage hub of converter pump from crankshaft, lower transmission and remove it from beneath car.

CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (Cont.)

DISASSEMBLY

▷**DISASSEMBLY CAUTION:** ***CLEANLINESS IS EXTREMELY IMPORTANT when disassembling and working on transmission. Thoroughly clean exterior before disassembling, use CLEAN tools on CLEAN workbench, provide CLEAN storage space for all parts, and separate parts to avoid nicking or burring of ground and polished surfaces.***

DISASSEMBLY OF TRANSMISSION (into Major Components): With transmission on bench, first remove shift lever by taking off retaining nut and washer on shaft while holding lever forward (to avoid strain on linkage), remove oil cooler and pipes if this unit removed with transmission, remove both band adjusting covers and gaskets using Remover Tool J-2655. Remove both pipe plugs in primary cover to completely drain converter, then place transmission on bench with oil pan upward and remove various sub-assemblies as follows:

Converter & Bell Housing Removal: 1) Remove all nuts, plain washers, and bolts attaching cover to converter pump then remove cover Check cover seal for damage or evidence of oil leakage before removing it from cover Shift into "Parking" and pry up on reverse band operating lever with a screw driver to lock input shaft while removing the bolt, lockwasher, retainer washer and thrust washer from front end of input shaft

2) Insert a screwdriver into the first turbine disc to aid in removing the twin turbine assembly from input shaft Remove bronze thrust washer from turbine hub

3) Turn sun gear clockwise to make sure it free wheels, then turn it counter-clockwise to make sure it locks in this direction Remove sun gear assembly with thrust washer from reaction shaft

4) Install tool J-5806 over input shaft with beveled end outward Pull stator forward on reaction shaft, grasp thrust washer located behind stator to retain all free wheel parts in stator, then slide the assembly forward on the tool and remove from input shaft Pull converter pump forward from the reaction shaft and immediately check for evidence of oil leakage Radial streaks of fresh oil on back of pump and fresh oil streaks on face of front oil pump body indicate leakage past the oil pump seal

5) Before removing bell housing check to see whether all attaching bolts are tight Loose bolts may be cause of oil leakage at this point Put bell housing over edge of bench and remove it Examine rubber oil seal located around front oil pump to see whether it has been uniformly compressed by the bell housing, if not, check for any obstacle that may be around the oil pump or opening in bell housing that would prevent compression of the seal *See Overhaul data for disassembly of converter stator and pump.*

Oil Pan and Valve & Servo Body Removal: *(For removal of only the valve and servo body assembly, the converter and bell housing need not be removed. The following procedure also may be used with transmission in car).*

1) Remove shift lever to avoid damage to valve operating lever Hold lever forward while removing the retaining nut and lock washer so that linkage will not be strained, then remove lever from cross shaft Remove both band adjustment covers and gaskets using tool J-2655 (if not already done)

2) Turn transmission bottom side up, rolling it over on left side to avoid damage to oil pan filler pipe Remove oil pan and gasket Lift oil screen away from the suction pipe to which it is held by a rubber grommet snapped into hole in screen body Remove suction pipe spring support, retaining spring, suction pipe and cork gasket which seats in recess in servo body

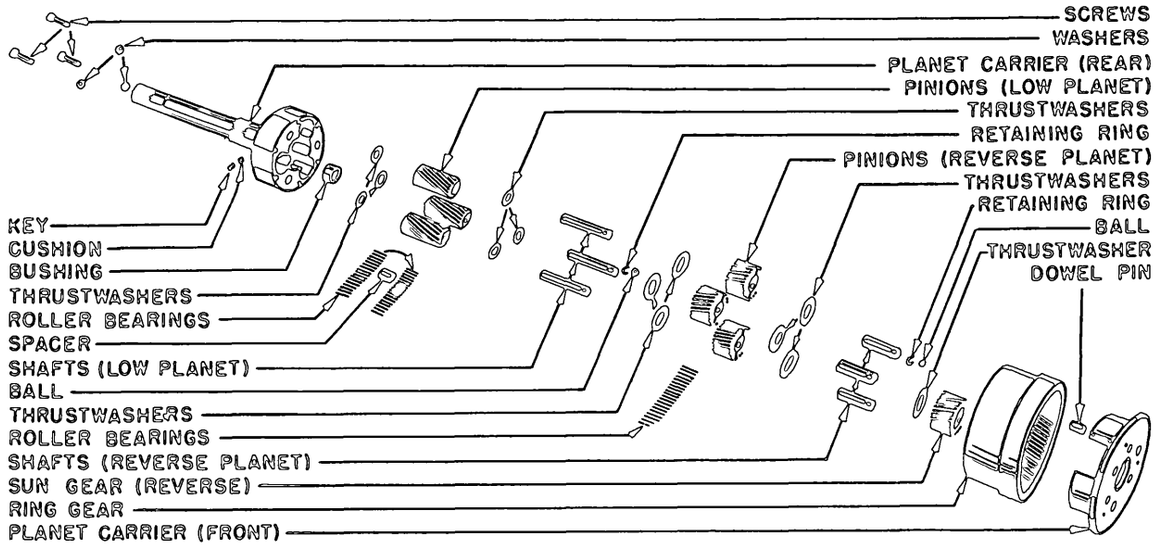
3) Disconnect valve operating rod from valve operating lever (upper) by placing a screwdriver on rod close to lever and exerting slight pressure A spring loaded socket on rod engages a ball stud on lever Slightly loosen all valve and servo body attaching bolts, then remove bolts and lockwashers *CAUTION —Do not loosen or remove the slotted safety nuts on valve-to-servo body studs.*

4) Lightly pry upward on assembly to free gasket between servo body and transmission case Push shift control valve and lower operating lever inward to align lower lever with opening in transmission case, then remove the assembly *(CAUTION —Do not grasp slotted end of control valve because sharp edges may cut hand).* Remove gasket and check for indications of oil leakage

5) Remove reverse band operating strut by extending fingers through adjustment hole to prevent strut falling into transmission case, then release strut by raising the operating lever *See Overhaul data for disassembly of valve and servo body.*

Reaction Shaft Flange, Front Oil Pump and Accumulator & Clutch Removal: *(Converter and bell housing and the valve and servo body must be removed first).*

1) Remove retaining ring from groove in input shaft Loosen, but do not remove caps on both accumulators Remove bolts which attach accumulators and oil pump cover but do not remove the stud nuts which attach these parts



2) Tap very lightly on rear of accumulator bodies with fiber hammer to loosen reaction shaft flange, then remove the assembly and gasket Leave input shaft in place in transmission Check reaction flange gasket for good imprint and freedom from damage which would cause oil leak at this point

3) Pull input shaft and clutch hub front thrust washer from clutch assembly, then remove clutch assembly

4) Compress low band with operating lever while applying Band Clip tool J-2595 across strut flanges of band Release lever and remove low band, then remove struts which will drop into case Remove low band operating lever by threading a ¼"—20 capscrew into lever shaft and pulling shaft from case *See Overhaul for disassembly of above parts.*

Torque Ball & Universal Joint Removal: *(Does not require removal of any other parts first).* Remove torque ball rubber boot Take out attaching bolts in thrust plate, remove thrust plate and gasket, torque ball inner and outer retainers, and paper adjusting shims Remove speedometer driven gear and sleeve assembly Lock drive shaft by engaging parking pawl (use shift lever to press forward on shift lever shaft while turning universal joint, until pawl engages), remove universal joint bolt, lockwasher and flat washer, pull universal joint using puller J-682A

Rear Bearing Retainer & Parking Lock Ratchet Wheel Removal: *(Universal Joint, Oil pan, and Torque Ball must be removed first).* Disconnect valve operating rod from upper operating lever by inserting screwdriver through hole in case and pressing rod away from lever (ball stud on lever engages socket in rod) Remove universal joint retaining ring from slot in output shaft using a screwdriver and hammer to free ends of this lock ring Take out retaining bolts and remove rear bearing retainer and gasket and check gasket for evidence of oil leakage Take out ratchet wheel outer retaining ring (use snap ring pliers to free ring) *See Overhaul data for disassembly of rear bearing retainer.*

VARIABLE PITCH DYNAFLOW TRANSMISSION PLANETARY ASSEMBLY

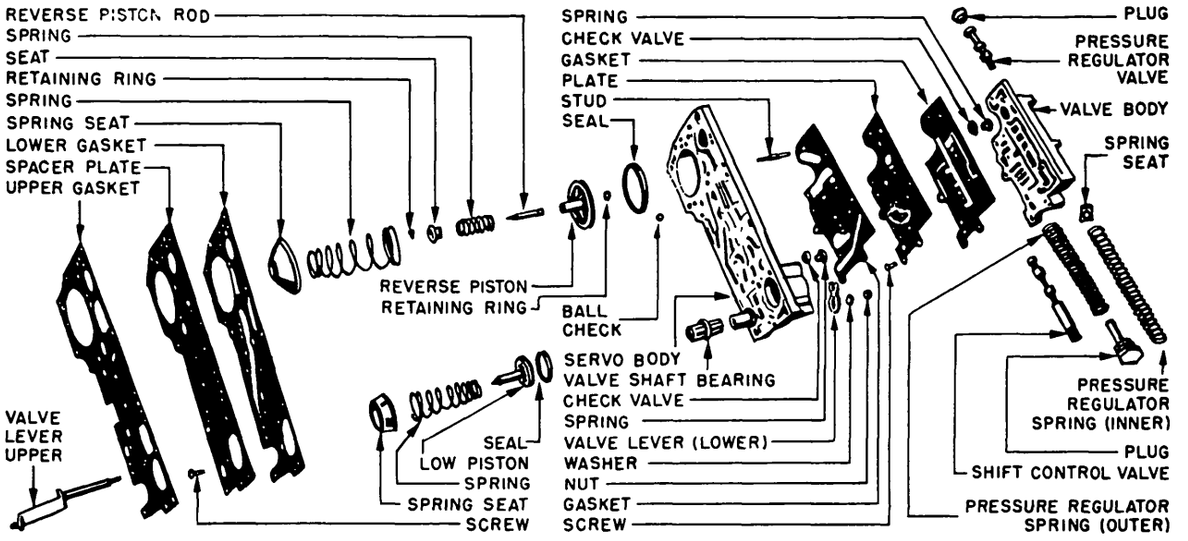
CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (C nt.)

Rear Oil Pump and Lubrication Oil Pressure Regulator Valve Removal: ***Rear Bearing Retainer (preceding) must be removed first.*** Take out retaining bolts and remove pump body and gears as an assembly. Check gaskets for evidence of oil leakage. Remove pump drive key from shaft recess, remove rubber cushion located under drive key with a pointed tool. If possible, lift off rear pump plate and gasket (if plate sticks, tap plate out **after planetary gear set removed**). Check gasket for evidence of oil leakage. Remove lubrication pressure oil regulator valve seat from rear face of transmission case (use special drag link socket to turn valve seat out), remove valve and spring.

Planetary Gear Set, Reverse Ring Gear, and Reverse Brake Band Removal: ***All parts listed in preceding removal sections must be removed first.*** Pull planetary gear set out through front of transmission case. Lift out reverse ring gear and two planet carrier thrust washers (if these parts did not come out with planetary gear set). If rear oil pump plate and gasket not removed previously (see above), tap out with hammer handle inserted through front of case. Remove reverse band operating lever by threading a ¼"-20 capscrew into tapped hole in anchor shaft and pulling shaft out, then lift out lever. Rotate reverse band toward adjusting hole until anchor accessible, disengage and lift out anchor. Compress reverse band and install Band Installing Clip J-2595 across strut flanges to hold band compressed, lift band out. ***See Overhaul data for disassembly of Planetary Gear Set.***

OVERHAUL



►***SHIFT CONTROL VALVE PRODUCTION CHANGE:*** Three control valves have been used in production, all of which are interchangeable. The valves are identified as follows: First (no extension), Second (plain extension), Third (grooved extension).

►***EXCESSIVE DYNAFLOW WHINE CORRECTION: (This condition is usually the result of excessive clearance between input shaft and bearing in the reaction flange). See "Trouble Shooting" above.***

►***CONVERTER COVER PRODUCTION CHANGE:*** A later type converter primary pump cover having three impeller blades replaces the former type having impeller ribs completely around the cover. Either type can be used for service replacement.

►***REACTION SHAFT & FLANGE, INPUT SHAFT, AND FRONT END REACTION SHAFT BEARING PRODUCTION CHANGE & SERVICE REPLACEMENT CAUTION:*** A new needle bearing is now used in production in the front end of the reaction shaft. The new type bearing has a larger inside and outside diameter and cannot be used as a service replacement for the babbit type bearing used in early production. The needle type bearing made necessary a change in reaction shaft & flange, and input shaft. In order to service a first type transmission to use the new bearing it will be necessary to replace the above parts. ***See Overhaul data below for removal and installation of the later type bearing.***

►***PRIMARY PUMP COVER SEAL NOTE: Both a .120" and a .135" diameter oil seal have been used in production. Either type may be used for service replacement.***

VARIABLE PITCH DYNAFLOW VALVE & SERVO BODY ASSEMBLY

►***VARIABLE PITCH STATOR PISTON PRODUCTION CHANGE:*** The crank thrust washer and retaining ring have been eliminated in later production which necessitates the use of a special fixture (made locally) for reassembly. ***See Overhaul data below for assembly procedure and fabrication of fixture.***

Converter Twin Turbine & Sun Gear: Disassembly—Pry retaining ring out of groove in first turbine, insert screwdriver in hole in the disc and lift disc and hub assembly out of first turbine. Lift second turbine and carrier out of first turbine. Remove four bolts and lockwashers and the pinion pin lock plate from second turbine (it is not necessary to remove turbine from carrier at this time). Remove pins, then remove the four planet pinions and thrust washers from turbine carrier. Remove bearing rollers from each piston. Remove thrust washer (with tangs) from front face of sun gear and carefully tap the cupped thrust washer from other end. Remove the sprag (free wheel clutch) from inside of sun gear.

Converter Variable Pitch Stator: Disassembly—Remove stator thrust washer and selective spacers from rear side of stator, remove tool J-5806 (installed on input shaft when converter removed from transmission), then remove free wheel rollers and springs from the cam. Pry retaining ring from groove in stator blade rear carrier, and remove free wheel cam and three driving keys. Use screwdriver, tool J-5826 to remove stator blade front carrier screws and lockwashers, then remove front carrier which is also held to rear carrier by two dowels. Remove retaining ring and thrust washer (on early cars), from hub of stator piston. Remove stator blade carrier ring and all stator blades from rear carrier. Remove stator piston with sealing ring from rear carrier.

Inspection (All Converter Parts)—Wash all parts in clean solvent and dry thoroughly. Inspect converter pump hub for scores and for wear caused by front pump seal. (If pump is suspected of leaking oil, it may be tested as described below). Inspect converter pump and turbines for cracked or damaged vanes. Inspect turbine carrier, planetary gear teeth, thrust washers, bushings and related bearing surfaces for wear, scoring or damage. Inspect stator free wheel rollers and cam for nicks or burrs, which should be removed with an Arkansas stone, and polished with crocus cloth. Discard any roller springs that are damaged or distorted. Inspect stator blades for distortion, cracks, loose on cranks, or other damage. Inspect piston oil seal ring and bore of blade carrier for scoring or wear. If bushings of carrier are worn, they should be replaced, using installer tool J-5913. If second turbine or the carrier must be replaced, use care in separating them to avoid damage to the good part With second turbine suitably supported, tap carrier free of counter-bore in turbine, using a hammer and a hardwood dowel or other soft punch ***CAUTION—Do not drive against surface of thrust boss in carrier.***

Testing Converter Pump for Leakage: ***(NOTE***—Prepare a special stopper to close opening in converter pump for testing, as follows: Using ¼" steel plate, cut a disc 3¼" in diameter and drill a ¼" hole in the center. Install a ¼" x 2¾" bolt thru hole and braze head of bolt to plate to seal bolt hole. From a piece of ⅛" rubber, make a gasket 3¼" O.D. x 1⅞" I.D. and cement this gasket to side of disc from which the bolt protrudes. Drill a ¼" hole in a piece of plate ¼" x 1" x 2" and install this on bolt, retaining it in place with a nut). To test pump, install the plate (with rubber washer) over inside surface of pump hub, securing it in place with the ¼" x 1" x 2" plate against outside surface of pump hub. Tighten clamp nut sufficiently to make stopper air tight. Install pump cover with seal and tighten all bolts to 25-30 ft. lbs., in same sequence as used for installation of torque converter (see Reassembly of Transmission below). Install one drain plug, and install a Barrett fitting No. 365 in other drain hole.

C NTINUED N NEXT PA E

DYNAFLOW DRIVE (C nt.)

Tighten parts securely Attach air hose to Barrett fitting and fill pump with compressed air at 80 to 100 lbs per sq in Submerge pump in water tank and check for leaks *CAUTION—After pump cover seal is used for this test, it should not be used when rebuilding the transmission.*

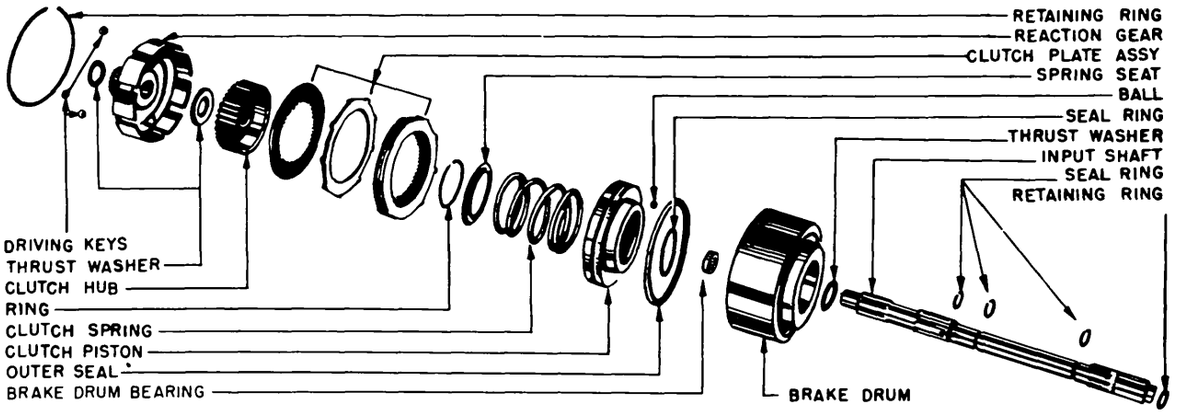
►*VARIABLE PITCH STATOR PISTON PRODUCTION CHANGE: The crank thrust washer and retaining ring have been eliminated in later production which necessitates the use of a special fixture (made locally) for reassembly.*

Variable Pitch Stator (First Type): Reassembly—1) Install oil sealing ring in stator piston, then tilt piston slightly to install it in bore of rear carrier, placing piston so that hub extends through flanged end of carrier Mount piston on a suitable support (such as ring of spring compressor J-2590) so that piston is held up against flange of carrier

2) With stator blade carrier ring resting on bench with holes upward, insert stator blades with concave sides upward and cranks toward center of ring Blades should be in the nearly closed position Carefully place the carrier ring with blades in position on rear carrier so that all cranks engage the groove in carrier Install thrust washer over cranks and install retaining ring in groove of piston hub

3) Place front carrier over rear carrier so that screw holes are aligned when dowels enter their holes, then install screws with countersunk external tooth lockwashers After screws are turned down snug with screwdriver tool J-5826, check stator blades and piston for smooth operation Blades should move throughout range without binding If they do not, check for misalignment of cranks in carrier grooves Tighten screws to 10-12 ft lbs , and make sure that blades still operate freely

4) Install free wheel cam with three driving keys and retaining ring in carrier Check free wheel springs and alter length as necessary to assure equal length of all springs Place free wheel rollers and springs in cam, with rollers at rounded ends of cam recesses



5) Install tool J-5806 through free wheel rollers by turning it slightly clockwise so that flat end of tool is flush with rollers and cam Make certain that surfaces of cam, spacers and thrust washer are free of grease and dirt, then install spacers and washer with tangs of washer extending through holes in spacers and cam

Variable Pitch Stator (Second Type): Reassembly—*NOTE—A special fixture which can be made locally is required for reassembly of the second type stator. See Stator Fixture Note below.*

1) Insert stator piston and oil seal in rear carrier and push it to the extreme forward position Place rear carrier on center block of fixture to hold piston in position

2) Place stator outer ring on two outer blocks of fixture with crank pin up Holding the blade in the approximate "low pitch" position insert the crank pin in the outer ring Then rotate the blade to bring the crank throw into the piston groove Hold the piston, blades, and outer ring together while installing the blades

3) Install the remainder of the blades, working in a clockwise direction To insert the last blade it will be necessary to tilt the adjacent three blades

VARIABLE PITCH DYNAFLOW DIRECT DRIVE CLUTCH ASSEMBLY

4) Install the front carrier and bolt into place Be sure that blades operate freely in carrier Complete the assembly of stator as indicated for first type stator (above)

►**Stator Fixture Note**—The fixture is composed of four blocks of wood as follows One piece ¾" x 3½" x 11" (base piece) One piece ¾" x 3" x 2" (center piece) Two pieces 1⅛" x 3½" x 2¼" (end pieces) Place base piece on bench and position center piece in center of base piece so that each end of center piece is ¼" from edge of base Position the two end pieces on extreme ends of base piece so they lay lengthwise across base piece flush with end and sides Stator hub will rest on center piece and ring will rest on the two end pieces for installation of the blades

Converter Twin Turbine & Sun Gear: Reassembly—1) Install sprag in bore of sun gear with shouldered end outward then carefully press the cupped thrust washer over end of gear Use a smooth flat plate or block of wood to press against washer to avoid damaging its surface

2) Install tanged thrust washer on opposite end of sun gear If second turbine was separated from the carrier, make certain that counterbored recess in turbine and mating surfaces of carrier are clean and free of burrs, and apply a film of lubricant to these surfaces

3) Support carrier on suitable blocks, install several pinion pins to serve as pilots, then place turbine in position so that carrier is squarely started into recess in turbine Use a hammer and hardwood dowel or other soft punch to tap turbine down over the carrier *CAUTION—Avoid distortion of turbine by using light blows applied midway between holes and alternated from side to side to keep parts square with each other.*

►*NOTE If turbine cannot be assembled on carrier with moderate force, remove it and check for burrs in counterbore recess.*

4) With turbine and carrier supported on wood blocks, hub side down, assemble and install the four pinions as follows Place planet pinion on a thrust washer, install 22 needle bearing rollers in pinion and place a thrust washer on top of pinion *(NOTE* —A loading tool can be made from a piece of ⅜" steel rod 11/16" long which will simplify loading and installation of pinion) Place assembled pinion in carrier and install a pinion pin with notched end up After loading tool is pushed out of carrier, slide a block under pinion pin to hold it in place Turn all pins so that notches face center of carrier

5) Install pinion pin lock plate so that it engages the notches of all pins, then install the four turbine-to-carrier bolts with lockwashers Place second turbine and carrier assembly in first turbine and install the first turbine disc and hub assembly over the second turbine

6) Rotate disc until the ring gear meshes with carrier pinions, then align driving lugs on disc with notches in first turbine and push the assembly all the way down into turbine

7) Note that turbine disc retaining ring is "dished " Place ring in position with "dish" upward so that inner edge will bear firmly against disc when ring is engaged in groove in first turbine Start one end of ring into groove in turbine, then twist ring upward to lay ring flat on disc so that it can be progressively entered into groove all the way around *NOTE—Inner diameter of ring must lay against disc.*

Valve & Servo Bodies: Disassembly—Remove safety nuts and washers from body studs, lift off valve body and gasket, examine gasket for evidence of oil leakage. Remove shift control valve from valve body and rear pump delivery check valve and spring from servo body. Remove large pressure regulator valve plug from valve body *(CAUTION*—hold plug to prevent it flying off due to heavy spring pressure), remove springs and spring seat. Remove small valve plug and lift out pressure regulator valve. Remove valve body plate and gasket, examine gasket for evidence of oil leakage. Lift out front pump delivery check valve and spring. Take off nut and lockwasher attaching upper and lower valve operating levers in servo body and remove levers. Use wooden block placed across low and reverse servo spring seats to hold them in place with springs compressed while taking out spacer plate attaching screws, carefully relieve spring pressure *(CAUTION*—use care not to spring spacer plate or allow servo springs to fly out), lift off spacer plate and gasket, examine gasket for evidence of oil leak-

C NTINUED N NEXT PAGE

DYNAFLOW DRIVE (C nt.)

age. Lift out low and reverse servo spring seats, springs and pistons. Remove check valve from reverse servo feed channel.

Inspection—Wash valve and servo bodies and parts with clean solvent, blow out all passages and dry parts with air. Inspect bodies for cracks, damaged gasket surfaces, and scored piston and valve cylinders. Inspect valves and pistons for nicks, scores, scratches, or rounded shoulders (edges must be sharp to keep out foreign material which might cause sticking). Replace worn or damaged piston seals.

►**Piston Seal Installation Caution**—Lip on seal must fit over SMALLER diameter land on piston.

Reassembly—Install low and reverse servo pistons in servo body (CAUTION—use care not to damage seals), check to see that pistons move freely in body. Install piston springs and spring seats (small end of low servo spring in groove in piston, large end of both reverse servo springs in grooves in piston). Place check ball in reverse servo feed channel. Use new spacer plate gasket, compress servo springs and tighten all spacer plate attaching screws uniformly. Install both upper and lower operating levers with lower lever pointing to low servo cylinder and upper lever to reverse piston spring seat, tighten lever shaft nut to 15-20 ft. lbs. torque. Install front pump delivery check valve spring (large end down), and valve (ridged side up), then install valve body plate using new gasket and making sure that valve seats against plate (must not hang on gasket). Install pressure regulator spring seat, inner and outer springs, and valve plug in valve body, tighten plug to 20-25 ft. lbs. torque. Install pressure regulator valve (see that oil orifice in end land is clear and place this land outward), tighten valve plug to 20-25 ft. lbs. torque. Install shift control valve with slotted end of valve pointing toward large pressure regulator plug. Install rear pump delivery check valve (ridged face inward), and spring (large end upward). Install valve body on servo body using new gasket *(CAUTION*—see that pump delivery check valve spring below gasket), tighten all stud nuts to 11-15 ft. lbs. torque.

►**Front Pump Tightening Sequence**—Tighten nuts in following order: Top, Bottom, Right Center, Left Upper Center, Right Lower Center, Left Lower Center, Right Upper Center.

High & Low Accumulators: Disassembly—Remove retaining pin and check ball from high accumulator body (low accumulator does not have the check ball) Remove the pipe plug, cap, gasket, spring (2 in low accumulator) and piston from accumulator body. *(NOTE—Keep parts separated so same parts will be installed in same body).* On high accumulator body only, remove clamp bolt, lever, bearing with seal, gasket, thrust washer and control valve crank, then remove valve stop with gasket, control valve and spring

Inspection—Clean all parts with solvent, blow out all passages and dry with air. Check parts for excessive wear, scoring, nicks, burrs, and other damage. Remove nicks and burrs from pistons and valves by stoning but **do not round off sharp dges of pistons and valves** (edges must be sharp to keep out foreign material which might cause sticking). Check mounting face of accumulator body for flatness with a straightedge (face can be trued up by using emery cloth on a surface plate but all traces of emery must be removed). Replace accumulator assembly if body, or piston worn (these parts not furnished separately). Check piston for wear by placing it in cylinder (all parts clean and dry). Piston should slide freely as body is tilted back and forth.

Reassembly—Lubricate each piston and install it in the accumulator body from which it was removed *(CAUTION—Start piston squarely into body, do not tap or force it).* Install proper piston springs in each body The high accumulator uses one heavy spring approximately 4 5/16" The low accumulator uses one shorter heavy spring and one inner spring Install caps with new gaskets (do not tighten caps at this time) On high accumulator only, install spring, control valve and stop, then install crank with thrust washer, bearing with new gasket and seal (grooved side inward), operating lever and clamp bolt Adjust operating lever on crank so that lever contacts its stop and the crank contacts the valve without depressing the spring, then tighten clamp bolt Install pipe plugs in both accumulators and install check ball and retaining pin in high accumulator body *NOTE—Accumulator body caps will be tightened at time transmission is reassembled.*

►*REACTION SHAFT & FLANGE, INPUT SHAFT, AND FRONT END REACTION SHAFT BEARING PRODUCTION CHANGE & SERVICE REPLACEMENT CAUTION:* A needle bearing (replacing babbitted bearing) is now used in production in front end of the reaction shaft The later type bearing has a larger inside and outside diameter and cannot be used as a service replacement for the early type bearing The use of the needle bearing made necessary a change in reaction shaft and flange, and input shaft In order to service a first type transmission to use the new bearing it will be necessary to replace Reaction Shaft & Flange, Input Shaft, and Reaction Shaft Bearing

Reaction Shaft Flange & Oil Pump: Disassembly—Remove high and low accumulators from reaction shaft flange, using care to prevent the retaining pin and check ball from dropping out of high accumulator and being lost Check gaskets for indications of oil leakage Inspect input shaft bearing in front end of reaction shaft (see Production Change above) If bearing is damaged or excessively worn, remove outer bearing ring and then remove bearing, using Remover J-5822 installed on Remover J-1436 *(NOTE—Both types of bearings are removed in the same manner).* Oil pump must be in place to support the reaction flange during bearing removal If inner retainer ring remained in place in shaft make sure it is firmly seated in its groove, otherwise replace it Check front oil pump bolts to make sure they are tight (loose bolts would be the cause of oil leakage around pump) Remove front oil pump body and gears, tapping body lightly with a mallet to free it Remove front oil pump cover and gasket from reaction shaft flange, and check gasket for evidence of oil leakage If the check ball located in clutch feed passage is free to drop out, remove ball to avoid loss in handling parts. Do not remove if securely retained by peened edge of hole

Oil Pump Inspection & Repair—Clean pump parts with solvent and dry with air. Check pump gears and mounting faces of body and cover for excessive wear. Check front pump bushing for excessive wear or looseness which will require replacement of pump assembly *(NOTE*—Check flywheel and primary pump hub run-out and bell housing misalignment if bushing worn or loose). Check front oil pump seal and replace if damaged or any evidence of leakage noted. Drive out old seal, coat outside of new seal with Permatex #3, start seal in place with deep groove in retainer outward, tap seal into place with wood block and mallet. Check following clearances and replace pump parts if excessive:

Pump Gear Side Clearance—Place straightedge across face of pump body and gears. Clearance between face of gears and straightedge should be .001-.0025" (front pump), .001-.002" (rear pump).

Pump Gear Clearances—Check pump gears with feeler gauge between gear teeth and crescent while pressing gear away from crescent. Clearance should be .005-.009" (front pump driven gear), .0045-.007" (rear pump driven gear), .010-.016" (front pump driving gear), .006-.012" (rear pump driving gear).

Pump Cover Gear Wear—Replace cover if gear bearing area scored or worn to depth of more than .001".

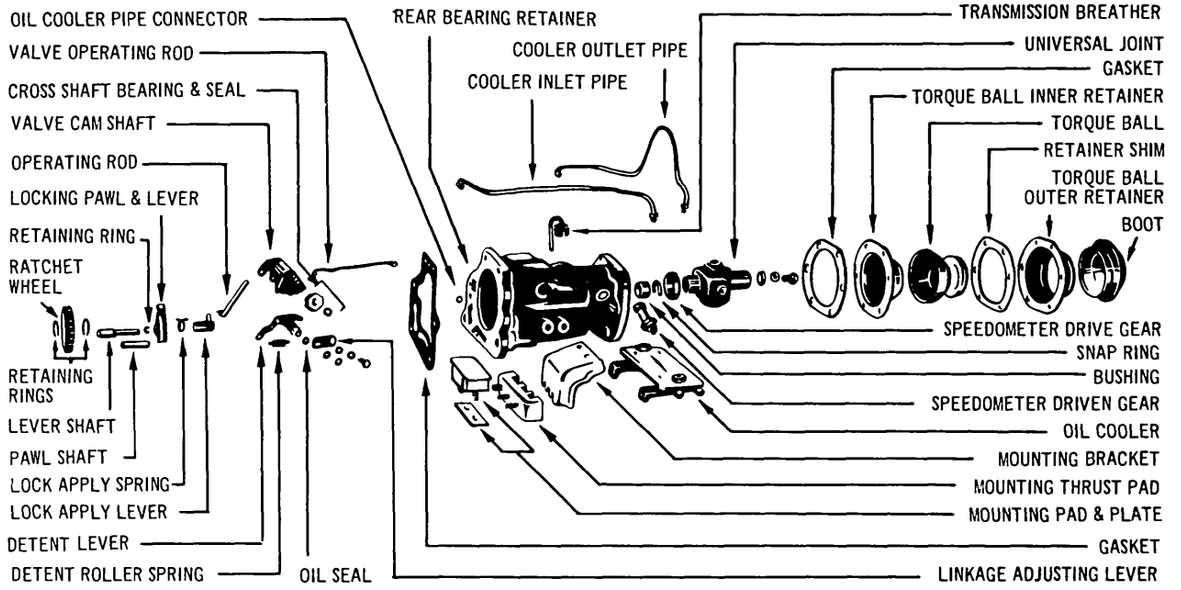
Reaction Shaft Flange Inspection—Wash flange in clean solvent and blow out all passages with air Inspect surfaces of reaction shaft flange and transmission case for nicks or burrs and remove with a mill file Inspect race for clutch drum roller bearings on rear end of reaction shaft If this bearing is worn excessively or scored, replace reaction shaft flange *(NOTE—If reaction shaft flange is replaced, stamp transmission identification number in lower edge of new part in same place as on original flange).* Check all studs for tightness and replace any with damaged threads If stud threads are stripped in reaction shaft flange, it will be necessary to tap out the hole for installation of step studs which are available for service replacement *(The 5/16"—18 step studs have a ⅜"—16 thread on flange end).* Inspect the oil seal rings on hub of reaction shaft flange and replace if damaged in any way

Reaction Shaft Flange & Oil Pump: Reassembly—*(NOTE—Early type Reaction Shaft Flange Front Bearing is babbitted type. Later bearing is needle bearing type. See procedure below for installation of both types).*

Babbitted Bearing Installation—Make sure that inner retaining ring is firmly seated in groove in reaction shaft, then install a new bearing using Installer J-5816. Support shaft on wooden block to avoid damage and drive bearing into place with a light hammer until shoulder of tool contacts reaction shaft Install outer retainer ring

Needle Bearing Installation—To install new bearing in reaction shaft, tool J-6248 must be used because of the 15° angle step which presses against the hardened outer circumference of the bearing to prevent damage to the needle bearing rollers *NOTE* —The needle bearing has a rounded shoulder on one side and a flat surface with the manufacturers markings on the other To install the bearing, support reaction shaft vertically on a block of wood Place flat side of bearing (with markings) against driving surface of the tool, then press into place

CONTINUED N NEXT PAGE



DYNAFLOW DRIVE (C nt.)

until tool bottoms on reaction shaft. ***CAUTION—Bearing can be installed either way, but damage to the needles will result if not installed as directed above.*** Complete reassembly as follows Install check ball in clutch feed passage if ball was removed, then install a new gasket and the pump cover on reaction shaft flange Lubricate and install gears in front pump body The driving gear must be installed with the beveled side outward so that this side will be against cover when pump is installed ***(CAUTION—Reversing this gear in pump body will result in severe damage to transmission).*** Install oil pump on cover so that the two dowel pins and the bolt holes match holes in cover, then install bolts with lockwashers Tighten bolts to 5 ft lbs in the sequence shown in illustration, and then tighten in same sequence to 25-30 ft lbs Bend a tang of each lockwasher up against flat of bolt head Tighten cover attaching stud nut to 25-30 ft lbs

Multiple Disc Clutch & Input Shaft: Disassembly. Remove retainer ring from reaction gear flange, use pointed tool to remove three flange driving keys. Lift out Low Range Reaction Gear, Thrustwasher, Clutch Hub, and all 10 Clutch Plates. Install Clutch Spring Compressor J-2590 in clutch drum placing slot in compressor ring over ends of spring seat retainer ring, compress spring sufficiently to remove retainer ring, release clutch spring pressure ***(CAUTION—use care that spring seat does not hang up in retainer ring groove in drum).*** Remove compressor, lift out spring seat and spring. Tap drum, open end down, on block of wood to dislodge clutch piston ***(CAUTION—if check ball in piston unseated during this operation, snap ball back in place).***

Inspection—Wash parts in solvent and dry with air ***(CAUTION—use only gasoline or kerosene on clutch bands and plates—do not use chemical degreasers or commercial solvents).*** Inspect and replace all clutch plates which are worn, scored, burred, or warped ***(CAUTION—new plates must slide freely on clutch hub—tight plates will prevent full disengagement).*** Inspect oil seal ring on clutch hub and replace if damaged (ring has interlocked ends and is released by compressing ring and depressing one end while raising the other). Replace clutch piston outer seal if hardened, broken, or with turned lip (install new seal with lip extending over smaller diameter piston land). Inspect Low Range Band and replace if worn smooth without visible grooves. Inspect oil seal ring and replace if damaged (same type ring with interlocked ends as used on clutch hub). Check to make sure retaining ring in place in shaft groove. See that small bleed hole in piston is open and that check ball is staked in place ***(CAUTION—ball must be free to move in recess).*** If needle bearing in drum is excessively worn or scored, carefully remove it and install a new one using tool J-5191 This tool will locate bearing flush with shoulder drum Place numbered end of bearing, which is hardened, toward shoulder of tool to avoid distortion of cage

Reassembly—Lubricate piston seal and inner surface of drum with light oil, install piston using extreme care not to distort or turn lip of seal Top of piston should be approximately even with shoulder in drum when installed. Install clutch spring, use

VARIABLE PITCH DYNAFLOW REAR BEARING RETAINER & TORQUE BALL ASSY.

Compressor J-2590 to compress spring, install spring retaining ring in groove in drum, remove compressor. Place reaction gear on bench with flange upward and install all clutch parts in following order: Clutch Hub Thrustwasher, Clutch Hub (open end upward), and all clutch plates (see Clutch Plate Caution below). Bottom clutch plate should be internally splined (faced) type and top clutch plate externally splined (plain steel) type with the two types alternating in the assembly. Install drum and clutch piston assembly over reaction gear and clutch assembly with driving key recesses in drum and gear flange aligned. After drum pressed evenly in place, fully align driving key recesses by tapping reaction gear flange, install three driving keys and flange retainer ring.

►**Clutch Plate Caution**—Externally splined (plain steel) clutch plates are concave or "dished" and these plates must be installed with "dished" face in same direction (either up or down). Check each plate with straightedge and stack plates with dished faces in same direction before beginning installation. ***NOTE***—Internally splined clutch plates are flat and can be installed in either direction.

Rear Bearing Retainer: Disassembly—Remove spring from detent roller lever and support inside rear bearing retainer, remove adjusting lever on outside of retainer, then remove lever and support assembly Disconnect parking lock operating rod from cross shaft by unscrewing rod end from cross shaft lever Push clip from valve operating rod to remove clip and rod from cross shaft. Screw a ¼"—20 bolt into parking lock operating lever shaft and the lock pawl shaft and pull these parts from bearing retainer, then remove lock pawl and lever assembly Remove cross shaft bearing, using a box wrench (a socket that does not fully engage bearing, or an end wrench will distort the bearing) remove cross shaft

Rear Bearing Retainer Inspection—Wash parts in solvent and dry with air. Check parking brake pawl, pawl locking link, and ratchet wheel for worn teeth, cracks, or other damage preventing positive locking. Check valve operating cross-shaft and bearing for wear, remove and discard rubber seal in bearing. Inspect output shaft bushing in retainer for wear scoring, check clearance by inserting output shaft in bushing. Clearance should be .001-.006". Replace bushing with Bushing Remover & Replacer Tool J-2997 (not necessary to ream new bushing).

Universal Joint Inspection—Check for wear and excessive play between spider pins and bushings (should be .002-.004"). Check yokes for wear on shaft splines. Front yoke must be tight fit on output shaft (play will allow "snap" between forward and reverse), rear yoke backlash on propeller shaft should be .0005-.0045". Rear yoke clearance in torque ball bushing should be .004-.006" and bearing surfaces must not be scored.

Torque Ball Inspection—Replace torque ball and retainers if bearing surfaces scored or pitted. Inspect oil seal and replace if worn (use seal which has been soaked in neatsfoot oil), press seal squarely into place until flush with torque ball flange and with feather edge of seal pointing into torque ball. Check universal rear yoke for excessive wear at point where seal bears.

Reassembly—Install valve operating cross shaft, and cross shaft bearing Install a new seal in bearing, with grooved side facing inward. Install parking lock pawl and lever assembly in rear bearing retainer, then install lock pawl shaft and operating lever shaft with tapped ends outward. Attach valve operating rod with retainer clip to cross shaft lever

CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (C nt.)

and snap clip into place over rod. Connect parking lock operating rod to cross shaft lever, using a lockwasher on threaded end of rod. Install detent lever and support assembly with a new seal in groove of shaft, then install linkage adjusting lever on shaft with nut and lockwasher. Attach adjusting lever to bearing retainer with bolt, plain washer and lockwasher, but do not tighten until the following detent adjustment is made.

Parking Pawl Adjustment—Temporarily install shift lever on cross shaft and shift parking pawl into parking position. Shift linkage adjusting lever at slotted end until pawl lock contacts the parking pawl, then tighten adjusting lever lock bolt, being certain to maintain contact between lock and pawl. Move shift lever back and forth to check detent adjustment. Parking lock must contact parking pawl when detent roller in deepest portion of parking notch of detent lever and should break contact at same instant that detent roller starts to move toward neutral position.

Planetary Gear Set: Disassembly—Take out three planet carrier screws and special lockwashers (use 7/32"Allen wrench), separate front and rear halves of planet carrier (hold carrier by output shaft, tap down on flange on front end). Lift out sun gear rear thrustwasher and reverse sun gear. Remove all planet pinion assemblies (three long low pinions, three short reverse pinions) by tapping shaft out of front half of carrier using care not to lose steel ball imbedded in end of each shaft to prevent shaft rotating in carrier. Disassemble pinion assemblies by removing thrustwashers and shafts from pinions and then taking out bearing rollers (long pinions have two sets of rollers separated by spacer, short pinions have one set of rollers).

Inspection: Wash all parts in solvent and dry with air. Inspect planet pinion shaft and rollers, replace if worn. Inspect all gear teeth for wear, remove all nicks and burrs by stoning. Replace bushing in rear end of planet carrier if worn or scored (use Bushing Remover J-3197, Bushing Replacer J-2996—new bushing may be installed either end first and need not be reamed). Inspect reverse band anchor for cracks. Replace reverse band if cracked or the lining worn smooth.

Reassembly—Assemble each planet pinion with its bearing rollers, thrust washers, and shaft (24 rollers in each reverse pinion, 20 rollers at each end of low pinion and separated by a spacer). Make certain that thrustwasher installed at each end of each pinion (lower washer against retaining ring on shaft, upper washer on outer end of shaft). Install planet pinion assemblies in carrier making certain that **steel ball imbedded in lower end of each shaft** (necessary to prevent shafts turning). Install reverse sun gear with bronze thrustwasher on top of gear, align assembly marks on both planet carrier halves when installing upper half (numbers stamped on dividing line during production), make certain that special lockwasher used on each carrier screw, tighten screws evenly to 25-30 ft. lbs. torque. Install reverse ring gear thrustwasher.

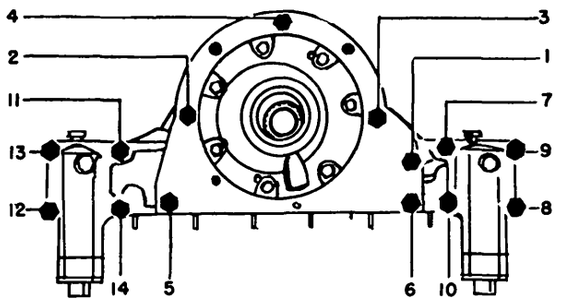
Transmission Case (Cleaning & Inspection): Wash case and blow out all passages. Inspect for cracks, and stripped bolt threads. Check machined surfaces for nicks and burrs and clean these up with a mill file. Check bushing in case for wear by inserting planet carrier in bushing and checking clearance with a feeler gauge. Clearance should be .002-.004". Replace bushing if clearance excessive or if scored.

Bushing Replacement—To remove old bushing, support case with rear end down, drive bushing out with tool J-3175-1 (part of replacer set). To install new bushing, place pilot J-3175-2 (part of replacer set) in rear oil pump recess in case, slip bushing over J-3175-1 and drive bushing into case from front side until bushing is flush with front surface of case wall which supports the bushing. **Bushing must be installed with wide deep ends of oil grooves toward rear of case.**

Flywheel & Primary Pump Run-out and Bell Housing Alignment Check: ***Make this check if front oil pump noisy, bushing and oil seal worn, or if oil leakage noted at Converter or Front Oil Pump Body.***

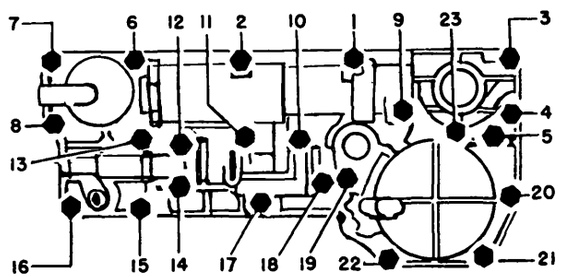
Flywheel Run-out—Remove all burrs from around drilled holes in face of flywheel, mount dial indicator on flywheel housing with strip of .005" shim stock between dial indicator and face of flywheel (clamp shim stock under a flywheel housing bolt so that it covers bolt holes and provides smooth surface for dial indicator pick-up). Turn flywheel **holding end thrust in one direction.** Run-out should not exceed .008". If excessive run-out cannot be corrected by tapping high side with mallet or by removing flywheel and cleaning up burrs at crankshaft flange mounting holes, install new flywheel and re-check run-out.

Primary Pump Hub Run-out—With converter primary pump and bell housing installed, mount dial indicator on bell housing so that it bears against primary pump hub. If run-out exceeds .012" when flywheel turned, mark flywheel and primary pump, remove and re-install pump at point 180° from first position. If pump run-out still exceeds .012", install new primary pump and recheck run-out. When position found where run-out is less than .012", mark flywheel and pump with paint and **align these marks when transmission is finally re-installed.**



Bell Housing Alignment—Mount dial indicator on oil pump driving lug on rear end of converter primary pump hub (*CAUTION*—do not clamp indicator on bearing surface) so that it bears against rear face of bell housing at 3¾"" radius. Rotate flywheel **holding end thrust in one direction.** Run-out should not exceed .005". If run-out of bell housing face exceeds .005", cement paper shims of proper thickness to rear face of crankcase to bring run-out to .005" or less, with all bolts securely tightened.

Pilot Hole Run-out—Mount dial indicator and Hole Attachment KMO-30-F to bear against inner edge of pilot hole in bell housing. Run-out of pilot hole should not exceed .004". If run-out greater, remove bell housing and remove the two dowels, and reinstall bell housing, leaving bolts just loose enough to permit shifting housing by tapping with a lead hammer. Set up dial indicator as indicated above and bring pilot hole of bell housing within .004" run-out by tapping in required direction with a lead hammer. If it is not possible to move housing far enough, remove housing and drill bolt holes with a ½" drill. When bell housing is placed so that run-out is .004" or less, tighten all bolts securely. Ream the two dowel holes through housing and crankcase using Reamer J-2548-3 (17/32"), until this reamer bottoms in hole, then finish with bottoming Reamer J-4710-6 to provide full size to bottom of hole. Remove bell housing and install oversize dowels J-808-5 in crankcase.



REASSEMBLY

After overhaul of Major Components, make certain that all parts absolutely clean, oil moving parts with 10-W engine oil before installation, use ALL NEW GASKETS & SEALS. Tighten all parts evenly to specified torque and in correct sequence (see illustrations). Proceed in reverse order of disassembly directions and note all of following points:

Planetary Gear Set Installation: After reverse ring gear thrustwasher and reverse band installed in case (with Installing Clip J-2595 on band), rotate band 45° toward servo opening, insert anchor and engage hooked end of band, then rotate assembly back into position. Position band operating lever in place with strut shoulder toward inside of case, install anchor shaft **with tapped end outward.** If installation correctly made, adjustment screw will be centered in servo opening (lever has offset end). See that planet carrier front (steel) thrustwasher installed on carrier with three tangs engaging holes in carrier, install rear (bronze) thrustwasher in case with three tangs engaging holes in case, then install planet carrier. If correctly installed, chamfer on output shaft journal will be flush with rear end of transmission case bushing.

REACTION SHAFT FLANGE & ACCUMULATOR BOLT TIGHTENING SEQUENCE

VALVE & SERV BODY BOLT TIGHTENING SEQUENCE

Rear Oil Pump & Lubrication Oil Pressure Regulator Valve Installation: Install rear gasket (gasket with LARGER hole—do not confuse with cover gasket) and plate on transmission case with bolt holes aligned, install drive key cushion and key in output

CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (Cont.)

shaft, then install driving gear to engage key (old gear should face in same direction as before, new gear with either face in). Tighten attaching bolts to 5 ft. lbs. torque in following sequence: Top, Bottom, Right, Left; then retighten bolts to 25-30 ft. lbs. torque in same sequence. Check pump for free operation by rotating output shaft. Install lubrication oil check valve assembly in case.

Parking Lock Ratchet Wheel & Rear Bearing Retainer: Make certain that retaining ring installed on each side of ratchet wheel on output shaft, insert valve operating rod through square hole in front face of bearing retainer and connect rod to cross-shaft lever, then install rear bearing retainer and gasket, tighten attaching bolts evenly to 35-40 ft. lbs.

Low Brake Band, Clutch, & Input Shaft Installation: Install low band operating lever and anchor lever with strut shoulders of levers toward inside of case and tapped ends of shaft outward (operating lever on side of case having large servo opening, anchor lever on opposite side). Install low band struts in ends of levers with notched ends together using two wooden blocks (1" x 2" x 3½") to support struts and band while assembling. Install low band with J-2595 band installing clip holding band compressed *(CAUTION*—used band must be installed in original position with point of heavier wear at anchor end, (new band can be installed either way). With struts engaging ends of band (notches on struts must straddle pins on band), apply operating lever and remove clip. Place bronze reaction gear thrustwasher on sun gear, install clutch assembly (use wire hook to lift low band if clutch does not go down fully), place bronze thrustwasher on front face of clutch hub. Install input shaft (make certain that oil seal ring ends properly locked and that retaining ring installed in shaft groove). If shaft does not go down into place, make certain all four thrustwashers are properly centered.

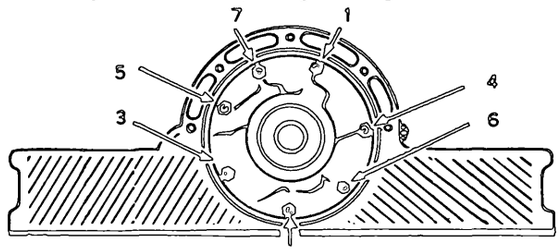
Reaction Shaft Flange, Front Oil Pump, & Accumulator Installation: Install special guide pins (see Guide Pin Note below) in accumulator bolt hole at each end of flange on transmission case, then proceed as follows:

1) Place reaction shaft flange gasket in position on case so that holes in gasket and case are aligned *(CAUTION—It is possible to install this gasket incorrectly).* Make certain that oil seal rings are on flange hub, then install flange assembly on case using care to avoid damaging oil seal rings.

2) Install three special bolts (⅜" - 16 x 2") with plain washers in #2, 3, 4 positions (see Tightening Sequence illustration) for assembly purposes (these bolts removed after assembly completed). Install regular pump cover bolts, nuts and lockwashers at positions marked #1, 5, 6 *(CAUTION—Coat threads of #5 bolt with Permatex No. 3).*

3) Tighten bolts in #1 through #4 positions to 35-40 ft. lbs., and bolt in #5 position to 20-25 ft. lbs., in numerical sequence.

4) Thread Endplay Gauge J-5804 into rear end of output shaft and thread Extension Rod J-5808 into bolt hole in rear bearing retainer. Tighten both tools firmly. Use Clamp KMO-30-G and Sleeve KMO-30-K to mount Dial Indicator KMO-30-B and Extension J-5339 so that extension bears squarely against end of Gauge J-5804.



5) Push Gauge J-5804 as far forward as possible, set dial indicator at zero, then pull gauge rearward toward indicator with sufficient force to remove all endplay from input shaft. Note indicator reading, which will be between .020" and .034" if output shaft endplay is within proper limits. If endplay not within proper limits, remove reaction shaft flange, clutch assembly, and the thrust washer located between reaction gear and reverse sun gear.

6) Measure thickness of washer and substitute another one of proper thickness to bring output shaft endplay within specified limits. If endplay less than .020", use a thinner washer, and if greater than .034", use a thicker washer. Reinstall parts and recheck for correct endplay.

7) Place accumulator gaskets in position so that holes match holes in reaction shaft flange. Install low accumulator on same side as low band operating lever and install high accumulator on opposite side of flange, first making sure that check ball and retaining pin are in place in high accumulator body.

8) Coat accumulator bolt threads with Permatex No. 3 (non-hardening) and install bolts and stud nuts with lockwasher, but do not tighten. Tighten all bolts and nuts in positions #1 through #14 to 5 ft. lbs., in numerical sequence. Following the same sequence again, tighten bolts #1 through #4 to 35-40 ft. lbs., and the remaining bolts and nuts to 20-25 ft. lbs.

9) Remove the three special bolts from positions #2, 3, 4, and tighten accumulator body caps to 40-50 ft. lbs. CAUTION—If edge of flange gaskets project beyond bottom surface of transmission case, carefully trim it flush, using a sharp knife.

FRONT OIL PUMP TIGHTENING SEQUENCE

▷Guide Pin Note—These 5/16" guide pins can be made up from 5/16" round stock, 2½" long, with 5/16"-18 thread ½" long on one end and screwdriver slot on opposite end (chamfer this end slightly).

▷*SHIFT CONTROL VALVE ADJUSTMENT CHANGE:* The previous valve adjustment procedures included a clearance check between the shift control valve and stop pin which have been superseded by the instructions outlined below. The following adjustment applies whether the adjustment is made with the transmission in the car or during transmission assembly.

Valve & Servo Body Installation: With transmission inverted on bench, raise reverse band operating lever and insert strut between lever and end of band *(CAUTION*—rounded ends of strut must be against band and lever). After strut installed, do not raise lever while installing valve and servo body (will allow strut to fall into case). Install two 5/16" guide pins (same pins as used for reaction shaft flange—see above) in case to guide each end of servo body. Install spacer plate gasket over guide pins. Install valve and servo body on case (hold anchor piston from falling out and move shift control valve and lower operating lever inward to align upper level with opening in case). Engage control valve pin in slot in operating lever. Install correct length bolts and lockwashers in all mounting holes using copper washer on #10 bolt (see Tightening Sequence illustration), remove guide pins. Tighten all attaching bolts and nuts to 5 ft. lbs. torque in correct sequence (see illustration), then fully tighten all ¼" bolts and nuts to 11-15 ft. lbs. and all 5/16" bolts to 15-20 ft. lbs. torque in same sequence *(CAUTION*—When tightening nuts and bolts adjacent to shift control valve, operate valve to make sure that it does not bind—if necessary, readjust bolts to lower torque limit to correct binding). Remove #18 and stud nut #9, install cork gasket, oil suction pipe, retaining spring and spring support, tighten this #18 bolt and stud nut #9 to 11-15 ft. lbs. Connect valve operating rod to upper operating lever by reaching into case with Linkage Hook-up Finger J-2591 and pulling upward on rod to engage ball in socket. Install shift lever on cross-shaft temporarily to check and adjust linkage. Valve linkage must operate freely. Move lever toward front of transmission to engage parking lock. Pawl must fully engage ratchet wheel and pawl lock must be in full contact with pawl in this position. Place transmission in "D" (Drive) range, and note position of land on end of control valve in relation to hole in valve body. The edge of the land on shift control valve must be flush with edge of hole in valve body *(NOTE*—Do not confuse an extension on end of valve with the valve land. Three different valves have been used in production as follows: First (no valve extension), Second (plain extension), Third (grooved extension), all of which are interchangeable). If edge of valve land does not line up with edge of hole in valve body, loosen the adjusting lever locknut and properly position shift control valve, then securely tighten locknut.

Oil Pan Installation: Coat area on transmission case where case cut away under oil pan gasket thinly with Permatex #3. Install 5/16" guide pin at each end (same pin as used for reaction shaft flange—see note above), install new oil pan gasket over guide pins. Install oil pan (use heavy-duty internal tooth lockwashers on bolts and stud nuts), tighten all bolts and nuts evenly to 15-18 ft. lbs. torque.

Universal Joint Installation: Make certain that joint retaining ring fully seated in groove in output shaft before installing universal joint. Install universal joint using Replacer Tool J-855 to draw universal joint snug against retaining ring. Install plain washer, lockwasher, and bolt and tighten bolt to 30-35 ft. lbs. *(CAUTION—Make certain that oil passage in gear is clear).* Install speedometer driven gear and sleeve assembly in rear bearing retainer.

Torque Ball Installation & Adjustment: *See "Torque Ball Adjustment" in Buick Special Data in Car Model Section.*

Bell Housing & Torque Converter Assembly Installation: 1) Install front oil pump seal ring around pump body against pump cover. Install bell housing, using lockwashers on bolts and stud. Sparingly coat threads of lower right side bolt with Permatex No. 3 (because bolt hole opens into transmission case). Tighten bolts and stud nut evenly to 35-40 ft. lbs.

CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (C nt.)

2) Support converter pump firmly on blocks and carefully place stator in proper position, with original selective spacers and the thrust washer between stator and pump hub *CAUTION—Do not use grease to hold spacers in place.*

3) Place sun gear on stator with tanged thrust washer up, then carefully lower twin turbine assembly into place, making sure that planet pinions enter and mesh properly with sun gear Install Converter Gauge J-5899 on converter pump flange, making sure that indicator post does not contact turbine Loosen wing screw, firmly press gauge plunger down against first turbine hub and tighten wing screw

4) Support converter pump cover firmly on blocks with inner side up and place bronze thrust washer in its recess Remove Gauge J-5899 from pump, **invert it,** and center it on cover so that it rests squarely on the gasket surface

►*CONVERTER COVER PRODUCTION CHANGE:* A later type converter primary pump cover having three impeller blades replaces the former type having impeller ribs completely around the cover Either type can be used for service replacement

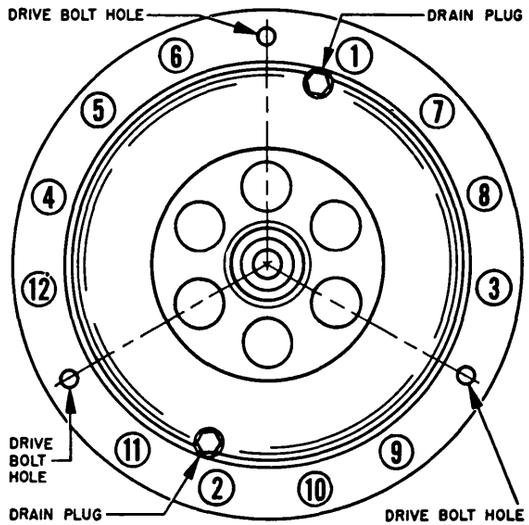
5) Use Sleeve KMO-30-K to mount dial indicator KMO-30-B on the adjustable post of clearance gauge so that indicator button bears squarely against upper end of clearance gauge plunger **Set dial at zero.**

6) Loosen plunger wing screw, firmly press plunger down against the thrust washer and note dial reading The dial reading is clearance that will exist between turbine pump and pump cover when parts are installed, and should be 018- 029" If dial reading not within specified limits, change the total thickness of selective spacers located under the stator *Increasing* spacer thickness will *decrease* clearance at cover and *decreasing* spacer thickness will *increase* the clearance

Part No.	Spacers	Thickness
1167710		013- 010"
1167711		023- 020"
1167712		033- 030"

7) Install converter pump on reaction shaft, turning it until lugs on pump hub enter slots in front pump driving gear Coat selective spacers and thrust washers with petroleum jelly so they will adhere to stator during installation Make sure that all rollers and springs are in place and held in stator with tool J-5806

8) While holding thrust washers and spacers to rear side of stator, slide stator off of installing tool onto the reaction shaft Make certain that washer and spacers remain in place as stator is pushed back against converter pump Install converter sun gear with the tanged thrust washer outward If sprag is properly installed, the sun gear may be turned on reaction shaft in clockwise direction only



9) Make sure that retaining ring is seated in groove of input shaft, then install the twin turbine assembly, turning it as required to mesh planet pinions with sun gear Install selective thrust washer, retaining washer and bolt, with external tooth lockwasher on front end of input shaft Shift into "P" (parking) and pry up on reverse band operating lever with a screwdriver to lock input shaft, then tighten bolt to 30-35 ft lbs

10) Check clearance between selective thrust washer and first turbine hub, using feeler gauges Clearance should be 002- 009" If clearance not correct, substitute another thrust washer of proper size Two sizes furnished for selective fitting (Part No 1166113, 063- 060" Part No 1166112, 070- 067")

11) Looking at front face of converter pump cover, select the three bolt holes used for pump to flywheel drive bolts (see illustration) Install a new "O" ring seal on pump cover, making sure that surfaces are clean and that seal has even tension all around and is not twisted

►*FRONT PUMP COVER OIL SEAL NOTE: Both a .120" and .135" diameter oil seal has been used in production. Either type may be used for service replacement.*

12) Grease the selected thrust washer so it will adhere and place it in recess in cover, then install cover on pump so that the three marked driving bolt holes are not aligned with any hole in pump rim at which a balance weight is located Install bolts with plain washers and special nuts in all but the three driving bolt holes, insert shank of a 11/32" drill through one bolt hole to align all bolt holes, then tighten bolts to approximately 5 ft lbs in numerical order (see sequence in illustration) Finally tighten bolts in same sequence to 25-30 ft lbs *NOTE—When tightening bolts, insert a wide screwdriver between flat side of bolt head and the pump to prevent a corner of bolt from digging into casting.*

CONVERTER PUMP COVER TIGHTENING SEQUENCE

INSTALLATION IN CAR

After transmission and torque converter completely assembled, install unit in reverse order of removal procedure and note following important points:

Alignment of Parts—See that flywheel, converter primary pump, and converter cover positioned so that paint marks (as made for removal) will be aligned when transmission installed.

►*CAUTION—This alignment necessary to maintain converter assembly balance.*

Shift Rod Installation—Check and adjust linkage when installing shift rod. *See LINKAGE ADJUSTMENT.*

Filling Transmission—*See LUBRICATION.*

Bell Housing Mounting Bolt Installation—Adjust lifting equipment so that bell housing meets engine crankcase squarely and engages the two dowels, then install all bell housing bolts with lockwashers. Tighten all bolts to 45-55 ft. lbs. torque.

Transmission Support & Thrust Pad Installation & Adjustment—*See ENGINE MOUNTING in Buick Special Data.*

Converter Mounting Bolt Installation—Use the shank of a 11/32" drill to align bolt holes in flywheel and converter, install bolts and tighten to 25-30 ft. lbs. torque.

Final Road Test—After transmission installed and all adjustments made, road test car by driving approximately 20 miles with frequent starts and stops to duplicate heavy traffic conditions. After transmission thoroughly warmed up, check transmission and all oil lines and connections for leaks. If vibration noted due to unbalance of replacement parts, correct this condition as follows:

ENGINE BALANCING

►*IF VIBRATION NOTED AFTER INSTALLATION OF CRANKSHAFT, FLYWHEEL, AND OTHER ROTATING PARTS, CORRECT THIS UNBALANCE AS FOLLOWS·*

►*CAUTION·* Procedure below will correct minor unbalance caused by replacement of individually balanced parts Extreme vibration caused by parts abnormally out of balance, or different in weight from corresponding parts, should be corrected by replacement of these parts

Critical Speed of Vibration—Determine speed at which vibration is most evident (use tachometer) and operate engine at this speed to check results from the following corrective procedures

1)—Remove bell housing cover and bell housing hand hole cover for access to flywheel

2)—Install one 060" balance weight of correct type (see Balance Weight Note following step 5 below) under the head of one of the primary pump cover bolts, tighten bolt to 25-30 ft lbs torque

►*CAUTION—DO NOT install weight at flywheel-to-converter driving bolt (bolts are too short for addition of weights).*

3)—Operate engine and check for vibration Mark location of balance weight on converter pump, then remove weight and tighten cover bolt to 25-30 ft lbs torque

4)—Repeat steps (2) and (3) at other converter pump cover bolts and compare engine vibration noted at each location

5)—At point where balance weight results in smoothest engine operation, vary weight thickness (see Balance Weight Note following), until vibration has been eliminated After balance weights selected and installed, tighten cover bolts to 25-30 ft lbs torque, attach weights permanently as follows Use 5/32" drill to spot center of both holes in weights, then drill pump flange with #32 (116") drill to depth of ⅜", use correct length drive screws ⅜" long (No 145067) or ½" long (No 450543) depending on the weight thickness to permanently attach weights to pump cover

Balance Weight Note—Balance weights furnished in three thicknesses as follows:

Thickness	Balance Weight Part Nos.	Part No.
0345"		1166600
.060"		1166601
120"		1166602

1950-52 POWERGLIDE

Chevrolet Pass. Cars (1950-52)

▷CHANGES, CAUTIONS, CORRECTIONS

▷STARTING ENGINE BY PUSHING CAR: Pushing recommended rather than towing car. Place selector lever in Neutral "N" position. When car reaches speed of approximately 15 MPH., move lever to "L" position to crank engine, then move lever to "N" position to warm up engine.

Wet or Icy Road Caution—Push car until speed of 20 MPH. reached, then place lever in "D" position to crank engine (do not use "L" position).

▷TOWING POWERGLIDE CARS: Do not tow car with rear wheels on ground EXCEPT with selector lever in "N" (Neutral) and at speeds less than 45 MPH. (if transmission in good condition) If selector lever cannot be placed in Neutral, transmission can be placed in neutral as follows: Disconnect long control rod from idler lever on left side of transmission case, push idler lever toward rear of car as far as possible, then move lever toward front of car to third detent position which is neutral.

▷TRANSMISSION LOCKING OR SLIPPING OUT OF PARK "P" POSITION: Correct as follows:

Locking in "P" Position—May be caused by slight depression at top of cam ramp on parking pawl which makes disengagement of cam roller difficult. Correct by disassembling transmission and replacing parking pawl. See Disassembly data.

Slipping out of "P" Position—May be caused by weak apply spring on parking lock lever shaft which allows detent pin to ride out of detent in parking lock pawl. Correct by disassembling transmission and replacing Parking Lock Lever Shaft & Apply Spring Assembly. See Disassembly data.

Difficulty in Engaging "P" Position—Difficulty in moving control lever far enough into Park position to allow control shaft lever to pass upper tang of lower support may be corrected by new linkage setting. *See Linkage Adjustment.*

▷UNIVERSAL JOINT & PROPELLER SHAFT BUSHING LUBRICATION CAUTION ON POWERGLIDE CARS: These parts lubricated from transmission output shaft through drilled passage in special universal joint retaining bolt No. 3690869 (bolt drilled completely through and has special flat head nail in hole to keep oil passage open). If universal or bushing lubrication trouble experienced, make certain that drilled bolt used and that nail is free in oil passage (1/32-1/16" clearance between head of nail and head of bolt).

CAUTION—Plain bolt used for transmission run-in at factory must be replaced by this special drilled bolt when transmission installed in car.

▷PUMP CHECK VALVE CHANGE: New valve assembly with changed contour of tab ends which cover pump inlet ports now used to insure proper installation of valve in body. This valve interchangeable with first type.

CAUTION—When installing check valve, see that tab end of valve does not extend beyond face of valve body (turn valve over and re-install, or grind edge of tab off slightly to prevent interference with valve body gasket).

▷REPLACEMENT LOW SERVO PISTON CAUTION: Both stamped metal pistons and cast iron pistons will be found in transmissions in service. Cast iron piston has thicker head and special Piston Return Spring must be used for each type as listed below. *NOTE*—Cast type piston, No. 3694460, is furnished as service replacement for all transmissions.

Low Servo Piston Assemblies

Piston Part No.	Type	Return Spring No.
3689820	Stamped	①3689840
3694460	Cast	②3694463

①—1 11/64" O.D.
②—1 29/64" O D.

▷CLUTCH ASSY. PRODUCTION CHANGE (Beginning Trans. No. JT-232315-D-23-D): Redesigned clutch with cast iron piston used in transmissions after this number to prevent possibility of partial clutch engagement due to centrifugal force under certain conditions. This clutch has relief valve located in piston (instead of cylinder) and individual *parts are not interchangeable with 1st type parts.*

▷REPLACEMENT LOW & REVERSE BAND CAUTION: Bands furnished for service have increased thickness at strut slots and correct type Struts must be used with these bands as listed below. *CAUTION*—When replacing bands in 1950 transmission, all three parts must be installed as a unit. When replacing bands in 1951-52 transmission, make certain that struts are correct type for use with new type band.

Low Band Assemblies

Low Band Part No.	Apply Strut	Anchor Strut
3694493 ('50-52)①	②3697562	③3697564
5454217 ('50-53)	3702910	3702911

Reverse Band Assemblies

Reverse Band Part No.	Apply Strut
3694493	(1950) 3689827
	(1951-53) 3694491

①—Superseded by Part No 5454217.
②—Supersedes No 3694496.
③—Supersedes No 3694498

▷CONVERTER OIL LEAK (INTO TRANSMISSION HOUSING) CORRECTION: Correct by replacing primary pump "O" ring seal. See Turbine Disassembly for data.

CAUTION—Primary pump and pump hub balanced as an assembly and must be marked first and reassembled to these marks to maintain balance.

▷POWERGLIDE OIL COOLER CAUTION: Whenever broken parts or other foreign material found in transmission oil, or if transmission temperatures excessive, check oil cooler and lines for clogged passages. Replace cooler if circulation restricted.

▷REPLACEMENT TRANSMISSION CASE CAUTION If 1952 production case, No. 3701156, is used for 1950-51 replacement purposes, the following precautions must be noted. *NOTE*—1950-51 type case, No. 3694354, is also furnished for service.

Rear Mounting Holes—Two sets of holes provided; two forward holes must be used for 1950-51 cars (rear holes used for 1952 cars only).

Spacer Installation—⅛" spacer furnished with case must be used on 1950-51 cars (due to differences in machining at rear transmission support).

Servo Cover Replacement—1952 type Servo Cover No. 3697554 must be installed with this case on 1950-51 cars (required by change in location of rear pump pressure checking hole which is now located on servo cover assembly).

▷TURBINE BOLT PRODUCTION CHANGE & REPLACEMENT CAUTION: Beginning Trans. No. KT-22574A-15-D, new Torque Converter Flanged Nut No. 3697544 was used in production to replace Bolt No. 3694455. If this new flanged nut used for replacement on earlier transmissions, other parts must also be installed as follows:

Trans. Prior to KT-22574A-15-D—Flanged nut must be used with special 5/16"-24 x 3/4" bolt No. 181595 and special lock No. 3697543.

Trans. Prior to HT-29008-C-17—In addition to special bolt and lock (above), turbine front washer must be replaced with new type No. 3691817 which has larger chamfer on inside diameter.

▷REPLACEMENT VALVE BODY CAUTION: Some 1952 transmissions used a valve body with a .006" oversize manual valve bore and corresponding .006" oversize manual valve. Only the .006" Oversize Valve Part No. 3697567 is furnished for service. If oversize valve body requires replacement, use new standard size valve body and new standard size manual valve.

These oversize parts can be identified as follows:

Valve Body—No. 3697568. Stamped +6 between suction and lubrication ports where body-to-case gasket installed.

Manual Valve—No. 3697567. Stamped or etched +6 on idler lever end of valve.

▷PRIMARY PUMP HUB & BUSHING ASSEMBLY REPLACEMENT PART: Hub & Bushing Assembly No 3692982 furnished for service. When this assembly used, it will not be necessary to replace entire Pump, Housing, & Cover Assembly to correct worn bushing or damaged hub or bushing. *See OVERHAUL data for installation of this assembly and new parts which must be used.*

▷TRANSMISSION GASKET CAUTION: Gasket Kit 3701030 should be stored flat in warm dry place to insure gaskets fitting properly when installed This is important for Servo Cover Gasket No 3697556 and Valve Body Gasket No. 3693098.

DESCRIPTION

Powerglide transmission is an automatic type and consists of a Torque Converter and a Planetary gear unit providing automatic operation in the Drive range, and additional Low, Reverse, Neutral, and Parking positions controlled by the operator.

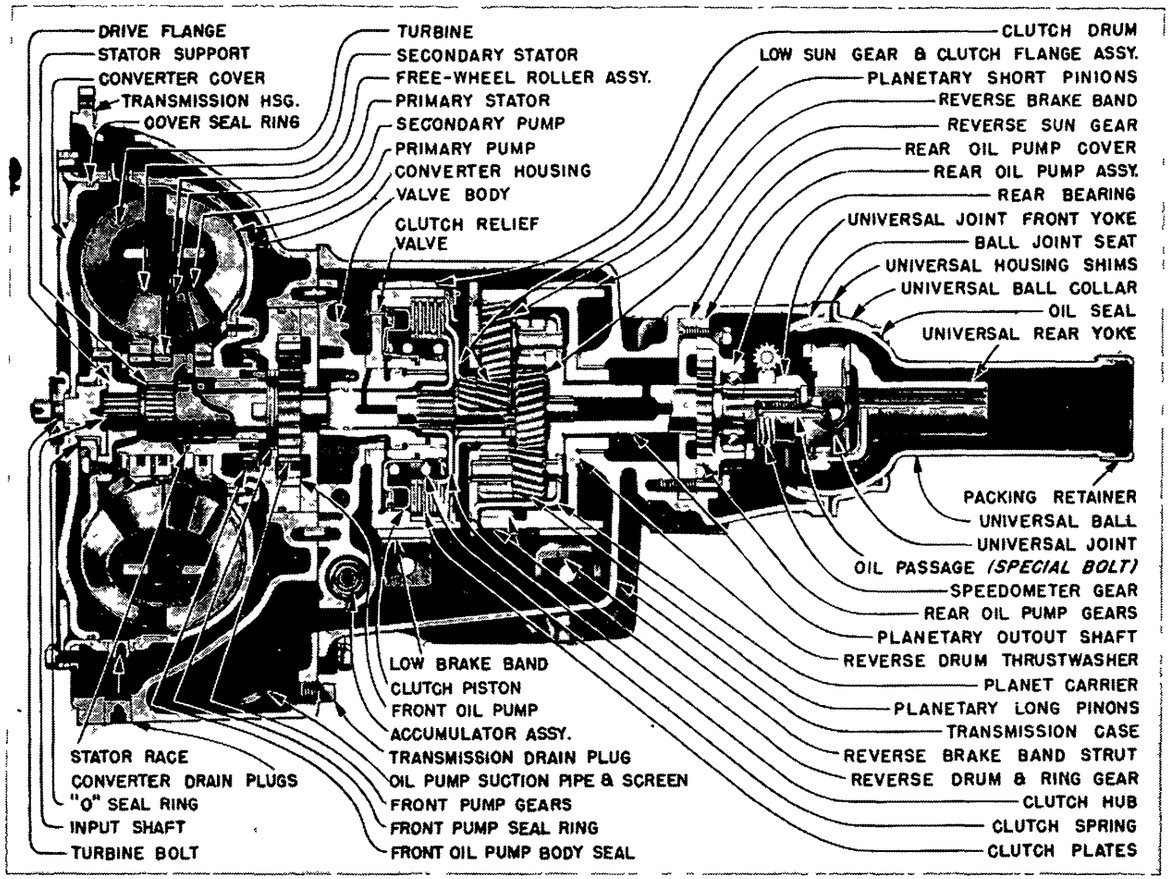
Torque Converter: This assembly mounted in a housing which replaces the flywheel used on cars with conventional transmission and consists of the units listed below. Torque converter operation is entirely automatic and unit operates as a torque converter (for starting and low speed operation) or as a fluid coupling (at higher car speeds). The change from one type of operation to the other, and also the operational phases of each unit as described below, are governed entirely by the car operating conditions and do not occur at any set car speed.

CHEVROLET POWERGLIDE (C nt.)

Primary Pump (Driving Member): Mounted directly on engine crankshaft (bolted within turbine cover) and rotates at engine speed to transmit engine power to the turbine through the oil.

Turbine (Driven Member): In converter housing directly ahead of primary pump and driven by oil flow from the pump. Turbine hub is splined on input shaft through which power is transmitted into the planetary gear unit (for Low and Reverse operation), or directly through to the propeller shaft (for Drive Range operation).

Primary & Secondary Stators: Two similar units consisting of sets of curved vanes located between inner ends of turbine and secondary pump vanes. Each stator is mounted on a free-wheeling unit on a stationary stator support. Stators are locked or held stationary when unit is operating as a torque converter and act to redirect the oil flow from the turbine to the secondary pump thus supplying the torque multiplication. When the turbine speed becomes equal to the pump speed, stators rotate freely with the other members (rotation permitted by free-wheel units) without torque multiplication and the converter operates as a simple fluid coupling.



Secondary Pump: Consists of a set of curved vanes mounted on a free-wheel unit on the primary pump hub just ahead of the inner end of the primary pump vanes (between pump and primary stator). Secondary pump overruns the primary pump when unit operating as a torque converter but is locked to the primary pump and operates with it to provide greater capacity when operating as fluid coupling.

Planetary Transmission: Consists of a double planetary gear set, controlling bands, servo mechanisms, and disc clutch located in transmission case.

Planetary Sun Gears: Two separate gears, Front (Low) Sun Gear and Rear (Reverse) Sun Gear are mounted in tandem within the planetary unit. Front sun gear is part of the clutch flange assembly (locked to input shaft when clutch engaged) and meshes with the short planetary pinions. Rear sun gear is splined on rear end of input shaft (acts as driving gear for Low & Reverse) and meshes with the long planetary pinions.

Planetary Pinions: Assembly consists of three short (Reverse) pinions and three long (Low) pinions mounted alternately in the Planet Carrier and all meshing together. The short Reverse Pinions mesh with the front Low Sun Gear and with the Reverse Ring Gear (internal gear controlled by the reverse brake band). The long Low Range Pinions mesh with the rear Reverse Sun Gear.

Multiple Disc Clutch & Low Range Drum: This assembly mounted on input shaft ahead of planetary pinion assembly. Clutch hub (inner member) is splined on input shaft and rotates with the shaft. Clutch drum (outer member) is locked to the front Low Sun Gear. Clutch is engaged by a hydraulic piston within the clutch drum and locks the Low Sun Gear to the input shaft. Clutch is disengaged by a spring and allows the sun gear to revolve freely (except when sun gear held stationary by application of the Low Brake Band). A relief valve is located in front face of clutch drum (first type), clutch piston (later type), to insure complete drainage of oil from clutch cylinder when clutch is disengaged.

POWERGLIDE TRANSMISSION ASSEMBLY

Low Range Brake Band & Servo Mechanism: Band holds front sun gear stationary when it is applied on the clutch drum by the Low Servo which consists of a hydraulic piston linked to one end of the band by a strut. The opposite end of the band is held stationary by a strut and anchor which has an adjusting screw for band adjustment.

Reverse Brake Band & Servo Mechanism: Band holds the Reverse Ring Gear stationary when it is applied on the reverse drum (integral with the gear) by the Reverse Servo which consists of a hydraulic piston linked to the band by a lever-and-link mechanism. One end of the band is held stationary by a strut and anchor which has an adjusting screw for band adjustment.

Oil Pumps: Two pumps used to supply oil pressure for hydraulic controls, oil supply for torque converter and transmission lubrication.

Front Pump—Internal-external gear type mounted between the transmission and torque converter and driven directly by the converter primary pump through a tongue-and-slot coupling. This operate as soon as the engine started, supplying oil to the torque converter and for transmission lubri- pump has relatively large capacity and begins to cation. It also supplies oil pressure for hydraulic control for idling, low speed, and reverse.

Rear Pump—Internal-external gear type mounted in rear end of transmission case and driven by the output shaft. Pump operates whenever rear wheels are turning and supplies oil pressure for transmission operation when pushing car to start engine. At car speeds above 15 MPH., rear pump normally supplies all oil pressure for transmission operation and front pump idles (pressure regulator valve bypasses front pump output by connecting output line to pump suction line).

Hydraulic Controls: Consist of manual and automatic Control Valves, Accumulator, and Vacuum & Hydraulic Modulator.

CONTINUED ON NEXT PAGE

CHEVROLET POWERGLIDE (Cont.)

Manual Valve—Linked to transmission selector lever on steering column and controls oil pressure supply to servo mechanisms, multiple disc clutch, and modulator as required for operation in each range (Park, N, D, L, R depending on selector lever position).

Pressure Regulator Valve—Spring-loaded type with extended stem contacting modulator lever. Valve has following functions: 1) Controls maximum pressure of both oil pumps (and allows front pump to by-pass when rear oil pump takes over), 2) Controls oil pressure requirements for transmission operation (modulator acting on this valve "boosts" oil pressure as required for Low & Reverse Band application), 3) Supplies oil to Converter and prevents oil draining out of converter case when engine not running.

Vacuum & Hydraulic Modulator—Vacuum modulator consists of a spring-loaded, diaphragm type vacuum unit mounted on the transmission case with the vacuum chamber connected to the engine intake manifold. Diaphragm is connected to a lever bearing on the pressure regulator valve stem so that diaphragm movement tends to modify the action of the regulator valve springs in accordance with load requirements which affect engine vacuum. With light loads and high vacuum, no pressure is exerted on the valve stem and valve is controlled entirely by the valve springs. With increase in load and decrease in manifold vacuum, modulator lever exerts pressure on the valve stem and assists the valve springs which has the effect of increasing hydraulic pressures within the transmission. Hydraulic modulator is built-in the vacuum modulator diaphragm plunger (hydraulic plunger and body assembly). Oil pressure expands this plunger and body assembly and increases modulator pressure when selector lever placed in Low or Reverse position (manual valve directs oil pressure to hydraulic modulator).

Accumulator—Consists of a surge chamber in the hydraulic line between the manual valve and the hydraulic modulator. Accumulator cushions the band application when shifting into Low or Reverse.

Pump Check Valve—This valve controls oil delivery from each pump and prevents oil from the operating pump bleeding back through the pump that is not operating (cuts off rear pump at low speed and when operating in reverse).

By-Pass & Lubrication Check Valve—By-pass valve controls oil flow from converter to oil cooler. With oil temperature below 240°F., by-pass valve remains open so that oil goes directly to transmission lubrication system (through lubrication check valve) without passing through oil cooler. When oil temperature reaches 240°F., by-pass valve closes and oil flows through oil cooler and then returns to the lubrication check valve for use in the transmission lubrication system.

Parking Mechanism: Consists of a pawl controlled by the transmission selector lever which engages gear teeth cut on edge of planet carrier and locks the planet carrier to the transmission case when selector lever placed in Park position.

OPERATION

Powerglide Torque Converter automatically provides a torque multiplication ranging from 2.2-1 (maximum for starting and acceleration) to 1-1 (normal driving range with torque converter acting as a fluid coupling). This torque multiplication is supplemented by the planetary gears when selector lever placed in Low or Reverse range (gears provide 1.82-1 reduction). Transmission operation in each range is as follows:

Neutral "N" Position—Multiple disc clutch, Low Brake Band, and Reverse Brake Band are all released so that gears are free to spin. Drive is not transmitted through transmission and this "N" position can be used to start and warm up engine with car standing still.

Low Range "L" Position—Multiple Disc Clutch is released and Low Brake Band is applied so that the front sun gear is held stationary. Power is transmitted through the reverse sun gear to the planetary pinions which "walk" around the stationary sun gear. This results in a 1.82-1 gear reduction between the input and output shafts.

Drive Range "D" Position—Multiple Disc Clutch is engaged and both brake bands are released. In this position both of the sun gears are locked to the input shaft so that the entire planetary gear system is locked and revolves as a unit. Power is then transmitted straight through from input shaft to output shaft with no gear reduction.

Reverse Range "R" Position—Multiple Disc Clutch and Low Brake band are released, Reverse Brake Band is applied. Power is transmitted through the Reverse Sun Gear to the planetary pinions which "walk" around the stationary Reverse Ring Gear. This results in reverse rotation and a 1.82-1 gear reduction between the input and output shafts.

Parking "Park" Position—Parking pawl engages gear teeth cut on edge of planet carrier and locks carrier to transmission case. Planet carrier is integral with output shaft so that shaft and rear wheels are held stationary.

CAUTION—Park position of selector lever should never be engaged when car is in motion.

LUBRICATION

The transmission oil level should be checked at 1000 mile intervals and oil should be changed at 25,000 mile intervals.

Recommended Oil—Use only Automatic Transmission Oil Type "A" (in sealed containers with "AQ-ATF" number).

Capacity—Approximately 9 qts. (refill), 10 qts. (dry—after overhaul and reassembly).

Checking Oil Level—Check only with transmission warm and engine idling with selector lever in "N" position (NOTE—this procedure supersedes original recommendation that selector lever be placed in "D" drive position). Check with dipstick located on right side in engine compartment. Add fluid only when level falls to "ADD ONE QUART" mark on dipstick, fill only to "FULL" mark on stick.

▷*CAUTION—High fluid level (above FULL mark) will cause foaming and loss of fluid.*

▷*LOW OIL LEVEL CAUTION: If oil level in transmission is consistenly low, check for internal and external oil leaks. See "OIL LEAKAGE OR HIGH OIL CONSUMPTION" in TROUBLE SHOOTING.*

Draining & Refilling—Warm up transmission. Drain transmission by removing drain plug in rear face of transmission housing under case. On first cars with converter lubrication check valve, fold back floor mat, remove toe pan plate, turn engine over until one converter drain plug is at top, remove this plug (later cars have only one drain plug). Then drain converter by taking out plug on bottom of housing, turning converter until drain plug visible through hole, and removing drain plug. Clean dirt away from filler tube housing cover on right side of transmission, remove this side cover, remove oil suction screen and seal and clean thoroughly in cleaning solvent. Replace screen and side cover using new pipe seal and gasket. Replace all drain plugs. Install 3 qts. new fluid through filler tube (Oil Filler Tube and Funnel J-4264 will facilitate filling, since this assembly vented and transmission case is not). Start engine and allow it to idle with selector lever in N (Neutral), add additional 6 qts. fluid. Allow engine to idle for several moments. Check oil level (see above), make certain that oil level is up to "FULL" mark on dipstick.

LINKAGE ADJUSTMENT

LINKAGE ADJUSTMENT: Adjust as follows:

Control Lever Clearance: 3/32-1/8" clearance between lower edge of control lever and top upper support cover. To adjust, remove screws attaching upper support to mast jacket, screw support up or down, as necessary, until clearance correct, re-install support screws.

Control Lever Position: 1 1/2" ± 5/16" between upper face of control lever knob and lower face of steering wheel with selector lever in "R" reverse position. To adjust, loosen lower support clamp bolts, move lower support up or down, tighten clamp bolts.

▷*CAUTION—Dowel in support must be located in slot in mast jacket.*

Reverse Stop Clearance: .090" clearance between Reverse Stop on control shaft lower support and lower lever with selector lever in "R" reverse position. To adjust, loosen control rod swivel, make certain that manual control valve lever on left side of transmission is in top detent position, and selector lever in "R" position, move selector lever as necessary for correct clearance, then tighten control rod swivel.

▷*REVERSE STOP SETTING CHANGE*—Above setting of .090" supersedes previous recommendation of 3/64" or .045" and will tend to prevent difficulty of moving selector lever into Park position.

CAUTION—Short connector rod (bellcrank-to-parking lock lever) must be correctly installed with arrow pointing UP.

Neutral Safety Switch: Located on bracket on lower end of lower support assembly on steering column.

CONTINUED ON NEXT PAGE

CHEVROLET POWERGLIDE (C nt.)

To adjust, loosen two switch assembly mounting screws. Place selector lever in neutral, make certain that switch clip is over flats on end of shifter shaft. Insert locating pin through holes in switch mounting bracket and locating plate. Tighten switch mounting screws, remove locating pin.

BAND ADJUSTMENT

BAND ADJUSTMENT: Not ordinarily required in service. Use adjusting tool J-4277 (combination screwdriver and locknut wrench) to adjust bands.

►*REVERSE BAND ADJUSTING NOTE*—Reverse band ordinarily adjusted when reassembling transmission (requires removal of transmission). *See "TRANSMISSION REASSEMBLY" data.*

Low Servo Band—Adjusting screw located on left side of transmission case. Tighten adjusting screw until band is tight, then back screw off 3 turns, tighten locknut.

Reverse Band—Adjusting screw located on right side of case under servo cover. With servo cover removed, turn adjusting screw in slowly and at the same time check endplay in linkage by pushing and pulling on servo return spring directly below adjusting screw. Continue to turn screw in until endplay is just taken up (at this point band must be free on drum so that drum can be easily rotated by hand), then **back adjusting screw off ⅛-¼ turn** and tighten locknut.

►***CAUTION—Above procedure supersedes previous instructions and will provide sensitive adjustment without possibility of false settings.***

TROUBLE SHOOTING

OIL LEAKAGE OR HIGH OIL CONSUMPTION: If oil level in transmission case consistently low, and to correct complaints of oil leakage or high oil consumption, check for external and internal leaks as follows:

External Oil Leaks—Make thorough inspection of entire transmission, check mating surfaces of servo case, modulator housing and cover, universal joint ball collar, transmission case, converter housing and side covers for signs of leakage. Check and tighten all test plugs.

Internal Leak in Vacuum Modulator—Disconnect vacuum line from vacuum modulator to intake manifold and check for transmission lubricant in this line which would indicate a torn or fractured modulator diaphragm. Replace diaphragm.

Internal Leak to Rear Axle—Inspect rear axle lubricant level. A too high level indicates a leak at the universal joint shaft seal allowing transmission lubricant to leak back through torque tube to rear axle, or plugged drain-back hole from universal joint to transmission case. Make certain this hole open and replace universal joint seal.

CAUTION—DO NOT re-use rear axle lubricant which has been diluted with transmission lubricant.

Internal Leak to Flywheel Housing—If oil leakage noted at front of flywheel housing, remove plug from bottom of transmission housing. If oil found in housing, check for oil leaks at the following points: "O" Ring Seal between primary pump and primary pump hub, Front Pump oil seal or "O" ring seal, Front Pump oil drain plugged, Converter Cover "O" ring seal, Turbine Bolt "O" ring seal, or sand hole in transmission housing allowing leaks between oil sump and converter cavity.

EXCESSIVE SLIPPAGE (High engine speed in relation to car speed, poor acceleration, or engine runs away on turns).

1) In all Speed Ranges—Low oil level. Incorrect control linkage adjustment. Air leak in oil pump suction pipe. Low front oil pump pressure.

2) In Drive Range—Incorrect control linkage adjustment. Damaged or leaking clutch piston seal (worn or burned clutch plates resulting from partially engaged clutch).

3) In Low Range—Incorrect control linkage adjustment. Low Band out of adjustment. Sticking accumulator valve, modulator lever, or modulator valve. Damaged or worn Low Servo Piston Ring resulting in poor band application or excessive oil leakage into clutch apply circuit causing partial clutch application and possibly burned clutch plates Check this condition by connecting pressure gauges to Low Servo Apply and to High Clutch test points (see Pressure Tests) and proceed as follows: Set brakes securely, place selector lever in "L" low range, accelerate engine to stall speed of 1560-1610 RPM., note pressure indicated on both gauges. Low servo apply gauge should indicate 160-200 lbs. and High Clutch gauge should read zero. If pressure registered on High Clutch gauge, oil leakage into clutch apply circuit is indicated.

CAR CREEPS (Forward or Backward).

1) With Control Lever in Neutral—Incorrect control linkage adjustment. Clutch piston vent valve stuck closed. Clutch plates sticking or incorrectly assembled (not "stacked" in correct order).

2) Creeps forward with Control Lever in Reverse or backward with Lever in Low—Incorrect control linkage adjustment.

CAR WILL NOT MOVE (Wheels may be locked or free):

1) With Control Lever in any range (rear wheels free). If this occurs at other times than after reversing car, see causes listed under EXCESSIVE SLIPPAGE above. If this occurs only after reversing car (indicating loss of front pump pressure) check: Rear pump air leakage into front pump suction line (causing front pump to lose its prime). Rear pump gasket leakage. Front pump clearance excessive.

2) With Control Lever in any range (rear wheels locked). Parking pawl lock engaged. Broken parts in transmission. Parking brake applied.

3) With Control Lever in Drive Range (rear wheels free). If engine runs away and transmission is hot, check for: Low radiator water level, clogged oil cooler, sticking thermostatic valve, or dragging Low Range Band (causing over-expansion of clutch parts due to excessive heat).

SHIFTS ARE ROUGH.

1) Low-to-Drive Shift (car in motion). Incorrect Low Band adjustment. Clutch plates worn or binding. Modulator control lever or piston sticking (will cause excessive pressures). Accumulator dump valve orifice plugged.

If engine speeds up during this shift—Check for incorrect low band adjustment and worn or binding clutch plates.

2) Drive-to-Low Shift. Incorrect Low Band adjustment. Accumulator piston stuck closed. Modulator control lever or piston stuck (will cause excessive pressure).

3) Neutral-to-Reverse. Incorrect reverse band adjustment. Accumulator piston stuck closed. Modulator control lever or piston stuck (will cause excessive pressure).

CHATTERS WHEN STARTING.

1) In Low Range. Incorrect Low Band adjustment. Worn or rough band, scored drum. Clutch not disengaging properly due to distorted or binding plates, sticking clutch piston, sticking piston vent valve, or damaged or worn Low Servo Piston Ring allowing oil leakage into clutch apply circuit and causing partial clutch application (see tests for Excessive Slippage in Low Range above).

2) In Drive Range. Incorrect Low Band or Reverse Band adjustment. Bands worn or rough, drums scored.

3) In Reverse Range. Incorrect Reverse Band adjustment. Worn or rough band, scored drum. Reverse ring gear and drum bushing worn or damaged.

REVERSE OPERATION JERKY OR DRAGGING.

1) Clutch plates are incorrectly assembled (not "stacked" properly) or sticking. Clutch piston vent valve stuck closed.

REVERSE CAN NOT BE ENGAGED WITH ENGINE RUNNING: If reverse can only be engaged when engine not running, check for accumulator snap ring being out of place (allowing accumulator valve and body to be forced against clamp nut on parking lock lever shaft and apply spring assembly, blocking shift into reverse). *NOTE*—Above condition will not prevent shift into Low Range).

DRIVE-TO-LOW OR LOW-TO-DRIVE SHIFT DIFFICULT: May be caused by improperly drilled high clutch feed orifice in valve body resulting in slow clutch application in Drive Range and slow clutch release when shifting from Drive to Low (restricted orifice will cause slow oil flow). Check by connecting pressure gauges to Low Servo Apply and to High Clutch (low servo release side) and noting pressures as follows:

1) Move selector from Neutral to Drive with engine idling. If pressure builds up much more rapidly on Low Servo Apply gauge than on High Clutch gauge, a restriction in the passage (undersized orifice) is indicated.

2) Move selector from Drive to Low. If pressure in High Clutch gauge drops slowly, oil drainage from clutch is restricted. NOTE—This will result in slow Low Band application and clutch drag (may cause burned clutch plates).

HIGH CLUTCH PLATES BURNED OR CLUTCH FAIL

►***CAUTION—When High Clutch failure noted, following tests should be made before transmission removed, and transmission should also be carefully examined after removal and disassembly.***

1) Connect pressure gauges to Low Servo Apply, High Clutch (low servo release side), and to Reverse Servo points. Operate engine to supply oil pressure.

2) Place selector lever in Drive position and note pressure build-up in High Clutch gauge. Slow build-up indicates restriction in high clutch apply orifice resulting in clutch slippage and burned plates.

3) Place selector lever in Low position. High Clutch gauge should not show any pressure. Pressure at

CONTINUED ON NEXT PAGE

CHEVROLET POWERGLIDE (Cont.)

this point indicates leakage past Low Servo Piston Ring resulting in partial clutch application and burned clutch plates.

4) Place selector lever in Reverse position. High Clutch gauge should not show any pressure. Pressure at this point indicates leakage between the converter "out" and low servo "release" channels in valve body or damaged Housing-to-Valve Body gasket. Also check valve body for porosity or sand holes permitting leakage. *NOTE*—even a slight clutch drag will cause clutch to burn out (clutch plates rotate in opposite directions in Reverse).

NOISE IN TRANSMISSION.

1) Buzzing Noise (All Ranges). Low oil level. Pump gear interference with crescent in pump. Pump check valve not seating.

2) Ringing Noise in Converter. Low oil level. Air leak in pump suction line (pipe not seated properly) resulting in low oil level in converter. Pressure regulator valve stuck (closing converter inlet port). Leakage in oil line between front pump and regulator valve.

3) Clicking Noise. Incorrect manual linkage adjustment (causing interference between parking lock pawl and gear).

4) Whining Noise. Transmission gear teeth worn. Pump gear clearance excessive or pump gear bushings worn.

FUEL CONSUMPTION EXCESSIVE.

1) Transmission Causes. Converter stator or secondary pump free-wheeling cams and roller incorrectly assembled. Converter secondary pump locked to primary pump hub. Clutch piston vent valve stuck open.

TRANSMISSION OIL BEING FORCED OUT OF FILLER PIPE: Caused by aeration and foaming of the oil due to one or more of the following:

NOTE—This condition may also cause Loss of Power and Lower Stall Speed (due to converter turbulence and lower pressures in control circuits).

1) Oil level too high allowing planet carrier to revolve in oil and aerate it. Correct by lowering oil level to correct point (see LUBRICATION) and driving car for 5 miles to work out air bubbles.

2) Oil suction pipe split, seal damaged, bore for suction pipe in housing too deep, or suction pipe retainer ears bent (preventing proper compression of the seal) resulting in air leaks in oil suction line.

3) Sand hole in suction bore of transmission case or housing or in suction cavity in valve body resulting in air leaks in oil suction line.

TESTING

▷*TESTING CAUTION*—Transmission oil level must be checked and corrected (see LUBRICATION) and *transmission must be warmed up before tests made.*

Warming Up Transmission: Transmission must be warmed up by road driving or in the shop exactly as follows before checking for oil leaks or trouble.

Road Warm Up—Drive car for approximately 5 miles with frequent starts and stops to approximate heavy-traffic conditions.

Shop Warm-Up—Set hand brake tight to hold car, place selector lever in "D" range, start engine and run for 15 minutes at 750 RPM. At end of 15 minutes, transmission will be warmed up sufficiently for testing regardless of initial temperature.

▷*CAUTION—Recheck oil level after warm-up and before making following tests.*

▷*NOTE—Above supercedes original procedures for shop warm-up of transmission.*

STALL TEST: Connect accurate tachometer to engine, set brakes firmly to hold car, test as follows:

▷*CAUTION—Do not test longer than 10 seconds in each range and allow at least 2 minutes between tests to prevent overheating of converter oil.*

Place selector lever in each range in turn as noted below. Depress accelerator and run engine speed up until maximum speed reached in each range. Maximum stall speed should be between 1560 RPM. and 1610 RPM. and should be almost identical in each range. If engine speed not within this range, following trouble is indicated:

Engine Speed Low (During Stall Test)—If several hundred RPM., less than minimum stall speed, secondary pump may be frozen on its hub or stators may not be "locking up" for converter operation.

Engine Speed varies or exceeds maximum (During Stall Test)—May be caused by insufficient oil pressure (see test below) or slippage in following units:

Slippage in "D" Range—Multiple disc clutch.

Slippage in "L" Range—Low Band.

Slippage in "R" Range—Reverse Band.

PRESSURE TESTS: Support rear of car on stands so that rear wheels will be free to turn during tests. Connect pressure gauges at the following points and make the tests listed below (special test gauge assembly of four gauges on a mounting plate recommended to allow complete testing without changing gauge connections):

1) Low Servo Apply (at plug on lower front of servo cover on right side of transmission. *CAUTION—do not confuse this plug with Modulator Lever Pivot Pin Retaining Plug which is slightly to rear of this Low Servo Apply Plug.*

2) High Clutch (Low Servo release side).

3) Reverse Servo (at reverse servo apply outlet plug on bottom of transmission case at right rear).

4) Rear Pump (at rear pump outlet plug on rear of transmission case to right of universal joint ball housing) or on Rear Servo Cover on 1952 transmissions.

Drive Range Test: Check and adjust the engine idling speed to 430-450 RPM. Place selector lever in Drive "D" range and proceed as follows:

1) Note pressure with engine idling (see Gauge Note below). This pressure should be 40-45 lbs.

2) Increase speed to approximately 30 MPH. and note pressure. Then load engine several times by applying brakes while maintaining 30 MPH. speed. Pressure should rise each time load increased (see Gauge Note below). If no rise noted, check vacuum lines for leaks and if no leaks found, check for defective Vacuum Modulator.

▷Gauge Note—In above tests, check pressures indicated on both Low Servo Apply gauge and High Clutch (low servo release side). Pressures shown on both gauges should be approximately the same with selector lever in "D" position.

3) Apply brakes and accelerate engine to normal stall speed (1560-1610 RPM.). Check pressure which should be 75-100 lbs. If pressure within these limits, but engine speed exceeds 1610 RPM., high clutch slippage is indicated. If pressure below 75 lbs. with engine at full throttle and brakes locked, check for: Oil Suction Screen plugged, Oil Suction Line leaking air, Pressure Regulator Valve stuck, Clutch Piston Seals or Clutch Drum Oil Seal Rings leaking, Valve Body-to-Case Gasket leaking or leaks between valve body and housing, Front Pump clearances excessive.

Low Range Test: Place selector lever in Low "L" range and proceed as follows:

1) Note pressure on Low Servo Apply gauge with engine idling. This pressure should be 125-150 lbs.

2) Apply brakes and accelerate engine to normal stall speed (1560-1610 RPM.). Pressure reading should be 160-200 lbs. If pressure within these limits but engine speed exceeds 1610 RPM., adjust Low Band (see Band Adjustment) and recheck pressure. If pressure is below 160 lbs., check Hydraulic Modulator and Accumulator (see Hydraulic Modulator Testing below). If pressure is below 125 lbs. and the same at both the Low Servo Apply and the Modulator test points, check for: Oil Suction Screen plugged, Low Servo Ring damaged or broken, Pressure Regulator Valve stuck, Valve Body-to-Case Gasket leaking or leakage between valve body and housing, Servo Cover leaking, Front Pump clearances excessive, Modulator Control Lever or Piston stuck, leakage between modulator and servo cover.

Hydraulic Modulator Testing—Connect pressure gauge at modulator test point (plug at top of modulator housing). Repeat low range idling test (1 above). If pressure is zero or very low, check for defective accumulator. If pressure is below 125 lbs. but the same as shown on Low Servo Apply gauge, see 2 (above) for possible troubles.

Reverse Range Test: Place selector lever in Reverse "R" position and proceed as follows:

1) Note pressure on Reverse Servo gauge with engine idling. This pressure should be 125-150 lbs.

2) Apply brakes and accelerate engine to normal stall speed (1560-1610 RPM.). Pressure reading should be 160-200 lbs. If pressure within these limits but engine speed exceeds 1610 RPM., adjust Reverse Band (requires removal of transmission—see Band Adjustment). If pressure is below 160 lbs., check for: Oil Suction Screen plugged, Reverse Servo Piston Ring damaged or broken, Pressure Regulator Valve stuck, Valve Body-to-Case Gasket leaking or leakage between valve body and housing, Front Pump clearances excessive, Modulator Control Lever or Piston stuck, leakage between modulator and servo cover.

Rear Pump Test: Place the selector lever in Drive "D" range and release parking brake so that rear wheels are free to turn. Then proceed as follows:

CONTINUED ON NEXT PAGE

CHEVROLET POWERGLIDE (C nt.)

1) Accelerate engine to 30 MPH. speed (as registered on speedometer), note pressure on Rear Pump gauge. This pressure should be 50-75 lbs.

2) Move selector lever to Low "L" range and again check pressure at 30 MPH. speed. This pressure should be 140-180 lbs.

3) If pressures low in (1) and (2), check for: Leaks at Servo Cover, Valve Body-to-Case Gasket, or between valve body and housing. Check for excessive rear pump clearances.

REMOVAL FROM CAR

Transmission & Torque Converter are removed as an assembly:

1) Raise car and support securely on jack stands. Remove floor mat and transmission cover plate, remove toe pan plate.

2) Take out three top turbine housing attaching bolts (through toe pan hole).

3) Disconnect speedometer cable at transmission and hand brake rod from cross-shaft. Drop cross-shaft, brake cables, and spring.

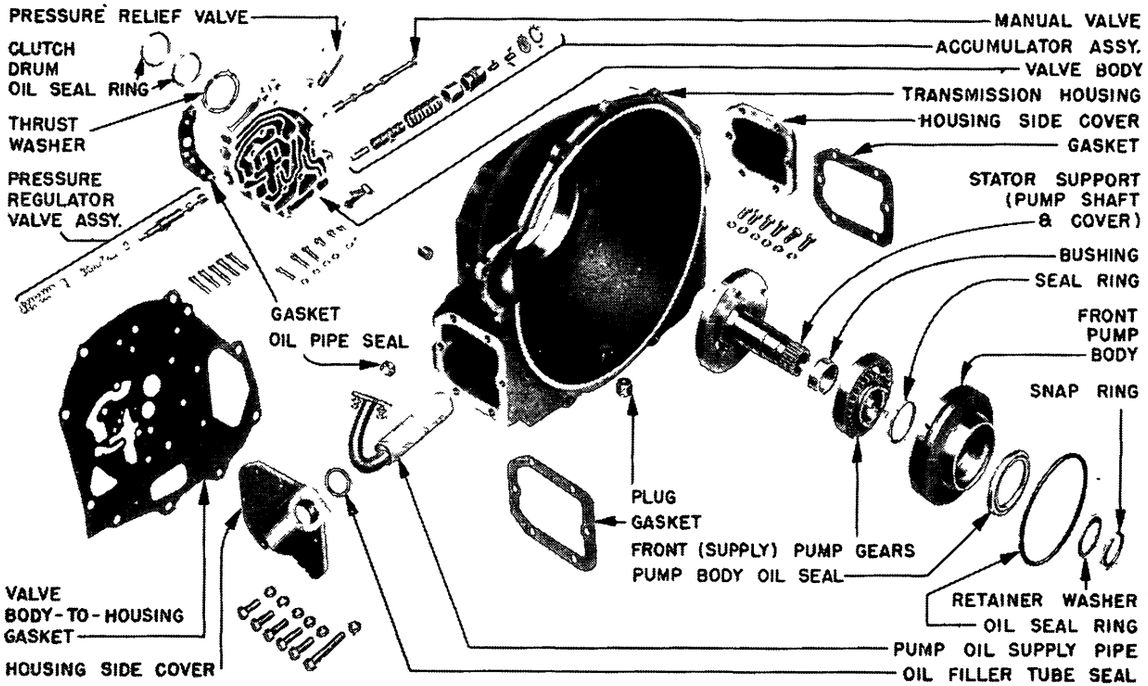
4) Free universal joint collar by taking out cap screws on back of transmission case, slide ball and collar back on shaft. Support propeller shaft with jack, take out front universal trunnion bearing cap screws, split universal, lower front end of propeller shaft.

5) Remove the two upper transmission-to-converter housing bolts, install lift sling (J-4262) and attach cable of J-4279 hoist positioned in front compartment. Attach lift chain (part of hoist assembly) to two top universal joint collar screws at rear of transmission.

6) Drain transmission and turbine (see Draining instructions). Disconnect transmission oil cooler lines and vacuum line.

7) Take out two lower turbine housing attaching bolts. Remove flywheel cover and flywheel underpan extension.

8) Remove all spark plugs. Disconnect exhaust pipe at manifold, disconnect muffler support. Tie exhaust pipe and muffler to left frame side member out of the way.



9) Disconnect both short and long shift rods at transmission levers, tie long shift rod up out of the way. Remove bell crank lever and stud from transmission case.

10) Remove all six flywheel-to-converter bolts working through housing opening on left side (use tool J-4281 to turn engine crankshaft and align each bolt with housing opening for access).

11) Clean all dirt from around filler tube and dipstick fitting on transmission side cover, remove housing bolt holding filler tube, remove filler tube and dip stick.

►*CAUTION—Cover the filler tube opening with masking tape or plug with rubber stopper to keep out dirt.*

12) Support engine with jack under oil pan. Remove transmission-to-rear support bolts, remove the transmission support.

TURBINE HOUSING, FRONT OIL PUMP, & VALVE BODY ASSEMBLY

13) Take out all remaining turbine housing bolts (lift or lower engine, as necessary, for access to bolts).

14) Move transmission straight back to clear flywheel pilot from flywheel.

►*CAUTION—Use extreme care not to damage flywheel pilot.*

15) Lower transmission slightly, lift rear end as far as possible and secure by hooking lift chain in notch on back of hoist. Use pry bar between transmission and right side of floor opening to clear servo cover bolts. Repeat this process (lowering front end of transmission and lifting rear end) until lubrication by-pass valve plug clears floor opening.

16) Lower transmission and remove from beneath car.

►*CAUTION—Transmission must not be allowed to strike against flywheel.*

DISASSEMBLY—TRANSMISSION

►**DISASSEMBLY & REASSEMBLY CAUTION:** *CLEANLINESS IS EXTREMELY IMPORTANT when opening up transmission. Thoroughly CLEAN exterior of case first, CLEAN each part as removed with cleaning solvent or gasoline and dry with air—do not use wiping cloths which will leave lint on parts. Store all parts in clean storage bins.*

DISASSEMBLY OF TRANSMISSION (Into Major Units): With transmission on bench (fixture J-3361 recommended for holding transmission), remove all units from transmission case as follows:

1) Take out right side cover attaching bolts, remove side cover and oil suction screen.

2) Install locking strap on turbine to hold unit stationary (install bolt in one flywheel attaching hole to hold strap). Remove all turbine cover bolts. Thread three 10/32x2" T-screws (part of J-3387 Pilot Stud Set) into three tapped holes in turbine cover to loosen cover, remove cover and turbine assembly. Remove primary and secondary stators as a unit, test for slippage of free-wheel clutches by rotating units by hand (should rotate freely in one direction but lock when turned in opposite direction). Check secondary pump free-wheeling clutch for slippage in same manner as stators. Take out converter retaining ring and washer. Slide primary pump from stator support and examine pump hub for bearing surface damage.

3) Take out Modulator assembly attaching bolts on right side of case, lift Modulator assembly off.

►*CAUTION—Use care that hydraulic plunger and body do not fall out of modulator when it is removed.*

4) Loosen all servo cover bolts slightly and break servo cover loose if it sticks to case (reverse servo spring and pressure regulator spring bear against cover) using care not to allow cover to tip which

C NTINUED N NEXT PAGE

CHEVROLET POWERGLIDE (Cont.)

may damage or break tip of pressure regulator valve. Use guide bolts to maintain cover alignment or turn all cover bolts out evenly while exerting pressure on cover, then lift cover and gasket straight off until cover clears tip of pressure regulator valve. Remove reverse servo spring and pressure regulator springs, lift regulator valve out.

▷*CAUTION—Handle valve carefully to prevent damage and store it by itself to avoid nicking or scratching of the polished surfaces.*

5) Loosen low band adjusting screw locknut and tighten adjusting screw until low band grips clutch assembly to hold it in place. Take out transmission-to-turbine housing bolts, separate turbine housing from transmission.

6) Remove manual valve from valve body on rear of turbine housing, remove manual valve lever, remove bronze thrustwasher from valve body delivery sleeve. Take out bolts attaching valve body to turbine housing and also pump-to-valve body bolts, remove valve body and gasket.

▷*CAUTION—Handle manual valve carefully to prevent damage and store it by itself to avoid nicking or scratching of the polished surfaces.*

7) Remove front pump from turbine housing using J-4263 pump driver tool.

8) Loosen low servo band adjusting screw to free clutch assembly, lift input shaft and clutch assembly out of transmission case.

9) Back off low servo band adjusting screw until band is free, lift out servo band and strut assembly, remove low servo piston and release spring.

10) Take out universal joint retainer bolt on rear end of output shaft, remove lockwasher and plain washer, slide universal joint yoke off shaft.

11) Install Mainshaft Removing & Replacing Tool J-938 (see Tool Note below) on rear face of transmission case and engage planet carrier output shaft. Turn puller handle clockwise to force planet output shaft out of rear bearing, disconnect and remove tool, remove planet carrier assembly through front of case. Remove reverse brake drum.

▷Mainshaft Removing & Replacing Tool J-938 Note: This tool designed for use on 3-speed Synchromesh Transmission and must be reworked for use on Powerglide Transmission as follows: Enlarge two attaching bolt holes in tool yoke to ½" and elongate overall hole span to 6" to permit tool to be mounted on rear face of Powerglide case.

12) Loosen reverse servo locknut, back off reverse band adjusting screw until band is free, remove band assembly and reverse servo piston.

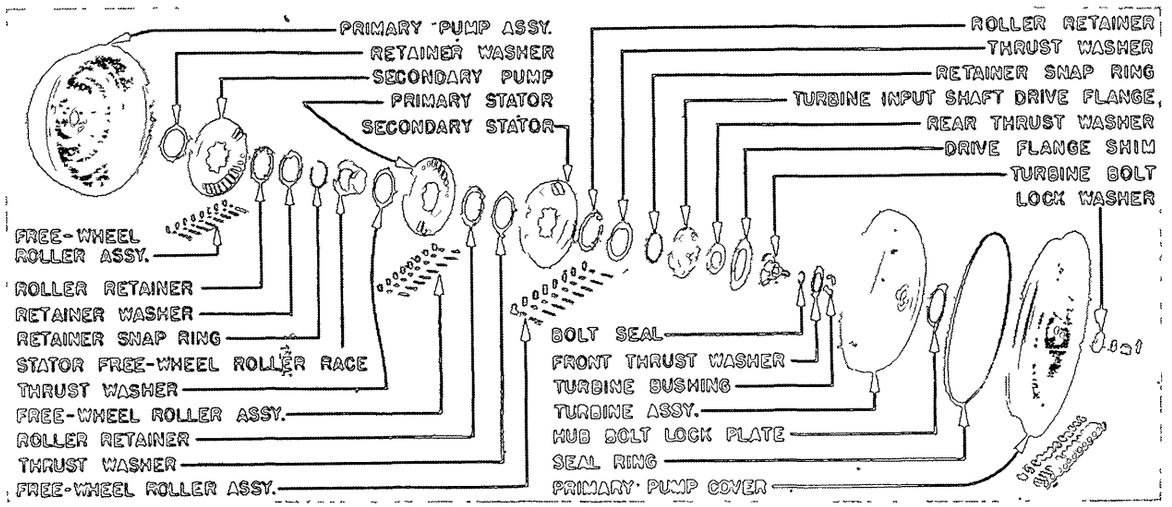
13) Take out rear pump mounting screws, remove rear pump assembly and gasket.

14) Use Tool J-3383 engaged in parking lock pawl spring to rotate spring so that end can be unhooked from case, remove spring and parking lock pawl from case. Remove parking lock lever and steel washer, then remove parking lock lever shaft and apply spring assembly from case. *NOTE—Parking Lock Lever Shaft No. 3697552 (used on later transmissions) does not have spring and this later type shaft can be used on all previous transmissions.*

▷*For disassembly of all above units, see OVERHAUL data*

OVERHAUL

▷"O" RING SEAL CAUTION: *These seals must be discarded when removed and a new seal installed exactly as directed below.* "O" ring rubber seals are special design and are installed with side clearance in ring groove so that oil pressure on seal deforms the rubber and extrudes a portion of the rubber into the clearance space between the mating parts to provide a positive seal against loss of oil pressure. Seals must not be re-used.



"O" Ring Seal Installation—Make certain that parts are clean and that burrs and sharp edges are removed. Seal must be free of any twists (place ring on flat surface and allow it to assume natural position) and must not be twisted during installation. Engage one side of ring in groove, pull other side straight back until it can be fitted in groove without twisting. Work ring against trailing edge of groove (last side to enter when parts assembled) using flat tool entered between ring and leading edge of groove to move ring without twisting. Lubricate "O" ring and parts with transmission oil.

Converter Primary Pump: Disassembly. Remove stator race thrust snap ring (use snap ring pliers KMO-410), remove thrustwasher. Rotate secondary pump clockwise to release free-wheel clutch, withdraw secondary pump. Remove free-wheel cam roller and spring retainer, remove cam rollers, spring retainers, springs, and thrustwasher.

Inspection—Wash all parts in cleaning solvent and dry with air. Inspect cam rollers and inner and outer primary pump hubs for scoring or galling. Inspect bushing for damage or wear. NOTE—Special Primary Hub & Bushing Assembly No. 3692982 furnished for use if hub damaged or bushing damaged or worn. See Note below for installation cautions for this assembly. Check roller springs for distortion, spring retainers for wear or damage, check primary and secondary pump vanes for looseness or damage. If pump disassembled to correct oil leak between primary pump and primary pump hub, install new "O" ring seal as follows:

▷Replacement Primary Pump Hub & Bushing Assembly Installation Caution—When installing this assembly DO NOT install dowels as used in production. Dowel holes in service hub are unfinished and not to size. IT IS IMPORTANT THAT NO ATTEMPT BE MADE TO INSTALL DOWELS IN THESE HOLES. Install NEW Primary Hub "O" Ring Seal, Part No. 3692860, when assembling hub and bushing assembly to primary pump (See "O" Ring Seal Replacement Data following but DISREGARD all data on dowel pin installation). Install NEW Converter Cover "O" Ring Seal, Part No. 3689754, when reassembling converter unit.

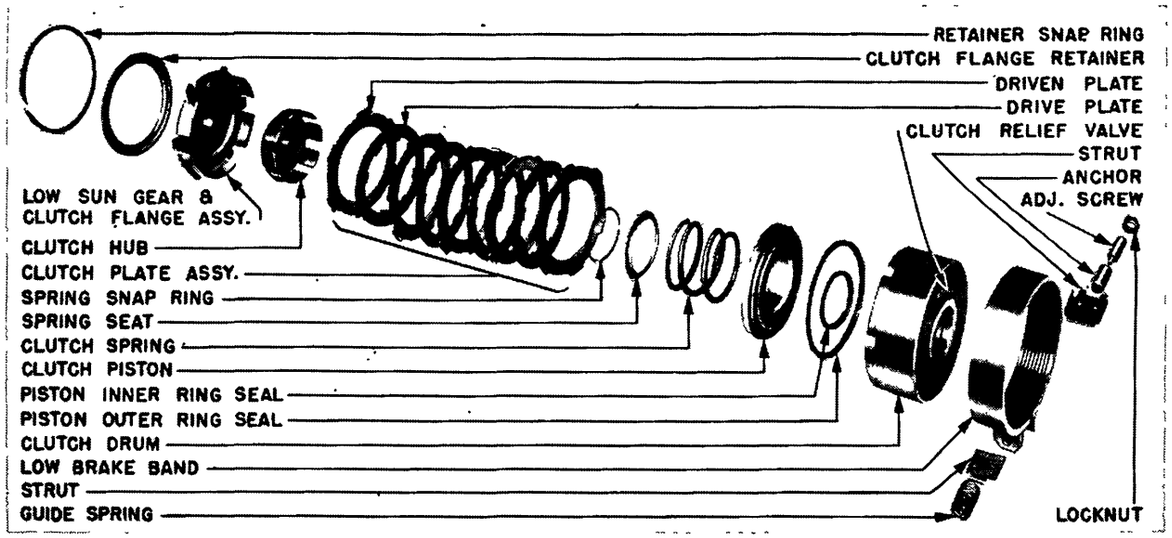
▷Primary Pump "O" Ring Seal Replacement—Mark both primary pump hub and pump with a center-punch to insure reassembly in same relative position (*CAUTION*—Assembly is balanced and balance will be disturbed if relative position of parts changed). Remove six screws attaching pump to hub. Support pump on two wooden blocks and use ⅛" pin punch on tops of three dowels to remove hub from assembly (dowels are swaged or peened over during assembly). Remove "O" ring seal from hub. Inspect pump and hub mating surfaces, clean up tops of screw holes with a burring tool to remove all burrs that might prevent seating of pump on hub, remove all chips and burrs from mating surfaces with an Arkansas stone, remove burrs from ends of dowels. Wash all parts in solvent and dry with air. Inspect hub and pump for galling or scoring, inspect bushing for excessive wear, check fit of pump hub in pump, make certain "O" ring groove is not nicked and is free from chips and dirt. Install new "O" ring seal in groove (*CAUTION*—Select "O" ring that remains in groove—some rings may have tendency to roll out of groove). Place pump hub on bed of arbor press, position primary pump on hub (*CAUTION*—line up marks made before disassembly), use a piece of thin wall pipe (3½" I.D., square at both ends and approximately 4" long) to carefully press

TORQUE CONVERTER

CONTINUED ON NEXT PAGE

CHEVROLET POWERGLIDE (C nt.)

pump over hub. Install six attaching screws and lockwashers, tighten screws evenly to 4½ ft. lbs. torque. Use a small punch to peen dowel holes around ends of the three dowels to prevent possibility of dowels working out into converter. **Check pump run-out** as follows: Install primary pump assembly on stator support with front pump drive gear tangs aligned with drive slots in pump hub (*CAUTION*—face of pump must be flush with face of bell housing). Mount dial indicator on transmission mounting fixture so that indicating button contacts forward face of primary pump, check pump run-out. Run-out must be less than .010". If run-out excessive, check for burrs or dirt between mating faces of pump and hub or "O" ring seal not seated in groove.



Reassembly—Install free-wheel cam roller and spring retainer with prongs to rear. Assemble rollers, spring retainers, and springs in cam pockets with spring retainer curvature fitting curvature of unit, then install cam thrustwasher (CAUTION—hold retainer on opposite side to prevent its being pushed out of position). Use loading tool J-3362 to install secondary pump on primary pump hub. Check installation (should turn freely in clockwise direction and lock in opposite direction). Remove loading tool. Install stator race thrustwasher and snap ring.

Primary & Secondary Stators: Disassembly. Remove stator race snap ring and thrustwasher, rotate secondary stator clockwise and withdraw from stator race, then remove stator race similarly from primary stator (CAUTION—use care not to lose cam rollers and springs). Remove cam roller and spring retainer from stators, remove cam rollers, springs, and spring retainers.

Inspection—Wash all parts in solvent and dry with air. Check cam rollers and stator hub for galling or scoring, check roller springs and retainers for distortion or damage. Check stators for loose or damaged vanes.

Reassembly—Install cam rollers and spring retainer in secondary stator (this retainer has LONG tabs), then install cam rollers, springs, and spring retainers with retainer curvature corresponding to hub curvature. Install cam thrustwasher. Repeat this entire procedure for primary stator. Place loading tool J-3362 on stator race, slide primary stator over tool and onto race with thrustwasher down, rotating stator clockwise during installation to prevent pushing cam rollers out of position; install secondary stator, with thrustwasher down, following same procedure. Install bronze thrustwasher and snap ring. Check assembly by rotating stators. Both stators should turn freely on race in clockwise direction but lock in opposite direction.

Converter Turbine: Disassembly. Remove "O" seal ring from converter cover. On transmissions before No. KT-22574A-15-D, remove turbine bolt cotter key, nut, flat washer, and slotted washer. On transmissions after above number, bend down ears on special lock plate, remove the center bolt, special lock plate, and slotted washer. On all models, lift turbine cover from special bolt (first type), flanged nut (later type). Bend down lockplate ears and remove three turbine drive flange-to-turbine capscrews. Remove turbine drive flange and the special bolt or flanged nut from the turbine, then remove the special bolt or flanged nut and thin thrustwashers from the flange. Remove "O" ring seal from the special bolt or flanged nut.

MULTIPLE DISC CLUTCH & LOW BAND ASSEMBLY

Inspection—Discard seal rings, wash all parts in solvent and dry with air. Check bolt, hub and thrustwasher for scoring or wear. Check turbine for loose or damaged vanes. Check turbine hub bushing for excessive wear and replace bushing as follows:

Turbine Hub Bushing Replacement—Precision type bushing, No. 3689929, furnished for service. Press old bushing out of turbine hub with tool J-4375, use same tool set to install new bushing. Support turbine on special collar of tool set (has three locating pins to center turbine) on arbor press with turbine vanes downward, place new bushing on small end of driver and press bushing in place in turbine hub. New bushing need not be reamed.

Reassembly—Install new "O" seal on turbine bolt (see "O" ring installation note). Install thick thrustwasher (with lugs engaging holes in turbine), install turbine bolt (first transmissions) or flanged nut (later transmissions), thin thrustwasher, turbine hub (three dowels engaging holes in turbine) in this order. Install new lockplate and three input shaft drive flange-to-turbine capscrews, tighten these screws evenly to 12½-15 ft. lbs. torque and lock the screws. Install turbine cover, assemble slotted washer with nibs engaging locating holes in pilot. On transmissions before No. KT-22574A-15-D, install flat washer and nut, tighten nut to 12½-15 ft. lbs. minimum (if cotter pin hole does not line up, tighten nut until holes line up). On transmissions after above number, install special lockplate and center bolt, tighten bolt to 12½-15 ft. lbs. and lock the bolt by bending up lockplate ears. Install new "O" ring seal on converter cover.

Turbine Bolt Endplay Adjustment—Check endplay with dial indicator mounted on end of bolt after bolt assembled in turbine. Endplay should be .002-.016". Adjust by installing shims (No. 3691922—.014", No. 3691923—.019") between turbine and input shaft drive flange, as required, for this endplay.

►*CAUTION—Transmissions beginning No. HT-19226-B24 do not use above shims but endplay limits for these transmissions are also .002-.016".*

Multiple Disc Clutch: *CAUTION—New design clutch with cast piston used beginning Trans. No. JT-232315-D-23-D.* Both types serviced alike except that parts not interchangeable and relief valve on later type located in piston (ball seating in relief hole and retained by staking of the piston metal around the hole) instead of being located in clutch drum.

Disassembly—After converter removed, remove clutch flange retainer ring and retainer, low sun gear and clutch flange assembly, thrustwasher, hub, and clutch plates from clutch drum. Place clutch drum in arbor press (CAUTION—on early transmissions, use care not to damage pressure relief valve on end of drum), install piston spring compression tool No. J-3364 (Transmissions before No. JT-232315D-23-D) No. J-5133 (Transmissions after above number), compress clutch release spring, remove clutch spring snap ring using KMO-410 snap ring pliers, relieve spring pressure, remove spring seat and spring. Remove clutch piston by rapping the drum face down on a wood block. Remove piston outer seal ring from piston and inner seal from clutch drum hub.

Inspection—Wash all parts in solvent and dry with air. Inspect drum brake band surface for excessive scoring or burring, and drum bushing for scoring or wear. Examine clutch hub and clutch flange for galling (see Note below for installation of special thrustwasher to prevent this trouble developing in service). Slight galling can be cleaned up with emery cloth. See that clutch flange has no radial play in drum slots and that plates are free fit over clutch hub and in clutch flange. Check clutch plates for burning and wear. Check low sun

CONTINUED ON NEXT PAGE

CHEVROLET POWERGLIDE (Cont.)

gear for nicked, burred, or scored teeth. Check relief valve for free operation. If necessary to replace valve, proceed as follows:

▷Relief Valve Replacement (First Type—on clutch drum)—Use sharp chisel to cut off heads of valve spring retainer rivets, drive rivets out with a small punch, remove old valve spring and valve. Install new relief valve and valve spring with two new rivets, support drum carefully and peen over ends of rivets securely. Check valve for free operation.

▷Relief Valve Replacement (Later Type—in clutch piston)—Remove old ball from hole in piston, make certain that all burrs removed from ball retaining hole and that ball seat is not burred or nicked, see that orifice leading to rear of piston is open and clean. Place new steel ball in retaining hole and carefully stake edges of hole to prevent ball falling out. Make certain that ball is free to move after staking completed.

▷Clutch Hub Thrustwasher Note—New .020" thick spring-steel thrustwasher, No. 3694444, now installed between clutch hub and clutch flange to prevent galling. This washer can be installed on earlier transmissions if galling noted at this point when transmission being overhauled. Install washer with four equally spaced tabs engage slots in clutch hub which will prevent washer riding on mainshaft.

▷*CAUTION*—Following parts not interchangeable between first and later (cast piston) type clutches: Clutch Piston, Drum and Bushing Assy., Spring, Spring Seat, and Snap Ring.

Reassembly—Install new outer ring seal on piston (lip of seal toward oil pressure end of piston) and new inner ring seal on clutch drum inner hub (lip in toward bottom of clutch chamber). Lubricate inner diameter of clutch drum and seals with transmission oil, install piston (CAUTION—use feeler gauge to seat outer seal ring in drum without damaging seal lip). Install clutch spring and spring seat, compress spring using proper tool in press (*CAUTION*—see that spring seat does not hang up in snap ring groove), install snap ring. Place clutch hub thrustwasher on hub with four tabs engaging slots in clutch hub, place clutch hub and thrustwasher on clutch flange with open side of hub up. Install clutch plates, starting with steel plate concave "dished" side down toward clutch flange, and alternating steel and composition plates. Install clutch drum assembly over flange assembly, invert and install clutch flange retainer and retainer ring. Check endplay with feeler gauge inserted in drive slot in drum below clutch flange drive lug. Maximum allowable endplay is .013" and is adjusted by selecting clutch flange retainer of correct thickness (.055" .064", .073").

Modulator: Disassembly. First lift out hydraulic plunger and body assembly (CAUTION—do not allow plunger to drop out or assembly to be damaged). Take out outer cover attaching screws while holding cover down against spring pressure, lift off cover, diaphragm spring, and diaphragm.

Inspection—Wash all parts in solvent, blow out all passages and dry with air. Check diaphragm and outer cover for cracks. Check diaphragm spring for distortion or loss of tension. Inspect hydraulic plunger and body for wear, nicks, or scoring. See that plunger operates freely in body and that body is free in modulator bore.

Reassembly—Place assembly tool J-4261 (centering plug) in modulator body in place of hydraulic plunger and body, assemble diaphragm and spring, install two 10-24x3" guide pins in opposite cover holes, install attaching screws and tighten evenly and securely, remove guide pins and install screws in these holes. Remove assembly tool, install hydraulic plunger and body (body against diaphragm, plunger pointing out so that it will engage modulator lever when assembly completed).

Servo Cover: Disassembly. Take out retaining screw and remove lubrication valve bi-metal strip and retainer. Take out lubrication by-pass valve plug and copper gasket, remove by-pass ball spring and ball. Do not remove modulator control lever.

Inspection—Wash all parts in solvent, blow out all passages and dry with air. Inspect cover for cracks and nicks or burrs on mounting face. Check by-pass ball spring and valve bi-metal strip for distortion. See that modulator lever operates freely without binding. *CAUTION—Lever must not bind on guide pin.*

Reassembly—Install valve by-pass ball, spring, and plug (use new gasket), tighten plug to 17-20 ft. lbs. torque. Install bi-metal strip retainer, bi-metal, and retaining screw, tighten screw securely.

Front Oil Pump: Disassembly. Remove stator support from pump body, lift out pump gears (CAUTION—gears not heat-treated and must be handled carefully to avoid nicking or marring). Remove seal ring from drive gear (compress one end into groove and push other end out to free interlocked ends). Remove and discard "O" seal ring on pump body.

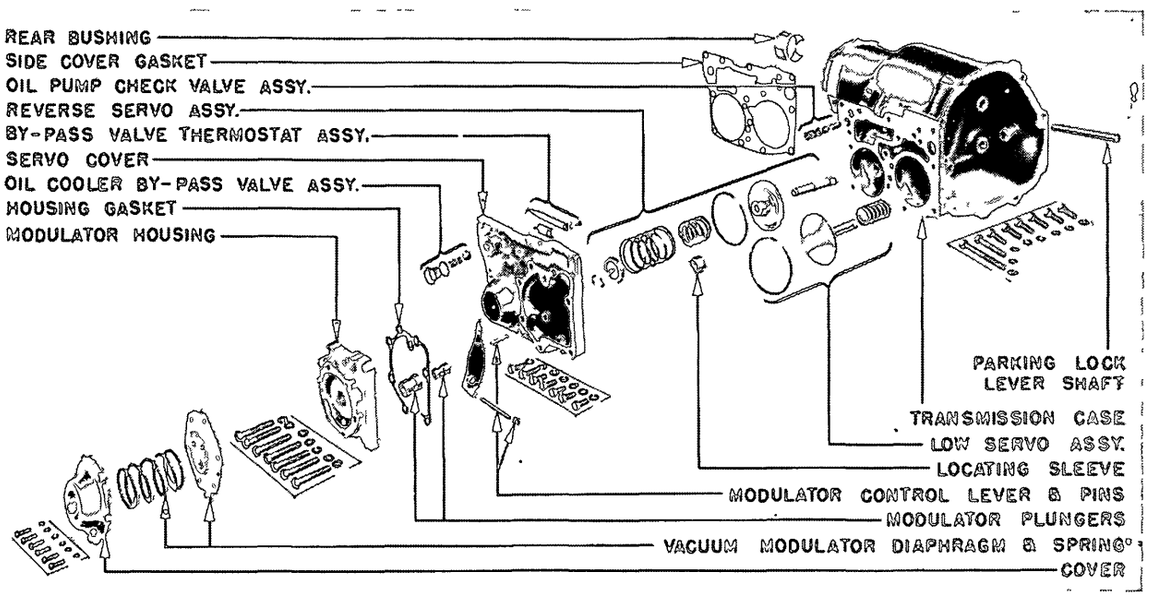
Inspection—Wash all parts with solvent, blow out all passages and dry with air. Check drive gear oil ring and ring groove for nicks and burrs (ring must be free in groove), and check ring in pump body bore (hooked ring ends must have clearance). Inspect pump body and face of stator support for nicks, burrs, or scoring. Inspect oil seal in pump body and replace if worn or damaged (pry out old seal, use Driver J-4240 to install new seal). Install pump gears and check all clearances with feeler gauges:

Driven Gear Clearance—.0025-.0055" clearance between outer diameter of gear and pump body.

Gear-and-Crescent Clearance—Check by pressing gear away from crescent and inserting feeler gauge between end of gear teeth and face of crescent. Should be .003-.009" (Internal Gear).

Gear End Clearance—Check with feeler gauge inserted between gear face and straightedge on face of pump housing. Should be .0005-.0015".

Reassembly—Install new "O" seal ring in pump body (see "O" Ring Installation Note), install drive gear seal ring and pump gears (lubricate gears with transmission oil—insert drive gear with drive lugs extending through oil seal). Assemble stator support on body and align mounting holes.



Rear Oil Pump: Disassembly. Take out two flat head screws in pump body plate, remove plate, lift out pump gears. Do not remove ball bearing unless new bearing to be installed.

Inspection—Wash parts in solvent, blow out oil delivery holes and dry parts with air. Inspect rear bearing for roughness but do not remove bearing unless replacement required (see Bearing Installation below). Inspect pump body and cover for nicks or burrs. Inspect gears and check gear clearances with feeler gauge as follows:

Driven Gear Clearance—.003-.007" clearance between outer diameter of gear and pump body.

Gear & Crescent Clearance—Check by pressing gear away from crescent and inserting feeler gauge be-

CONTINUED ON NEXT PAGE

TRANSMISSION CASE, SERVO COVER, & MODULATOR ASSEMBLY

CHEVROLET POWERGLIDE (Cont.)

tween end of gear teeth and crescent. Clearance should be .002-.009" (Internal Gear).

Gear End Clearance—Check with feeler gauge inserted between gear face and straightedge placed across face of pump housing. Clearance should be .0005-.0015".

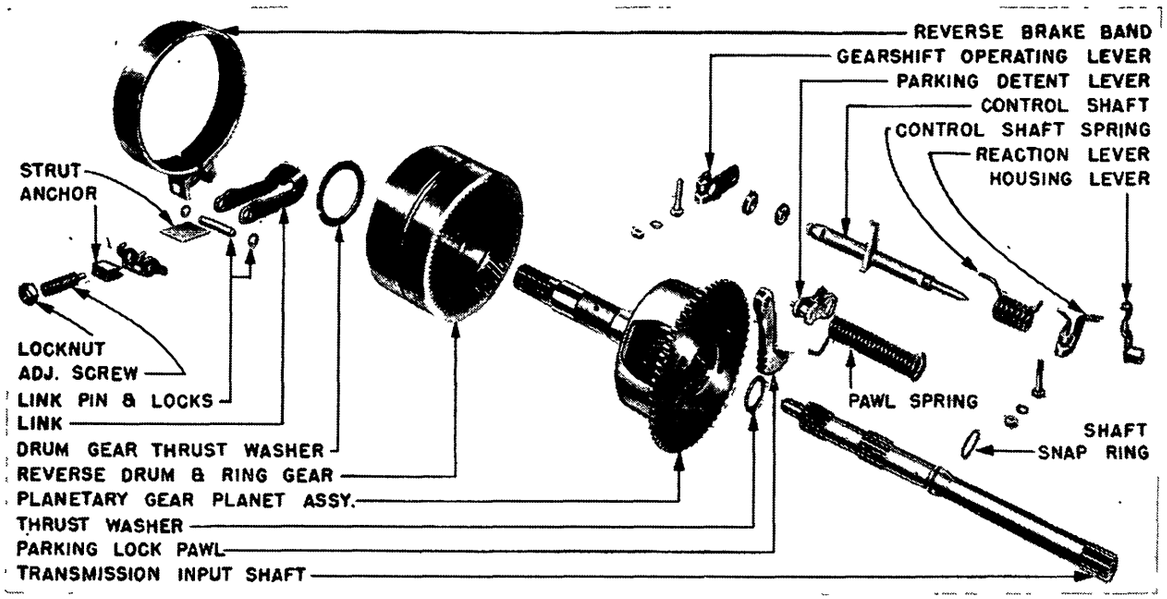
►**Pump Bearing Replacement**—Remove three retaining capscrews, lockwashers, and lockplate. Drive out old bearing. Press new bearing in place, install lockplate, and retaining capscrews with lockwashers, tighten screws securely. *NOTE—Lockplate not used on first transmissions, but should be installed on these models when pump being reassembled.*

Reassembly—Lubricate gears with transmission oil and install in body. Install pump body plate and tighten the two flat head screws securely.

Valve Body: Disassembly. Use special pliers J-4245 to remove special snap ring in end of accumulator cylinder, remove accumulator valve spring washer and all accumulator valve parts from valve body. Remove two oil seal rings from valve body hub (rings have interlocking ends, released by pressing one end into groove and pushing other end out). Unscrew and remove pressure relief valve assembly. *NOTE*—Beginning with late 1951 production, pressure relief valve was replaced by a dryseal pipe plug.

Inspection—Wash all parts in solvent, blow out all passages and dry with air. Check accumulator body, piston, and body for scoring, see that these parts operate freely. Check small fibre valve in accumulator valve body for free operation. Check springs for distortion. Inspect oil seal rings for nicks and burrs, see that rings are free in grooves and that hooked ends have clearance in clutch drum bore (check by installing rings in drum).

Reassembly—Install all accumulator parts in valve body (CAUTION—accumulator piston must seat over inner and outer accumulator springs and special snap ring must seat firmly in snap ring groove in valve body). Install both oil seal rings in hub grooves. Install pressure relief valve assembly or dryseal pipe plug and tighten securely.



Low Servo Piston: Low servo piston and spring can be lifted out after servo cover removed. Check piston ring gap by installing ring in cylinder. Gap should be .005-.010".

Reverse Servo Piston: Disassembly. Place assembly in bench press with spring end up, use tool J-3377 to compress spring (position tool legs on spring retainer), remove retainer key locks. Release spring tension, lift off retainer, springs, and piston.

Checking & Reassembly—Check piston ring gap by installing ring in cylinder. Gap should be .005-.010". Assemble parts on piston stem and use tool J-3377 to compress springs. Make certain key locks fully engaged in groove in stem.

Planet Carrier Assembly: *Furnished as an assembly and should not be disassembled unless inspection procedure below indicates overhaul required. See Planet Carrier Overhaul below.*

Inspection—Wash in solvent, blow out all passages and dry with air. Inspect all gear teeth for nicks, scoring, or other damage. Check end clearance of planetary pinions with feeler gauge (endplay should be .006-.030"). Check reverse sun gear rear thrustwasher for wear and damage. Inspect drum bushing for wear, scoring, or damage; check outer diameter of drum for scoring or burning. Check output shaft bearing surface for wear, nicks, or scoring. Check input pilot bushing for wear or scoring.

PLANET CARRIER ASSEMBLY, REVERSE BAND, & PARKING LOCK MECHANISM

Planet Carrier Overhaul: *If inspection (above) indicates that parts require replacement, proceed as follows:*

Disassembly—Place assembly in holding fixture or clamp in a vise with front end upward. Mark each pinion shaft and also mark planet carrier (use prick punch or other means) so that shafts can be re-installed in same position *(CAUTION*—pinion shafts are selective fit in carrier and location must not be changed). Then proceed as follows:

1) Remove pinion shaft lockplate screws, rotate plate counter-clockwise until it is free and remove the plate.

2) Starting with one short planet pinion, use a soft steel drift to drive on lower end of pinion shaft until shaft raised above the press-fit area of the output shaft flange, then insert tool J-4599 (one piece only—second piece of tool set used for reassembly) into short planet pinion from lower end and push shaft out until tool is centered in the pinion and shaft is removed. Remove short planet pinion from assembly. Remove tool from pinion, remove needle bearings and needle bearing spacer *(CAUTION*—use care not to lose any of the needle bearings).

3) Remove **adjacent** long planet pinion (paired to the just-removed short pinion by using same thrustwashers) by repeating procedure in step (2) above. Then remove the pinion upper and lower thrustwashers.

4) Remove all remaining planet pinions **in pairs** (short pinion first, followed by long pinion) by following procedures in steps (2) and (3) above.

5) Remove reverse sun gear and sun gear thrustwasher.

Inspection—Wash all parts in cleaning solvent and dry with air. Inspect all pinion gears and reverse sun gear for nicked or otherwise damaged teeth, inspect all thrustwashers for wear, nicks, or scores. Inspect needle bearings for wear and replace **all** needle bearings if worn excessively.

Reassembly—*CAUTION—Pinion shafts must be reinstalled in accordance with marks made before disassembly (shaft is selective fit in particular hole in carrier).* Assemble and install parts as follows:

1) Install tool J-4599 in one long planet pinion, assemble needle bearing spacer and needle bearings in pinion (20 at each end) using cup grease to hold needle bearings in position.

2) Install pinion assembly in planet carrier with tool centered in assembly and with thrustwasher at each end of pinion. *NOTE*—Long pinions are located opposite closed portion of carrier, short pinions are located opposite carrier openings. Feed the second part of tool J-4599 in from the top of the planet carrier *(CAUTION*—make certain tool picks up thrustwasher) and push first part of tool down and out at the lower end *(CAUTION*—make certain this tool picks up thrustwasher as it is pushed down). Lubricate correct pinion shaft (see Reassembly Caution above) and install it from top pushing the assembling tools out ahead of it. Turn shaft so that slot in upper end faces toward center of assembly, tap shaft down with a brass or soft steel drift until lower end is flush with lower face of carrier.

3) Assemble and install **adjacent** short planet pinion (paired with just-installed long planet pinion by using same thrustwashers) by repeating procedure in steps (1) and (2) above.

CONTINUED ON NEXT PAGE

CHEVROLET POWERGLIDE (Cont.)

4) Install reverse sun gear thrustwasher and reverse sun gear.

5) Install all remaining planet pinions in pairs (long pinion first, followed by short pinion) by following the procedure in steps (1), (2), (3) above.

6) Check end clearance of planet pinions using feeler gauge inserted between end of pinion and thrustwasher. This clearance should be .006-.030".

7) Install pinion shaft lock plate with extended portions in line with pinion shaft slots, rotate plate clockwise until plate locks all pinion shafts and attaching screw holes line up. Install lock plate attaching screws and tighten to 2½-3 ft. lbs.

Input Shaft: Inspect shaft splines for wear, nicks, or other damage; check spline fit in clutch hub, reverse sun gear, and turbine hub. Inspect oil seal ring for wear and free fit in shaft groove, remove ring (compress one end and expand the other to free interlocked ends), install ring in valve body bore and check clearance of hooked ends, re-install ring on shaft.

Transmission Case & Rear Bushing: Check case for cracks, inspect rear bushing for wear or damage and replace if necessary.

Bushing Replacement—Press old bushing out using tool J-4275 in an arbor press (place case on press with rear end upward). Install rear oil pump in case so that rear bearing can be used as a pilot in installing new bushing. Place case on press with front end upward, assemble bushing on Installer Tool J-4276 (square end of bushing against shoulder on tool), enter tool pilot in rear bearing, press new bushing into place. Bushing is precision type and does not require reaming.

Low & Reverse Brake Bands: Inspect bands for wear, cracks, and scored or burnt lining. Lining is bonded to band. Inspect linkage for wear.

REASSEMBLY

After all Major Units reassembled (see OVERHAUL), make certain that all parts and units are absolutely clean and all moving parts lubricated, use all NEW GASKETS & SEALS, and tighten all parts evenly to specified torques. Proceed in reverse order of disassembly directions and note the following important points:

Valve Body & Front Oil Pump Installation: Install suction screen in converter housing oil sump. Install two ¼-20 x 3½" guide pins in valve body attaching holes in housing, install valve body and new gasket over guide pins, tighten attaching bolts evenly (in criss-cross pattern) to 10 ft. lbs. torque EXCEPT bolt over pressure regulator valve tightened to 8 ft. lbs, torque (CAUTION—check manual valve and pressure regulator valve for free operation after all bolts tightened). Align bolt holes in stator support and front pump body assembly, install two ¼-20 x 3½" guide pins through pump body, then use driver J-4263 to seat assembly in converter housing (CAUTION—See "O" Ring installation note) and make certain pump suction and delivery holes on left side of pump are lined up. Install five self-locking bolts through valve body and into pump, tighten the bolts directly above and below regulator valve to 8 ft. lbs. torque, tighten remaining bolts to 10 ft. lbs. torque.

▷*CAUTION—Check pressure regulator valve, manual valve, and front pump for free operation after all bolts tightened.*

Rear Oil Pump, Planet Carrier & Output Shaft, Reverse Servo Installation: Install two 5/16-18 x 3" guide pins in two rear pump attaching bolt holes in rear end of transmission case, install pump and new gasket over guide pins aligning oil suction and delivery holes, tighten all pump mounting bolts evenly to 12½-15 ft. lbs. Install reverse servo piston (use Compressor J-3365 to avoid damage to piston ring) with notch on shaft toward front of transmission. Install reverse brake band and strut assembly in case with thin end of band away from piston, thread adjusting screw in case until it indexes with hole in anchor. Place bronze thrustwasher on reverse drum hub, install drum within reverse band in case. Position rear pump drive gear with lug at top, install planet carrier assembly in case with slot in shaft aligned with pump gear lug. Check planet carrier for correct position and seating of pump gear lug by measuring output shaft for ⅞" minimum protrusion through rear bearing. Install shaft of tool J-938 into threaded end of planet carrier output shaft and bolt tool yoke on rear face of transmission case, turn tool handle counter-clockwise to seat output shaft in rear bearing, then remove tool. Install universal joint front yoke, washer, lockwasher, and bolt, tighten bolt to 25-30 ft. lbs. torque.

Reverse Servo Band Adjustment: Use tool J-4277 (combination screwdriver and locknut wrench). Tighten adjusting screw slowly and at the same time, check endplay in linkage by pushing and pulling on servo return spring. Continue to turn screw in until endplay is just taken up (at this point band must be free on drum and drum should be easily rotated by hand), then back adjusting screw off ⅛-¼ turn and tighten locknut.

▷*CAUTION—Above procedure supersedes previous instructions and will provide sensitive adjustment.*

Sun Gear Endplay Adjustment: After planet carrier assembly installed in case, determine thickness of sun gear thrustwasher needed for correct transmission endplay of .007-.035" as follows:

(1) Measure distance from face of transmission case flange to face of reverse sun gear in planetary unit with tool J-4260 by placing bar of tool against case flange and extending tool stem until it contacts face of gear, tighten thumbscrew to retain this tool setting.

(2) Install bronze thrustwasher and clutch assembly on oil delivery sleeve on rear of converter housing.

(3) Without disturbing tool setting secured in step 1 above, place .120" steel washer over tool pilot (short plug on tool bar), install tool over clutch assembly with tool pilot entered in low sun gear and tool stem against gasket on rear face of housing. Measure clearance between face of low sun gear and steel washer on tool pilot with a feeler gauge. If clearance not within .007-.035", repeat this procedure with .095" or .145" steel washer on tool pilot (see Note below on .070" washer). On transmissions before No. HT-3837-A3, if .070" washer required to bring clearance within limits of .007-.035", replace Low Sun Gear and Flange Assembly with later type parts and repeat above procedure (these later parts will not require less than .095" thick washer).

▷Tool Washer Note—This tool originally furnished with three washers—.070", .095", .120" thick. The .070" washer is now obsolete (.070" bronze thrustwashers not furnished) and tool sets now furnished with .145" washer instead (.095" and .120" washers continued). This .145" washer is available to replace .070" washer on early tool sets.

(4) When correct clearance of .007-.035" obtained in step (3), note thickness of steel washer used on tool and select bronze thrustwasher of same thickness for installation on input shaft splines when this shaft installed (see below). Remove clutch assembly and thrustwasher from oil delivery tube.

▷Low Sun Gear Thrustwasher Note—This bronze thrustwasher now furnished in three thicknesses as follows: Part No. 3694467—.095", No. 3694468—.120", No. 3694469—.145". *NOTE*—.070" thrustwasher is no longer furnished.

▷*EARLY TRANSMISSION CAUTION*—On Transmissions before No. HT-3837-A3, if .070" thrustwasher required for correct clearance (3 above), replace Low Sun Gear and Flange Assembly with later type parts (new parts will not require less than .095" thrustwasher).

Parking Lock Mechanism Installation: Install parking lock lever shaft and apply spring assembly in case, place small seal over end of shaft and into counterbore in case with small lip on seal toward inside of case, install flat washer and lever on shaft pressing lever in until clearance between lever and washer is .000" to .010", then tighten lever clamp-screw to 8-12 ft. lbs. Install parking lock pawl over pawl support rod and install parking pawl spring. Use tool J-3383 to wind up spring until end of spring catches on inside of case.

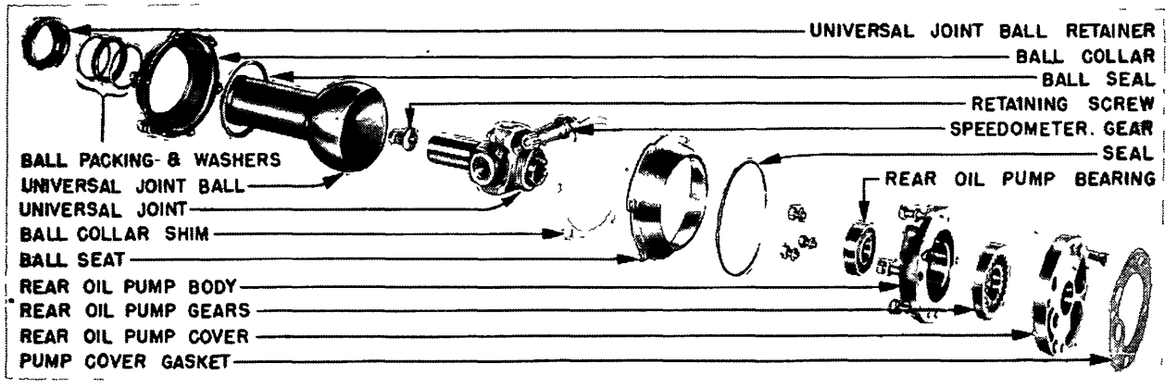
NOTE—Latest type Parking Lock Lever Shaft (used in production after approximately March 1952 and furnished for replacement on earlier cars) has a redesigned parking lock detent lever and does not require a parking lock lever apply spring.

Low Servo & Input Shaft Assembly Installation: Install input shaft in clutch assembly, place bronze thrustwasher of correct thickness (as selected in "Sun Gear Endplay Adjustment" above) on rear end of input shaft aligning missing spline opening on washer with oil hole in splines on shaft and flat side of washer toward reverse sun gear. Install the entire input shaft and clutch assembly in the case, indexing input shaft pilot with pilot in output shaft and meshing low sun gear with short pinions in planet carrier. Assemble low servo piston release spring on servo piston shaft, install assembly in case (CAUTION—use Ring Compressor J-3365 to avoid damage to piston ring). Install low brake band over clutch drum with thin end of band toward piston, place strut guide spring over end of piston stem, install strut with one end engaging slotted end of piston stem and other end engaging brake band. Install second strut similarly with one end engaging band and opposite end engaging slotted anchor with anchor fitted over end of adjusting screw in transmission case. Install speedometer driven gear and tighten to 40-45 ft. lbs. Do not adjust low band at this time.

Transmission & Turbine Housing Assembly: Install manual valve in valve body, install manual valve inner lever in turbine housing and engage lever pin in valve slot, position valve so that outer end is

CONTINUED ON NEXT PAGE

CHEVROLET POWERGLIDE (C nt.)



1½" from face of valve body (reverse position). Install new valve body-to-case gasket on valve body. Raise transmission manual valve lever to top detent position (reverse) to align reaction lever with manual valve inner lever. Install clutch drum thrust-washer over oil delivery sleeve. Install two ⅜"-16 x 3¾" guide pins in turbine housing, install transmission assembly over guide pins, making certain that reaction lever engages manual valve inner lever properly (CAUTION—remove left hand sump cover to check this engagement). Install transmission case-to-turbine housing bolts and tighten evenly to 25-30 ft. lbs. torque.

Servo Cover Installation: Install lubrication check valve parts: spring, ball, ball seat (with radius toward ball), lubrication sleeve. Install two 5/16"-18 x 3" guide pins in servo cover mounting bolt holes, install new gasket over guide pins. Install pressure regulator valve and assemble inner and outer valve springs on valve stem. Install large return spring on reverse servo piston rod. Install servo cover over guide pins (CAUTION—see that regulator and servo springs seat properly in pockets in cover), apply pressure to cover to compress springs, install and tighten all servo cover bolts to 12½-15 ft. lbs. torque. Install new modulator cover gasket and modulator cover, tighten attaching bolts to 12½-15 ft. lbs. torque.

Low Servo Band Adjustment: Using tool J-4277 (combination screwdriver and locknut wrench), tighten adjusting screw until band is tight, then back screw off 3 complete turns, tighten adjusting locknut and install adjusting screw cap.

Converter Assembly: Align front oil pump drive gear tangs with drive slots in primary pump hub, install primary pump in turbine housing (CAUTION—see that drive tangs and slots engaged—face of primary pump will be flush with face of bell housing if properly installed), install retaining washer and snap ring in stator support. Install stator assembly (CAUTION—smaller primary stator must be to rear). Install two 5/16"-24 x 1½" guide pins in primary pump bolt holes, align dowel pin hole in cover with dowel in primary pump, install turbine cover on primary pump, remove guide pins and install cover capscrews, installing one capscrew on each side of dowel, then skipping one hole (for flywheel attaching bolt), and installing screws in next two holes, repeating this order around cover rim. This will leave six evenly spaced holes around cover for flywheel attaching bolts (when transmission installed in car). Tighten capscrews evenly to 15-20 ft. lbs. torque. Install sump cover using new gasket and tightening attaching screws securely.

Universal Joint Ball Adjustment: Before installing transmission, determine thickness of shims required for universal ball adjustment: Install ball seat and "O" ring seal. Install universal joint ball and collar with four new ball shims (*CAUTION*—DO NOT install cork collar oil seal at this time), tighten collar attaching bolts to 8-12 ft. lbs. Ball should be a firm

REAR OIL PUMP, UNIVERSAL JOINT, & JOINT BALL ASSEMBLY

smooth fit. If ball cannot be moved by hand, add additional ball shim and repeat test; if ball moves freely by hand, remove one ball shim and repeat test. After correct shim pack determined, remove universal joint ball, collar, and seat; place shims aside for use when transmission installed in car. Install universal ball, collar oil seal, and collar on end of propeller shaft.

Bench Testing of Overhauled Transmission: Transmissions can be tested and checked for oil leakage before installation in the car. Proceed as follows:

1) Use ½" or ⅝" electric drill to drive converter at 300 RPM. or greater (J-4920 Transmission Torque Converter Cover Turning Tool and ¾" drive socket and extension will be required to hook up drill to converter).

2) Replace drilled universal joint yoke attaching bolt with plain undrilled bolt to prevent oil loss at this point during test.

CAUTION—Special drilled bolt must be replaced after testing completed (drilled passage in bolt provides lubrication for universal joint and propeller shaft bushing).

3) Disconnect oil cooler line fittings at rear of transmission and install pipe plugs at these points.

4) Connect four pressure gauges at following points: (1) Front Pump; (2) Low Servo Apply; (3) High Clutch (release side of Low Servo); (4) Reverse Servo.

5) Fill transmission with 8 qts. of Automatic Transmission Fluid Type A. *CAUTION*—Use electric drill to rotate transmission while adding last 5 qts. of fluid (necessary to fill converter and oil passages).

6) Rotate transmission with electric drill and note pressures indicated on gauges with selector lever in each position as follows:

Neutral—150-160 lbs. (higher than for regular operation because Vacuum Modulator not operating).

Drive—80-100 lbs. (higher than for regular operation because Vacuum Modulator not operating).

Low & Reverse—125-130 lbs. in each position.

7) Check for oil in converter housing indicating leakage at primary pump hub "O" ring seal, front pump oil seal, front pump "O" ring seal, or at sand hole in converter housing. Also check for leakage at Converter Cover or Turbine Bolt "O" ring seals.

8) Check for leakage at servo cover and housing side covers, check vacuum line connection in modulator cover.

9) If transmission checks OK., drain transmission, remove drill and drive attachment tool, re-install special drilled universal joint yoke bolt, remove pipe plugs and re-install oil cooler line fittings.

INSTALLATION IN CAR

Reverse the Transmission Removal procedure and note the following important points:

►**Balance Mark Caution**—When installing transmission on car, "X" mark stamped on front face of torque converter cover (lightest point of assembly) must be lined up with "X" mark stamped on face of flywheel (heaviest point) to nearest bolt hole.

Flywheel Pilot Caution—Lubricate pilot with Lubri-plate and use extreme care not to damage pilot by bumping or scratching when raising transmission into place.

Flywheel Attaching Bolt Installation—Turn flywheel until one bolt hole visible in bell housing opening, install one 5/16"-24 guide pin in corresponding hole in turbine cover, carefully guide pin through flywheel hole as transmission raised into position, install all turbine housing-to-bell housing bolts, tighten bolts evenly and securely. Remove guide pin, install all six flywheel-to-turbine cover bolts (rotate flywheel with J-4281 indexing tool for access to bolt holes), tighten bolts evenly and securely.

1953-54 POWERGLIDE TRANSMISSION

Chevrolet "210" (1953)
Chevrolet "Bel Air" (1953)
Chevrolet, All Models (1954)
Pontiac 6 & 8 (Late 1953)

▷CHANGES, CAUTIONS, CORRECTIONS

▷*STARTING ENGINE BY PUSHING CAR (Pushing recommended rather than Towing):* Place selector lever in Neutral "N" position. When car reaches speed of approximately 16 MPH. (20 MPH. if road wet or icy with resultant poor traction), move selector lever to Low "L" position to crank engine. After engine started, move lever to "N" for engine warm-up.

(CHEVROLET)

▷*1953 PRESSURE REGULATOR VALVE PRODUCTION CHANGE & REPLACEMENT PARTS CAUTION:* Beginning with 1953 transmissions having serial number prefix "M27D," a Two-Piece Pressure Regulator Valve is used with a plunger in the inner (governor pressure) end of valve which cushions the assembly and prevents excessive pulsation. First and later type Main Pressure Regulator Valves and Valve Bodies *ARE NOT INTERCHANGEABLE* and correct type parts must be used together as follows:

Service Parts:	First Type	①Later Type
Valve Body Assembly	3702337	3703238
Pressure Regulator Valve	3702808	②3705486

①—Transmission with serial no. suffix "M27D."
②—Unit including valve and plunger.

▷*1953 CONVERTER PRESSURE REGULATOR VALVE PRODUCTION CHANGE & REPLACEMENT PARTS CAUTION:* Converter pressure regulator valve and spring changed in production so that new type valve seals converter up to pressure of approximately 10 lbs., to aid in preventing converter drain-down when car standing (previous type valve merely restricted converter return line). ***First and later type valves and springs are interchangeable, but the above sealing action will only be secured when new type valve and spring used with new type valve body (see "Pressure Regulator Valve Production Change" above).***

Service Parts:	First Type	Later Type
Converter Press. Reg. Valve	3702058	③3703243
Valve Spring	3702059	③3703242

③—Must be used with Valve Body Assy. 3703238 for above-mentioned converter "sealing" action.

▷*1953 "RAPPING" NOISE WHEN ENGINE FIRST STARTED (Early Transmission):* Caused by Main Pressure Regulator Valve pulsating when converter is filling with oil. ***This is not detrimental and should be of short duration.*** This noise should not be noted in later transmissions with new type regulator valve.

▷*1953 SHIFT LEVER RATTLE CORRECTION:* Rattle may be caused by hour-glass shaped spring in lever working loose from ball on end of gear shift control lever. To correct, remove shift lever and spring, install a #6x½" sheet metal screw in lower side of lever at point 3 3/16" from pivot hole toward outer end of lever. Screw will provide seat for spring and prevent disengagement. *NOTE*—Gear shift lever on later cars has metal tang at this point to provide a spring seat.

▷*1953 CONVERTER DRAIN PLUG ELIMINATION:* On Powerglide Transmissions after April 7, 1953 (Serial Suffix D-7-D), Converter Drain Plug has been eliminated. Only the Transmission Case need be drained at 25,000 mile intervals.

▷*1953 PLANETARY CLUTCH & SPRING PRODUCTION CHANGES & REPLACEMENT PARTS CAUTION:* Three different clutch springs have been used in 1953 production as listed below. Only the third type spring is furnished for service and this spring (together with new type spring seat) should be installed in all transmissions prior to serial suffix C-2-D whenever these transmissions disassembled.

1st Type Spring (Trans. before serial suffix C-2-D)—No. 3702827. Has right hand helix.

2nd Type Spring (Trans. serial suffix C-2-D to D-10-N)—No. 3703427. Same as 1st type except diameter at center is .040" less (hour-glass type).

3rd Type Spring (Trans. serial suffix D-10-N and later)—No. 3703248. Same as 2nd type except left hand helix. Use this spring for all replacements.

Clutch Piston Assy. Change—Spring seat area changed to prevent possibility of spring hanging up in seat (used beginning with B-21-D).

Clutch Spring Seat Change—No. 3692699. Size changed to provide better pilot for spring (used in all trans. beginning serial suffix B-17-N). Use this seat with 3rd type spring for replacements.

▷*1953 LOW CLUTCH GEAR & CLUTCH FLANGE ASSEMBLY CAUTION:* 1953 Flange, Part No. 3703220 (identified by "220" stamped in flange hub), has different flange depth and is not interchangeable with 1952 type. Do not use 1952 part in 1953 transmissions.

▷*1953 (FIRST TRANSMISSIONS) GOVERNOR GEAR FAILURE CORRECTION (Transmissions before Serial No. LT-97500 C-23-N):* May be caused by bore in case not being deep enough to clear inner end of bearing diameter causing thrust to be taken on this shoulder instead of end of gear. Correct as follows:

1) If Transmission not removed—Grind back end of bearing diameter of governor for distance of 1/16" to a diameter of 7/8" (same as inner end of shaft) finishing with a slight chamfer at upper end and polishing with crocus cloth.

2) If Transmission removed or disassembled—Use 1" expansion reamer (king pin reamer, etc.) or small grinding stone in drill chuck to deepend governor bore (grind floor of case) until governor bottoms on gear thrust face and turns freely. *CAUTION* DO NOT enlarge size of governor mounting hole.

▷*1953 ACCUMULATOR ELIMINATION ON LATE TRANSMISSIONS:* Beginning Transmission No. C-725-D, new Valve Body No. 3703296 was used (superseding No. 3703237. New valve body is same as previous type except that accumulator feed and hydraulic link channel is blocked and a .061-.071" hole is drilled to connect these channels. The accumulator bore in the casting is not finished.

▷*LATE 1953 FLYWHEEL & CONVERTER PRODUCTION CHANGE & REPLACEMENT PARTS CAUTION:* Starting with Engine Serial No. LAQ-49336 (Approx. Sept. 15, 1953), a Spoke Type Flywheel (with three 3/8" converter mounting holes) was used and converter attachment to flywheel was changed from six 5/16"-24 bolts to three 3/8"-24 bolts. Service Flywheel will be furnished with three 5/16" holes and three 3/8" holes spaced alternately. *See "INSTALLATION IN CAR" for instructions on use of old and new flywheel and converter combinations.*

▷*1954 CORVETTE TORQUE CONVERTER-TO-FLYWHEEL DRIVE LUG PRODUCTION CHANGE:* Three additional drive lugs have been added to torque converter for attaching converter to flywheel. This change entered production with Corvette Powerglide Transmission No. C-409-D. These additional drive lugs can be installed on earlier cars as follows:

1) Remove transmission, being careful not to drop torque converter. Loosely attach drive lugs, Part No. 3713602 to the converter cover under the converter cover attaching nuts. Remove flywheel from engine, or take flywheel from stock and fasten flywheel to converter, using all the drive bolts, and tighten bolts securely. Tighten lug retaining nut (converter cover nuts) and remove flywheel. *NOTE—It is necessary to install flywheel to converter to assure centering of the drive lugs and the flywheel attaching bolt holes. Do Not disturb drive lugs after removing flywheel.*

2) Reinstall flywheel to engine and transmission to car, making sure that "X" mark on converter cover and "X" mark on flywheel are aligned.

(PONTIAC)

▷*FLYWHEEL AND CONVERTER FRONT PLATE & FRONT COVER BALANCE CAUTION:* Mark these parts BEFORE disassembly to insure re-installation in orignal positions. If noticeable vibration or unbalance noted, *see "INSTALLATION IN CAR" for recommended procedure.*

▷*POWERGLIDE TRANSMISSION - TO - FLYWHEEL HOUSING ATTACHING BOLT CAUTION:* FOUR different length bolts required which must be installed in correct mounting holes. *See "INSTALLATION IN CAR" data for bolt specifications and locations.*

▷*POWERGLIDE CONVERTER PLATE-TO-FLYWHEEL ATTACHING BOLT CAUTION:* Converter plate has six lugs but only THREE 3/8" bolts are used. These bolts should be installed in the 3/8" bolt holes in the flywheel (alternate bolt holes in flywheel are 5/16" size and are not used). *DO NOT attempt to install additional bolts in the unused converter plate lugs.*

▷*PONTIAC ENGINE ROUGHNESS CORRECTION (POWERGLIDE CARS):* Roughness may be caused by incorrectly adjusted engine side supports. Check and adjust as follows: 1) Make sure that side support frame brackets are in the lowest position in the elongated holes in frame and that all support bracket bolts are tight. 2) Loosen upper support bracket-to-frame bracket bolts on both sides. With engine supported by front and rear mounts only, hold engine in a vertical position by blocking between manifold and right fender (with car on a level floor, a spirit level can be used across cylinder head to determine when engine is vertical). 3) Using shims, Part No. 378005, shim as required (3 shims maximum top and bottom), fill up the space between cushion and brackets on right side plus one shim (to obtain a one shim compression on right side support assembly). Engine can be moved to left to install the additional shim.

4) Fill in the space on the left side in same manner as for right side, and remove one shim (to obtain a one shim clearance on left side). Tighten all bolts and remove block from between manifold and right fender.

DESCRIPTION

The 1953-54 Powerglide Transmission with Automatic Shift differs from previous type transmission in having a new Control System to provide automatic shifting, new torque converter, and other changes as follows:

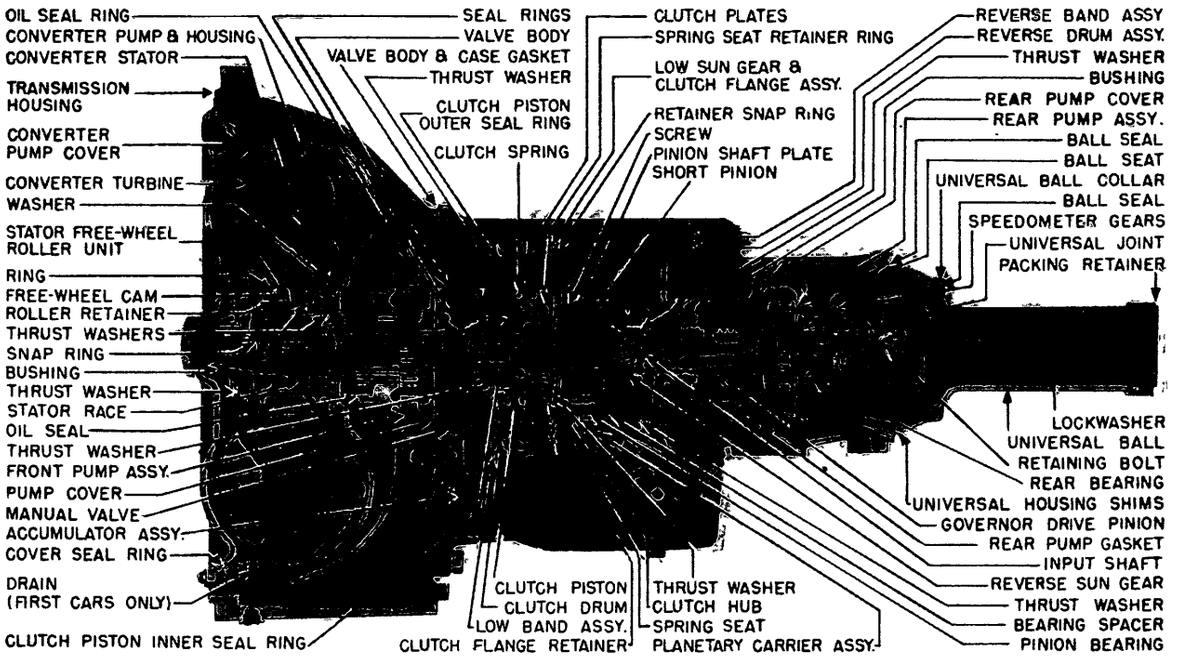
CONTINUED ON NEXT PAGE

POWERGLIDE (C ntinu d)

Control System: The following new control units have been added to provide automatic shifting (starting and accelerating in Low Range with selector lever in Drive Range):

Throttle Linkage System—Consists of control rods and bellcranks linking the throttle control to a throttle lever on the side of the transmission case which controls the Low & Drive Valve Assembly.

Low & Drive Valve Assembly—This unit is mounted on the left side of the converter housing (replaces sump cover used on previous transmissions). See illustration for valve parts. Valve assembly is controlled by accelerator pedal (through throttle linkage) and by the hydraulic governor as explained under Operation.



Hydraulic Governor—Mounted under cover on left side of transmission case and gear-driven from the transmission output shaft. Governor is two-stage, fly-ball type controlling a plunger type valve which regulates oil pressure to Low & Drive Valve Assembly as explained under Operation. Governor also controls oil pressure to Pressure Regulator Valve (through Pressure Regulator Governor Valve) to assist regulation in "D" range (pressure directed to end of pressure regulator valve keeps line pressure at minimum in "D" range). In low and Reverse Range, this governor action is cut off by the governor valve so that the higher normal oil pressure prevail in the system.

High Clutch Low Servo Valve—Consists of a spring-loaded valve with a fixed orifice in the release side of the low servo (valve is located in channel on front side of valve body). At pressures under 65 lbs., the orifice retards the servo release and allows for a soft initial band application upon down-shifts. At pressures greater than 65 lbs., valve lifts off its seat and allows quick servo release. ***See Valve Body illustration.***

Converter Pressure Regulator Valve—Consists of a spring loaded valve controlling the converter outlet orifice (through which converter oil is returned to oil cooler and transmission lubricating system). On first transmissions, this valve acted as a restriction in the line until the pressure reached 43-58 lbs. when the valve opened to prevent any greater pressure increase within the converter. On later transmissions, the valve seals the converter off when it is closed to aid in preventing converter oil drain-down when the car is standing and the engine is not running. When converter pressure reaches 10 lbs., valve opens slightly to permit a restricted flow to the oil cooler and transmission lubrication lines, and at 43-58 lbs., the valve opens fully to prevent any greater pressure increase within the converter.. ***See Valve Body Illustration.***

Lubrication Pressure Relief Valve—Consists of a spring-loaded disc type valve assembly located at the rear of the transmission and within the case. Valve connects with lubrication oil feed line and opens at 16-22 lbs. (by-passes oil back into the case) to prevent back-pressure build-up in converter.

Torque Converter: Simplified design with a single stator (former primary and secondary stators and secondary pump not used). Stator is located between inner rim of pump and turbine and is mounted in similar manner as former types (on stator support with free-wheeling device in hub). See Converter Pressure Regulator Valve and Lubrication Pressure Relief Valve (above) also.

POWERGLIDE TRANSMISSION ASSEMBLY

Clutch & Planetary Unit: Similar to previous type except that clutch piston is ¼" less in diameter (to provide smoother downshift) and new type clutch plates are used: **Steel Driven Plates**—waved type (instead of "dished"), **Drive Plates**—Have new type combination paper-and-cork facing.

OPERATION

Operation of the Torque Converter and Transmission is similar to the previous type except for automatic shifting in "Drive Range" as follows:

Starting in Drive Range—With the selector lever in Drive "D" position, the manual valve is positioned to direct oil pressure to apply side of the Low Servo and to the Low Drive Valve Body so that the car starts out in low range (torque converter plus planetary gear) providing an equivalent gear reduction of 2.2-1 (torque converter) plus 1.82-1 (gears). Depressing the accelerator pedal applies throttle valve pressure behind the shifter valve in the low drive valve body which assists the spring in keeping the shifter valve closed and the transmission in low range. As soon as the car begins to move, the rear pump begins to operate and to supply oil pressure to the governor which controls the upshift as follows:

Normal Upshift—When the rear pump pressure balances the force of the centrifugal weights in the governor, the governor valve directs oil pressure to the Shifter Valve in the low drive valve body and moves the valve to the drive position. This directs main line pressure to the clutch assembly and to the release side of the low servo piston (balancing of low servo pressures allows spring to release band). Application of the clutch and release of the band places the transmission in Drive Range (converter drops out independently when reversal of pressure on stator vanes causes stator to "free-wheel" so that torque converter acts merely as a fluid coupling). Upshift can be delayed by greater throttle opening as follows:

Delayed Upshift—The shift from Low to Drive Range is dependent on the extent to which the accelerator pedal is depressed and will occur at a higher car speed with greater throttle opening. In addition, if the accelerator pedal is depressed beyond the "detent point" (this point reached just before throttle is wide open and will be noted as a definite resistance to further movement of the accelerator pedal), this movement of the pedal compresses the detent spring in the low drive valve body and moves the Detent Valve which then directs throttle valve pressure to the large plunger which assists in holding the shifter valve in the low range position (see Forced Downshift operation below). This delays the upshift to drive range until the car speed reaches 42 MPH. when the governor pressure becomes great enough to move the shifter valve to the high position regardless of the accelerator pedal position (governor pressure increases with car speed until it equals main line pressure).

Normal Downshift—With closed throttle, transmission remains in drive range until car speed drops to approximately 9 MPH. and shifts down to low range at this point. However, transmission can be downshifted at will at higher car speeds to provide greater torque for rapid acceleration as follows:

Forced Downshift—At car speeds below 37 MPH., the transmission can be downshifted from drive to low range for rapid acceleration by depressing the accelerator pedal. The amount of pedal movement required, and the resulting action of the transmission control depends on car speed as follows:

CONTINUED ON NEXT PAGE

POWERGLIDE (Continued)

Car Speed under 16½ MPH.—Depressing the pedal to the detent point (almost to the floor) increases the throttle valve spring pressure and the resulting increased throttle valve pressure on the shifter valve unbalances the valve (increased throttle valve pressure with no increase of governor pressure) and the shifter valve moves to the low range position. At speeds greater than 16½ MPH. the governor pressure prevents this action occurring.

Car Speed Under 37 MPH (1953); 50 MPH (1954, Exc. Corvette); 40.3 MPH (Corvette)—Depressing the accelerator pedal to the floor (through detent) compresses the detent spring in the Low Drive Valve Body and moves the detent valve which then directs the throttle valve pressure to the large plunger which assists moving the shifter valve to the low range position. At speeds greater than those indicated above, the governor pressure is sufficient to prevent this action occurring. *NOTE*—In this detent position, if transmission in low range, the upshift will not occur until car speed reaches approximately 42 MPH (1953); 47½ MPH (1954).

1953 AUTOMATIC SHIFT SPEEDS
(In Drive Range)

Throttle Position	①Upshift	②Downshift
Light Throttle	10-20 MPH	8-10 MPH
Open to detent	23-33 MPH	13-17 MPH
Open thru detent③	④37-44 MPH	⑤32-37 MPH

①—From Low to Drive Range.
②—From Drive to Low Range.
③—Accelerator pedal depressed as far as possible (beyond point of detent resistance).
④—Slightly higher on first Chevrolet units.
⑤—Slightly higher on first Chevrolet units.

1954 AUTOMATIC SHIFT SPEEDS (Exc. Corvette)
(In Drive Range)

Throttle Position	①Upshift	②Downshift
Light Throttle	10-20 MPH	8-10 MPH
Open to Detent	23-33 MPH	13-16½ MPH
Open thru Detent③	46-53 MPH	46-50 MPH

1954 AUTOMATIC SHIFT SPEEDS (Corvette)

Throttle Position	①Upshift	②Downshift
Closed Throttle	11.3-13.1 MPH	6.7-8.7 MPH
Open to Detent	27.2-37.1 MPH	
Open thru Detent③	50.8-57.8 MPH	35.3-40.3 MPH

①—From Low to Drive Range.
②—From Drive to Low Range.
③—Accelerator pedal depressed as far as possible (beyond point of detent resistance).

LUBRICATION

Check oil level at 1,000 mile intervals, drain and refill transmission at 25,000 mile intervals.

▷*CONVERTER DRAIN NOTE*—Converter drain plug provided only on first Chevrolet units (omitted on later Chevrolet and all Pontiac units). Oil trapped in converter need be replaced only when transmission disassembled for overhaul.

Recommended Oil—Use only Automatic Transmission Oil Type A (as furnished in containers bearing "AQ-ATF" number).

Capacity—Approximately 5 qts. (refill after transmission case only drained), 11 qts. (after overhaul with transmission case and converter dry).

▷Warming Up Transmission (For Checking or Draining)—Drive car approximately 5 miles with frequent starts and stops OR warm up transmission in shop as follows: Run engine for 15 minutes at 750 RPM with selector lever in "Dr" position. *CAUTION*—Set hand brake tightly to prevent car moving.

Checking Oil Level—Check only with transmission warm and engine idling with selector lever in Neutral "N" position. Remove dipstick from filler tube in engine compartment on right side. Add oil only if level down to "ADD ONE QUART" mark on stick, fill only to "FULL" mark on stick. *CAUTION—High oil level (above "FULL" mark) will cause foaming and loss of fluid.*

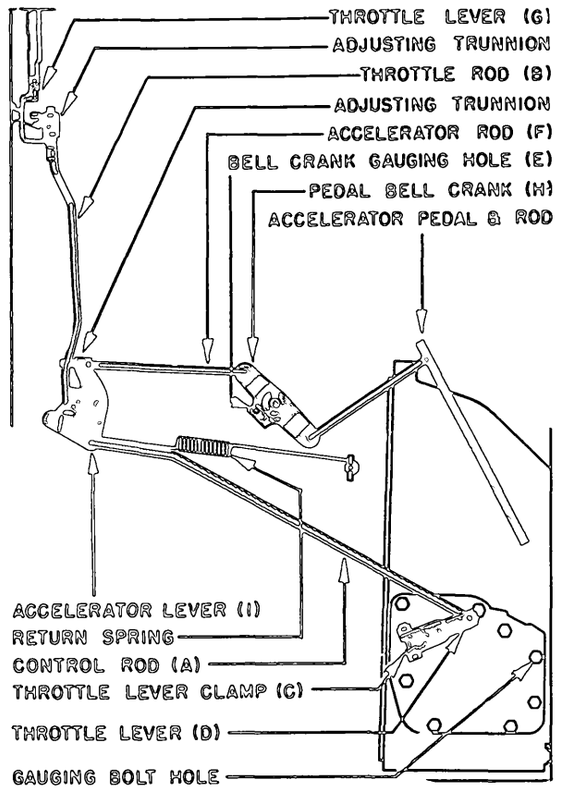
▷*OIL FILLER NOTE*—Use of Oil Filler Tube & Funnel No. J-4264 recommended to facilitate filling. This assembly is vented (transmission not vented and may blow back causing oil spillage if vented filler not used).

▷*PONTIAC OIL FILLER NOTE*—Use Funnel & Filler Tube J-4264A. On cars with windshield washer, it will be necessary to remove washer jar to permit oil funnel and filler tube to be installed.

▷*LOW OIL LEVEL CAUTION—If oil level in transmission found consistently low, check for internal and external oil leaks. See "OIL LEAKAGE OR HIGH OIL CONSUMPTION" in TROUBLE SHOOTING.*

Draining & Refilling—Transmission must be warm. Remove drain plug in rear face of transmission housing under the case to drain the transmission. *NOTE*—It is not necessary to drain converter. Replace and tighten drain plug. Install 5 qts. of new fluid through filler tube on right side of engine (see Oil Filler Notes above). Idle engine with selector lever in "N" until transmission warm, check fluid level and add additional fluid, as required, to bring level up to "Full" mark on dipstick. *CAUTION—Do not overfill (will cause foaming).*

Filling (After Overhaul)—Install 3 qts. of fluid through filler tube, start engine and allow it to idle with selector lever in "N", install additional 8 qts. of fluid. Run engine until transmission warm and check fluid level.



LINKAGE ADJUSTMENT

CHEVROLET LINKAGE ADJUSTMENT:

Throttle Linkage: *CAUTION—Engine must be at normal operating temperature and transmission warm (choke valve wide open and fast idle inoperative with throttle stopscrew against low step of fast idle cam) when adjustments are made. Proceed as follows:*

1) Adjust engine speed to 425 RPM. with selector lever in "D" range (set hand brake firmly to hold car while making this adjustment).

2) Disconnect control rod (A) from transmission throttle lever (D). Remove lower right side cover bolt from transmission (marked "Gauging Bolt Hole" in illustration). Hold clamp (C) back lightly against stop in transmission, install Throttle Lever Positioning Gauge J-5391 (1953); J-5588 (1954 Exc. Corvette); J-5391 (Corvette) on lever with one gauge pin in hole on lever. If second gauge pin does not enter bolt hole in cover *(see "Gauging Bolt Hole" in Throttle Linkage illustration)*, loosen lever-to-clamp attaching bolt and position lever so that gauge pin enters hole freely. *(CAUTION*—Hold adjustment clamp (C) back against its stop while making this adjustment). Tighten lever-to-clamp bolt securely, remove gauge, replace cover bolt. Connect throttle rod (A) to lever.

CHEVROLET THROTTLE LINKAGE

3) 1953 Models—Disconnect rod (B) from throttle lever (G), press control rod (A) lightly back against its stop in the transmission (this is the closed throttle position), adjust trunnion on upper end of rod (B) until trunnion pin freely enters hole in throttle rod, then shorten rod by turning trunnion upper check nut down three full turns, tighten lower check nut securely and connect rod to throttle lever.

3) 1954 Models—Rotate engine bellcrank clockwise to set transmission lever (D) in full detent (this is wide open throttle position, and adjust trunnion on upper end of rod (B) to length required for free entry of swivel pin into throttle lever when throttle lever is held at wide open (upper position), tighten lower check nut securely and connect rod to throttle lever.

4) Install 3/16" gauge pin through gauging hole (E) in pedal bell crank(H) and through hole in bracket to lock bell crank. With throttle rod (B) held up so that throttle lever is against idle stop in carburetor, adjust trunnion on forward end of rod (F) until trunnion pin freely enters hole in accelerator lever (I), tighten trunnion check nuts securely and connect rod. Remove gauge pin from bell crank (H).

Manual Control Linkage: Adjust in following order:

CONTINUED ON NEXT PAGE

POWERGLIDE (C ntinued)

Control Lever—1½ ± 5/16" (1953); 1 11/16" (1954 Exc. Corvette) between upper face of control lever knob and lower face of steering wheel with selector lever in Reverse "R" position. To adjust, loosen lower support clamp bolts, move lower support up or down as necessary. Tighten clamp bolts securely.

►*CAUTION—Dowel in support must be located in slot in mast jacket.*

Reverse Stop Clearance— .090" clearance between Reverse Stop on control shaft lower support and lower lever with selector lever in Reverse "R" position. To adjust, loosen control rod swivel, make certain that manual control valve lever on left side of transmission is in top detent position and that selector lever is in Reverse "R" position, move selector lever as necessary for correct clearance, tighten control rod swivel.

►*CAUTION—Short connector rod (bellcrank-to-parking lock lever) on transmission must be correctly installed with arrow pointing UP.*

Manual Control Linkage (Corvette): Set control rod bell crank (A) on transmission to reverse position (extreme rearward position). Place transmission selector lever (B) in reverse position (extreme forward position). Adjust rod (C) connecting lower end of selector lever with control rod bell crank so that rod will enter hole in lower end of selector lever (D) freely.

Neutral Safety Switch: Located on bracket on lower end of lower support assembly on steering column. To adjust, loosen two switch assembly mounting screws. Place selector lever in neutral, make certain that switch clip is over flats on end of shifter shaft. Insert locating pin through holes in switch mounting bracket and locating plate. Tighten switch mounting screws, remove locating pin.

PONTIAC LINKAGE ADJUSTMENT: *CAUTION—First make certain that linkage operates freely without binding or excessive looseness due to wear. Then proceed as follows:*

Throttle Linkage: Adjust with transmission warm and control lever in Neutral "N".

1) Disconnect throttle rear rod from throttle control (outer) lever on transmission. Adjust engine idle speed to 410-430 RPM with engine at normal operating temperature (150-160°F).

2) With engine not running, install gauge pin J-2544 through holes in lever and bracket at left end of carburetor throttle rod (6 Cyl.), at left end of cross-shaft (8 Cyl.) to lock the lever. With carburetor throttle closed and idle speed adjusting screw against its stop, adjust trunnion at rear end of carburetor throttle rod so that gauge pin is free in hole in lever, tighten trunnion locknuts and connect rod. **Do not remove gauge pin.**

3) Check position of lower idler lever on left side of crankcase by inserting second gauge pin J-2544 through hole in lever and hole in bracket. If pin does not enter both holes freely, adjust trunnion on upper end of throttle front rod (at upper idler lever). Tighten trunnion locknuts securely. **Remove both gauge pins.**

4) Remove upper rear side cover bolt on left side of transmission. Hold throttle valve outer lever lightly against its rear stop and check lever position with special gauge J-5525. With one pin of gauge entered in bolt hole in side cover, second pin of gauge should freely enter hole in lever. If lever position incorrect ,loosen lever-to-clamp attaching bolt and adjust lever position. Tighten clamp bolt, remove gauge, re-install side cover bolt.

5) Hold carburetor throttle in full open position, move transmission throttle valve outer lever to forward position against inner stop, adjust trunnion on rear end of throttle rear rod so that trunnion pin enters hole in lever freely, then **lengthen rod by turning forward locknut one complete turn,** tighten both locknuts securely and connect rod. Install two return springs.

6) Check accelerator pedal clearance with throttle in full open position. Adjust trunnion at forward end of pedal rod so that pedal clears floor mat by approximately ¼" at closest point.

Manual Control Adjustment: Disconnect control rod from shift lever on left side of transmission case. Adjust linkage as follows:

1) Place transmission case shift lever in "DR" position (second detent position from rearmost or reverse position).

2) Place selector lever on steering column in "DR" position and against the stop which prevents shifting into low without raising the lever.

3) Connect shift control rod to transmission lever and to lower control lever on steering column leaving both locknuts loose at adjusting trunnion on rod.

4) Adjust rear locknut finger-tight against trunnion to remove clearance from linkage, then tighten both locknuts securely.

Starter Neutralizer Switch: Place selector lever in "DR" position. Adjust neutralizer switch bracket so that starter will not operate when ignition key turned to start position, tighten switch mounting screws securely. Check to make certain that starter does operate with selector lever in "P" and "N" positions.

BAND ADJUSTMENT

►*BAND ADJUSTING NOTE—Band adjustment not ordinarily required in service (bands adjusted when reassembling transmission). Reverse Band adjustment requires removal of Servo Cover Assembly (see Disassembly data).*

Low Servo Bands—Adjusting screw located on left side of transmission case (under a cover). To adjust band, remove adjusting screw cover. Use tool J-4277 (see Tool Modification Note below), loosen adjusting screw locknut, turn adjusting screw in solidly, **then back screw out exactly four complete turns,** tighten locknut taking care not to allow screw to turn, replace adjusting screw cover.

►**Tool J-4277 Modification (for Low Servo Band Adjustment)**—Adjusting screw has recessed head for ¼" Allen wrench. To use tool, remove screwdriver retainer and special screwdriver from tool, use ¼" Allen Wrench in place of the screwdriver in the tool.

Reverse Servo Band—Adjusting screw located on right side of case **under servo cover.** With servo cover removed, install tool J-4277 on adjusting screw, loosen locknut. Turn adjusting screw in slowly and **at same time** check endplay in linkage by pushing-and-pulling on servo return spring directly below adjusting screw, continue to turn screw in until endplay is just taken up (at this point band must be free on drum so that drum can be rotated easily by hand), **then back adjusting screw out ⅛-¼ turn,** tighten locknut taking care not to allow adjusting screw to turn.

►*CAUTION—This reverse band adjustment is very sensitive and must be done carefully.*

TROUBLE SHOOTING

EXCESSIVE SLIPPAGE (High engine speed in relation to car speed, poor acceleration, or engine runs away on turns).

1) **In all Speed Ranges**—Low oil level. Incorrect control linkage adjustment. Air leak in oil pump suction pipe. Low front oil pump pressure.

2) **In Drive Range**—Incorrect control linkage adjustment. Damaged or leaking clutch piston seal (worn or burned clutch plates resulting from partially engaged clutch).

3) **In Low Range**—Incorrect control linkage adjustment. Low Band out of adjustment. Sticking accumulator valve, modulator lever, or modulator valve. Damaged or worn Low Servo Piston Ring resulting in poor band application or excessive oil leakage into clutch apply circuit causing partial clutch application and possibly burned clutch plates (check by connecting pressure gauges to Low Servo Apply and to High Clutch test points—there should be no pressure indicated at High Clutch point with selector lever in "L").

CAR CREEPS (Forward or Backward).

1) **With Control Lever in Neutral**—Incorrect control linkage adjustment. Clutch piston vent valve stuck closed. Clutch plates sticking or incorrectly assembled (not "stacked" in correct order).

2) **Creeps forward with Control Lever in Reverse or backward with Lever in Low**—Incorrect control linkage adjustment.

CAR WILL NOT MOVE (Rear wheels may be locked or free).

1) **With Control Lever in any rang (rear wheels free).** If this occurs at other times than after reversing car, see causes listed under EXCESSIVE SLIPPAGE above. If this occurs only after reversing car (indicating loss of front pump pressure) check: Rear pump air leakage into front pump suction line (causing front pump to lose its prime). Rear pump gasket leakage. Front pump clearance excessive.

2) **With Control Lever in any rang (rear whe ls locked).** Parking pawl lock engaged. Broken parts in transmission. Parking brake applied.

3) **With Control Lever in Drive Range (rear wheels free).** If engine runs away and transmission is hot, check for: Low radiator water level, clogged oil cooler, sticking thermostatic valve, or dragging Low Range Band (causing over-expansion of clutch parts due to excessive heat).

SHIFTS ARE ROUGH.

1) **Low-to-Drive Shift (car in motion).** Incorrect Low Band adjustment. Clutch plates worn or binding. Modulator control lever or piston sticking (will cause excessive pressures). Accumulator dump valve orifice plugged.

If engine speeds up during this shift—Check for incorrect low band adjustment and worn or binding clutch plates.

2) **Drive-to-Low Shift.** Incorrect Low Band adjustment. Accumulator piston stuck closed. Modulator control lever or piston stuck (will cause excessive pressure).

CONTINUED ON NEXT PAGE

POWERGLIDE (C ntinu d)

3) **Neutral-to-Reverse.** Incorrect reverse band adjustment. Accumulator piston stuck closed. Modulator control lever or piston stuck (will cause excessive pressure).

CHATTERS WHEN STARTING.

1) **In Low Range.** Incorrect Low Band adjustment. Worn or rough band, scored drum. Clutch not disengaging properly due to distorted or binding plates, sticking clutch piston, sticking piston vent valve, or damaged or worn Low Servo Piston Ring allowing oil leakage into clutch apply circuit and causing partial clutch application (see tests for Excessive Slippage in Low Range above).

2) **In Drive Range.** Incorrect Low Band or Reverse Band Adjustment. Bands worn or rough, drums scored.

3) **In Reverse Range.** Incorrect Reverse Band adjustment. Worn or rough band, scored drum. Reverse ring gear and drum bushing worn or damaged.

REVERSE OPERATION JERKY OR DRAGGING.

1) Clutch plates are incorrectly assembled (not "stacked" properly) or sticking. Clutch piston vent valve stuck closed.

REVERSE CAN NOT BE ENGAGED WITH ENGINE RUNNING: If reverse can only be engaged when engine not running, check for accumulator snap ring being out of place (allowing accumulator valve and body to be forced against clamp nut on parking lock lever shaft and apply spring assembly, blocking shift into reverse). *NOTE*—Above condition will not prevent shift into Low Range).

DRIVE-TO-LOW or LOW-TO-DRIVE SHIFT DIFFICULT: May be caused by improperly drilled high clutch feed orifice in valve body resulting in slow clutch application in Drive Range and slow clutch release when shifting from Drive to Low (restricted orifice will cause slow oil flow). Check by connecting pressure gauges to Low Servo Apply and to High Clutch (low servo release side) and noting pressures as follows:

1) Move selector from Neutral to Drive with engine idling. If pressure builds up much more rapidly on Low Servo Apply gauge than on High Clutch gauge, a restriction in the passage (undersized orifice) is indicated.

2) Move selector from Drive to Low. Pressure in High Clutch gauge drops slowly, oil drainage from clutch is restricted. NOTE—This will result in slow Low Band application and clutch drag (may cause burned clutch plates).

HIGH CLUTCH PLATES BURNED OR CLUTCH FAIL

►***CAUTION—When High Clutch failure noted, following tests should be made before transmission removed, and transmission should also be carefully examined after removal and disassembly.***

1) Connect pressure gauges to Low Servo Apply, High Clutch (low servo release side), and to Reverse Servo points. Operate engine to supply oil pressure.

2) Place selector lever in Drive position and note pressure build-up in High Clutch gauge. Slow build-up indicates restriction in high clutch apply orifice resulting in clutch slippage and burned plates.

3) Place selector lever in Low position. High Clutch gauge should not show any pressure. Pressure at this point indicates leakage past Low Servo Piston Ring resulting in partial clutch application and burned clutch plates.

4) Place selector lever in Reverse position. High Clutch gauge should not show any pressure. Pressure at this point indicates leakage between the converter "out" and low servo "release" channels in valve body or damaged Housing-to-Valve Body gasket. This condition will cause partial clutch application and burned clutch plates.

NOISE IN TRANSMISSION.

1) **Buzzing Noise (All Ranges).** Low oil level. Pump gear interference with crescent in pump. Pump check valve not seating.

2) **Ringing Noise in Converter.** Low oil level. Air leak in pump suction line (pump not seated properly) resulting in low oil level in converter. Pressure regulator valve stuck (closing converter inlet port). Leakage in oil line between front pump and regulator valve.

3) **Clicking Noise.** Incorrect manual linkage adjustment (causing interference between parking lock pawl and gear).

4) **Whining Noise.** Transmission gear teeth worn. Pump gear clearance excessive or pump gear bushings worn.

FUEL CONSUMPTION EXCESSIVE.

1) **Transmission Causes.** Converter stator freewheeling cams and roller incorrectly assembled. Clutch piston vent valve stuck open.

TRANSMISSION OIL BEING FORCED OUT OF FILLER PIPE: Caused by aeration and foaming of the oil due to one or more of the following:

NOTE—This condition may also cause Loss of Power and Lower Stall Speed (due to converter turbulence and lower pressures in control circuits).

1) Oil level too high allowing planet carrier to revolve in oil and aerate it. Correct by lowering oil level to correct point (see LUBRICATION) and driving car for 5 miles to work out air bubbles.

2) Oil suction pipe split, seal damaged, bore for suction pipe in housing too deep, or suction pipe retainer ears bent (preventing proper compression of the seal) resulting in air leaks in oil suction line.

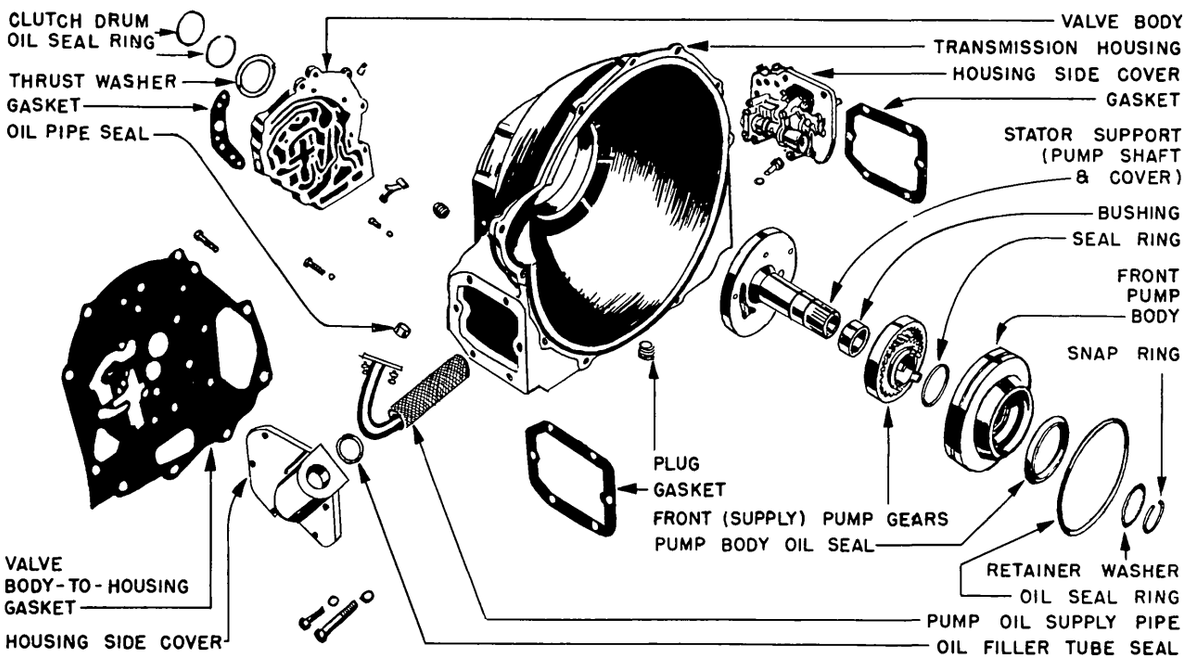
3) Sand hole in suction bore of transmission case or housing or in suction cavity in valve body resulting in air leaks in oil suction line.

TESTING HYDRAULIC UNITS

►*TESTING CAUTION*—Transmission oil level must be checked and corrected (see LUBRICATION) and ***transmission must be warmed up before tests made.***

Warming Up Transmission: Transmission must be warmed up by road driving or in the shop exactly as follows before checking for oil leaks or trouble.

Road Warm-Up—Drive car for approximately 5 miles with frequent starts and stops to approximate heavy-traffic conditions.



Shop Warm-Up—Set hand brake tight to hold car, place selector lever in "D" range, start engine and run for 15 minutes at 750 RPM. At end of 15 minutes, transmission will be warmed up suffcientl-ly for testing regardless of initial temperature.

►***CAUTION—Recheck oil level after warm-up and before making following tests.***

Pressure Tests: Correct pressure gauges at the following points and make the tests listed below.

►*TEST GAUGE NOTE*—Five gauges are required. The

CONTINUED ON NEXT PAGE

POWERGLIDE TURBINE HOUSING & FRONT OIL PUMP

POWERGLIDE (C ntinued)

previous four-gauge panel, No. J-4872, can be modified for use on 1953 transmissions by installing additional gauge furnished in conversion package No. J-5491 (reverse original gauges on panel, drilling additional hole to mount new gauge on lower edge of panel).

Gauge Connections—Connect gauge at each of the following points:

1) **Low Servo Apply Pressure**—Plug on lower front of servo cover on right side of transmission. *CAUTION—Do not confuse this plug with Modulator Pivot Pin Retaining Plug which is slightly to rear of this Low Servo Apply Plug.*

2) **Clutch Apply Pressure (Low Servo Release)**—On bottom of transmission case at center and adjacent to servo mounting flange.

3) **Reverse Servo Apply Pressure**—On bottom of transmission case at rear and adjacent to servo mounting flange.

4) **Throttle Valve Pressure**—At hex-head plug in center of Low and Drive Valve Body Cover on left side of converter housing.

5) **Governor Pressure**—At plug on side or at upper end of channel in Low and Drive Valve Body Cover on left side of converter housing (upper plug is between second and third top cover screws (counting from top front corner of cover).

6) **Main Line Pressure**—At plug on upper end of channel in Low and Drive Valve Body Cover on left side of converter housing (plug is between third and fourth top cover screws (counting from top front corner of cover).

7) **Clutch Apply or Main Line Pressure**—At plug at outer end of channel in Low and Drive Valve Body Cover on left side of converter housing (this plug is at lower rear corner of cover).

Test Pressures—*CAUTION—Representative pressures listed below may vary 5% (higher or lower).*

LOW RANGE (MANUAL)

Idling at 450 RPM.

Pressure Point	Pressure
Main Line (Frt. Pump)	140 lbs.

At 30 MPH.

Pressure Point	Part Throttle (Road Load)	Full Throttle (Thru Detent)
Low Apply	160 lbs.	190 lbs.
Governor①	60 lbs.	60 lbs.

DRIVE RANGE (AUTOMATIC)

Transmission in Low Range

Pressure Point	Light Throttle (10 MPH.)	Thru Detent (30 MPH.)
Low Apply	70 lbs.	115 lbs.
Clutch Apply	0	0
Governor①	10 lbs.	60 lbs.
Throttle Valve	0-5 lbs.	45 lbs.

Transmission in High Range

Pressure Point	Light Throttle (30 MPH.)	To Detent (40 MPH.)
Low Apply	55 lbs.	120 lbs.
Clutch Apply	55 lbs.	120 lbs.
Governor①	60 lbs.	75 lbs.
Throttle Valve	45 lbs.	58 lbs.

①—To check governor pressure only, vacuum line to modulator must be disconnected.

REMOVAL FROM CAR

Transmission & Torque Converter are removed as an assembly. *CAUTION—Torque converter is not retained in housing as on previous transmission and special holding tool must be used to prevent converter falling out when transmission assembly removed.*

CHEVROLET TRANSMISSION ASSY. REMOVAL:

1) Raise car and support securely on jack stands. Remove floor mat and toe pan plate.
2) Take out three top turbine housing attaching bolts (through toe pan hole).
3) Disconnect speedometer cable at transmission and hand brake rod from cross-shaft. Drop cross-shaft, brake cables, and spring.
4) Free universal joint collar by taking out cap screws on back of transmission case, slide ball and collar back on shaft. Support propeller shaft with jack, take out front universal trunnion bearing cap screws, split universal, lower front end of propeller shaft.
5) Take out two upper right transmission-to-converter housing bolts. Use Adapter No. J-5214 and Adapter Plate No. J-5526 mounted on a standard hydraulic floor jack to support transmission weight.
6) Drain transmission case (see Lubrication). Disconnect transmission oil cooler lines and vacuum line.
7) Take out two lower turbine housing attaching bolts. Remove flywheel cover and flywheel underpan extension.
8) Remove all spark plugs. Disconnect exhaust pipe at manifold, disconnect muffler support. Tie exhaust pipe and muffler to left frame side member out of the way.
9) Disconnect throttle control rod from control lever on left side of transmission case. Disconnect both long and short selector control rods from levers on left side of transmission, tie throttle control rod and long selector rod up out of the way. Remove bell crank lever and stud from transmission case.
10) Remove all six flywheel-to-converter bolts working through housing opening on left side (use tool J-4281 to turn engine crankshaft and align each bolt with housing opening for access).
11) Clean all dirt from around filler tube and dipstick fitting on transmission side cover, remove housing bolt holding filler tube, remove filler tube and dip stick.

►*CAUTION—Cover the filler tube opening with masking tape or plug with rubber stopper to keep out dirt.*

12) Support engine with a jack under the oil pan. Remove transmission-to-rear support bolts, remove the transmission support and cross-member.
13) Take out all remaining turbine housing bolts (lift or lower engine for access to bolts).
14) Move transmission straight back to clear flywheel pilot from flywheel. Install converter assembly holding tool J-5384 (attach tool with one converter turbine housing bolt). *NOTE—this tool will prevent converter assembly falling out while transmission being removed.*

►*CAUTION—Use care not to damage flywheel pilot.*

15) Lower the transmission and remove it from beneath the car.

►*CAUTION—Transmission must not be allowed to strike against flywheel.*

PONTIAC TRANSMISSION ASSY. REMOVAL:

1) Raise the car and support securely on jack stands or hoist.
2) Disconnect propeller shaft at rear universal joint, slide propeller shaft to rear to disengage front yoke from transmission, remove assembly.
3) Disconnect speedometer cable. Remove hand brake intermediate lever. Remove #2 pan screws (right and left) and remove crankcase ventilator pipe.
4) Install engine support tool. Disconnect right engine side support upper bracket at flywheel housing. Loosen engine left side support-to-shim and cushion assembly bolt and disconnect two engine side support upper bracket attaching bolts, swing side motor mount support forward so that it will clear starter motor when engine and transmission assembly lowered. *CAUTION*—DO NOT disassemble side motor mounts (would require alignment and shimming procedure when reassembled).
5) Disconnect manual shift rod and throttle rear rod from levers on left side of transmission. Disconnect modulator vacuum pipe at transmission
6) Drain transmission case. See Lubrication data.
7) Disconnect oil cooler lines at transmission. Remove transmission oil filler tube, take out exhaust pipe support bolt.
8) Remove rear motor support assembly (first take out two support-to-transmission bolts), then remove four lower engine support-to-frame bolts.
9) Remove flywheel housing inspection hole cover. Remove three converter-to-flywheel attaching screws (equally spaced around flywheel).
10) Install transmission jack under transmission case.
11) Lower engine and transmission assembly until top flywheel housing bolts are accessible. Remove all transmission-to-flywheel housing screws, noting location of each length screw *(CAUTION*—4 different length screws used—screws must be replaced in original positions).
12) Move transmission straight back to clear pilot from flywheel, install converter assembly holding tool J-5384 (attach tool with one converter housing bolt). *CAUTION—Use of tool necessary to prevent converter assembly falling out during removal.*
13) Lower transmission and remove from beneath car.

DISASSEMBLY—TRANSMISSION

►**DISASSEMBLY & REASSEMBLY CAUTION:** *CLEANLINESS IS EXTREMELY IMPORTANT when opening up transmission. Thoroughly CLEAN exterior of case first, CLEAN each part as removed with cleaning solvent or gasoline and dry with air—do not use wiping cloths which will leave lint on parts. Store all parts in clean storage bins.*

DISASSEMBLY OF TRANSMISSION (Into Major Units): With transmission on bench (fixture J-3361 recommended for holding transmission), remove all units from transmission case as follows:

1) Remove converter assembly holding tool J-5384 from housing, remove converter assembly by pulling it straight out of housing.
2) Take out right side cover attaching bolts, remove side cover and gasket, remove oil pump suction screen.

CONTINUED ON NEXT PAGE

POWERGLIDE (Continued)

3) Take out Low & Drive Valve Body attaching bolts on left side of transmission (replaces side cover used on previous transmissions), remove valve drive body assembly and gasket. CAUTION—do not remove outer lever assembly from valve body (this retains inner lever assembly in cover).

4) Take out Modulator assembly attaching bolts on right side of case, lift Modulator assembly off.

▷*CAUTION—Use care that hydraulic plunger and body do not fall out of modulator when it is removed.*

5) Loosen all servo cover bolts slightly and break servo cover loose if it sticks to case (reverse servo spring and pressure regulator spring bear against cover) using care not to allow cover to tip which may damage or break tip of pressure regulator valve. Use guide bolts to maintain cover alignment or turn all cover bolts out evenly while exerting pressure on cover, then lift cover and gasket straight off until cover clears tip of pressure regulator valve. Remove reverse servo spring and pressure regulator springs, lift regulator valve out.

▷*CAUTION—Handle valve carefully to prevent damage and store it by itself to avoid nicking or scratching of the polished surfaces.*

6) Remove low band adjusting screw cover on left side of transmission case, use tool J-4277 (see Tool Modification Note below) to loosen adjusting screw locknut, tighten adjusting screw so that low band grips clutch assembly to hold it in place.

▷Tool J-4277 Modification Note—Low band adjusting screw has recessed head for Allen wrench. To use tool, remove screwdriver retainer and special screwdriver from tool, use ¼" Allen wrench in place of screwdriver in tool.

7) Remove one converter housing-to-transmission case self-locking bolt from within the converter housing. Remove all transmission-to-converter housing bolts and lockwashers, carefully separate transmission from converter housing, remove valve body-to-transmission case gasket.

8) Remove manual valve from valve body on rear of converter housing, remove manual valve lever from housing, remove bronze thrustwasher from valve body oil delivery sleeve.

▷*CAUTION—Handle manual valve carefully to prevent damage and store it by itself to avoid nicking or scratching of the polished surfaces.*

9) Take out all bolts and lockwashers attaching valve body to converter housing and front pump to valve body. Remove valve body and gasket.

▷*CAUTION—Handle valve body and valves carefully to protect them from damage.*

10) Use Front Pump Driver Tool J-4263-5 to remove pump assembly from converter housing.

11) Loosen low servo band adjusting screw to free clutch assembly, remove input shaft, clutch assembly, and low sun gear thrustwasher from transmission case.

12) Remove low servo band, strut assembly, low servo piston and piston return spring from transmission case.

13) Remove speedometer driven gear assembly. Take out universal joint retainer bolt and lockwasher on rear end of output shaft, slide universal joint yoke off end of shaft.

14) Take out attaching bolts and remove governor cover on left side of transmission case, remove gasket. Remove governor assembly (allow governor to turn in clockwise direction while withdrawing it from case).

15) Use tool J-3383 to rotate parking lock pawl spring until end unhooked from case, remove spring and parking lock pawl. Remove parking lock lever and steel washer, parking lock lever shaft assembly, and oil seal from case.

16) Install tool J-938 on rear face of transmission case and engaging end of output shaft. Turn tool handle clockwise to force output shaft forward out of rear bearing. Remove tool. Remove planet carrier and output shaft assembly out through front of case.

17) Remove reverse brake drum from case. Use tool J-4277 to loosen reverse servo adjusting screw locknut and back off the adjusting screw, remove reverse brake band assembly and reverse servo piston from case.

18) Take out rear pump attaching bolts and lockwashers, remove pump assembly and gasket.

19) Remove lubrication pressure relief valve from within transmission case.

▷*For DISASSEMBLY of above units, see OVERHAUL data following.*

OVERHAUL

▷"O" RING SEAL CAUTION: *These seals must be discarded when removed and a new seal installed exactly as directed below.* "O" ring rubber seals are special design and are installed with side clearance in ring groove so that oil pressure on seal deforms the rubber and extrudes a portion of the rubber into the clearance space between the mating parts to provide a positive seal against loss of oil pressure. Seals must not be re-used.

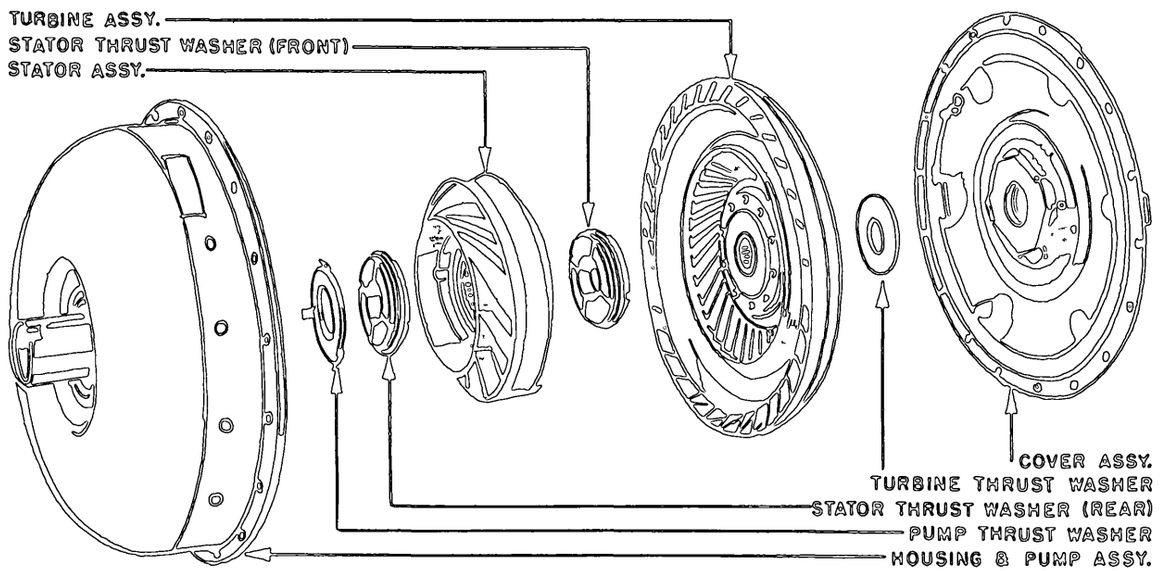
"O" Ring Seal Installation—Make certain that parts are clean and that burrs and sharp edges are removed. Seal must be free of any twists (place ring on flat surface and allow it to assume natural position) and must not be twisted during installation. Engage one side of ring in groove, pull other side straight back until it can be fitted in groove without twisting. Work ring against trailing edge of groove (last side to enter when parts assembled) using flat tool entered between ring and leading edge of groove to move ring without twisting. Lubricate "O" ring and parts with transmission oil.

CONVERTER OVERHAUL (Unit on bench—after removal from transmission):

Disassembly: 1) Remove all converter cover attaching bolts and locknuts, use small punch to drive out two split dowel pins in cover, lift cover off.

2) Remove turbine assembly, stator assembly, stator thrustwashers, and pump thrustwasher. Remove thrustwasher from turbine hub. Remove "O" ring seal from converter cover.

3) Remove stator race from stator assembly, remove snap ring and over-run cam retaining thrustwasher, remove cam rollers, springs, and guides (8 each).



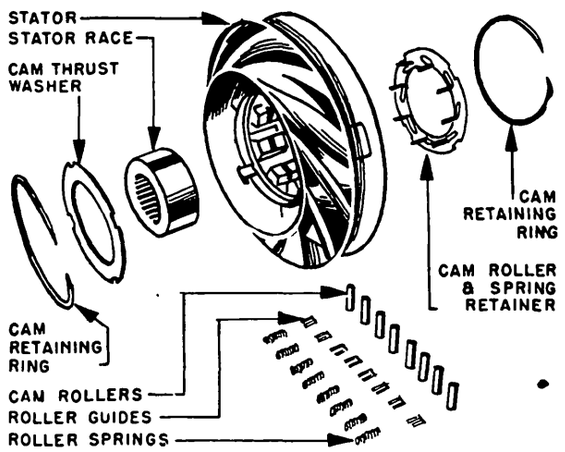
▷*CAUTION—Use care when separating parts so that cam rollers, springs, and guides do not fall out and become lost.*

4) Remove snap ring on opposite end of stator and remove over-run cam roller and spring retainer.

▷*CAUTION—Use care to prevent damage to over-run cam and see that cam does not become disengaged from stator hub.*

Inspection: Wash all parts in cleaning solvent and dry with air. Inspect converter pump hub, turbine hub, and converter cover bushing for galling, scoring, or excessive wear. Inspect all thrustwashers for galling, scoring, or excessive wear. Check turbine vanes and stator vanes for looseness or damage. Inspect stator race and cam rollers for galling or scoring. Inspect cam springs for distortion. Check spring guides for wear or damage. Inspect over-run cam roller and spring retainer for wear or damage.

CONTINUED ON NEXT PAGE



POWERGLIDE TORQUE CONVERTER

POWERGLIDE (C ntinu d)

If bushing in converter cover worn or damaged, install new bushing as follows:

Converter Cover Bushing Replacement: Precision type bushing, No. 3702078, furnished for field installation. Use bushing remover tool J-5381 to remove old bushing from cover. Place new bushing on pilot end of Bushing Replacer Tool J-5382 and press bushing into place in cover using an arbor press. *NOTE—Bushing is finished to size and does not require reaming.*

Reassembly: 1) Install over-run cam roller and spring retainer in stator with retainer prongs pointing toward **rear** of stator. *NOTE*—Stator has word "Front" cast in and stator vanes are thicker at front end.

TORQUE CONVERTER STATOR ASSY.

2) Assemble cam rollers, springs, and guides in cam pockets *(CAUTION*—Guides are curved and this curvature must follow curvature of cam). Install over-run cam thrustwasher and retaining snap ring.

3) Coat stator race and loading tool J-5930 with light film of oil, place stator race on pilot end of loading tool and carefully rotate the stator over the tapered end of the loading tool and the stator race *(CAUTION*—rotate stator in clockwise or freewheeling direction and use great care not to dislodge cam rollers). Check operation of stator. Stator should turn freely in clockwise direction viewed from front end.

4) Place converter pump on bench, open end up. Install thrustwasher on converter pump hub making certain that tabs are engaged in the hub flange notches. Assemble **both** thrustwashers on stator and install stator assembly on converter pump.

►*CAUTION—Make certain that cut-outs in over-run cam roller and spring retainer are facing upward or toward converter turbine.*

5) Install thrustwasher on turbine hub and assemble turbine on converter pump.

6) Install NEW "O" ring seal on converter cover, align dowel pin holes in cover with dowel pins in converter pump, install cover assembly. Install all cover attaching bolts and lockwashers and tighten evenly to 15-20 ft. lbs.

TRANSMISSION OVERHAUL: *After removal from case, overhaul sub-assemblies or units as follows:*

Planetary Unit Clutch: Place unit on bench with clutch flange upward.

Disassembly—1) Remove clutch flange retainer ring, lift out clutch flange retainer. Remove clutch flange assembly from clutch drum. Remove clutch hub thrustwasher, hub, and all clutch plates from clutch drum.

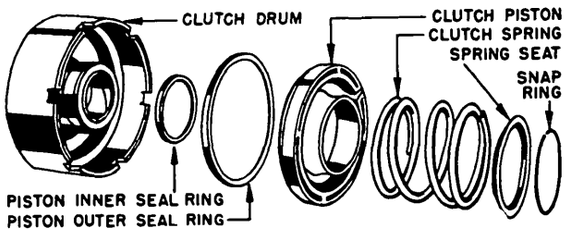
2) Place clutch drum in bench press, install spring compresion tool J-5133 and compress spring enough to remove snap ring, use KMO-410 pliers to remove snap ring. Relieve spring pressure, remove tool, lift out clutch spring seat and spring.

3) Rap clutch drum face down on a wood block to dislodge clutch piston, lift piston out, remove outer seal ring from piston and inner seal ring from clutch drum hub.

Inspection—Wash all parts in cleaning solvent and dry with air. Inspect drum brake band surface for scoring or burning, check drum bushing for scoring or excessive wear. See that clutch flange does not have any appreciable play in drum slots. Check all clutch plates for burning or galling, see that composition plates are free fit on clutch hub and that steel plates are free fit in clutch flange. Check low sun gear for nicked or burred teeth. Inspect relief valve steel ball in clutch piston and make certain that ball is free to move in hole and that orifice to rear of piston is open. If necessary, replace ball as follows:

Relief Valve Check Ball Replacement—Remove staking and remove ball. Inspect hole and ball seat and make certain it is free from burrs or nicks, see that new ball seats perfectly. Insert ball and carefully stake around edges of hole so that ball cannot fall out. *CAUTION—Ball must be free to move in hole after staking completed.*

►*REPLACEMENT PARTS CAUTION: See Chevrolet Changes, Cautions, Corrections for clutch production changes and latest type replacement parts.*



Reassembly—1) Install new outer seal ring on clutch piston with lip of seal toward pressure side of piston *(CAUTION*—use care not to stretch seal). Install new inner seal ring on inner hub of clutch drum with lip of seal toward bottom of clutch pocket.

2) Lubricate inner diameter of clutch drum and both seals with transmission oil, carefully install piston in clutch drum using a piece of feeler stock to insure seating of outer seal ring in clutch drum.

3) Install clutch spring and spring seat, use tool J-5133 in an arbor press to compress spring *(CAUTION*—Make certain spring does not hang up in snap ring groove which would damage spring seat and groove), install snap ring. Release pressure, remove tool.

4) Install thrustwasher on clutch hub *(CAUTION*—see that four tabs on washer fit into slots in clutch hub), install clutch hub and thrustwasher on clutch flange with open side up. Install five steel and four composition clutch plates, starting with a steel plate and alternating plates *(NOTE*—Steel plates are "waved" and can be installed either side up). Install clutch drum assembly on clutch flange assembly, then invert entire unit, install clutch flange retainer and flange retainer ring.

5) Check endplay using a feeler gauge inserted between clutch flange drive lug and drive slot in drum. This endplay must not exceed .013". Adjust by installing retainer ring of correct thickness to provide correct endplay. *NOTE*—Retainer ring furnished .055", .064", .073" thick.

POWERGLIDE CLUTCH PISTON ASSY.

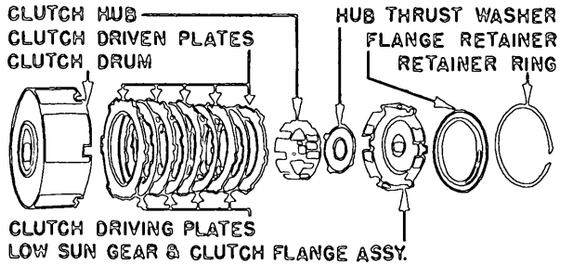
Modulator: Disassembly—Carefully lift out hydraulic pistons and place in safe position so they will not be damaged. Take out outer cover attaching screws **while holding cover down** against the spring pressure, lift off cover, remove diaphragm spring and diaphragm.

Inspection—Wash all parts in cleaning solvent, blow out all passages, dry with air. Check modulator cover for cracks, check diaphragm for wear or cracks, check diaphragm spring for distortion or loss of tension. Inspect hydraulic pistons for nicks or wear, see that pistons operate freely in modulator bore.

Reassembly—Place assembly tool J-5389 in hydraulic piston bore in modulator, assemble diaphragm and diaphragm spring. Install two 10—24 x 3" guide pins (part of Pilot Stud Set J-3387) in modulator body and install cover over guide pins. Install attaching screws and tighten securely. Install hydraulic pistons with crowned end toward modulator lever and diaphragm.

Servo Cover: Disassembly—Take out retaining screw and remove lubrication valve bi-metal strip and retainer. Remove lubrication by-pass valve plug and copper gasket, remove by-pass ball spring and ball. Do not remove modulator control lever.

Inspection—Wash all parts in cleaning solvent, blow out all passages, dry with air. Inspect cover for cracks, nicks, or burrs on mounting face. Check by-pass ball spring and valve bi-metal strip for distortion. See that modulator lever operates freely without binding. *CAUTION—Lever must not bind on guide pin.*



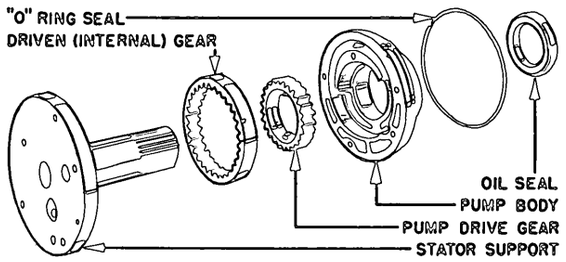
Reassembly—Install valve by-pass ball, spring, and plug (use new gasket), tighten plug to 17-20 ft.lbs. torque. Install bi-metal strip retainer, bi-metal, and retaining screw, tighten screw securely.

Front Pump: Disassembly—Slide stator support out of pump body, lift out pump gears (CAUTION—use extreme care not to drop or nick gears), remove and discard "O" ring seal.

CONTINUED N NEXT PAGE

POWERGLIDE (Continued)

Inspection—Wash all parts in cleaning solvent and dry with air. Inspect pump gears for wear, nicks, or other damage. Inspect pump body and pump face of stator support for nicks and scoring. Inspect pump body oil seal for excessive wear, damage, or evidence of leaking (see Oil Seal Replacement below). Inspect pump body bushing for galling or scoring, check bushing wear or clearance as directed below. Check pump gear clearances as follows:



POWERGLIDE MULTIPLE DISC CLUTCH

1) Pump Gear Clearances—Install clean, dry gears in pump body, check clearances with feeler gauge:

Drivem Gear Clearance—.0025-.0055" clearance between outer diameter of gear and pump body.

Driving Gear Clearance—.003-.009" clearance between end of gear teeth and crescent.

Gear End Clearance—Place scale across face of pump body, measure clearance between scale and face of gears. This clearance should be .0005-.0015".

POWERGLIDE FRONT OIL PUMP

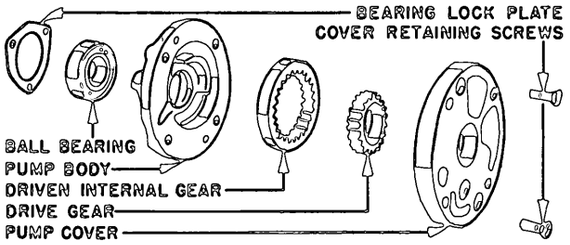
2) Pump Body Bushing Clearance—Temporarily install pump body on converter pump hub, measure bushing-and-hub clearance with a feeler gauge. This clearance should be .0005-.0025".

3) Oil Seal Replacement—Pry out old seal, use special driver J-5386 to press new seal in place in pump body.

Reassembly—Install new "O" ring seal in pump body, oil pump gears thoroughly with transmission oil and install in pump body, install stator support through pump body and driving gear and line up attaching bolt holes.

Rear Pump: Disassembly—Take out two screws and remove pump body plate, lift out pump gears.

Inspection—Wash all parts in cleaning solvent, blow out all oil delivery holes, dry with air. Inspect pump body for nicks and scoring, inspect gears for wear, nicks, or other damage. Check gear clearances (clearances are same as for front pump—see Pump Gear Clearances above). Inspect rear bearing for roughness but do not remove bearing unless replacement required (see Bearing Installation below).



Pump Bearing Replacement—Remove three retaining capscrews, lockwashers, and lockplate. Drive old bearing out. Press new bearing in place, install lockplate and retaining screws and lockwashers, tighten screws securely.

Reassembly—Oil pump gears thoroughly with transmission oil and install in pump body. Install pump body plate and two slotted attaching screws, tighten screws to 3½-5 ft.lbs. torque.

Valve Body: *NOTE—Accumulator not used on late 1953 & 1954 transmissions (see Production Change Note above). When overhauling late 1953 & 1954 valve body, disregard the following Accumulator data.*

▷*VALVE BODY CAUTION: Handle all valves with care to avoid damage, keep valve and spring assemblies separate to avoid confusion and interchange of parts.*

Disassembly—1) Use Pliers J-4245 to remove the special snap ring retaining accumulator valve, remove accumulator parts: Valve Spring Washer, Valve Spring, Valve, Valve Body Assembly, Piston, Inner and Outer Springs, and Piston Stop.

POWERGLIDE REAR OIL PUMP

2) Remove Clutch Low Servo Valve Assembly (located in inner face of valve body).

3) Support valve body on wooden blocks (face down), use a small pin punch to drive out pressure regulator governor valve retaining pin from body, withdraw pressure regulator governor valve spring and valve.

4) Drive out converter pressure regulator valve retaining pin (same procedure as 3 above), withdraw converter pressure regulator valve spring and valve.

5) Remove the two clutch drum oil seal rings from oil delivery sleeve of the valve body (*NOTE*—rings have interlocking ends which must be freed by pressing one end into the groove and pushing opposite end out until ends are unlocked).

Inspection—Wash all parts in cleaning solvent, blow out all passages, dry with air. Inspect valve body for nicks or burrs on mounting face, check all valve bores for scoring. Inspect all valves for wear, scoring, or galling, make certain valves operate freely in valve body bores. Inspect all valve springs for distortion or damage. See that small fibre valve in accumulator valve body assembly and bakelite valve in low servo valve assembly operate freely. Inspect oil seal rings for nicks or burrs, see that rings are free in ring grooves. Install rings in clutch drum bore and make sure hooked ends have clearance.

Reassembly—Install all parts in reverse order of disassembly (above) with particular attention to following points:

Accumulator Installation—Install inner and outer springs and piston stop in accumulator piston and then install this assembly in the valve body bore.

NOTE—Accumulator not used on later Chevrolet and Pontiac transmissions.

Converter pressure regulator valve and pressure regulator governor valve retaining pins—After each valve and spring installed in valve body, place body face down on wooden block and drive retaining pin in hole in body so that it retains the spring and valve.

Low-and-Drive Valve Body: *CAUTION—Do not disturb Throttle Valve Adjustments (two adjusting screws—one in boss on valve body and one in throttle valve inner lever) unless required by installation of new parts. THROTTLE VALVE MUST BE ADJUSTED IF THESE SETTINGS DISTURBED (see Throttle Valve Inner Lever Adjustment).*

Disassembly—1) Remove valve body-to-side cover attaching bolts and lockwashers. While holding detent valve in place, use soft hammer to carefully tap inner face of side cover until it is free of the locating pins (*CAUTION*—Use care to keep parts from falling out and being lost or damaged while performing this opertion).

2) Withdraw detent valve, spring, spring seat, and throttle valve spring regulator assembly from valve body. Remove throttle valve spring and throttle valve.

3) Use Pliers J-5403 to remove special snap ring retaining low-and-drive regulator valve cap, then remove the valve parts as follows: Valve Cap, Sleeve and Valve (as an assembly), Inner and Outer Springs, and Valve.

4) Take out two attaching screws and remove clutch exhaust cover plate ("L" shaped strip) from the side of the valve body.

5) Take out three attaching screws and lockwashers in end plate (CAUTION—exert pressure on plate while removing screws to prevent parts flying out), remove plate, remove valve parts as follows: Clutch Exhaust Secondary Control Valve, Spring, Stop (from upper valve bore), Clutch Exhaust Primary Control Valve Spring, Stop, Valve (from center valve bore).

6) Remove throttle valve outer lever assembly, shield, and inner lever assembly (CAUTION—do not disturb adjusting screw in inner lever unless required by parts replacement). Remove throttle valve lever shaft seal.

Inspection—Wash all parts in cleaning solvent, blow out all passages, dry with air. Inspect all valves for nicks, burrs, scoring, or galling. Check all valves for free operation in their respective bores. Inspect all valve springs for distortion or damage. Inspect throttle lever assembly shaft for wear, scoring, or galling, see that shaft operates freely in side cover and that inner lever is tight on shaft. Inspect detent valve stop in side cover for distortion or dam-

CONTINUED ON NEXT PAGE

POWERGLIDE (C ntinued)

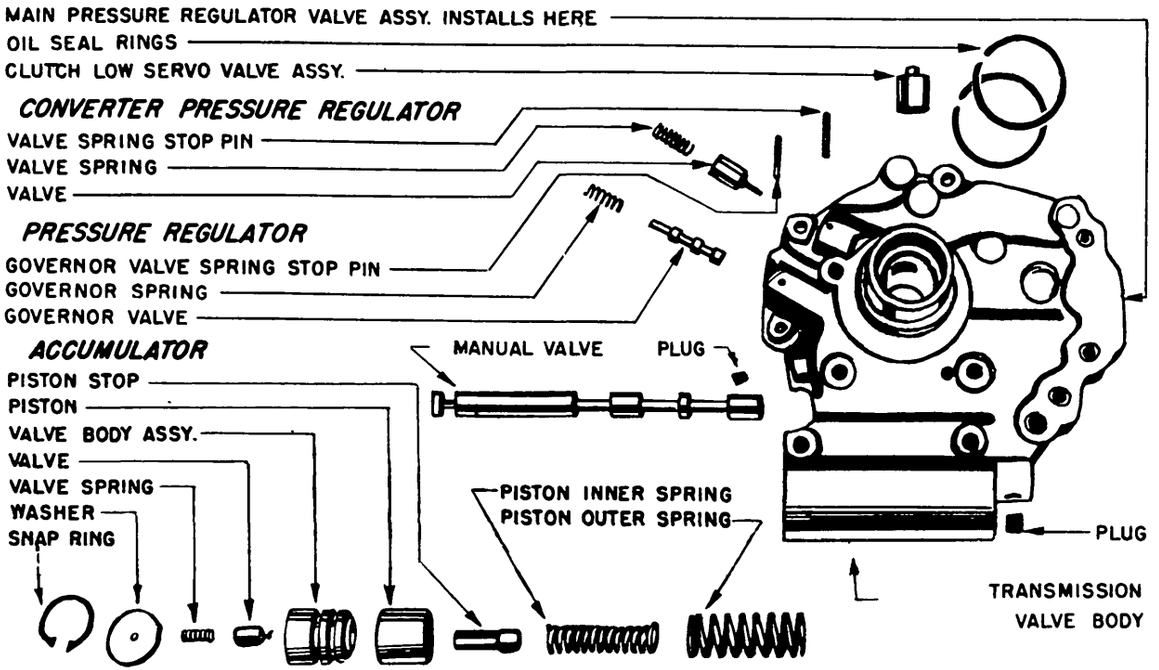
age, install new stop if necessary. Inspect locating pins in valve body and side cover for distortion or damage (one pin should be in side cover, other pin in valve body), replace pins if necessary. Inspect mating surfaces of valve body and side cover and make certain they are free of nicks or burrs.

Reassembly—1) Install low-and-drive valve in body bore (CAUTION—valve must be guided to prevent damage to the bore—use a piece of brake tubing inserted in valve shank bore at rear of valve body, engage nib on valve in end of tubing, move valve into position slowly). Install remaining low-and-drive valve parts in reverse order of disassembly (install regulator valve and cap on valve sleeve first and then install in valve bore as an assembly making certain inner spring is seated on sleeve). Compress assembly in valve bore while installing special snap ring, make certain ring properly seated in groove in valve body.

2) Install clutch exhaust secondary and primary valve assemblies (CAUTION—use care not to confuse these valve parts—primary control valve stop is the longer of the two stops, and primary control valve spring is the shorter of the two springs). Install throttle valve spring and valve in valve body, then install end plate and hold plate in position while tightening end plate attaching screws, tighten these screws to 2½-3½ ft.lbs. torque.

3) Install throttle valve spring regulator assembly in valve body and see that it is seated on throttle valve spring. Install detent valve spring seat, valve spring, and valve (thread pin of the throttle valve spring regulator assembly through the opening in the spring seat and valve).

4) Clamp side cover in a vise (face upward), align locating pin in side cover with hole in valve body, exert pressure on valve body to keep locating pin in the hole and at the same time compress detent valve in valve body bore and rotate valve body counter-clockwise until the locating pin in the valve body enters the locating hole in the side cover (CAUTION—make certain face of detent valve is resting against stop pin in side cover). Install attaching bolts and lockwashers, tighten bolts evenly to 3½-5 ft.lbs. torque.

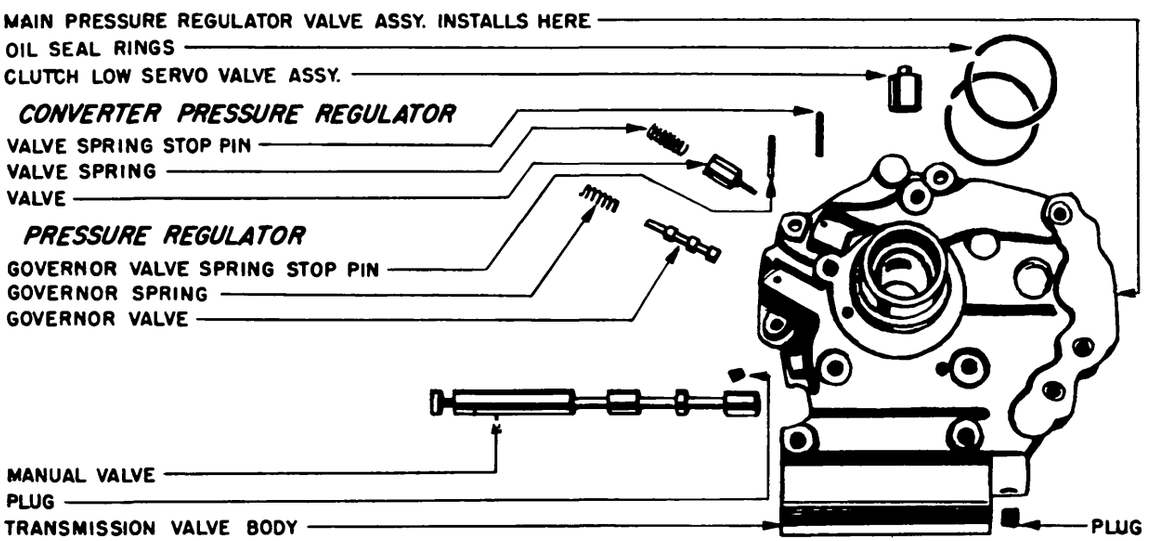


5) Install throttle valve inner lever assembly in side cover, install new seal on shaft and into counterbore in cover, install shield. Install outer lever assembly on inner lever shaft, install outer lever attaching bolt from underside, tighten nut securely.

If lever adjustments disturbed during overhaul, readjust throttle valve as follows:

►**1953 Throttle Valve Inner Lever Adjustment:** *CAUTION—Two adjustments required. Adjust valve in the following order.*

1) Rotate throttle valve inner lever until it just contacts face of detent valve, **hold lever in this position,** turn long adjusting screw (in boss in valve body) in until it just contacts the flat surface of the step on the lever, then **back screw out one complete turn** and lock screw in this position by tightening the locknut securely.



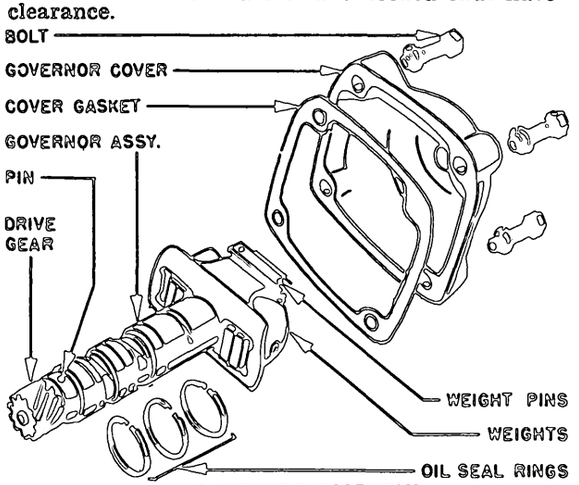
2) Install Throttle Valve Inner Lever Positioning Gauge J-5385 between the face of the detent valve and the throttle valve inner lever. Hold gauge in this position and turn the shorter adjusting screw (in end of inner lever) in until it just contacts the threaded body of the longer adjusting screw, lock the adjusting screw by tightening the locknut securely.

EARLY 1953 POWERGLIDE VALVE BODY ASSEMBLY

►**1954 Throttle Valve Inner Lever Adjustment:** Rotate throttle valve inner lever until it just contacts face of detent valve. Hold lever in this position and turn adjusting screw until it just contacts

CONTINUED ON NEXT PA E

LATE 1953 & 1954 POWERGLIDE VALVE BODY ASSEMBLY



POWERGLIDE (Continued)

flat surface of the step in the lever. Back off one complete turn and lock in this position by tightening the adjusting screw locknut securely.

Governor: *CAUTION—Governor oil seal rings are only parts furnished for service (other than Governor Assy.) so that governor should not require disassembly except for cleaning and removal of foreign material causing incorrect operation. All parts are calibrated and selective fit.*

Disassembly—Cut off one crimped end of each governor weight pin and remove pins *(CAUTION—* Pin diameter should be measured with micrometer so that same gauge piano wire can be used when reassembling governor—calibration will be upset if other size wire used). Lift off governor thrust cap and weight assemblies, withdraw governor valve from sleeve, remove oil seal rings from governor sleeve *(NOTE—*rings have interlocked ends which must be freed by pressing one end into groove and pushing other end out until ends are unlocked).

Inspection—Wash all parts in cleaning solvent, blow out all passages, dry with air. Inspect governor sleeve and governor valve for nicks, burrs, scoring, or galling; see that sleeve is free in transmission case bore and that valve operates freely in sleeve. Inspect driven gear for wear, nicks, burrs, or other damage and make certain gear is tight on sleeve. Inspect weights for free operation in their retainers and see that springs are not distorted or damaged *(CAUTION—*DO NOT disassemble weights). Inspect oil seal rings for damage, make certain rings are free in grooves, install rings in governor bore in transmission case and see that hooked ends have clearance.

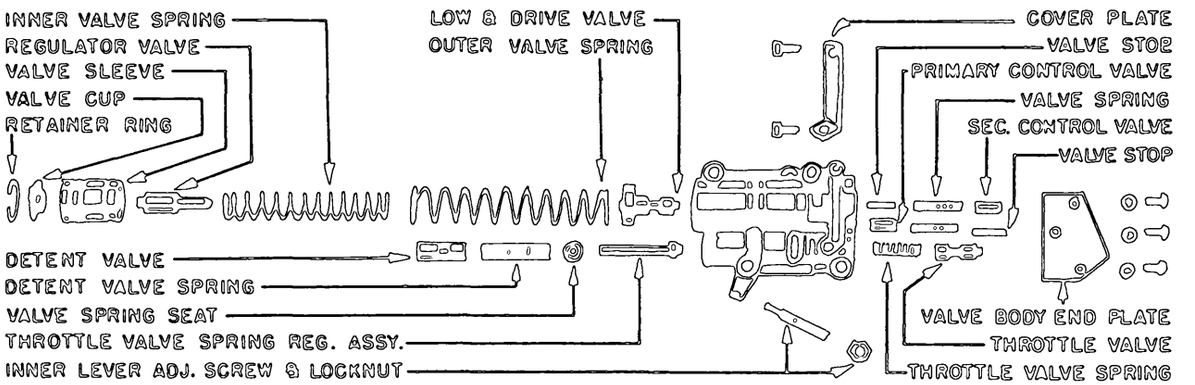
GOVERNOR ASSEMBLY

Reassembly—Install oil rings on governor sleeve and make certain ring ends are properly hooked together. Install governor valve, weight assemblies, and thrust cap, install new pins using same gauge piano wire as original pins, crimp both ends of pins to retain them in place. Make certain weight assemblies operate freely on pins.

Low Servo Piston: Disassembly—Place piston assembly in bench press supporting notched end of shaft on wooden block, install tool J-3377 (same tool used for Reverse Servo) on top of piston, compress spring sufficiently to enable rod retainer "C" washer to be removed from end of rod, relieve spring pressure, remove piston, spring, and washer from piston rod. Remove piston ring from piston.

Inspection—Wash all parts in cleaning solvent, dry with air. Inspect all parts for wear or damage. Install piston ring in low piston bore and check ring gap with feeler gauge. Gap should be .005-.010".

Reassembly—Assemble all parts on piston rod, compress spring in bench press and install piston rod retainer making certain that it is properly seated in groove. *CAUTION—Spring pressure is 150 lbs. and assembly must be handled carefully.*



Reverse Servo Piston: Disassembly—Place assembly in bench press with spring end up, install tool J-3377 on spring retainer, compress spring sufficiently to enable retainer key locks to be removed, relieve spring pressure, lift off retainer, springs, and piston. Remove piston ring from piston.

Inspection—Wash all parts in cleaning solvent, dry with air. Inspect all parts for wear or damage. Install piston ring in reverse piston bore and check ring gap with feeler gauge. Gap should be .005-.010".

Reassembly—Assemble all parts on piston rod, compress spring in bench press and install retainer locks, make certain locks seated properly in rod groove.

Planet Carrier Assembly: *Should not be disassembled unless inspection below indicates overhaul required. See Planet Carrier Overhaul below.*

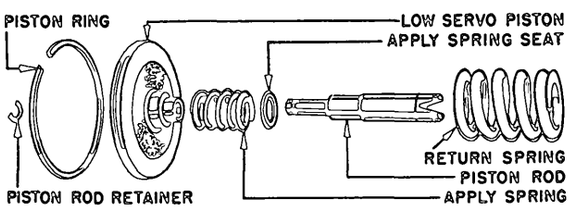
Inspection—Wash in cleaning solvent, blow out all passages, dry with air. Inspect all gear teeth for nicks, scoring, or other damage. Check end clearance of planetary pinions with feeler gauge inserted between ends of pinion and thrustwasher. This clearance should be .006-.030". Check reverse sun gear rear thrustwasher for wear or damage. Inspect drum bushing for wear, scoring, or damage; inspect outer diameter of drum for scoring or burning. Check output shaft bearing surfaces for wear, nicks, or scoring. Check input pilot bushing for wear or scoring.

POWERGLIDE LOW & DRIVE VALVE BODY ASSY.

Planet Carrier Overhaul: *If inspection (above) indicates that parts require replacement, proceed as follows:*

Disassembly—Place assembly in holding fixture or clamp in a vise with front end upward. Mark each pinion shaft and also mark planet carrier (use prick punch or other means) so that shafts can be re-installed in same position *(CAUTION—*pinion shafts are selective fit in carrier and location must not be changed). Then proceed as follows:

1) Remove pinion shaft lockplate screws, rotate plate counter-clockwise until it is free and remove the plate.



2) Starting with one short planet pinion, use a soft steel drift to drive on lower end of pinion shaft until shaft raised above the press-fit area of the output shaft flange, then insert tool J-4599 (one piece only —second piece of tool set used for reassembly) into short planet pinion from lower end and push shaft out until tool is centered in the pinion and shaft is removed. Remove short planet pinion from assembly. Remove tool from pinion, remove needle bearings and needle bearing spacer *(CAUTION—*use care not to lose any of the needle bearings).

3) Remove adjacent long planet pinion (paired to the just-removed short pinion by using same thrustwashers) by repeating procedure in step (2) above. Then remove the pinion upper and lower thrustwashers.

4) Remove all remaining planet pinions in pairs (short pinion first, followed by long pinion) by following procedures in steps (2) and (3) above.

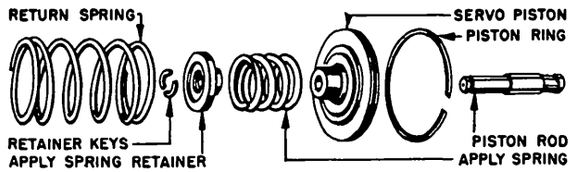
5) Remove reverse sun gear and sun gear thrustwasher.

CONTINUED ON NEXT PAGE

POWERGLIDE LOW SERVO ASSY.

POWERGLIDE (C ntinu d)

Inspection—Wash all parts in cleaning solvent and dry with air. Inspect all pinion gears and reverse sun gear for nicked or otherwise damaged teeth, inspect all thrustwashers for wear, nicks, or scores. Inspect needle bearings for wear and replace all needle bearings if worn excessively.



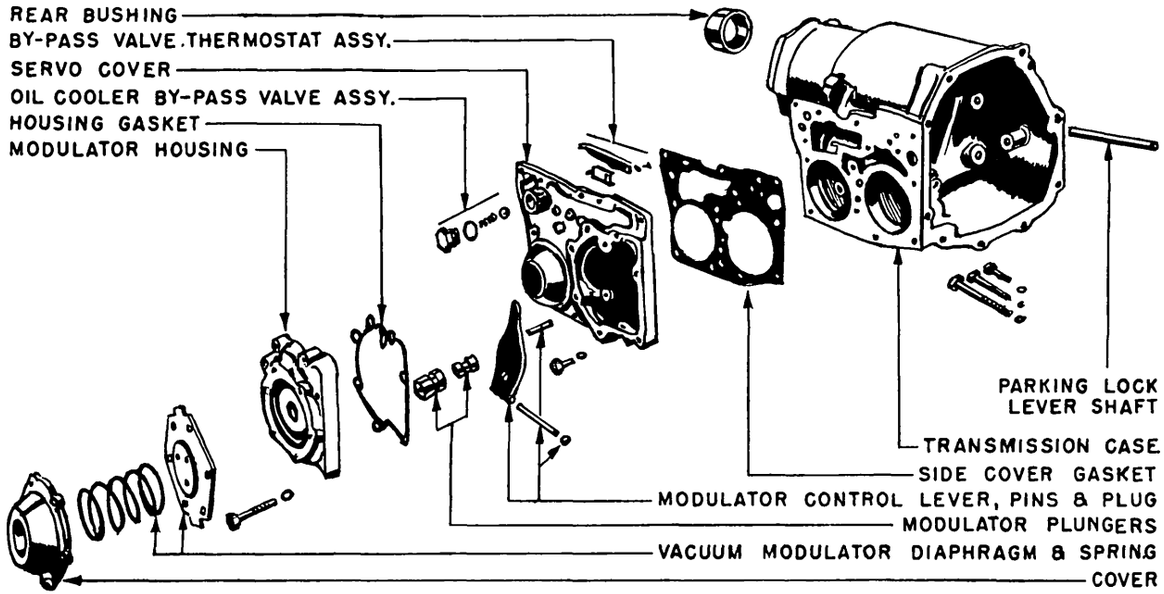
Reassembly—***CAUTION—Pinion shafts must be reinstalled in accordance with marks made before disassembly (shaft is selective fit in particular hole in carrier).*** Assemble and install parts as follows:

1) Install tool J-4599 in one long planet pinion, assemble needle bearing spacer and needle bearings in pinion (20 at each end) using cup grease to hold needle bearings in position.

2) Install pinion assembly in planet carrier with tool centered in assembly and with thrustwasher at each end of pinion. *NOTE*—Long pinions are located opposite closed portion of carrier, short pinions are located opposite carrier openings. Feed the second part of tool J-4599 in from the top of the planet carrier *(CAUTION*—make certain tool picks up thrustwasher) and push first part of tool down and out at the lower end *(CAUTION*—make certain this tool picks up thrustwasher as it is pushed down). Lubricate correct pinion shaft (see Reassembly Caution above) and install it from top pushing the assembling tools out ahead of it. Turn shaft so that slot in upper end faces toward center of assembly, tap shaft down with a brass or soft steel drift until lower end is flush with lower face of carrier.

3) Assemble and install **adjacent** short planet pinion (paired with just-installed long planet pinion by using same thrustwashers) by repeating procedure in steps (1) and (2) above.

4) Install reverse sun gear thrustwasher and reverse sun gear.



POWERGLIDE REVERSE SERVO ASSY.

5) Install all remaining planet pinions in pairs (long pinion first, followed by short pinion) by following the procedure in steps (1), (2), (3) above.

6) Check end clearance of planet pinions using feeler gauge inserted between end of pinion and thrustwasher. This clearance should be .006-.030".

7) Install pinion shaft lock plate with extended portions in line with pinion shaft slots, rotate plate clockwise until plate locks all pinion shafts and attaching screw holes line up. Install lock plate attaching screws and tighten to 2½-3 ft.lbs.

Input Shaft: Inspect shaft splines for wear, nicks, or other damage. Check spline fit in clutch hub, reverse sun gear, and converter hub. Inspect oil seal ring for wear and free fit in groove, remove ring (compress one end, push other end outward to free locked ends) and install ring in valve body bore to make certain hooked ends have clearance, then reinstall ring on shaft. Check snap ring in groove at forward end of shaft (this ring first used in 1953 transmissions and prevents shaft floating forward), replace if worn or damaged using snap ring pliers KMO-410.

POWERGLIDE TRANSMISSION CASE, SERVO COVER, & MODULATOR ASSY.

Transmission Case & Rear Bushing: Check case for cracks, inspect rear bushing for wear or damage and replace if necessary.

Bushing Replacement—Press old bushing out using tool J-4275 in an arbor press (place case on press with rear end upward). Install rear oil pump in case so that rear bearing can be used as a pilot in installing new bushing. Place case on press with front end upward, assemble bushing on Installer Tool J-4276 (square end of bushing against shoulder on tool), enter tool pilot in rear bearing, press new bushing into place. Bushing is precision type and does not require reaming.

Low & Reverse Brake Bands: Inspect bands for wear, cracks, and scored or burnt lining. Lining is bonded to band. Inspect linkage for wear.

REASSEMBLY

AFTER ALL MAJOR UNITS REASSEMBLED (See Overhaul above), install units as directed below using ALL NEW GASKETS AND SEALS and tightening all parts evenly to SPECIFIED TORQUES.

CONVERTER HOUSING ASSEMBLY: *Install units:*

Valve Body: First install suction screen in oil sump *(CAUTION*—screen must be thoroughly cleaned), see that sealing ring is in place. Install two ¼—20 x 3½" guide pins (part of Pilot Stud Set J-3387) in two valve body attaching bolt holes, place new valve body gasket in position over guide pins, install valve body assembly. Install all attaching bolts *(CAUTION*—lower left bolt over accumulator bore is special self-locking type and must be installed in this position), tighten all bolts evenly in a criss-cross pattern to 7½-10 ft.lbs. torque. **Check manual valve and pressure regulator valve for free operation after all bolts tightened.**

Front Pump: Align holes in stator support with mounting holes in pump body, install two ¼—20 x 3½" guide pins (part of Pilot Stud Set J-3387) in pump mounting holes, use Driver J-4263-5 to install pump in converter housing *(CAUTION*—line up suction and oil delivery holes on left side of pump). Install five self-locking bolts through valve body and into pump, tighten all bolts evenly to 7½-10 ft.lbs. torque. ***CAUTION—Check pressure regulator valve for free operation after bolts tightened and make certain that pump operates freely.***

Low-and-Drive Valve Body: Install two 5/16—18 x 3" guide pins (part of Pilot Stud Set J-3387) in two valve body mounting bolt holes on left side of converter housing, place new gasket in position over guide pins, install valve body assembly. Install attaching bolts and lockwashers, tighten bolts evenly to 12½-15 ft.lbs. torque.

TRANSMISSION CASE ASSEMBLY: Install units·

Rear Pump: Install two 5/16—18 x 3" guide pins (part of Pilot Stud Set J-3387) in pump attaching bolt holes, place new gasket in position over guide pins, install pump *(CAUTION*—align oil suction and delivery holes), tighten pump mounting bolts evenly to 12½-15 ft.lbs. torque.

Lubrication Pressure Relief Valve: Make certain that valve is clean and openings free from obstructions, see that valve disc and spring operate freely. Install relief valve in mounting hole in rear of transmission case and tighten securely.

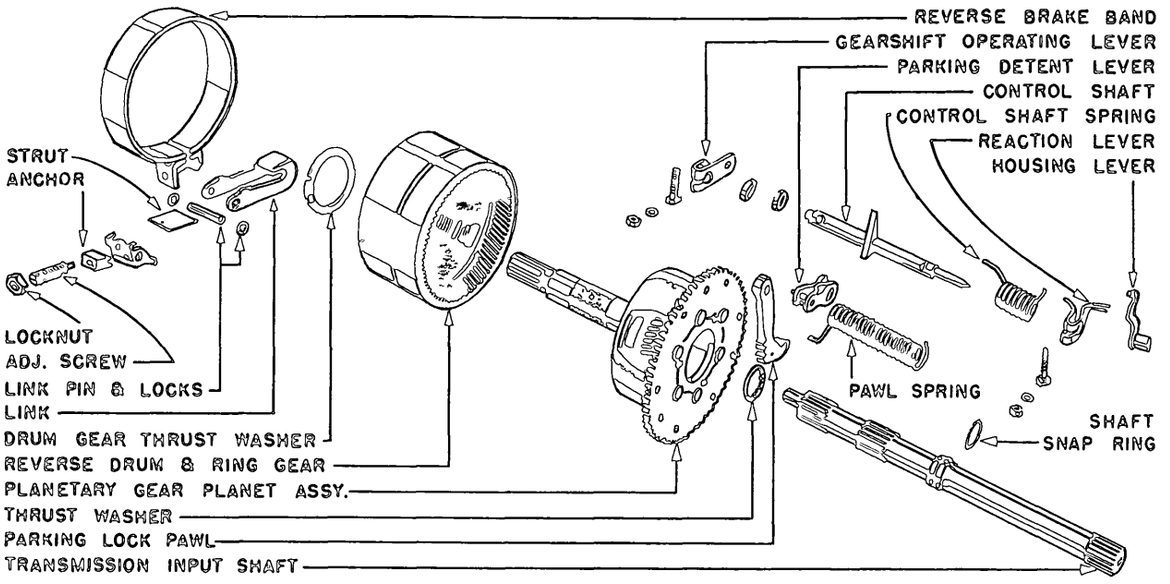
Reverse Servo Piston, Band, & Drum: Compress piston ring with Ring Compressor J-3365, install servo piston in case with notch in shaft toward front of case. Install reverse brake band and strut assem-

C NTINUED ON NEXT PAGE

POWERGLIDE (Continued)

bly with thin end of band away from piston, thread adjusting screw in until it indexes with hole in anchor. Install bronze thrustwasher on reverse drum hub, install drum in case and into brake band. *DO NOT adjust band at this point.*

Planet Carrier Assembly: Rotate rear pump so that drive lug is at top of pump, install planet carrier assembly in case aligning slot on carrier shaft with pump drive gear lug *(CAUTION*—Shaft must protrude out of rear bearing a minimum of 7/8" indicating proper seating of drive lug in carrier shaft slot). Install tool J-938 on rear of transmission case (thread shaft tool into rear end of output shaft, bolt tool yoke on rear face of case), turn tool handle counter-clockwise to seat output shaft in rear bearing, then remove tool. Install universal joint front yoke, washer, lockwasher, and bolt; tighten bolt to 25-30 ft.lbs. torque.



Reverse Band Adjustment: Adjust band at this point. *See BAND ADJUSTMENT.*

Transmission Endplay Check & Adjustment: After planet carrier assembly installed in case, the correct thickness of the low sun gear-to-reverse sun gear thrustwasher must be determined for the correct transmission endplay of .007-.035" as follows:
(1) Use Tool J-4260 to measure distance from face of transmission case flange to face of reverse sun gear in planetary unit (place tool bar against case flange, extend tool stem until it contacts gear face), tighten thumbscrew to retain this tool setting.
(2) Install bronze thrustwasher and clutch assembly temporarily on oil delivery sleeve.
(3) Without disturbing tool setting obtained in step 1 (above), place .120" steel washer over tool pilot (short plug on tool bar), install tool over clutch assembly with tool pilot entered in low sun gear and tool stem against gasket on rear face of housing. Use feeler gauge to measure clearance between face of low sun gear and steel washer on tool pilot. If clearance not within .007-.035", repeat this procedure with .095" or .145" steel washer on tool pilot.
(4) When correct clearance of .007-.035" secured in step 3 (above), note thickness of steel washer used on tool and select bronze thrustwasher of same thickness for installation on input shaft splines at final installation (below). Remove clutch assembly and thrustwasher from oil delivery tube.

▷Thrustwasher Note—This bronze thrustwasher furnished in three thicknesses as follows: Part No. 3694467—.095", No. 3694468—.120", No. 3694469—.145".

Parking Lock Mechanism: Install parking lock lever shaft assembly in case, install seal over end of parking lock lever shaft and into counterbore in case with lip seal toward inside of case. Install flat washer and parking lock lever on end of shaft, push lever on shaft for clearance of .000-.010" between lever and washer, tighten clampscrew to 8-12 ft.lbs. Install parking lock pawl over pawl support rod, install parking lock pawl spring, wind up pawl spring (tool J-3383) until spring catches on case.

Input Shaft & Clutch Assembly: Install input shaft in clutch unit. Install bronze thrustwasher selected in "Transmission Endplay Check & Adjustment" (above) on reverse sun gear splines of input shaft *(CAUTION*—flat side of washer must be toward reverse sun gear). Install assembly in case indexing input shaft pilot with pilot in output shaft and mesh low sun gear with short planetary pinions.

POWERGLIDE PLANET CARRIER ASSY., REVERSE BAND, & PARKING LOCK

Low Servo Piston & Band Assembly: Install release spring on servo piston rod, use Ring Compressor J-3365 to compress piston ring and install assembly in transmission case. Install low brake band over the drum. Install apply strut guide spring over piston rod, engage apply strut in piston rod slot and engage opposite end of strut in the band. Engage anchor strut assembly in band groove and locate opposite end of anchor over the adjusting screw. *DO NOT adjust the band at this point.*

Governor: Install governor assembly in bore in transmission case *(CAUTION*—Governor must be allowed to rotate counter-clockwise as gear teeth mesh and care must be taken not to damage gear teeth). Install two 5/16—18 x 3" guide pins (part of Pilot Stud Set J-3387) in governor cover mounting holes, place new gasket in position over guide pins, install governor cover, attaching bolts and lockwashers. Tighten cover bolts evenly to 6½-8½ ft.lbs. torque. Install speedometer driven gear assembly and tighten to 45-50 ft.lbs. torque.

TRANSMISSION & CONVERTER HOUSING ASSEMBLY:
1) Install manual valve in valve body and manual valve inner lever in converter housing. Index lever pin with pick-up slot in valve, set manual valve so that it protrudes 1½" out from face of valve body *(NOTE*—This is Reverse position).
2) Install new valve body-to-transmission case gasket.
3) Place transmission manual valve lever in top detent position *(NOTE*—this is Reverse position and will align reaction lever so that it will index with manual drive inner lever in converter housing).
4) Place clutch drum thrustwaher in position on oil delivery sleeve.
5) Install two ⅜—16 x 3¾" guide pins (part of Pilot Stud Set J-3387) in two opposite converter housing mounting bolt holes, carefully bring transmission case and converter housing together making certain that reaction lever indexes properly with manual valve inner lever. Install all case-to-housing bolts and tighten evenly to 25-30 ft.lbs. Install special self-locking bolt through front face of converter housing and tighten this bolt to 25-30 ft.lbs.
6) Install two 5/16—18 x 3" guide pins (part of Pilot Stud Set J-3387) in two servo cover attaching bolt holes, place new gasket in position over guide pins. Install pressure regulator valve and inner and outer valve springs (see Note below) through servo and into case, install reverse servo return spring. Install servo cover over guide pins *(CAUTION*—see that pressure regulator springs and reverse servo spring seat properly in pockets in cover), maintain pressure on cover while installing and tightening cover bolts, tighten bolts evenly to 12½-15 ft.lbs.
7) Install modulator cover with a new gasket, tighten attaching bolts to 12½-15 ft.lbs.
8) Adjust Low Servo Band. *See BAND ADJUSTMENT.*
9) Install converter assembly in converter housing making certain that front pump drive lugs aligned with drive slots in converter pump hub (see Installation Check below). Install converter holding tool J-5384 using one housing bolt to hold tool (tool will prevent converter falling out while being installed on engine).

▷*CONVERTER INSTALLATION CHECK*—Check assembly for proper engagement of front pump drive lugs in converter pump hub slots by placing scale on one converter cover-to-flywheel mounting brac-

CONTINUED ON NEXT PAGE

POWERGLIDE (C ntinu d)

ket and measuring from edge of scale to face of mounting flange on converter cover. This dimension must not exceed 9/16".

10) Check and adjust position of throttle valve outer lever. *See step 2 (Chevrolet), step 4 (Pontiac) of THROTTLE LINKAGE ADJUSTMENT.*

CHEVROLET UNIVERSAL JOINT BALL ASSEMBLY: Install new "O" ring seal on universal joint ball seat. Temporarily install universal joint ball seat, **four** new ball shims, ball and collar but **do not install the cork ball joint collar oil seal.** Check and adjust the ball joint (see below). Then remove universal joint ball, collar, and seat and replace these parts together **with collar oil seal** on end of propeller shaft.

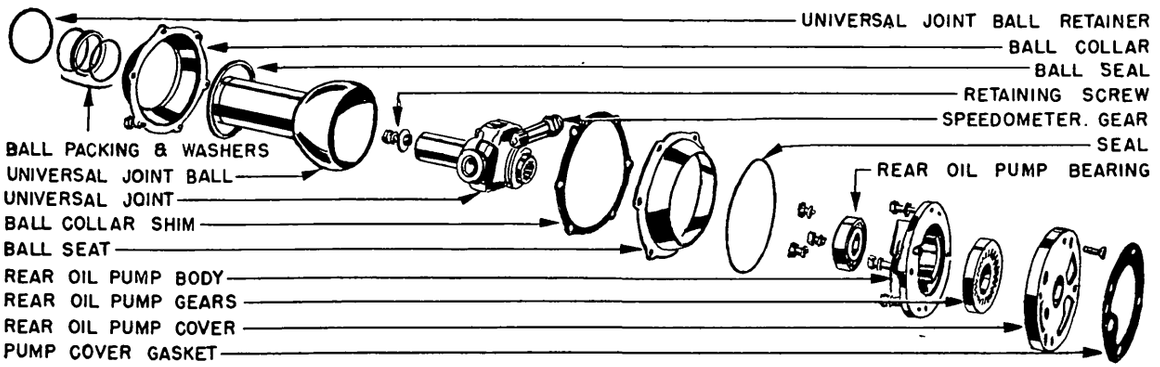
►**Universal Joint Ball Adjustment**—With all parts except collar oil seal installed on rear of transmission, ball should have a smooth firm adjustment. If ball cannot be moved by hand, add a shim and recheck adjustment. If ball moves freely by hand, remove one shim and recheck adjustment. After correct number of shims determined, place these shims to one side for later use when installing transmission.

INSTALLATION IN CAR

Install transmission in each car model as follows:

CHEVROLET TRANSMISSION INSTALLATION:

►*1953 FLYWHEEL & CONVERTER CAUTION:* First type flywheel & converter attachments consist of SIX 5/16"-24 bolts, later type with spoke type flywheel consisted of THREE 3/8"-24 bolts. Service flywheels furnished with three 5/16" holes and three 3/8" holes spaced alternately. When using old and new flywheel and converter combinations, install bolts as follows:



New Converter & Old Type Flywheel—Enlarge alternate holes in flywheel from 5/16" to 3/8" to take new 3/8"-24 bolts.

Old Converter & New Type Flywheel—Use six old type 5/16"-24 bolts.

1) Lubricate flywheel pilot with Lubriplate.

2) Raise transmission in place under car while lifting up on rear end, use pry bar if necessary to gain clearance at servo cover. *Use extreme care not to bump or damage flywheel pilot.*

3) Turn torque converter until "X" mark on turbine cover is lined up with "X" mark on flywheel as nearly as possible (to nearest bolt hole). *CAUTION—Alignment of marks is necessary to maintain balance.*

REAR OIL PUMP, UNIVERSAL JOINT, & JOINT BALL (CHEVROLET)

4) Remove converter holding tool. *CAUTION—After tool removed, use extreme care not to allow converter to move forward which would disengage pump drive lugs from converter hub slots.*

5) Using guide pin installed in converter cover (pin can be made up by cutting head off a 5/16" or 3/8" bolt), carefully enter guide pin in flywheel hole, raise or lower transmission to align flywheel pilot, enter pilot in flywheel. *CAUTION—DO NOT force transmission in place. guide transmission by hand until pilot enters and housings come together.*

6) Install transmission housing-to-bell housing bolts and tighten securely.

7) Remove guide pin and install flywheel-to-turbine bolts using 5/16"-24 or 3/8"-24 bolts as required. *See Flywheel & Converter Caution above.*

8) Install universal ball seat on rear of transmission case using a new "O" ring seal, connect universal joint, slide universal ball and collar forward on propeller shaft and fasten to case **using shim thickness determined in "Universal Joint Ball Adjustment" above** (under CHEVROLET UNIVERSAL JOINT BALL ASSEMBLY).

9) Connect linkage and other attachments. Fill transmission with lubricant (see LUBRICATION), adjust linkage (see LINKAGE ADJUSTMENT).

PONTIAC TRANSMISSION INSTALLATION:

1) Raise transmission into place from beneath car, removing converter holding tool J-5384. *CAUTION—After holding tool removed, use care that converter does not move forward which would disengage front pump drive lugs.*

2) Carefully align marks (as made before disassembly) on flywheel and converter front plate and front cover. *CAUTION—This is necessary to maintain balance (see VIBRATION OR UNBALANCE CORRECTION below).*

3) Install all flywheel housing-to-transmission bolts using correct bolt in each hole (see Note below), tighten bolts evenly to 25-30 ft. lbs. torque.

►**Flywheel Housing-to-Transmission Bolt Note**—All bolts are 5/16"-18 type but FOUR different lengths used as follows. **1 3/8" (4 used)** in topmost holes in housing, **7/8" (3 used)** two behind starter, one through oil pipe clip (two on right and one on left side directly below the above 1 3/8" bolts), **2 1/2" (2 used** one on each side directly below the above 7/8" bolts), **1 7/8" (2 used)** in bottom holes of housing. Use 5/16" heavy lockwashers on all bolts.

4) Install converter-to-flywheel attaching bolts working through hole in flywheel front housing, tighten these bolts evenly to 15-20 ft. lbs. torque. *CAUTION—Three 3/8" bolts are used and should be installed in the three 3/8" holes in the flywheel (other three holes in flywheel are 5/16" size and are not used). DO NOT attempt to install additional bolts in these flywheel bolt holes or in unused converter plate lugs.*

5) Install engine rear cross-member, and engine side support bracket attaching bolts, tighten left side support bracket-to-cushion and shim the assembly attaching bolt.

6) Connect linkage and other attachments. Fill transmission with lubricant (see LUBRICATION), adjust linkage (see LINKAGE ADJUSTMENT).

►*VIBRATION OR UNBALANCE CORRECTION:* If noticeable vibration or unbalance condition noted, remove converter front plate-to-flywheel attaching bolts, rotate converter assembly 120° on flywheel and re-install bolts. Check performance.

CHEVROLET POWERGLIDE TRANSMISSION

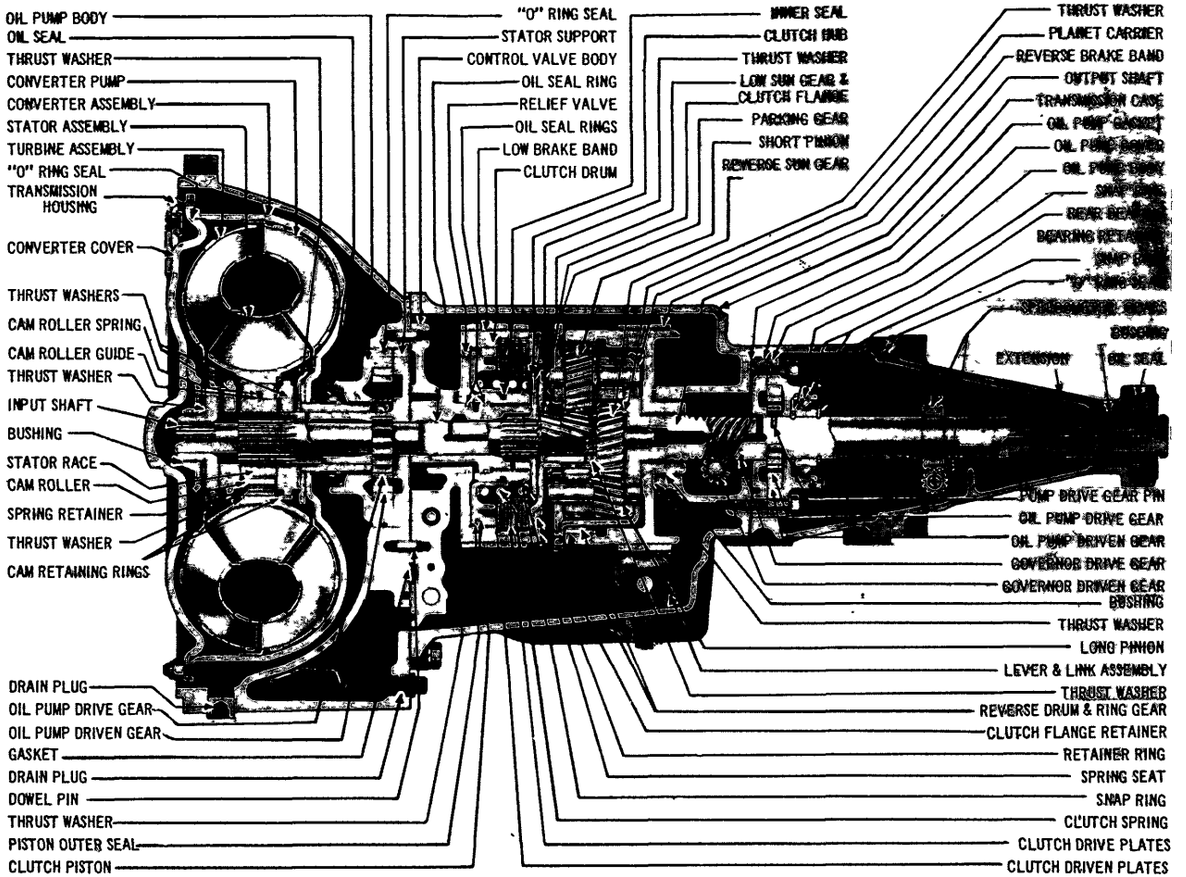
Chevrolet Pass. Cars (1955)
Chevrolet Corvette (1955)

►CHANGES, CAUTIONS, CORRECTIONS

►***STARTING ENGINE BY PUSHING CAR (Pushing recommended rather than Towing):*** Place selector lever in Neutral "N" position. When car reaches speed of approximately 16 MPH. (20 MPH. if road wet or icy with resultant poor traction), move selector lever to Low "L" position to crank engine. After engine started, move lever to "N" for engine warm-up.

►***CONTROL VALVE & GASKET PRODUCTION CHANGE AND SERVICE REPLACEMENT NOTE (To eliminate a harsh closed throttle downshift):*** A new control valve assembly, Part No. 3719234 (see "Later Type Control Valve Identification Note" below) entered production at Transmission Serial C-103-D. ***(NOTE*** —The later type control valve assembly is also furnished as a service replacement for transmissions before the above serial number). The later Valve Body & Case Gasket, Part No. 3719232 is NOT INTERCHANGEABLE with the early type gasket.

►**Later Type Control Valve Identification Note:** Transmissions between Serial Numbers C-103-D and C-128-N will be identified by an "X" stamped adjacent to Casting No. 3709023 on rear surface. After Transmission Serial No. C-128-N will have Casting No. 3719221 on rear surface.



►***CONTROL VALVE BODY & CASE GASKET CAUTION: Early and late type gaskets are not interchangeable. These gaskets are identical except for an additional elongated hole in the later gasket.***

►***CLOSED & FORCED THROTTLE VALVE SPRING RETAINER PRODUCTION CHANGE (To prevent retainer breakage):*** Spring retainers are increased in size from .134" to .148" beginning with Transmission Serial No. C-128-N. The larger retainers can be installed in valve bodies prior to the above serial number by drilling out the retainer hole with a 5/32" drill. Both retainers can be checked for being in the proper position by removing the right hand side cover. ***See "Trouble Shooting" (below) for conditions resulting from broken valve spring retainers.***

►***TRANSMISSION PLANET REVERSE RING GEAR & DRUM ASSEMBLY PRODUCTION CHANGE (to accommodate a new .020" steel thrust washer):*** Beginning in production with transmission serial number C-128-D, a new steel thrust washer is used between planet carrier and reverse gear and drum to prevent galling of thrust surfaces. A service package, Part No. 3721564, consisting of a Planet Reverse Ring and Drum Assembly, Part No. 3720472, and an Output Shaft Thrust Washer, Part No. 3720474, is available for service replacement on 1953-54 & Early 1955 models.

►***GOVERNOR PRESSURE TEST PLUG PRODUCTION CHANGE:*** Test plug on side of left hand side cover has been eliminated beginning in production with Trans. Serial No. C-428-D. Earlier model side covers will retain this plug.

►***CHECKING FLUID LEVEL & FILLING TRANSMISSION NOTE (AIR CONDITIONED CARS):*** A filler plug has been added to transmission side cover for use in checking fluid level and adding fluid to transmission. This change is made necessary because filler tube and dipstick is not accessible from under hood on air conditioned cars.

POWERGLIDE TRANSMISSION SECTIONAL VIEW

►***6 CYL. POWERGLIDE LINKAGE ADJUSTMENT PRODUCTION CHANGE:*** On later cars the part throttle upshift has been lowered to 12-18 MPH by changing the angle of the transmission throttle control outer lever, and shortening the throttle valve control rod. **Throttle Linkage Adjustment differs from early cars** as indicated in "Throttle Linkage Adjustment" below.

►***DECREASING PART THROTTLE UPSHIFT ON EARLY 6 CYL. MODELS):*** If it is desired to decrease the part throttle upshift from 26-28 MPH to 12-18 MPH, replace the early type Throttle Valve Outer Lever, Part No. 3710634, with the later type Part No. 3720323. Replace early type Throttle Valve Control Rod, Part No. 3710632 with later type, Part No. 3715711. Adjust throttle linkage as indicated below for later type cars.

1) Adjust engine idle speed to 425 RPM with Selector lever in "D" range (set hand brake firmly to hold car while making adjustments).

2) Disconnect control rod from throttle lever on transmission cover. On early type cars (see Production Change above), remove the extra lower rear transmission side cover bolt. On later cars remove the top bolt at rear edge of transmission side cover. Rotate throttle valve control outer lever assembly counter-clockwise to the open throttle position

3) Hold lever in this position and with throttle valve outer lever positioning gauge J-5906 (see "Rework of Transmission Outer Lever Positioning Gauge J-5906" below) set at 6⅜" (early cars), 6" (later cars), measure distance between bolt hole in side cover and hole in throttle lever. If pins of gauge will enter holes, adjustment is correct. If necessary to adjust, loosen lever to clamp attaching bolt and adjust lever on throttle shaft as necessary.

►***REWORK OF TRANSMISSION OUTER LEVER POSITIONING GAUGE J-5906 (So tool may be used on both 6 Cyl. & V8 Models):*** Remove bolt hole locating pin (larger pin) from gauge, pressing pin from back of lever leg to remove. Cut 5/16" from pin and replace pin in lever leg, pressing it into place to allow

C NTINUED N NEXT PAGE

POWERGLIDE (C ntinued)

apex of pin to project ¾" above lever leg surface. Stake pin in place securely. Separate lever legs and place a 3/16" spacer between legs. Reassemble lever legs. *NOTE*—In some cases it may be necessary to grind a beveled radius on the outer end of bolt lever leg as required.

DESCRIPTION

The 1955 Powerglide Transmission is similar to 1954 design, consisting of a torque converter and a hydraulic operated transmission.

OPERATION

Operation of the 1955 Powerglide Transmission is the same as 1954. *See 1953 Annual Data or later Manual editions.*

LUBRICATION

Check oil level at 1,000 mile intervals, drain and refill transmission at 25,000 mile intervals.

Recommended Oil—Use only Automatic Transmission Oil Type A (as furnished in containers bearing "AQ-ATF" number).

Capacity—Approximately 5 qts. (refill after transmission case only drained), 11 qts. (after overhaul with transmission case and converter dry).

►**Warming Up Transmission (For Checking or Draining)**—Drive car approximately 5 miles with frequent starts and stops OR warm up transmission in shop as follows: Run engine for 15 minutes at 750 RPM with selector lever in "Dr" position. *CAUTION*—Set hand brake tightly to prevent car moving.

Checking Oil Level—Check only with transmission warm and engine idling with selector lever in Neutral "N" position. Remove dipstick from filler tube in engine compartment on right side. Add oil only if level down to "ADD ONE QUART" mark on stick, fill only to "FULL" mark on stick. *CAUTION—High oil level (above "FULL" mark) will cause foaming and loss of fluid.*

►*OIL FILLER NOTE*—Use of Oil Filler Tube & Funnel No. J-4264 recommended to facilitate filling. This assembly is vented (transmission not vented and may blow back causing oil spillage if vented filler not used).

►*LOW OIL LEVEL CAUTION—If oil level in transmission found consistently low, check for internal and external oil leaks. See "OIL LEAKAGE OR HIGH OIL CONSUMPTION" in TROUBLE SHOOTING.*

Draining & Refilling—Transmission must be warm. Remove drain plug in rear face of transmission housing under the case to drain the transmission. *NOTE*—It is not necessary to drain converter. Replace and tighten drain plug. Install 5 qts. of new fluid through filler tube on right side of engine (see Oil Filler Notes above). Idle engine with selector lever in "N" until transmission warm, check fluid level and add additional fluid, as required, to bring level up to "Full" mark on dipstick. *CAUTION—Do not overfill (will cause foaming).*

Filling (After Overhaul)—Install 3 qts. of fluid through filler tube, start engine and allow it to idle with selector lever in "N", install additional 8 qts. of fluid. Run engine until transmission warm and check fluid level.

LINKAGE ADJUSTMENT

Throttle Linkage Adjustment (6 Cyl. Cars): *Engine must be at normal operating temperature and transmission warm (choke valve wide open and fast idle inoperative with stop screw of throttle against low step of fast idle cam), when adjustments made.*

►*EARLY 1955 (WITH FIRST TYPE THROTTLE VALVE LEVER) THROTTLE LINKAGE PRODUCTION CHANGE (To improve shift control characteristics):* Outer Lever Positioning Gauge J-5906 should be set at 7 3/32" instead of 6⅜" as originally recommended. See adjustment data below. In addition to reworking the gauge for use with V8 Cars (see "Rework of Outer Lever Positioning Gauge" above), the pivot hole of gauge will have to be elongated slightly to provide the necessary extension of the tool.

►*POWERGLIDE LINKAGE ADJUSTMENT PRODUCTION CHANGE:* On later cars the part throttle upshift has been lowered to 12-18 MPH by changing the angle of the transmission throttle control outer lever, and shortening the throttle valve control rod

Throttle Linkage Adjustment differs from early cars as indicated in the procedure following. To identify early and later type cars it will be necessary to check the part throttle upshift speed. Early cars will be 26-28 MPH, and later cars will be 12-18 MPH.

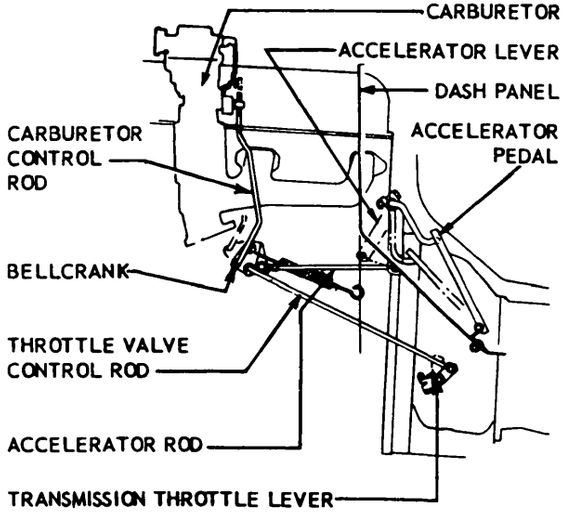
►*DECREASING PART THROTTLE UPSHIFT ON EARLY CARS:* If it is desired to decrease part throttle upshift speed from 26-28 MPH to 12-18 MPH, replace the early type Throttle Valve Outer Lever, Part No. 3710634, with later type Part No. 3720323. Replace early type Throttle Valve Control Rod, Part No. 3710632 with later type Part No. 3715711. Adjust throttle linkage as indicated below.

1) Adjust engine idle speed to 425 RPM with Selector lever in "D" range (set hand brake firmly to hold car while making adjustments).

2) Disconnect control rod from throttle lever on transmission cover. On early cars (see Production Change above), remove the extreme lower rear transmission side cover bolt. On later cars remove the top bolt at rear edge of transmission side cover. Rotate throttle valve control outer lever assembly counter-clockwise to the open throttle position.

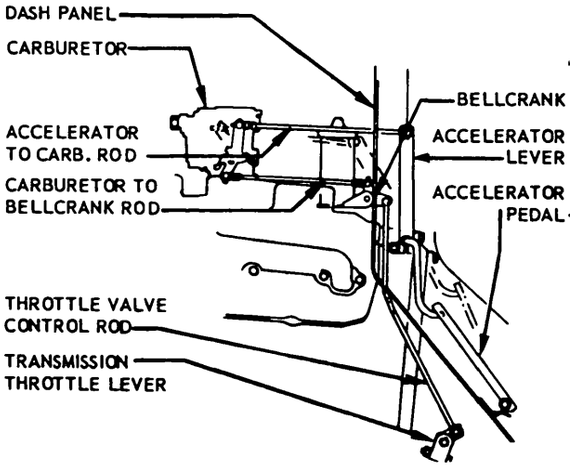
3) Hold lever in this position and with throttle valve outer lever positioning gauge J-5906 (see "Rework of Transmission Outer Lever Positioning Gauge J-5906 (above) set at 7 3/32" (cars with first type throttle lever *(NOTE—This setting supersedes the 6⅜" setting formerly recommended. See production change above)*, 6" (cars with second type throttle lever), measure distance between correct hole in side cover (see above) and hole in throttle lever. If pins of gauge will enter holes, adjustment is correct. If necessary to adjust, loosen lever clamp attaching bolt and adjust lever on throttle shaft as necessary. Reconnect control rod.

4) Disconnect bellcrank-to-carburetor throttle rod at throttle valve lever. Disconnect accelerator-to-bellcrank rod at bellcrank.



5) Force bellcrank-to-transmission throttle lever rod forward against its stop in transmission (open throttle position) and adjust bellcrank-to-carburetor throttle rod for free entry of swivel pin in throttle valve lever, with carburetor throttle valve in wide open position.

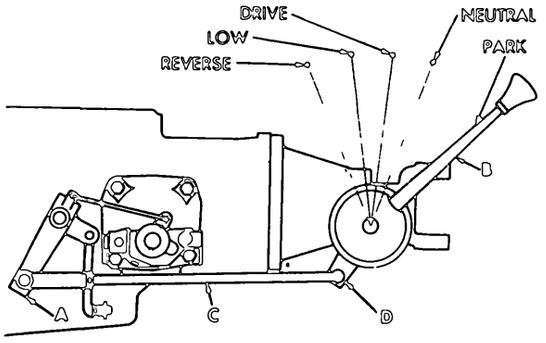
6) With carburetor throttle valve held in wide open position and accelerator fully depressed, adjust accelerator-to-bellcrank rod for free entry of swivel pin into hole in bellcrank.



Throttle Linkage Adjustment (V8 Cars): *NOTE—Adjust Transmission Throttle Control Linkage BEFORE adjusting Carburetor Throttle Linkage (see below).*

Carburetor Throttle Linkage—With accelerator pedal depressed fully and with throttle valve wide open, adjust accelerator-to-throttle lever rod (upper throttle rod) swivel for free entry into throttle lever. Then lengthen throttle rod by turning swivel **two full turns.** Connect rod to throttle lever.

CONTINUED ON NEXT PAGE



CHEVROLET 6 CYL. THR TTLE LINKAGE

CHEVROLET V8 THR TTLE LINKAGE

POWERGLIDE (Continued)

Transmission Throttle Lever Adjustment—1) With selector lever in "D" (Drive) range and with hand brake applied, adjust engine idle speed to 425 RPM (engine and transmission at normal operating temperature). Turn engine off and check choke valve to make sure it is fully open and that stop screw is against low step of fast idle cam.
2) Disconnect transmission throttle rod at lever on transmission. Remove extreme lower rear bolt in side cover on transmission. Rotate transmission throttle valve outer lever assembly clockwise to open throttle position (against stop). Hold in this position and with throttle valve outer lever positioning gauge J-5906 set to 2⅞", measure the distance between the bolt hole in side cover and hole in throttle lever. If pin of gauge enters hole, adjustment of lever is correct.
3) If necessary to adjust, loosen lever to clamp attaching screw and adjust outer lever to obtain correct adjustment. Install bolt in side cover and attach throttle rod to transmission lever.
4) Disconnect upper and lower rods from carburetor throttle lever. Force transmission throttle control rod forward against its stop in transmission (open throttle position) and adjust lower rod on carburetor throttle lever for free entry of swivel pin into carburetor throttle lever, with carburetor throttle valve in wide open position. Adjust upper control rod as outlined in Carburetor Throttle Linkage (above).

CORVETTE MANUAL CONTROL LINKAGE

Manual Control Linkage (Except Corvette): Loosen shifter tube lever clamp nut sufficiently to allow upper control rod to move freely in the swivel. Push control rod bellcrank (on left side of transmission case) toward front of car as far as it will go, placing transmission in "Park" position. Place shift control lever on steering column in "P" (Park) position. With both the control rod bellcrank and selector lever held in the "P" (Park) position, tighten shifter tube lever clamp nut securely.

Manual Control Linkage (Corvette): Set control rod bell crank (A) on transmission to reverse position (extreme rearward position). Place transmission selector lever (B) in reverse position (extreme forward position). Adjust rod (C) connecting lower end of selector lever with control rod bell crank so that rod will enter hole in lower end of selector lever (D) freely.

Neutral Safety Switch: Located on bracket on lower end of lower support assembly on steering column. To adjust, loosen two switch assembly mounting screws. Place selector lever in neutral, make certain that switch clip is over flats on end of shifter shaft. Insert locating pin through holes in switch mounting bracket and locating plate. Tighten switch mounting screws, remove locating pin.

BAND ADJUSTMENT

▷*BAND ADJUSTING NOTE—Band adjustment not ordinarily required in service (bands adjusted when reassembling transmission). Reverse Band adjustment requires removal of Servo Cover Assembly (see Disassembly data).*

Low Servo Bands—Adjusting screw located on left side of transmission case (under a cover). To adjust band, remove adjusting screw cover. Use tool J-4277 (see Tool Modification Note below), loosen adjusting screw locknut, turn adjusting screw in solidly, then back screw out exactly four complete turns, tighten locknut taking care not to allow screw to turn, replace adjusting screw cover.

▷Tool J-4277 Modification (for Low Servo Band Adjustment)—Adjusting screw has recessed head for ¼" Allen wrench. To use tool, remove screwdriver retainer and special screwdriver from tool, use ¼" Allen Wrench in place of the screwdriver in the tool.

Reverse Servo Band—Adjusting screw located on right side of case under servo cover. With servo cover removed, install tool J-4277 on adjusting screw, loosen locknut. Rotate reverse drum to center it in the reverse band. Tighten adjusting screw until all endplay between linkage and band is removed without compressing the band. The reverse drum must be free to rotate after this adjustment. If reverse drum is not free to rotate, back the adjusting screw ¼ turn at a time until drum is free to rotate. *(CAUTION—This is a sensitive adjustment and must be done carefully).* Tighten locknut taking care not to allow adjusting screw to turn.

TROUBLE SHOOTING

SEVERE CLOSED THROTTLE DOWNSHIFT "CLUNK": May be caused by a broken closed throttle cushion valve spring retainer. Check this condition by removing right hand side cover and inspecting retainer. *See "Closed & Forced Throttle Valve Spring Retainer Production Change" above.*

MOMENTARY RUN AWAY IN LOW UP TO 30 MPH (WIDE OPEN THROTTLE ACCELERATION): May be caused by a broken forced throttle cushion valve spring retainer. Check mainline pressure which will be lower just prior to shift, and the stall pressure will be low if the faulty transmission operation is caused by a broken retainer. *See "Closed & Forced Throttle Valve Spring Retainer Production Change" above.*

EXCESSIVE SLIPPAGE (High engine speed in relation to car speed, poor acceleration, or engine runs away on turns).
1) In all Speed Ranges—Low oil level. Incorrect control linkage adjustment. Air leak in oil pump suction pipe. Low front oil pump pressure.
2) In Drive Range—Incorrect control linkage adjustment. Damaged or leaking clutch piston seal (worn or burned clutch plates resulting from partially engaged clutch).
3) In Low Range—Incorrect control linkage adjustment. Low Band out of adjustment. Sticking accumulator valve, modulator lever, or modulator valve. Damaged or worn Low Servo Piston Ring resulting in poor band application or excessive oil leakage into clutch apply circuit causing partial clutch application and possibly burned clutch plates (check by connecting pressure gauges to Low Servo Apply and to High Clutch test points—there should be no pressure indicated at High Clutch point with selector lever in "L").

CAR CREEPS (Forward or Backward).
1) With Control Lever in Neutral—Incorrect control linkage adjustment. Clutch piston vent valve stuck closed. Clutch plates sticking or incorrectly assembled (not "stacked" in correct order).
2) Creeps forward with Control Lever in Reverse or backward with Lever in Low—Incorrect control linkage adjustment.

CAR WILL NOT MOVE (Rear wheels may be locked or free).
1) With Control Lever in any range (rear wheels free). If this occurs at other times than after reversing car, see causes listed under EXCESSIVE SLIPPAGE above. If this occurs only after reversing car (indicating loss of front pump pressure) check: Rear pump air leakage into front pump suction line (causing front pump to lose its prime). Rear pump gasket leakage. Front pump clearance excessive.
2) With Control Lever in any range (rear wheels locked). Parking pawl lock engaged. Broken parts in transmission. Parking brake applied.
3) With Control Lever in Drive Range (rear wheels free). If engine runs away and transmission is hot, check for: Low radiator water level, clogged oil cooler, sticking thermostatic valve, or dragging Low Range Band (causing over-expansion of clutch parts due to excessive heat).

SHIFTS ARE ROUGH.
1) Low-to-Drive Shift (car in motion). Incorrect Low Band adjustment. Clutch plates worn or binding. Modulator control lever or piston sticking (will cause excessive pressures). Accumulator dump valve orifice plugged.
If engine speeds up during this shift—Check for incorrect low band adjustment and worn or binding clutch plates.
2) Drive-to-Low Shift. Incorrect Low Band adjustment. Accumulator piston stuck closed. Modulator control lever or piston stuck (will cause excessive pressure).
3) Neutral-to-Reverse. Incorrect reverse band adjustment. Accumulator piston stuck closed. Modulator control lever or piston stuck (will cause excessive pressure).

CHATTERS WHEN STARTING.
1) In Low Range. Incorrect Low Band adjustment. Worn or rough band, scored drum. Clutch not disengaging properly due to distorted or binding plates, sticking clutch piston, sticking piston vent valve, or damaged or worn Low Servo Piston Ring allowing oil leakage into clutch apply circuit and causing partial clutch application (see tests for Excessive Slippage in Low Range above).
2) In Drive Range. Incorrect Low Band or Reverse Band Adjustment. Bands worn or rough, drums scored.

CONTINUED ON NEXT PAGE

POWERGLIDE (C ntinu d)

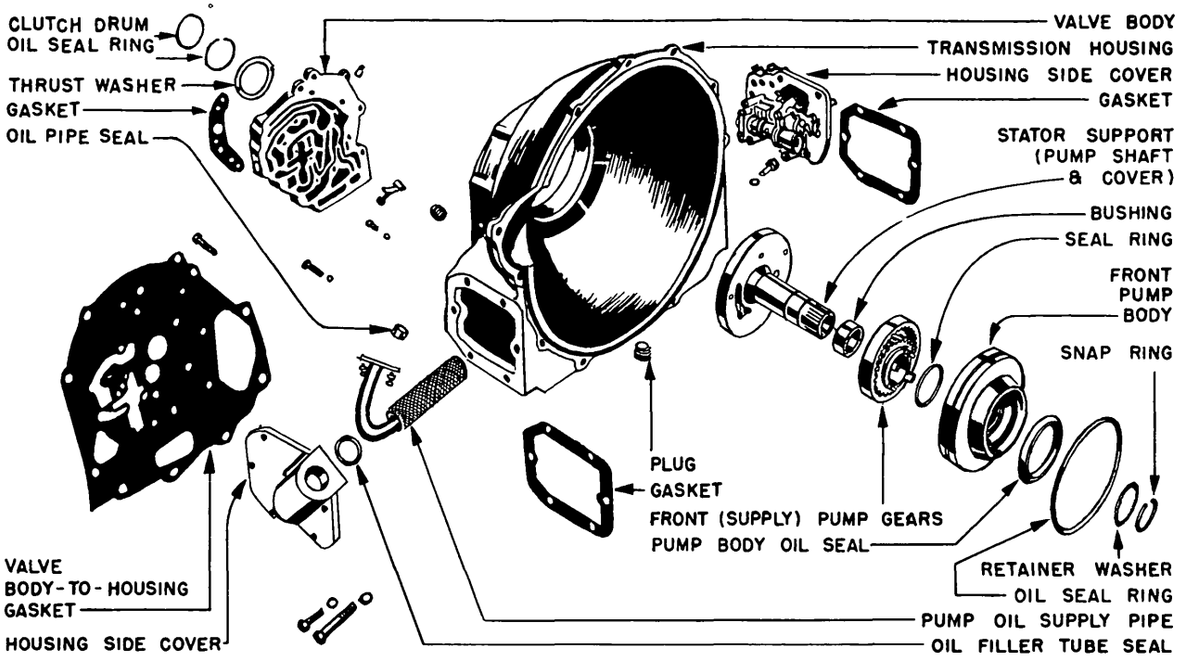
3) **In Reverse Range.** Incorrect Reverse Band adjustment. Worn or rough band, scored drum. Reverse ring gear and drum bushing worn or damaged.

REVERSE OPERATION JERKY OR DRAGGING.
1) Clutch plates are incorrectly assembled (not "stacked" properly) or sticking. Clutch piston vent valve stuck closed.

REVERSE CAN NOT BE ENGAGED WITH ENGINE RUNNING: If reverse can only be engaged when engine not running, check for accumulator snap ring being out of place (allowing accumulator valve and body to be forced against clamp nut on parking lock lever shaft and apply spring assembly, blocking shift into reverse). *NOTE*—Above condition will not prevent shift into Low Range).

DRIVE-TO-LOW or LOW-TO-DRIVE SHIFT DIFFICULT: May be caused by improperly drilled high clutch feed orifice in valve body resulting in slow clutch application in Drive Range and slow clutch release when shifting from Drive to Low (restricted orifice will cause slow oil flow). Check by connecting pressure gauges to Low Servo Apply and to High Clutch (low servo release side) and noting pressures as follows:
1) Move selector from Neutral to Drive with engine idling. If pressure builds up much more rapidly on Low Servo Apply gauge than on High Clutch gauge, a restriction in the passage (undersized orifice) is indicated.
2) Move selector from Drive to Low. Pressure in High Clutch gauge drops slowly, oil drainage from clutch is restricted. NOTE—This will result in slow Low Band application and clutch drag (may cause burned clutch plates).

HIGH CLUTCH PLATES BURNED OR CLUTCH FAIL
►*CAUTION—When High Clutch failure noted, following tests should be made before transmission removed, and transmission should also be carefully examined after removal and disassembly.*
1) Connect pressure gauges to Low Servo Apply, High Clutch (low servo release side), and to Reverse Servo points. Operate engine to supply oil pressure.
2) Place selector lever in Drive position and note pressure build-up in High Clutch gauge. Slow build-up indicates restriction in high clutch apply orifice resulting in clutch slippage and burned plates.
3) Place selector lever in Low position. High Clutch gauge should not show any pressure. Pressure at this point indicates leakage past Low Servo Piston Ring resulting in partial clutch application and burned clutch plates.
4) Place selector lever in Reverse position. High Clutch gauge should not show any pressure. Pressure at this point indicates leakage between the converter "out" and low servo "release" channels in valve body or damaged Housing-to-Valve Body gasket. This condition will cause partial clutch application and burned clutch plates.



NOISE IN TRANSMISSION.
1) **Buzzing Noise (All Ranges).** Low oil level. Pump gear interference with crescent in pump. Pump check valve not seating.
2) **Ringing Noise in Converter.** Low oil level. Air leak in pump suction line (pump not seated properly) resulting in low oil level in converter. Pressure regulator valve stuck (closing converter inlet port). Leakage in oil line between front pump and regulator valve.
3) **Clicking Noise.** Incorrect manual linkage adjustment (causing interference between parking lock pawl and gear).
4) **Whining Noise.** Transmission gear teeth worn. Pump gear clearance excessive or pump gear bushings worn.

FUEL CONSUMPTION EXCESSIVE.
1) **Transmission Causes.** Converter stator freewheeling cams and roller incorrectly assembled. Clutch piston vent valve stuck open.

TRANSMISSION OIL BEING FORCED OUT OF FILLER PIPE: Caused by aeration and foaming of the oil due to one or more of the following:

NOTE—This condition may also cause Loss of Power and Lower Stall Speed (due to converter turbulence and lower pressures in control circuits).

1) Oil level too high allowing planet carrier to revolve in oil and aerate it. Correct by lowering oil level to correct point (see LUBRICATION) and driving car for 5 miles to work out air bubbles.
2) Oil suction pipe split, seal damaged, bore for suction pipe in housing too deep, or suction pipe retainer ears bent (preventing proper compression of the seal) resulting in air leaks in oil suction line.
3) Sand hole in suction bore of transmission case or housing or in suction cavity in valve body resulting in air leaks in oil suction line.

POWERGLIDE TURBINE HOUSING & FRONT OIL PUMP

TESTING

►*TESTING CAUTION*—Transmission oil level must be checked and corrected (see LUBRICATION) and *transmission must be warmed up before tests made.*

Warming Up Transmission: Transmission must be warmed up by road driving or in the shop exactly as follows before checking for oil leaks or trouble.

Road Warm-Up—Drive car for approximately 5 miles with frequent starts and stops to approximate heavy-traffic conditions.

Shop Warm-Up—Set hand brake tight to hold car, place selector lever in "D" range, start engine and run for 15 minutes at 750 RPM. At end of 15 minutes, transmission will be warmed up suffcient-ly for testing regardless of initial temperature.

►*CAUTION—Recheck oil level after warm-up and before making following tests.*

ROAD TEST: Road test car when endeavoring to determine the reasons for the following difficulties:

Clutch Slippage: Connect gauges to the test points of the low servo apply and high clutch (release side of low servo). Position selector lever in "D" range and when car starts to move on acceleration, carefully check the pressure readings. Before the upshift takes place, the gauge connected to the low servo apply test point should record between 85 and 95 lbs. After a normal upshift takes place and the high clutch has time to become fully engaged, both gauges should record 85-95 lbs. If on this type of shift, the gauge on the high clutch (release side of

C NTINUED ON NEXT PAGE

POWERGLIDE (C ntinu d)

low servo) test point records 85-95 lbs., and the clutch slips or does not fully engage, it indicates a mechanical fault in the clutch. If the gauges do not record between 50-60 lbs. with engine idling at 425 RPM, or from 85 to 95 lbs. upon acceleration, the following items will require checking as it indicates leakage in the oil circuits. (a) Pressure regulator valve stuck, (b) Leak at low servo piston ring (between bore and ring), (c) Leak at low servo piston rod (between bore and rod), (d) Leak at valve body to case gasket, (e) Leak between valve body and housing, (f) Front pump clearances not correct, (g) Leak at low drive valve body (check gaskets and shifter valve), (h) Check passages in transmission housing for porosity, (i) Loose suction screen connection.

Closed Throttle Downshift "Clunk": High engine idle speed, or Closed Throttle Downshift Cushion Valve stuck.

Harsh Abrupt Upshift Above 25 MPH: Forced downshift cushion valve stuck closed.

Improper Upshifts and Downshifts: Refer to "Shift Patterns" below. Connect gauges to throttle valve and governor test points *(NOTE—See "Governor Pressure Test Plug Production Change" above).* Throttle valve pressure ranges from 0 to 62 lbs, depending to what extent the accelerator is depressed. Governor pressure is governed by road speed. If difficulty is experienced with the "Shift Patterns" it is recommended that the governor pressure be checked first to determine whether the pressure is within proper range, for if not, it will effect the "Shift Patterns" and the governor assembly is the first thing that should receive attention. Throttle valve pressure is another thing that effects "Shift Patterns" and if governor pressure is correct it is indicative that trouble is in the low drive valve body, provided the positive linkage and throttle valve linkage is in proper adjustment

SHIFT PATTERNS
Drive Range—Automatic

Throttle Position	①Upshift	②Downshift
Light Throttle③	12-14 MPH	④10-13 MPH
To Detent	30-45 MPH	14-18 MPH
Through Detent	48-53 MPH	45-50 MPH

①—From Low to Drive Range.
②—From Drive to Low Range.
③—Light Throttle on Upshift
④—Closed Throttle on Downshift.

STALL TEST: Check coolant level in radiator as a safety precaution. With tachometer connected to engine and service brakes securely locked, open throttle wide, with transmission in "D" (Drive) range, then in "L" (Low) range, and then in "R" (Reverse) range. Note maximum speed attained in each range and record. Speed should be almost identical in all ranges and be between 1560 and 1610 (6 Cyl.), 1600 and 1700 (V8). ***(CAUTION—Do not maintain stall condition longer than 10 seconds at one time to avoid overheating transmission fluid).*** If engine fails to attain minimum stall speed by several hundred RPM, it is likely that the stator is not locking up on the stator hub. If stall speed varies much between ranges or exceeds the maximum in all ranges, there is slippage which may be due to insufficient oil pressure or to a mechanical fault of clutch or bands.

PRESSURE TESTS: Connect pressure gauges at the following points and make the tests listed below.

►***TEST GAUGE NOTE:*** Five gauges are required. The four-gauge panel, No. J-4872, can be modified for use by installing an additional gauge furnished in conversion package No. J-5491 (reverse original gauges on panel, drilling additional hole to mount new gauge on lower edge of panel).

Gauge Connections—Connect gauge at each of the following points:

1) Low Servo Apply Pressure—Plug on lower front of servo cover on right side of transmission. ***CAUTION—Do not confuse this plug with Modulator Pivot Pin Retaining Plug which is slightly to rear of this Low Servo Apply Plug.***

2) Clutch Apply Pressure (Low Servo Release)—On bottom of transmission case at center and adjacent to servo mounting flange.

3) Reverse Servo Apply Pressure—On bottom of transmission case at rear and adjacent to servo mounting flange.

4) Throttle Valve Pressure—At hex-head plug in center of Low and Drive Valve Body Cover on left side of converter housing.

►***GOVERNOR PRESSURE TEST PLUG PRODUCTION CHANGE: Test plug on side of left hand side cover has been eliminated beginning in production with Trans. Serial No. C-428-D. Earlier model side covers will retain this plug.***

5) Governor Pressure—At plug on side or at upper end of channel in Low and Drive Valve Body Cover on left side of converter housing (upper plug is between second and third top cover screws (counting from top front corner of cover).

6) Main Line Pressure—At plug on upper end of channel in Low and Drive Valve Body Cover on left side of converter housing (plug is between third and fourth top cover screws (counting from top front corner of cover).

7) Clutch Apply or Main Line Pressure—At plug at outer end of channel in Low and Drive Valve Body Cover on left side of converter housing (this plug is at lower rear corner of cover).

Test Pressures—***CAUTION—Representative pressures listed below may vary 5% (higher or lower).***

FRONT PUMP PRESSURE

	Pressure
Idle (425 RPM)	50-60 lbs.
Above Idle	85-95 lbs.
Reverse (Idle 425 RPM)	50-60 lbs.
Reverse (Above Idle)	165-195 lbs

DRIVE (AUTOMATIC)
Transmission in Low Range

	Light Throttle (10 MPH)	Through Detent (45 MPH)
Low Apply	85-95 lbs	85-95 lbs.
Clutch Apply	0 lbs.	0 lbs.
Governor	8-13 lbs.	72½-76½ lbs.
Throttle Valve	①	①

Transmission in High Range

	Light Throttle (30 MPH)	To Detent (45 MPH)
Low Apply	85-95 lbs.	85-95 lbs.
Clutch Apply	85-95 lbs.	85-95 lbs.
Governor	52-56 lbs.	72½-76½ lbs.
Throttle Valve	①	①

①—Throttle valve pressure will vary from 0 to 62 lbs., depending on throttle position. At wide open throttle (through detent) pressure should read 61 to 63 lbs., on acceleration.

REMOVAL FROM CAR (EXCEPT CORVETTE)

Transmission & Torque Converter are removed as an assembly. ***CAUTION—Torque converter is not retained in housing as on previous transmission and special holding tool must be used to prevent converter falling out when transmission assembly removed.***

TRANSMISSION ASSEMBLY REMOVAL: (1) Raise car and install jack stands front and rear. Turn back floor mat and remove toe pan plate.
2) Remove spark plug wires on all models. Disconnect ground strap from battery and wires from starting motor solenoid on eight cyl. models only. Disconnect oil cooler lines retaining clip bolt from right side cover and disengage lines from retaining clip on engine. Move lines away from transmission and tie to right frame side rail.
3) Disconnect throttle valve control rod from throttle valve control outer lever and manual shift control rod (long rod) from bellcrank. Split rear universal joint. Then remove propeller shaft and front universal joint as an assembly by sliding it rearward until front joint is free of transmission output shaft.
4) Remove drain plug from rear of converter housing and drain transmission. Clean dirt from around filler tube, dipstick and transmission cover and remove side cover bolt retaining filler tube in position. Remove filler tube and dipstick. ***(CAUTION—Use masking tape or rubber stopper to cover filler tube opening.***
5) On V8 cars only, remove starter, and disconnect exhaust pipe from crossover pipe. On 6 Cyl. cars disconnect exhaust pipe from exhaust manifold.
6) Disconnect muffler from muffler support bracket and move the exhaust pipe and bracket as an assembly to the left and tie it to left frame side member.
7) Remove flywheel inspection hole cover and remove the three flywheel to converter attaching bolts through the opening that is adjacent to the starting motor, (opening on six cylinder cars is on left side of engine).
8) Remove all converter housing to flywheel housing attaching bolts except the top three. Install engine support bar or cradle to support engine. Position jack under transmission (using a suitable transmission handling device). Remove both rear engine mountings making sure that engine is properly supported before removing mountings
9) Remove the three upper converter housing to flywheel housing attaching bolts through opening in toe pan Move transmission to rear slightly and install converter holding tool J-5384. Lower transmission on jack and remove from under car.

C NTINUED N NEXT PAGE

POWERGLIDE (C ntinu d)

DISASSEMBLY—TRANSMISSION

►**DISASSEMBLY & REASSEMBLY CAUTION:** ***CLEANLINESS IS EXTREMELY IMPORTANT when opening up transmission. Thoroughly CLEAN exterior of case first, CLEAN each part as removed with cleaning solvent or gasoline and dry with air—do not use wiping cloths which will leave lint on parts. Store all parts in clean storage bins.***

DISASSEMBLY OF TRANSMISSION (Into Major Units): 1) Place transmission on bench (use holding fixture J-3361) and remove all units as indicated below.

2) Remove converter assembly holding tool J-5384 from housing, remove converter assembly by pulling it straight out of housing.

3) Take out right side cover attaching bolts, remove side cover, gasket, and oil pump suction screen.

4) Take out Low & Drive Valve Body attaching screws on left side of transmission, remove valve drive body assembly and gasket. CAUTION—Do not remove outer lever assembly from valve body (this retains inner lever assembly in body).

5) Loosen all servo cover bolts slightly and break servo cover loose if it sticks to case (reverse servo spring and pressure regulator spring bear against cover) **using care not to allow cover to tip** which may damage or break tip of pressure regulator valve. Use guide bolts to maintain cover alignment or turn all cover bolts out evenly while exerting pressure on cover, then lift cover and gasket straight off until cover clears tip of pressure regulator valve. Remove reverse servo spring and pressure regulator springs, lift regulator valve out.

►***CAUTION—Handle valve carefully to prevent damage and store it by itself to avoid nicking or scratching of the polished surfaces.***

6) Remove low band adjusting screw cover, loosen low band adjusting screw locknut using tool J-4277 (see Tool Modification below), and tighten low band adjusting screw to hold clutch assembly in place.

►***CAUTION—Make sure low piston assembly does not fall out of bore and become damaged.***

►**Tool J-4277 Modification Note**—Low band adjusting screw has recessed head for Allen wrench. To use tool, remove screwdriver retainer and special screwdriver from tool, use ¼" Allen wrench in place of screwdriver in tool.

7) Working from inside of converter housing, remove the converter housing-to-transmission case self locking bolt. Remove the converter housing-to-transmission bolts and lockwashers and install two ⅜"—16 x 3¾" guide pins (part of Pilot Stud Set J-3387). Shift transmission into Reverse and then carefully separate transmission from converter housing. Remove valve body to transmission case gasket.

8) Remove manual valve from valve body on rear of converter housing, remove manual valve lever from housing, remove bronze thrustwasher from valve body oil delivery sleeve.

►***CAUTION—Handle manual valve carefully to prevent damage and store it by itself to avoid nicking or scratching of the polished surfaces.***

9) Take out all bolts and lockwashers attaching valve body to converter housing and front pump to valve body. Remove valve body and gasket.

►***CAUTION—Handle valve body and valves carefully to protect them from damage.***

10) Use Front Pump Driver Tool J-4263-5 to remove pump assembly from converter housing.

11) Loosen low servo band adjusting screw to free clutch assembly, remove input shaft, clutch assembly, and low sun gear thrustwasher from transmission case.

12) Remove low servo band, strut assembly, low servo piston and piston return spring from transmission case.

13) Remove speedometer driven gear assembly. Take out universal joint retainer bolt and lockwasher on rear end of output shaft, slide universal joint yoke off end of shaft.

14) Take out attaching bolts and remove governor cover on left side of transmission case, remove gasket. Remove governor assembly (allow governor to turn in clockwise direction while withdrawing it from case).

15) Use tool J-3383 to rotate parking lock pawl spring until end unhooked from case, remove spring and parking lock pawl. Remove parking lock lever and steel washer, parking lock lever shaft assembly, and oil seal from case.

16) Remove transmission oil seal using tool J-5859 and remove transmission assembly and "O" ring seal. Remove speedometer drive gear from output shaft with tool J-5814.

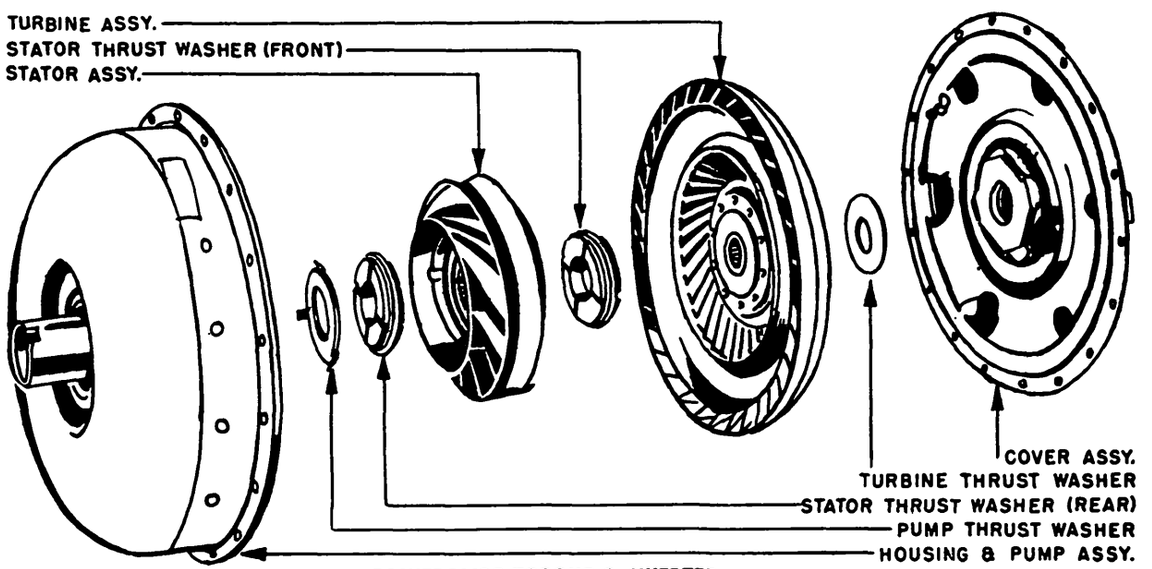
►***CAUTION—Do not attempt to remove planet carrier assembly until transmission rear bearing locating snap rings, retainer and bearing are removed.***

17) Remove the three bearing retainer screws and lockwashers and remove rear bearing retainer. Remove rear bearing locating snap ring from output shaft. Remove rear bearing from output shaft with tool J-5814, then remove bearing locating front snap ring from output shaft.

18) Working from front of transmission case, position the arrow on face of external gear of the planet carrier assembly at top center (this aligns the drive pin in output shaft with the eyebrow opening in the rear oil pump cover). Planet carrier assembly can now be removed through front of case. Do not lose rear oil pump drive pin.

►***CAUTION—Do not drive on end of output shaft.***

19) Remove reverse drum and thrust washer. Using tool J-4277, loosen reverse servo adjusting screw locknut, back off adjusting screw and remove reverse brake band assembly and reverse servo piston. Remove rear pump attaching bolts and lockwashers and remove rear pump assembly and gasket. Remove lubrication pressure relief valve from transmission case.



►***For DISASSEMBLY of above units, see OVERHAUL data following.***

OVERHAUL

►**"O" RING SEAL CAUTION:** ***These seals must be discarded when removed and a new seal installed exactly as directed below.*** "O" ring rubber seals are special design and are installed with side clearance in ring groove so that oil pressure on seal deforms the rubber and extrudes a portion of the rubber into the clearance space between the mating parts to provide a positive seal against loss of oil pressure. Seals **must not be re-used.**

"O" Ring Seal Installation—Make certain that parts are clean and that burrs and sharp edges are removed. Seal must be free of any twists (place ring on flat surface and allow it to assume natural position) and **must not be twisted during installation.** Engage one side of ring in groove, pull other side straight back until it can be fitted in groove

CONTINUED ON NEXT PAGE

POWERGLIDE TORQUE C NVERTER

POWERGLIDE (Continued)

without twisting. Work ring against trailing edge of groove (last side to enter when parts assembled) using flat tool entered between ring and leading edge of groove to move ring without twisting. Lubricate "O" ring and parts with transmission oil.

CONVERTER OVERHAUL (Unit on bench—after removal from transmission):

Disassembly: 1) Remove all converter cover attaching bolts and locknuts, use small punch to drive out split dowel pin in cover, lift cover off.

2) Remove turbine assembly, stator assembly, stator thrustwashers, and pump thrustwasher. Remove thrustwasher from turbine hub. Remove "O" ring seal from converter cover.

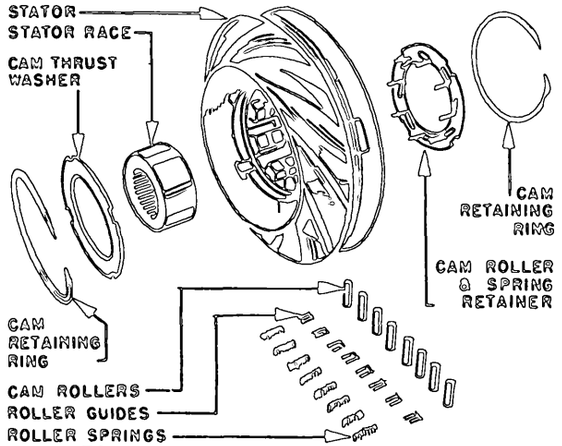
3) Remove stator race from stator assembly, remove snap ring and over-run cam retaining thrustwasher, remove cam rollers, springs, and guides (8 each).

▷*CAUTION—Use care when separating parts so that cam rollers, springs, and guides do not fall out and become lost.*

4) Remove snap ring on opposite end of stator and remove over-run cam roller and spring retainer.

▷*CAUTION—Use care to prevent damage to over-run cam and see that cam does not become disengaged from stator hub.*

Inspection: Wash all parts in cleaning solvent and dry with air. Inspect converter pump hub, turbine hub, and converter cover bushing for galling, scoring, or excessive wear. Inspect all thrustwashers for galling, scoring, or excessive wear. Check turbine vanes and stator vanes for looseness or damage. Inspect stator race and cam rollers for galling or scoring. Inspect cam springs for distortion. Check spring guides for wear or damage. Inspect over-run cam roller and spring retainer for wear or damage. If bushing in converter cover worn or damaged, install new bushing as follows:



Converter Cover Bushing Replacement: Precision type bushing, No. 3702079, furnished for field installation. Use bushing remover tool J-5381 to remove old bushing from cover. Place new bushing on pilot end of Bushing Replacer Tool J-5382 and press bushing into place in cover using an arbor press. *NOTE—Bushing is finished to size and does not require reaming.*

Reassembly: 1) Install over-run cam roller and spring retainer in stator with retainer prongs pointing toward rear of stator. *NOTE*—Stator has word "Front" cast in and stator vanes are thicker at front end.

2) Assemble cam rollers, springs, and guides in cam pockets (*CAUTION*—Guides are curved and this curvature must follow curvature of cam). Install over-run cam thrustwasher and retaining snap ring.

3) Coat stator race and loading tool J-5930 with light film of oil, place stator race on pilot end of loading tool and carefully rotate the stator over the tapered end of the loading tool and the stator race (*CAUTION*—rotate stator in clockwise or freewheeling direction and use great care not to dislodge cam rollers). Check operation of stator. Stator should turn freely in clockwise direction viewed from front end.

4) Place converter pump on bench, open end up Install thrustwasher on converter pump hub making certain that tabs are engaged in the hub flange notches. Assemble both thrustwashers on stator and install stator assembly on converter pump.

TORQUE CONVERTER STATOR ASSY.

▷*CAUTION—Make certain that cut-outs in over-run cam roller and spring retainer are facing upward or toward converter turbine.*

5) Install thrustwasher on turbine hub and assemble turbine on converter pump.

6) Install NEW "O" ring seal on converter cover, align dowel pin holes in cover with dowel pins in converter pump, install cover assembly. Install all cover attaching bolts and lockwashers and tighten evenly to 15-20 ft. lbs.

TRANSMISSION OVERHAUL: *After removal from case, overhaul sub-assemblies or units as follows:*

Planetary Unit Clutch: Place unit on bench with clutch flange upward.

Disassembly—1) Remove clutch flange retainer ring, lift out clutch flange retainer. Remove clutch flange assembly from clutch drum. Remove clutch hub thrustwasher, hub, and all clutch plates from clutch drum.

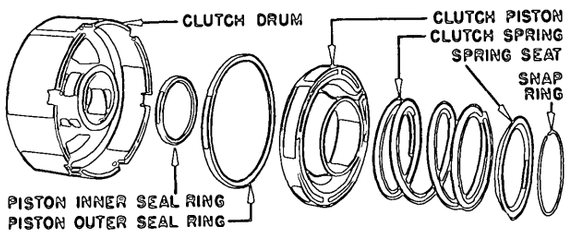
2) Place clutch drum in bench press, install spring compresion tool J-5133 and compress spring enough to remove snap ring, use KMO-410 pliers to remove snap ring. Relieve spring pressure, remove tool, lift out clutch spring seat and spring.

3) Rap clutch drum face down on a wood block to dislodge clutch piston, lift piston out, remove outer seal ring from piston and inner seal ring from clutch drum hub.

Inspection—Wash all parts in cleaning solvent and dry with air. Inspect drum brake band surface for scoring or burning, check drum bushing for scoring or excessive wear. See that clutch flange does not have any appreciable play in drum slots. Check all clutch plates for burning or galling, see that composition plates are free fit on clutch hub and that steel plates are free fit in clutch flange. Check low sun gear for nicked or burred teeth. Inspect relief valve steel ball in clutch piston and make certain that ball is free to move in hole and that orifice to rear of piston is open. If necessary, replace ball as follows:

Relief Valve Check Ball Replacement—Remove staking and remove ball. Inspect hole and ball seat and make certain it is free from burrs or nicks, see that new ball seats perfectly. Insert ball and carefully stake around edges of hole so that ball cannot fall out. *CAUTION—Ball must be free to move in hole after staking completed.*

▷*REPLACEMENT PARTS CAUTION: See Chevrolet Changes, Cautions, Corrections for clutch production changes and latest type replacement parts.*



Reassembly—1) Install new outer seal ring on clutch piston with lip of seal toward pressure side of piston (*CAUTION*—use care not to stretch seal). Install new inner seal ring on inner hub of clutch drum with lip of seal toward bottom of clutch pocket.

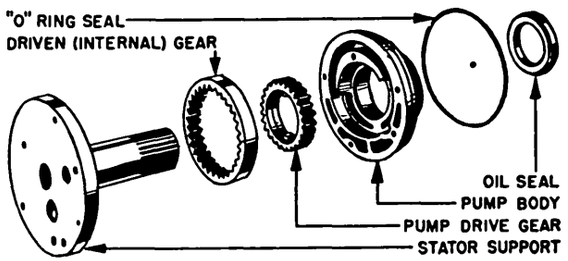
2) Lubricate inner diameter of clutch drum and both seals with transmission oil, carefully install piston in clutch drum using a piece of feeler stock to insure seating of outer seal ring in clutch drum.

3) Install clutch spring and spring seat, use tool J-5133 in an arbor press to compress spring (*CAUTION*—Make certain spring does not hang up in snap ring groove which would damage spring seat and groove), install snap ring. Release pressure, remove tool.

4) Install thrustwasher on clutch hub (*CAUTION*—see that four tabs on washer fit into slots in clutch hub), install clutch hub and thrustwasher on clutch flange with open side up. Install five steel and four composition clutch plates, starting with a steel plate and alternating plates (*NOTE*—Steel plates are "waved" and can be installed either side up). Install clutch drum assembly on clutch flange assembly, then invert entire unit, install clutch flange retainer and flange retainer ring.

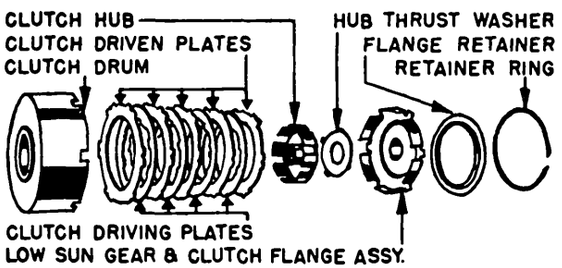
5) Check endplay using a feeler gauge inserted between clutch flange drive lug and drive slot in

POWERGLIDE CLUTCH PISTON ASSY.



drum. This endplay must not exceed .013". Adjust by installing retainer ring of correct thickness to provide correct endplay. *NOTE*—Retainer ring furnished .055", .064", .073" thick.

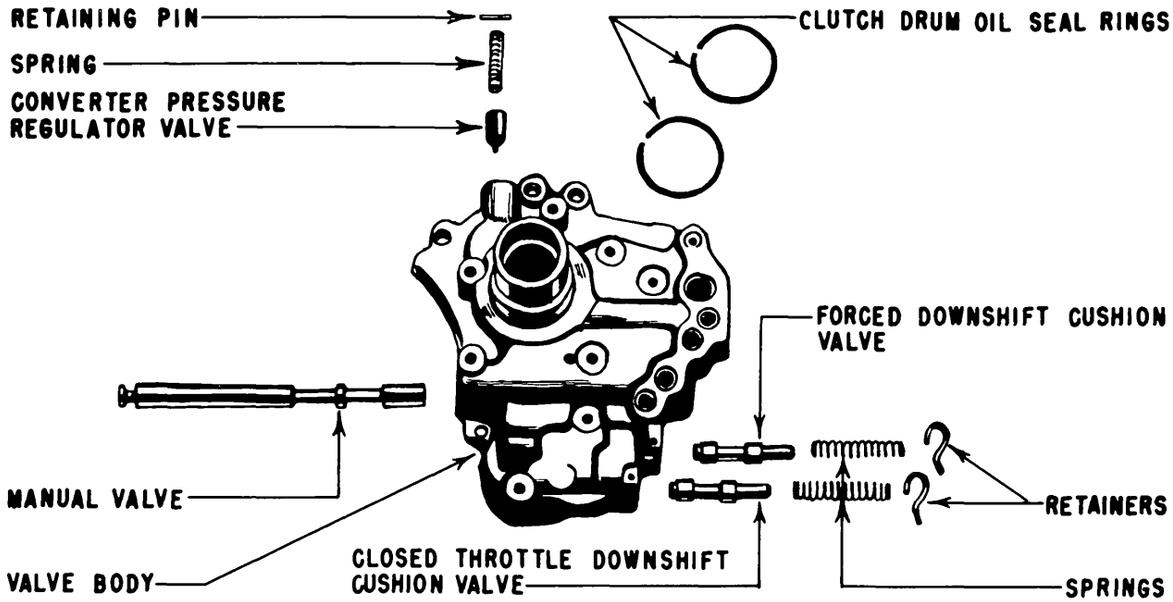
Servo Cover: Disassembly—Remove pressure regulator reverse booster valve and booster valve guide and seal assembly by holding servo cover in a stationary position and pulling on protruding end of booster valve. Remove booster valve spring and booster valve spring and seat.



CONTINUED ON NEXT PAGE

POWERGLIDE (C ntinu d)

Inspection—Inspect cover for nicks or cracks Using a small punch or similar tool, and working through the opening in the by-pass disc seat, exert pressure on the disc to make sure disc and spring are free and that disc is seating properly *(NOTE*—Do not remove disc seat unless there is evidence of damage) Inspect pressure regulator reverse booster valve springs for distortion or damage Inspect pressure regulator reverse booster valve for galling or scoring and make sure it operates freely in bore in guide Inspect snap ring for loose fit in groove Inspect bore in valve guide for galling or scoring and check seal for distortion or damage Check valve guide bore in servo cover for roughness or burrs and make sure that valve spring and guide spring and seat will seat properly in bottom of bore



POWERGLIDE FRONT OIL PUMP

POWERGLIDE MULTIPLE DISC CLUTCH

Lubrication By-Pass Valve Assembly Replacement—If during inspection it is evident that the lubrication by-pass valve assembly is not functioning properly, correct as follows Using a suitable tool remove the nylon by-pass disc seat, then remove disc and spring Inspect disc for burrs, and spring for distortion Inspect wall of by-pass valve cavity for roughness, nicks or burrs Insert by-pass disc in its cavity to make sure its movement is not restricted Remove disc from cavity Replace any part that is defective Install by-pass spring in its cavity in servo cover and install by-pass disc With servo cover inner surface facing upward, position a new disc seat over its opening in cavity and press into place using a socket of proper size It should be flush to 005" below inner surface of servo cover *CAUTION—Under no circumstances should the by-pass disc seat that was removed be re-installed.*

POWERGLIDE CONTROL VALVE ASSEMBLY

Reassembly—Install pressure regulator reverse booster valve spring seat in bottom of bore in servo cover, then install valve and valve guide springs Assemble booster valve and valve guide with the double seat of guide toward special snap ring on valve Place valve and guide into bore in servo cover, then with thumb and finger, press valve guide and seal into bore until guide is flush with surface of cover or slightly below *(CAUTION—Do not press booster valve guide too far below surface of servo cover as this would place heavy spring pressure on guide).*

Front Pump: Disassembly—Slide stator support out of pump body, lift out pump gears (CAUTION—use extreme care not to drop or nick gears), remove and discard "O" ring seal.

Inspection—Wash all parts in cleaning solvent and dry with air. Inspect pump gears for wear, nicks, or other damage. Inspect pump body and pump face of stator support for nicks and scoring. Inspect pump body oil seal for excessive wear, damage, or evidence of leaking (see Oil Seal Replacement below). Inspect pump body bushing for galling or scoring, check bushing wear or clearance as directed below. Check pump gear clearances as follows:

1) Pump Gear Clearances—Install clean, dry gears in pump body, check clearances with feeler gauge:

Driven Gear Clearance—.0025-.0055" clearance between outer diameter of gear and pump body.

Driving Gear Clearance—.003-.009" clearance between end of gear teeth and crescent.

Gear End Clearance—Place scale across face of pump body, measure clearance between scale and face of gears. This clearance should be .0005-.0015".

2) Pump Body Bushing Clearance—Temporarily install pump body on converter pump hub, measure bushing-and-hub clearance with a feeler gauge. This clearance should be 0005- 0015"

3) Oil Seal Replacement—Pry out old seal, use special driver J-5386 to press new seal in place in pump body.

Reassembly—Install new "O" ring seal in pump body, oil pump gears thoroughly with transmission oil and install in pump body, install stator support through pump body and driving gear and line up attaching bolt holes.

Rear Pump: Disassembly—Take out two screws and remove pump body plate, lift out pump gears.

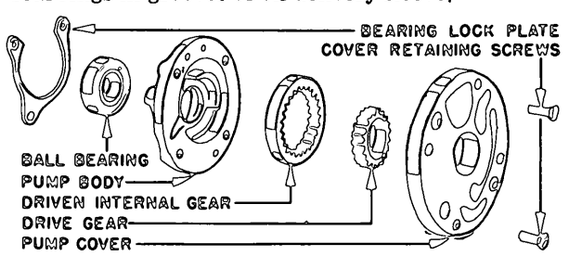
Inspection—Wash all parts in cleaning solvent, blow out all oil delivery holes, dry with air. Inspect pump body for nicks and scoring, inspect gears for wear, nicks, or other damage. Check gear clearances (clearances are same as for front pump—see Pump Gear Clearances above). Inspect rear bearing for roughness but do not remove bearing unless replacement required (see Bearing Installation below).

Pump Bearing Replacement—Remove three retaining capscrews, lockwashers, and lockplate. Drive old bearing out. Press new bearing in place, install lockplate and retaining screws and lockwashers, tighten screws securely.

Reassembly—Oil pump gears thoroughly with transmission oil and install in pump body. Install pump body plate and two slotted attaching screws, tighten screws to 3½-5 ft.lbs. torque.

Valve Body: ***CAUTION—Handle all valves with care to avoid damage, keep valve and spring assemblies separate to avoid confusing or interchanging parts.***

C NTINUED N NEXT PAGE

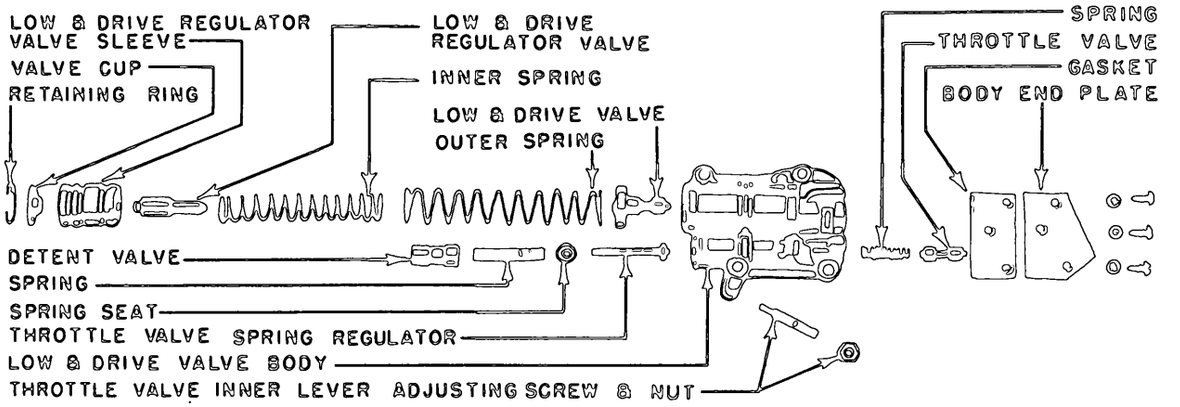


POWERGLIDE (Continued)

▷*VALVE BODY PRODUCTION CHANGES: See production and service replacement changes above.*

Disassembly—Using needle nose pliers remove the forced downshift cushion valve retainer from valve body and take cushion valve and spring from bore. Remove closed throttle downshift cushion valve in the same manner. Place valve body assembly, face down, on two wooden blocks of equal thickness and with a small pin punch drive out the converter pressure regulator valve retaining pin and remove spring and valve from bore. Remove the two clutch drum oil seal rings from oil delivery sleeve. Remove front and rear oil pump check valve from valve body.

Inspection—Wash all parts in clean solvent and blow dry with air. Do not use a rag to dry these parts. Check all springs for distortion or damage, and all valves for nicks, scores, burrs or galling, and for free movement of valves in their respective bores. Check oil seal rings for nicks or burrs and make sure that they are free in the ring grooves. Install rings in clutch drum and make sure that hooked ring ends have clearance.



Assembly—Place valve body, face down, on wood blocks. Assemble converter pressure regulator valve spring in valve and then, as an assembly, install in valve body bore. Install retaining pin. Assemble forced downshift cushion valve spring to valve and then as an assembly, install in valve body *(CAUTION*—Do not confuse the forced downshift cushion valve spring with the closed throttle downshift cushion valve spring. *The forced downshift cushion valve spring is the shorter of the two and is made of heavier gauge wire).* Assemble and install closed throttle downshift cushion valve spring in the same manner. Install front and rear oil pump check valve in valve body making sure it is flush with or below valve body face. Install the two clutch drum oil seal rings in grooves of oil delivery sleeve.

POWERGLIDE REAR OIL PUMP

Low-and-Drive Valve Body: *CAUTION—Do not disturb Throttle Valve Adjustments (two adjusting screws—one in boss on valve body and one in throttle valve inner lever) unless required by installation of new parts. THROTTLE VALVE MUST BE ADJUSTED IF THESE SETTINGS DISTURBED (see Throttle Valve Inner Lever Adjustment).*

Disassembly—1) Remove valve body-to-side cover attaching bolts and lockwashers. While holding detent valve in place, use soft hammer to carefully tap inner face of side cover until it is free of the locating pins *(CAUTION*—Use care to keep parts from falling out and being lost or damaged while performing this operation).

POWERGLIDE LOW & DRIVE VALVE ASSEMBLY

2) Withdraw detent valve, spring, spring seat, and throttle valve spring regulator assembly from valve body. Remove throttle valve spring and throttle valve.

3) Use Pliers J-5403 to remove special snap ring retaining low-and-drive regulator valve cap, then remove the valve parts as follows: Valve Cap, Sleeve and Valve (as an assembly), Inner and Outer Springs, and Valve.

4) Take out two attaching screws and remove clutch exhaust cover plate ("L" shaped strip) from the side of the valve body.

5) Take out three attaching screws and lockwashers in end plate (CAUTION—exert pressure on plate while removing screws to prevent parts flying out), remove plate, remove valve parts as follows: Clutch Exhaust Secondary Control Valve, Spring, Stop (from upper valve bore), Clutch Exhaust Primary Control Valve Spring, Stop, Valve (from center valve bore), and throttle valve and spring (NOTE—some early cars used two springs, one inside the other).

6) Remove throttle valve outer lever assembly, shield, and inner lever assembly (CAUTION—do not disturb adjusting screw in inner lever unless required by parts replacement). Remove throttle valve lever shaft seal.

Inspection—Wash all parts in cleaning solvent, blow out all passages, dry with air. Inspect all valves for nicks, burrs, scoring, or galling. Check all valves for free operation in their respective bores. Inspect all vaive springs for distortion or damage. Inspect throttle lever assembly shaft for wear, scoring, or galling, see that shaft operates freely in side cover and that inner lever is tight on shaft. Inspect detent valve stop in side cover for distortion or damage, install new stop if necessary. Inspect locating pins in valve body and side cover for distortion or damage (one pin should be in side cover, other pin in valve body), replace pins if necessary. Inspect mating surfaces of valve body and side cover and make certain they are free of nicks or burrs.

Reassembly—1) Install low-and-drive valve in body bore (CAUTION—valve must be guided to prevent damage to the bore—use a piece of brake tubing inserted in valve shank bore at rear of valve body, engage nib on valve in end of tubing, move valve into position slowly). Install remaining low-and-drive valve parts in reverse order of disassembly (install regulator valve and cap on valve sleeve first and then install in valve bore as an assembly making certain inner spring is seated on sleeve). Compress assembly in valve bore while installing special snap ring, make certain ring properly seated in groove in valve body.

2) Install clutch exhaust secondary and primary valve assemblies (CAUTION—use care not to confuse these valve parts—primary control valve stop is the longer of the two stops, and primary control valve spring is the shorter of the two springs). Install throttle valve spring and valve in valve body, then install end plate and hold plate in position while tightening end plate attaching screws, tighten these screws to 2½-3½ ft.lbs. torque.

3) Install throttle valve spring regulator assembly in valve body and see that it is seated on throttle valve spring. Install detent valve spring seat, valve spring, and valve (thread pin of the throttle valve spring regulator assembly through the opening in the spring seat and valve).

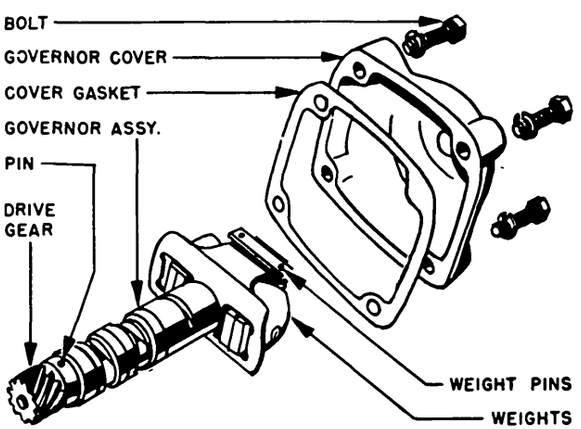
4) Clamp side cover in a vise (face upward), align locating pin in side cover with hole in valve body, exert pressure on valve body to keep locating pin in the hole and at the same time compress detent valve in valve body bore and rotate valve body counter-clockwise until the locating pin in the valve body enters the locating hole in the side cover (CAUTION—make certain face of detent valve is resting against stop pin in side cover). Install attaching bolts and lockwashers, tighten bolts evenly to 3½-5 ft.lbs. torque.

5) Install throttle valve inner lever assembly in side cover, install new seal on shaft and into counterbore in cover, install shield. Install outer lever assembly on inner lever shaft, install outer lever attaching bolt from underside, tighten nut securely.

If lever adjustments disturbed during overhaul, readjust throttle valve as follows:

Throttle Valve Inner Lever Adjustment: Rotate throttle valve inner lever until it just contacts face of the detent valve. Hold lever in this position and turn adjusting screw until it just contacts flat surface of

CONTINUED ON NEXT PAGE



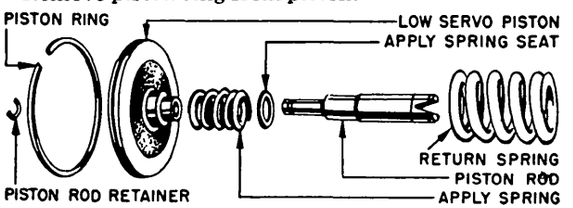
POWERGLIDE (C ntinu d)

the step in the lever. Back off one complete turn and lock in this position by tightening adjusting screw lock nut securely.

Governor: ***CAUTION—The only parts serviced for replacement are the governor assembly (complete), and driven gear. Governor should not require disassembly except for cleaning and removal of foreign material causing improper operation. See "Governor Driven Gear Replacement" below for disassembly & reassembly.***

Governor Driven Gear Replacement: A unit package containing a governor driven gear and pin, and two governor weight pins is available for service replacement. ***(CAUTION—The 1955 driven gear is not interchangeable with gears on previous models).*** Install new gear and pins in the following manner:

Installation—Cut off ends of governor weight pins and remove weights and governor valve. ***(NOTE***—Carefully protect governor valve to prevent damage. Weights are interchangeable from side to side). Drive out governor gear retainer split pin using a small punch. Support governor on 3/16" plates installed in exhaust slots of governor sleeve, place in arbor press and with a long punch, press gear out of sleeve. Carefully clean governor sleeve of chips and reinstall in arbor press. Position new gear in sleeve and with a suitable socket, press gear into sleeve until nearly seated. Then remove any chips that may have shaved off the gear hub and press gear in until it bottoms on shoulder. ***(CAUTION—It is important that a socket be used to prevent damage to thrust button on end of gear).*** Drill a new hole through sleeve and gear locating it 90° from existing hole, using a No. 24 (.152") drill. Install split pin retainer. Wash governor assembly thoroughly. Install governor valve and make sure that it operates freely. Install governor valve in bore of governor sleeve. Align governor weight pin holes in the governor thrust cap, governor weight assemblies and governor sleeve and install new pins. Crimp both pins to prevent them becoming dislodged. Check governor weight assemblies for free operation on pins.



GOVERNOR ASSEMBLY

Low Servo Piston: Disassembly—Place piston assembly in bench press supporting notched end of shaft on wooden block, install tool J-3377 (same tool used for Reverse Servo) on top of piston, compress spring sufficiently to enable rod retainer "C" washer to be removed from end of rod, relieve spring pressure, remove piston, spring, and washer from piston rod. Remove piston ring from piston.

Inspection—Wash all parts in cleaning solvent, dry with air. Inspect all parts for wear or damage. Install piston ring in low piston bore and check ring gap with feeler gauge. Gap should be .005-.010".

Reassembly—Assemble all parts on piston rod, compress spring in bench press and install piston rod retainer making certain that it is properly seated in groove. ***CAUTION—Spring pressure is 150 lbs. and assembly must be handled carefully.***

Reverse Servo Piston: Disassembly—Place assembly in bench press with spring end up, install tool J-3377 on spring retainer, compress spring sufficiently to enable retainer key locks to be removed, relieve spring pressure, lift off retainer, springs, and piston. Remove piston ring from piston.

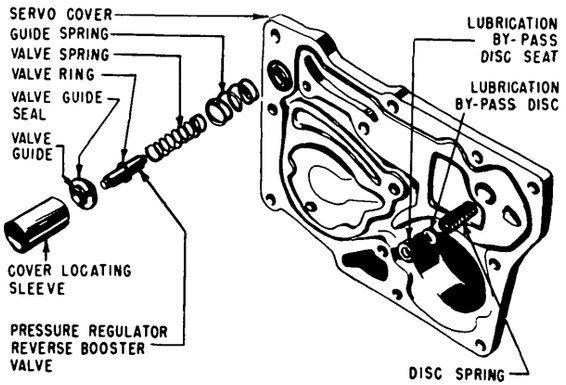
POWERGLIDE LOW SERVO ASSY.

Inspection—Wash all parts in cleaning solvent, dry with air. Inspect all parts for wear or damage. Install piston ring in reverse piston bore and check ring gap with feeler gauge. Gap should be .005-.010".

Reassembly—Assemble all parts on piston rod, compress spring in bench press and install retainer locks, make certain locks seated properly in rod groove.

Planet Carrier Assembly: ***Should not be disassembled unless inspection below indicates overhaul required. See Planet Carrier Overhaul below.***

►*PLANET REVERSE RING GEAR AND DRUM ASSEMBLY PRODUCTION CHANGE (to accommodate a new .020" steel thrust washer):* Beginning with transmission serial number C-128-D, a new steel thrust washer is used between planet carrier and reverse gear and drum to prevent galling of thrust surfaces. A service package, Part No. 3721564, consisting of a Planet Reverse Ring & Drum Assembly, Part No. 3720472, and an Output Shaft Thrust Washer, Part No. 3720474, is available for service replacement on 1953-54 & Early 1955 cars.



Inspection—Wash in cleaning solvent, blow out all passages, dry with air. Inspect all gear teeth for nicks, scoring, or other damage. Check end clearance of planetary pinions with feeler gauge inserted between ends of pinion and thrustwasher. This clearance should be .006-.030". Check reverse sun gear rear thrustwasher for wear or damage. Inspect drum bushing for wear, scoring, or damage; inspect outer diameter of drum for scoring or burning. Check output shaft bearing surfaces for wear, nicks, or scoring. Check input pilot bushing for wear or scoring.

Planet Carrier Overhaul: ***If inspection (above) indicates that parts require replacement, proceed as follows:***

Disassembly—Place assembly in holding fixture or clamp in a vise with front end upward. Mark each pinion shaft and also mark planet carrier (use prick punch or other means) so that shafts can be re-installed in same position ***(CAUTION***—pinion shafts are selective fit in carrier and location must not be changed). Then proceed as follows:

1) Remove pinion shaft lockplate screws, rotate plate counter-clockwise until it is free and remove the plate.

2) Starting with one short planet pinion, use a soft steel drift to drive on lower end of pinion shaft until shaft raised above the press-fit area of the output shaft flange, then insert tool J-4599 (one piece only —second piece of tool set used for reassembly) into short planet pinion from lower end and push shaft out until tool is centered in the pinion and shaft is removed. Remove short planet pinion from assembly. Remove tool from pinion, remove needle bearings and needle bearing spacer ***(CAUTION***—use care not to lose any of the needle bearings).

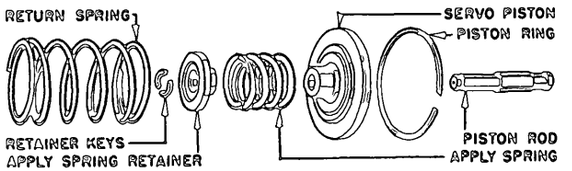
POWERGLIDE SERVO COVER ASSEMBLY

3) Remove **adjacent** long planet pinion (paired to the just-removed short pinion by using same thrustwashers) by repeating procedure in step (2) above. Then remove the pinion upper and lower thrustwashers.

4) Remove all remaining planet pinions **in pairs** (short pinion first, followed by long pinion) by following procedures in steps (2) and (3) above.

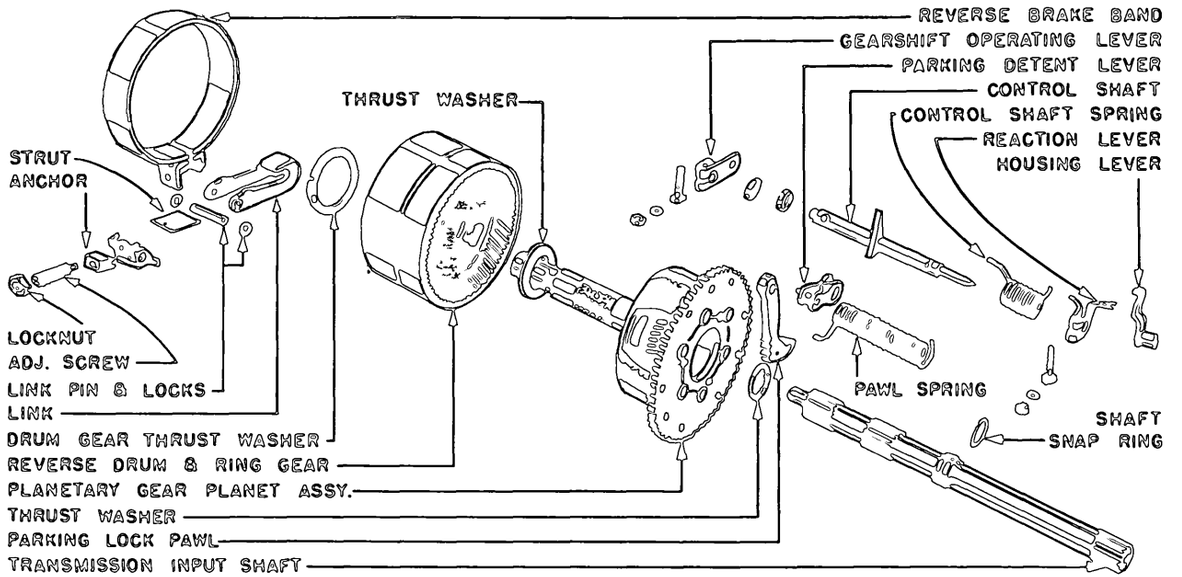
5) Remove reverse sun gear and sun gear thrustwasher.

Inspection—Wash all parts in cleaning solvent and dry with air. Inspect all pinion gears and reverse sun gear for nicked or otherwise damaged teeth, inspect all thrustwashers for wear, nicks, or scores. Inspect needle bearings for wear and replace **all** needle bearings if worn excessively.



Reassembly—***CAUTION—Pinion shafts must be reinstalled in accordance with marks made before disassembly (shaft is selective fit in particular hole in carrier).*** Assemble and install parts as follows:

1) Install tool J-4599 in one long planet pinion, assemble needle bearing spacer and needle bearings in pinion (20 at each end) using cup grease to hold needle bearings in position.



CONTINUED ON NEXT PAGE

POWERGLIDE (Continued)

2) Install pinion assembly in planet carrier with tool centered in assembly and with thrustwasher at each end of pinion. *NOTE*—Long pinions are located opposite closed portion of carrier, short pinions are located opposite carrier openings. Feed the second part of tool J-4599 in from the top of the planet carrier *(CAUTION*—make certain tool picks up thrustwasher) and push first part of tool down and out at the lower end *(CAUTION*—make certain this tool picks up thrustwasher as it is pushed down). Lubricate correct pinion shaft (see Reassembly Caution above) and install it from top pushing the assembling tools out ahead of it. Turn shaft so that slot in upper end faces toward center of assembly, tap shaft down with a brass or soft steel drift until lower end is flush with lower face of carrier.

POWERGLIDE REVERSE SERVO ASSY.

POWERGLIDE PLANET CARRIER, REVERSE BAND, & PARKING LOCK

3) Assemble and install adjacent short planet pinion (paired with just-installed long planet pinion by using same thrustwashers) by repeating procedure in steps (1) and (2) above.
4) Install reverse sun gear thrustwasher and reverse sun gear.
5) Install all remaining planet pinions in pairs (long pinion first, followed by short pinion) by following the procedure in steps (1), (2), (3) above.
6) Check end clearance of planet pinions using feeler gauge inserted between end of pinion and thrustwasher. This clearance should be .006-.030".
7) Install pinion shaft lock plate with extended portions in line with pinion shaft slots, rotate plate clockwise until plate locks all pinion shafts and attaching screw holes line up. Install lock plate attaching screws and tighten to 2½-3 ft.lbs.

Input Shaft: Inspect shaft splines for wear, nicks, or other damage. Check spline fit in clutch hub, reverse sun gear, and converter hub. Inspect oil seal ring for wear and free fit in groove, remove ring (compress one end, push other end outward to free locked ends) and install ring in valve body bore to make certain hooked ends have clearance, then reinstall ring on shaft. Check snap ring in groove at forward end of shaft (this ring first used in 1953 transmissions and prevents shaft floating forward), replace if worn or damaged using snap ring pliers KMO-410.

Transmission Case & Rear Bushing: Check case for cracks, inspect rear bushing for wear or damage and replace if necessary.

Bushing Replacement—Place transmission case in an arbor press with rear end up. Using a cape chisel, cut bushing and remove from bore in case. Install rear bearing in its bore in rear oil pump assembly and install rear oil pump in case to serve as a pilot when installing new bushing. Place transmission case in an arbor press with front end up. Place new bushing on bushing installer J-4276, with the square end of bushing against shoulder of installer. Insert in case, entering pilot of tool into rear bearing. and press bushing into place. Bushing is precision type and does not require reaming.

Low & Reverse Brake Bands: Inspect bands for wear, cracks, and scored or burnt lining. Lining is bonded to band. Inspect linkage for wear.

REASSEMBLY

AFTER ALL MAJOR UNITS REASSEMBLED (See Overhaul above), install units as directed below using ALL NEW GASKETS AND SEALS and tightening all parts evenly to SPECIFIED TORQUES.

CONVERTER HOUSING ASSEMBLY: *Install units:*

Valve Body: First install suction screen in oil sump *(CAUTION*—screen must be thoroughly cleaned), see that sealing ring is in place. Install two ¼—20 x 3½" guide pins (part of Pilot Stud Set J-3387) in two valve body attaching bolt holes, place new valve body gasket in position over guide pins, install valve body assembly. Install all attaching bolts *(CAUTION*—lower left bolt over accumulator bore is special self-locking type and must be installed in this position), tighten all bolts evenly in a criss-cross pattern to 7½-10 ft.lbs. torque. Check manual valve and pressure regulator valve for free operation after all bolts tightened.

Front Pump: Align holes in stator support with mounting holes in pump body, install two ¼—20 x 3½" guide pins (part of Pilot Stud Set J-3387) in pump mounting holes, use Driver J-4263-5 to install pump in converter housing *(CAUTION*—line up suction and oil delivery holes on left side of pump). Install five self-locking bolts through valve body and into pump, tighten all bolts evenly to 7½-10 ft.lbs. torque. *CAUTION—Check pressure regulator valve for free operation after bolts tightened and make certain that pump operates freely.*

Low-and-Drive Valve Body: Install two 5/16—18 x 3" guide pins (part of Pilot Stud Set J-3387) in two valve body mounting bolt holes on left side of converter housing, place new gasket in position over guide pins, install valve body assembly. Install attaching bolts and lockwashers, tighten bolts evenly to 12½-15 ft.lbs. torque.

TRANSMISSION CASE ASSEMBLY: Install units:

Rear Pump: Install two 5/16—18 x 3" guide pins (part of Pilot Stud Set J-3387) in pump attaching bolt holes, place new gasket in position over guide pins, install pump *(CAUTION*—align oil suction and delivery holes), tighten pump mounting bolts evenly to 12½-15 ft.lbs. torque.

Lubrication Pressure Relief Valve: Make certain that valve is clean and openings free from obstructions, see that valve disc and spring operate freely. Install relief valve in mounting hole in rear of transmission case and tighten securely.

Reverse Servo Piston, Band, & Drum: Compress piston ring with Ring Compressor J-3365, install servo piston in case with notch in shaft toward front of case. Install reverse brake band and strut assembly with thin end of band away from piston, thread adjusting screw in until it indexes with hole in anchor. Install bronze thrustwasher on reverse drum hub, install drum in case and into brake band. *DO NOT adjust band at this point.*

Planet Carrier Assembly: Rotate rear pump drive slot to top of pump. Fill drive pin hole in output shaft of planet carrier with cup grease and install drive pin. *(CAUTION—Make sure that drive pin does not fall out of shaft during assembly).* Install planet carrier assembly in drum positioning the arrow on face

CONTINUED ON NEXT PAGE

POWERGLIDE (C ntinu d)

of the external gear of planet carrier assembly at top center *(NOTE*—On late 1955 transmissions a steel thrust washer is used between planet carrier and reverse ring gear & drum *See "Planet Reverse Ring Gear and Drum Assembly Production Change" above).* Install rear bearing locating front snap ring in its groove in output shaft and install rear bearing using tool J-5814 *(NOTE*—Groove in outer diameter of rear bearing should be to rear of transmission) Install rear bearing retainer in groove in outer diameter of rear bearing and attach to rear oil pump with screws and lockwashers Tighten to 7-8½ lbs Install rear bearing rear locating snap ring in its groove in output shaft Using tool J-5814, install speedometer gear on output shaft Center raised ground surface of output shaft so that it will mesh properly with the speedometer driven gear Install new "O" ring seal on speedometer driven gear fitting Assemble driven gear in fitting and then install as an assembly in bore in extension Install retainer, attaching screw and lockwasher Tighten to 3½-5 ft lbs

Reverse Band Adjustment: Adjust band at this point *See BAND ADJUSTMENT.*

Transmission Endplay Check & Adjustment: After planet carrier assembly installed in case, the correct thickness of the low sun gear to-reverse sun gear thrustwasher must be determined for the correct transmission endplay of 007- 035" as follows

(1) Use Tool J-4260 to measure distance from face of transmission case flange to face of reverse sun gear in planetary unit (place tool bar against case flange, extend tool stem until it contacts gear face), **tighten thumbscrew to retain this tool setting.**
(2) Install bronze thrustwasher and clutch assembly temporarily on oil delivery sleeve
(3) Without disturbing tool setting obtained in step 1 (above), place 120" steel washer over tool pilot (short plug on tool bar), install tool over clutch assembly with tool pilot entered in low sun gear and tool stem against gasket on rear face of housing Use feeler gauge to measure clearance between face of low sun gear and steel washer on tool pilot If clearance not within 007- 035", repeat this procedure with 095" or 145" steel washer on tool pilot
(4) When correct clearance of 007- 035" secured in step 3 (above), note thickness of steel washer used on tool and **select bronze thrustwasher of same thickness** for installation on input shaft splines at final installation (below) Remove clutch assembly and thrustwasher from oil delivery tube

►**Thrustwasher Note**—This bronze thrustwasher furnished in three thicknesses as follows Part No 3694467— 095", No 3694468— 120", No 3694469— 145".

Parking Lock Mechanism: Install parking lock lever shaft assembly in case, install seal over end of parking lock lever shaft and into counterbore in case **with lip seal toward inside of case.** Install flat washer and parking lock lever on end of shaft, push lever on shaft for clearance of 000- 010" between lever and washer, tighten clampscrew to 8-12 ft lbs Install parking lock pawl over pawl support rod, install parking lock pawl spring, wind up pawl spring (tool J-3383) until spring catches on case

Input Shaft & Clutch Assembly: Install input shaft in clutch unit Install bronze thrustwasher **selected in "Transmission Endplay Check & Adjustment" (above)** on reverse sun gear splines of input shaft *(CAUTION*—flat side of washer must be toward reverse sun gear). Install assembly in case indexing input shaft pilot with pilot in output shaft and mesh low sun gear with short planetary pinions

Low Servo Piston & Band Assembly: Install release spring on servo piston rod, use Ring Compressor J 3365 to compress piston ring and install assembly in transmission case Install low brake band over the drum Install apply strut guide spring over piston rod, engage apply strut in piston rod slot and engage opposite end of strut in the band Engage anchor strut assembly in band groove and locate opposite end of anchor over the adjusting screw ***DO NOT adjust the band at this point.***

Governor: Install governor assembly in bore in transmission case *(CAUTION*—Governor must be allowed to rotate counter-clockwise as gear teeth mesh and care must be taken not to damage gear teeth) Install two 5/16—18 x 3" guide pins (part of Pilot Stud Set J-3387) in governor cover mounting holes, place new gasket in position over guide pins, install governor cover, attaching bolts and lockwashers Tighten cover bolts evenly to 6½-8½ ft lbs torque

Extension Housing Position new 'O" ring seal on transmission extension Then carefully install extension on transmission case Install attaching capscrews and lockwashers and tighten to 12-15 ft lbs Install transmission extension oil seal using tool J-5154

TRANSMISSION & CONVERTER HOUSING ASSEMBLY:

1) Install manual valve in valve body and manual valve inner lever in converter housing. Index lever pin with pick-up slot in valve, set manual valve so that it protrudes 1 11/16 out from face of valve body This places valve in Reverse position

2) Install new valve body-to-transmission case gasket

►*CAUTION* Two different valve body-to-case gaskets are used with the early and late type valve bodies THESE GASKETS ARE NOT INTERCHANGEABLE *See "Control Valve & Gasket Production Change and Service Replacement Note" above for control valve identification and gasket differences*

3) Place transmission manual valve lever in top detent position *(NOTE*—this is Reverse position and will align reaction lever so that it will index with manual drive inner lever in converter housing).

4) Place clutch drum thrustwaher in position on oil delivery sleeve

5) Install two ⅜—16 x 3¾" guide pins (part of Pilot Stud Set J-3387) in two opposite converter housing mounting bolt holes, carefully bring transmission case and converter housing together making certain that reaction lever indexes properly with manual valve inner lever Install all case to-housing bolts and tighten evenly to 25-30 ft lbs. Install special self-locking bolt through front face of converter housing and tighten this bolt to 25-30 ft lbs

6) Install two 5/16—18 x 3" guide pins (part of Pilot Stud Set J-3387) in. two servo cover attaching bolt holes, place new gasket in position over guide pins Install pressure regulator valve and inner and outer valve springs (see Note below) through servo and into case, install reverse servo return spring. Install servo cover over guide pins *(CAUTION*—see that pressure regulator springs and reverse servo spring seat properly in pockets in cover), maintain pressure on cover while installing and tightening cover bolts tighten bolts evenly to 12½-15 ft lbs.

7) Adjust Low Servo Band *See Band Adjustment*
8) Install converter assembly in converter housing making certain that front pump drive lugs aligned with slots in converter pump hub Install converter holding tool J-5384 using one housing bolt to hold tool (tool will prevent converter falling out while being installed on engine)
9) Check and adjust position of throttle valve outer ever *See Throttle Linkage Adjustment*

INSTALLATION IN CAR

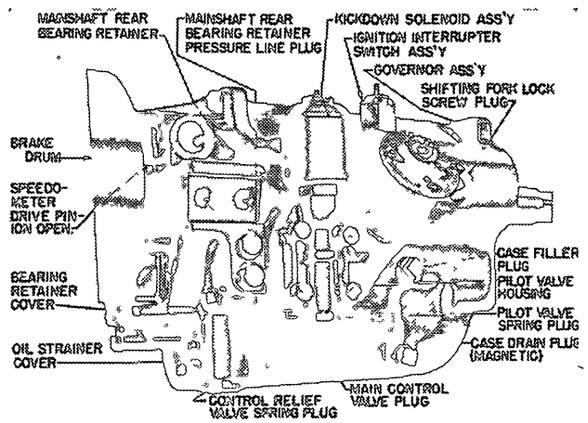
TRANSMISSION ASSEMBLY INSTALLATION: 1) Install assembly in handling fixture on hydraulic jack and roll into position under car Raise transmission until converter housing is in approximate alignment with flywheel housing
2) Remove converter assembly holding tool from converter housing Then carefully align "X" mark on converter cover with "X" mark on flywheel

►***CAUTION—After removing converter holding tool be careful that converter does not move forward causing disengagement of the pump hub drive slots from lugs of the front pump drive gear***

3) Install one 5/16 —24 guide pin in converter cover Rotate converter assembly until guide pin is in alignment with opening in flywheel housing Maneuver transmission assembly until converter housing-to-flywheel housing bolt holes are in alignment and the flywheel pilot enters flywheel
4) Install all but the uppermost three converter housing-to-flywheel housing attaching bolts Through the opening in flywheel housing, remove guide pin from converter cover and install three flywheel-to-converter bolts, rotating flywheel as necessary Tighten bolts to 25-30 ft lbs
5) Install filler tube and measuring dipstick Install flywheel inspection hole cover Install rear engine mountings (both sides) Remove engine support bar or cradle Disconnect hydraulic jack handling fixture from transmission and remove jack
6) On V8 cars, install starting motor On all models, connect oil cooler lines and engage them in retaining clip on right side cover Connect throttle valve control rod to throttle valve control outer lever and manual shift control rod (long rod) to bellcrank On V8 cars, install breather pipe in cylinder block
7) Engage internal splines of front yoke of front universal joint with external splines of transmission output shaft Then slide front universal joint and propeller shaft as an assembly forward enough to connect rear universal joint
8) Connect speedometer cable to transmission On V8 cars, connect exhaust pipe to exhaust crossover pipe On 6 Cyl cars, connect exhaust pipe to exhaust manifold Connect muffler to muffler support
9) Lower car to floor and install the three remaining upper converter housing-to-flywheel housing attaching bolts through opening in toe-pan Restore floor mat to its original position Install spark plugs on all models On V8 cars, connect battery ground strap and wires to starter solenoid
10) Fill transmission with Automatic Transmission Fluid Type A *See "Lubrication" above.*

1946-48 CHRYSLER HYDRAULICALLY OPERATED & DE SOTO TIP-TOE SHIFT

Chrysler 6, Model C38 (1946-47-48)
Chrysler 8, Models C39 & C40 (1946-47-48)
DeSoto, Model S11 (1946-47-48)



▷KICK-DOWN SWITCH CHANGE (For Improved Transmission Operation): *See "Chrysler, DeSoto, Dodge Kick-down Switch" in Electrical Equip. Section.*

DESCRIPTION: Own Make, semi-automatic, 4-speed transmission with hydraulic actuation and electrical (governor switch and throttle "kick-down" switch) control. Transmission has "Low Range" and "High Range" controlled by Shift Lever on steering column and two speeds within each range (First & Second in Low Range, Third and Fourth or Direct Speed in High Range) engaged automatically by the hydraulic shift mechanism. Automatic shifting is dependent on car speed and throttle position. Except for new automatic hydraulic shifting mechanism, transmission design is similar to the Vacamatic and Simplimatic "Underdrive" transmission used on previous Chrysler & DeSoto models.

Free-Wheel Control—Consists of a sleeve on the countergear cluster which is shifted forward by the movement of the Direct Speed clutch (Second and Fourth Speed position). Sleeve engages a lug on the free-wheel roller cage and rotates rollers to a disengaged position (cage is spring-loaded and returns to normal position when released). This action prevents roller engagement if the Direct Speed Clutch should happen to remain in the engaged (forward) position when the car is stopped.

Hydraulic Shift Mechanism: Consists of a spring-loaded hydraulically actuated piston mounted concentrically on the Direct Speed shift rail. This piston merely compresses the return spring and the engaging spring which perform the actual shifting operation (both springs compressed by initial movement of the piston, expansion of engaging spring moves Direct Speed Clutch forward for Second or Fourth, expansion of return spring moves clutch to rear for First or Third Speeds).

Control Units: Consist of hydraulic system units (Oil Pump, Pressure Regulator, Pilot Valve, and Main Valve), and electrical control units (Relay, Governor, Pilot Valve Solenoid, Ignition Interrupter Switch, Throttle Kick-down Switch).

1946-48 CHRYSLER, DE SOTO HYDRAULIC TRANSMISSION

Oil Pump—Pump is "Gerotor" type (same as engine oil pump) located under rear cover plate in transmission case and is driven from the mainshaft (operates whenever rear wheels are turning). Pressure should be 40 lbs. to approximately 60 lbs. at 15 MPH. (pressure drops when upshift starts).

Oil Pressure Regulator—In transmission case on right side. Set to maintain pump pressure at approx. 50 lbs. Regulator by-passes oil back to inlet side of pump when pressure exceeds this figure.

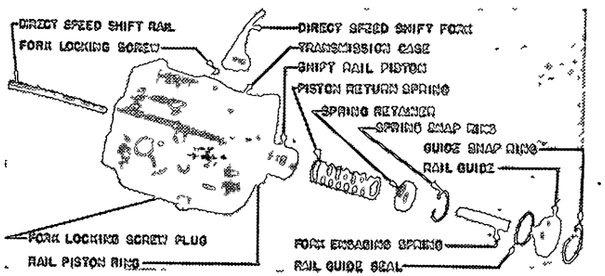
Pilot Valve Solenoid—Auto-Lite No. SSS-4002. Solenoid pushes pilot valve down when energized. Pilot valve should be in upper position with solenoid inactive or removed and should move freely.

Control Relay—Auto-Lite No. HRM-4102. Relay has two sets of contacts which open and close together (contacts closed when relay coil energized). Fuse on relay is 30 ampere capacity.

Governor Switch—Auto-Lite No. TG-4202R or TG-4203R. Governor contacts are closed (completing circuit to ground) with car at rest and are opened by action of the centrifugal weights at a car speed of 6-7 MPH (Low Range), 12-14 MPH (High Range).

Accelerator Pedal Kick-down Switch—Built in the carburetor. *See "Chrysler, DeSoto, Dodge Kick-down Switch" in Electrical Equipment Section.*

OPERATION: Manual control (Shift Lever on steering column) operates in the usual manner by shifting the "Manual Clutch Sleeve" on the transmission mainshaft. The automatic (hydraulically operated) control operates as follows:



Automatic Upshift—Governor switch contacts open at car speed of 6-7 MPH. (Shift Lever in "Low Range"), 12-14 MPH. (Shift Lever in "High Range"), de-energizing the control relay and pilot valve solenoid. The pilot valve actuates the main valve which admits oil under pressure from transmission oil pump to the hydraulic cylinder causing the piston in the cylinder to move forward which compresses the return spring and the engaging spring on the shift rail. When the throttle is released momentarily, the engaging spring causes the Direct Speed Clutch to engage the higher gear (Second in "Low Range," Fourth in "High Range").

NOTE—Hydraulic piston actuates Interrupter Switch in moving forward but ignition is not interrupted because circuit is open at upper relay contacts (no interruption required for shifting since transmission "free-wheels" before shift occurs.

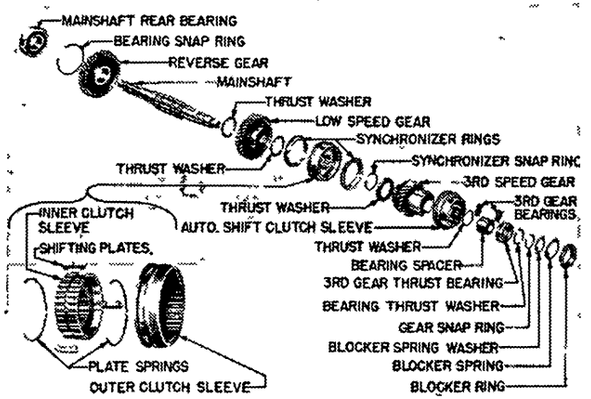
Automatic Downshift—When car speed drops to 6-7 MPH ("Low Range"), 12-14 MPH ("High Range"), governor switch contacts close, energizing control relay and pilot valve solenoid. The pilot valve causes the main valve to close, shutting off oil pressure (oil is by-passed into transmission case through pump pressure relief valve) and opening a passage to the case for oil drainage from the hydraulic cylinder. The return spring in the cylinder moves the piston backward and when the piston strikes the shoulder on the shift rail, the rail and Direct Speed Clutch are moved back into the lower gear position (First in "Low Range," Third in "High Range"). NOTE—During the initial movement of the piston, a shoulder on the piston causes the Interrupter Switch to close momentarily, grounding the ignition coil, and interrupting the ignition to relieve the engine torque and allow the shift to occur. Further movement of the piston opens the Interrupter Switch and restores the ignition.

Accelerator Pedal "Kick-down" Downshift—At car speeds under approximately 27 MPH (Low Range), 53 MPH (High Range), the transmission can be shifted down from Second to Low (Low Range), Fourth to Third (High Range) by fully depressing the accelerator pedal which causes the kick-down switch contacts on the carburetor to close and provides an alternative ground for the control relay circuit (governor switch contacts open) and energizes the relay. The downshift then occurs in exactly the same manner as for the Automatic Downshift (above). NOTE—The transmission can not be "kicked-down" at higher speeds since the kick-down contact plunger is held up out of engagement by manifold vacuum.

LUBRICATION: Check oil level in the transmission case every 1000 miles or 30 days, drain and refill with new oil every 10,000 miles or yearly. To check oil level, remove plug on right front side of case (to rear of lower transmission mounting bolt), maintain oil level even with bottom of filler plug hole. CAUTION—Clean magnetic plug (drain plug) and oil pump screen (under cover on lower left rear corner of transmission case) when transmission case drained. *Keep dirt out of transmission.*

DIRECT SPEED & KICKDOWN MECHANISM

Recommended Lubricant—Use only No. 10-W engine oil in this transmission. Capacity 3 pints.



REMOVAL OF TRANSMISSION: *See "Transmission" on car model page.*

DISASSEMBLY OF TRANSMISSION: With transmission off car and Governor assembly and solenoid removed, lift out governor pinion (use long-nosed pliers), remove ignition interrupter switch. Make certain manual gear shift controls in Neutral (selector shaft and gear engagement shaft), remove gearshift housing assembly from left side of case. Move reverse idler gear and clutch gear sleeve back so as to lock mainshaft, remove mainshaft flange nut, brake drum and flange (tool C-452). Take out rear bearing retainer mounting screws, pull out retainer and mainshaft assembly as a unit. Remove main drive gear bearing retainer on front end of case, remove snap ring and withdraw direct speed rail guide (in recess to right of bearing retainer). Remove main control valve plug and gasket, withdraw valve and spring. Remove pilot valve and spring. Remove shifting fork lock screw plug, loosen shifting fork locking screw so that fork is loose on rail (use screwdriver with ¼" blade or tool C-738 inserted through plug hole). Push direct speed gear-

CONTINUED ON NEXT PAGE

1946-48 CHRYSLER HYDRAULICALLY OPERATED AND DE SOTO TIP-TOE SHIFT (Cont.)

shift rail out through rear of case, remove fork, clutch sleeve and engaging spring and direct speed blocker ring. Push countershaft out through rear of case with arbor, C-716, allowing countershaft gear assembly to drop down in case (arbor remains in gear cluster to retain bearing rollers). Remove main drive gear assembly (pack recess in gear with grease to retain mainshaft front bearing rollers). Lift countershaft gear assembly out of case (CAUTION—use care that free-wheeling gear does not fall off). Remove reverse idler shaft through rear of case (Puller C-604), lift idler gear out. Remove oil strainer cover and strainer from case. Use Tool C-714 to compress direct speed rail return spring, remove snap ring from case in front of spring, slowly release spring tension, remove tool, lift out spring

MAINSHAFT DISASSEMBLED

retainer, spring, piston, and piston ring through front of case. This completes transmission disassembly. Disassemble sub-assemblies as required.

REASSEMBLY OF TRANSMISSION: Note the following points when installing transmission parts and sub-assemblies:

Free-wheeling Gear Assembly on Countershaft Gear Cluster—Install control sleeve key and slide control sleeve on countershaft gear. Hook anchor ends of two free-wheeling cam roller retainer springs in holes in countershaft gear so that springs wrap around gear in clockwise direction from anchor end. Install free-wheeling cam roller retainer with lugs over spring anchors, rotate retainer clockwise until lugs are over slots in control sleeve, make certain that spring ends are snapped into grooves in retainer, then press retainer in until lugs fully engage slots in control sleeve. Install free-wheeling cam rollers and thrust washer, then place free-wheeling gear on countershaft gear and install the 45 bearing rollers.

Mainshaft Manual Shift Clutch (Synchronizer) Installation—Install on front of mainshaft with long portion of hub toward rear of shaft, use thickest snap ring which can be installed to retain the clutch (snap rings furnished .087" and .090" thick). Install shifter plate spring and three shifter plates, then install clutch sleeve with taper of sleeve toward front end of shaft.

Mainshaft Third-and-Direct Speed Gear Installation—Install rear thrust washer with recess side toward rear end of shaft. Assemble bearings in Third Speed Gear as follows: Insert thrust bearing race (one with larger hole) in gear with groove toward forward end of shaft, assemble one set of 36 bearing rollers in forward end of gear, insert bearing spacer, insert second set of 36 bearing rollers in rear end of gear, install needle bearing thrust washer. Install the gear and bearing assembly on mainshaft, install ball thrust bearing and thrust bearing washer, then install gear snap ring using thimble and driver (Tool C-717). Check gear endplay which should be .003-.008". Adjust by installing snap ring of correct thickness (furnished .087", .092", .097", .101" thick).

Main Drive Gear Installation—With main drive gear assembly installed in case, install the bearing retainer **without a gasket** and secure it in place with regular mounting capscrews. Check clearance between bearing retainer flange and front of case with a feeler gauge. Select a gasket of same thickness as feeler gauge clearance (or nearest oversize) and **install this gasket under the bearing retainer.**

Mainshaft Assembly Installation—Use aligning studs (C-730) in case to align mainshaft gear assembly. Mesh gear teeth of Third-and-Direct speed gear hub with center space of each set of teeth on direct speed clutch sleeve. CAUTION—Do not force mainshaft assembly into place. Shaft will enter easily if main drive gear is turned in both directions until lugs on direct speed clutch blocker ring index with slots in direct-and-third speed gear.

NOTE—When installing mainshaft rear bearing retainer screws, use rubber gasket on middle screw on left hand side.

Countershaft Gear Assembly—Make certain that ridge on free-wheeling control sleeve engages groove in direct speed clutch sleeve when raising countergear cluster in position, install bronze thrust washer next to gear and steel thrust washer next to case at each end of gear cluster, check endplay which should be .002-.008". Adjust by selecting bronze thrust washer of correct thickness for installation at rear end of gear cluster (furnished .087", .090", .093", .096" thick).

TESTING (ELECTRICAL CONTROL UNITS): First check oil level in transmission, remove right side of front floor mat and floor panel cover for access to transmission. Inspect wiring and tighten all connections, make certain that engine properly tuned up so that it idles smoothly at 450-475 RPM. Use test lamp and test leads to make following tests in order as given:

Control Relay: (1) Connect one test lamp lead to relay "BAT" terminal, other lead to ground, turn on ignition. Lamp should light. If not, check for open-circuit between ignition switch and relay. (2) With engine idling, connect test lamp between relay "SOL" terminal and ground. Lamp should light. If not, check for blown fuse, or poor fuse contacts. Then ground relay "TH" terminal. If lamp does not light relay is defective. (3) With test lamp connected between relay "SOL" terminal and ground, increase engine speed. Lamp should go out. If lamp remains on, relay contacts are not opening. Disconnect lead at relay "TH" terminal. If lamp does not go out, relay contacts are sticking. (4) With engine idling, ground relay "INT" terminal. Engine should stall. If not, ground "PRI" terminal. If this causes engine to stall, relay contacts are not operating properly If engine does not stall, check for open-circuit between "PRI" terminal and ignition coil.

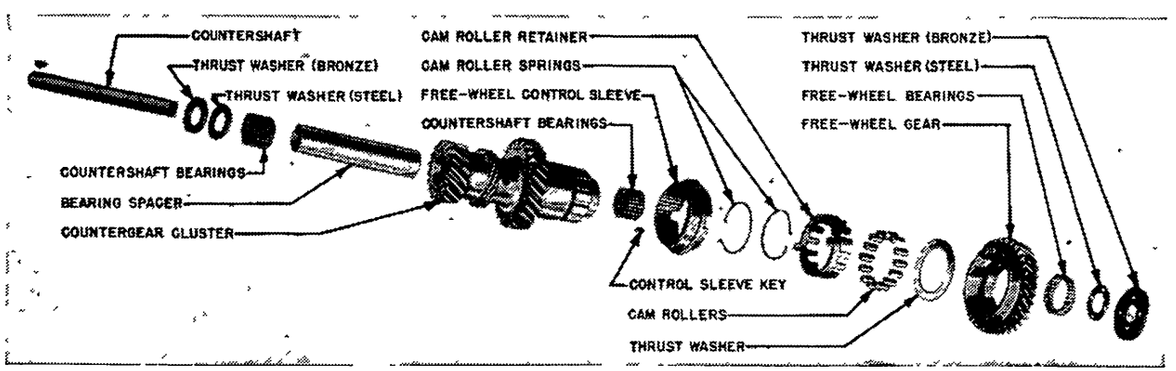
Relay Specifications

Auto-Lite Model HRM-4102. Both sets of contacts open and close together but circuits are independent (each set of contacts insulated from other).

Winding Resistance—17.6-19.4 ohms (measured between terminals #1 and #2).

Closing Voltage—3.0-4.0 volts (adjust both sets of contacts to open and close simultaneously). Adjust by bending lower spring hanger.

Armature Sealing to Core—5.0 volts maximum. Adjust by bending lower spring hanger.

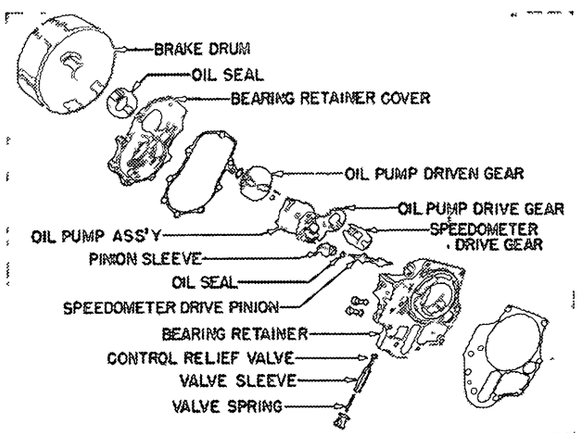


Opening Voltage—1.1-2.5 volts. Adjust by raising or lowering stationary contact.

Armature Air Gap—.031-.036". Adjust by bending armature stop.

Fuse Capacity—30 amperes.

Governor & Kick-down Switch: Connect test lamp between relay "SOL" terminal and ground. Idle en-



CONTINUED ON NEXT PAGE

C UNTERSHAFT GEAR ASSEMBLY

1946-48 CHRYSLER HYDRAULICALLY OPERATED AND DE SOTO TIP-TOE SHIFT (Cont.)

gine. Lamp should be lighted. If not, ground governor terminal. If lamp lights, governor contacts are sticking open and governor should be replaced or serviced. If lamp does not light, check for open-circuit between relay and governor. Increase engine speed. Lamp should go out. If lamp remains lighted, disconnect lead at kick-down switch on carburetor. If lamp is still lighted, governor contacts are not opening and governor should be replaced or serviced. If governor operation satisfactory with kick-down switch lead disconnected (lamp lighted at idle speed indicating governor contacts closed, lamp out at higher engine speed indicating governor contacts open), kick-down switch is defective and should be repaired or replaced. To check kick-down switch operation, with test lamp connected between relay "SOL" terminal and ground, increase engine speed to point where lamp goes out, depress kick-down switch plunger by hand. Lamp should light with switch plunger pressed in and should go out when plunger released.

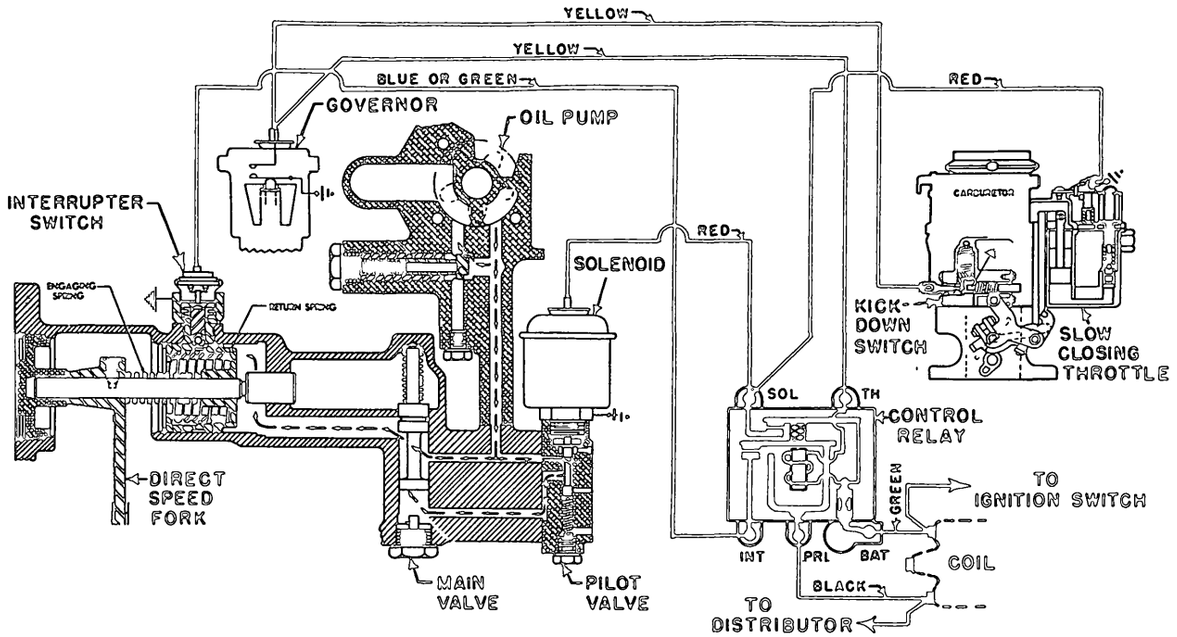
MAINSHAFT REAR BEARING RETAINER

Governor Specifications

Auto-Lite Model TG-4202R or TG-4203R (Early 1946), TG-4204R (1946-48). Rotation clockwise viewed from the top (all models).

Contact Closing (on deceleration)—(TG-4202R and TG-4203R) 450-550 RPM., (TG-4204R) 385-450 RPM. Difference between Closing & Opening—40-150 RPM. (all models).

Endplay—.005-.010" (all models).



Kick-down Switch: *See "Chrysler, DeSoto, Dodge Kick-down Switch" in Electrical Equipment Section.*

Slow-Closing Throttle: *Different type on Chrysler 8.*

Chrysler 6 & DeSoto—*See "Chrysler, DeSoto, Dodge Slow-Closing Throttle" in Carburetion Equipment Section.*

Chrysler 8—*See "Chrysler Eight Throttle Guard" in Carburetion Equipment Section.*

Transmission Valve Solenoid: With engine idling slowly, and with test lamp connected between solenoid terminal and ground, lamp should be lighted and distinct magnetic attraction noted at solenoid cap (test with small steel tools or other objects). If lamp not lighted, check for open-circuit in solenoid lead. If lamp lighted but no magnetic pull noted, solenoid coil is open and should be replaced. To check solenoid, remove solenoid, reconnect lead, turn ignition on, invert solenoid and ground it on transmission. Plunger should snap out. If not, replace solenoid.

1946-48 TRANSMISSION CONTROL UNIT WIRING DIAGRAM

Solenoid Specifications

Auto-Lite Model SSS-4002. Single winding type.

Winding Resistance—1.8-2.1 ohms measured between terminal and ground on base.

Plunger Position—At Rest—.632" maximum from mounting face to end of plunger rod. Energized—.778-.793" from mounting face to end of plunger rod. Load—Plunger force should be 6 lbs. minimum with 4 volts applied to coil at 77°F. Measure with plunger in "at rest" position.

Ignition Interrupter: Block rear wheels securely, run engine with transmission in third gear. Disconnect lead from "INT" terminal on relay. Connect test lamp between relay "BAT" terminal and interrupter switch terminal. Lamp should flash when engine speed increased. If lamp does not flash, replace interrupter switch. If lamp remains lighted more than momentarily, interrupter switch is sticking (would cause engine to stall).

TESTING (HYDRAULIC UNITS): Check transmission oil level and fill to filler plug hole level. Then test hydraulic system as follows:

Hydraulic Oil Pressure: Remove "Mainshaft Rear Bearing Retainer Pressure Line Plug" on right side of transmission (see illustration), connect test oil pressure gauge at this point. Block up rear wheels securely, run engine with transmission in high range. Oil pressure should be 40-60 lbs. at 15 MPH. If pressure less than 40 lbs., inspect and service oil pump, check oil pressure relief valve for sticking open, check for dirty or clogged oil pump screen and oil pressure leaks.

NOTE—Pressure will drop momentarily when transmission upshift occurs.

Automatic Shift Action: With rear wheels blocked up and engine running with transmission in gear, remove interrupter switch so that movement of hydraulic piston shift rail can be noted. Increase speed above 15 MPH. Piston should move forward and close off interrupter switch hole. If piston does not move forward, check hydraulic valves (see below). If piston moves forward but upshift does not occur, check hydraulic shift mechanism for binding. Stop engine and note if piston is in rear position (interrupter switch hole uncovered). If piston in rear position but transmission does not downshift, check for loose shift fork. If piston does not move to rear (hole remains covered), check for binding of shift rail, direct speed sleeve, or free-wheel control sleeve.

Hydraulic Valves: Check each valve as follows:

Pilot Valve—Remove solenoid assembly. Pilot valve should be up against upper stop and should work freely. If not, remove and clean valve and valve chamber.

Main Control Valve—Remove valve plug on right side of transmission (see illustration). Valve should work freely against spring tension. If not, remove and clean valve and valve chamber.

Control Relief Valve—Remove plug on right side of transmission (see illustration). Check valve for free movement. If valve is sticking or sluggish check for weak or broken spring, clean valve.

►CHANGES, CAUTIONS, CORRECTIONS

►**FLUID-TORQUE DRIVE**—*See "Chrysler Fluid-Torque Drive" article for complete data.*

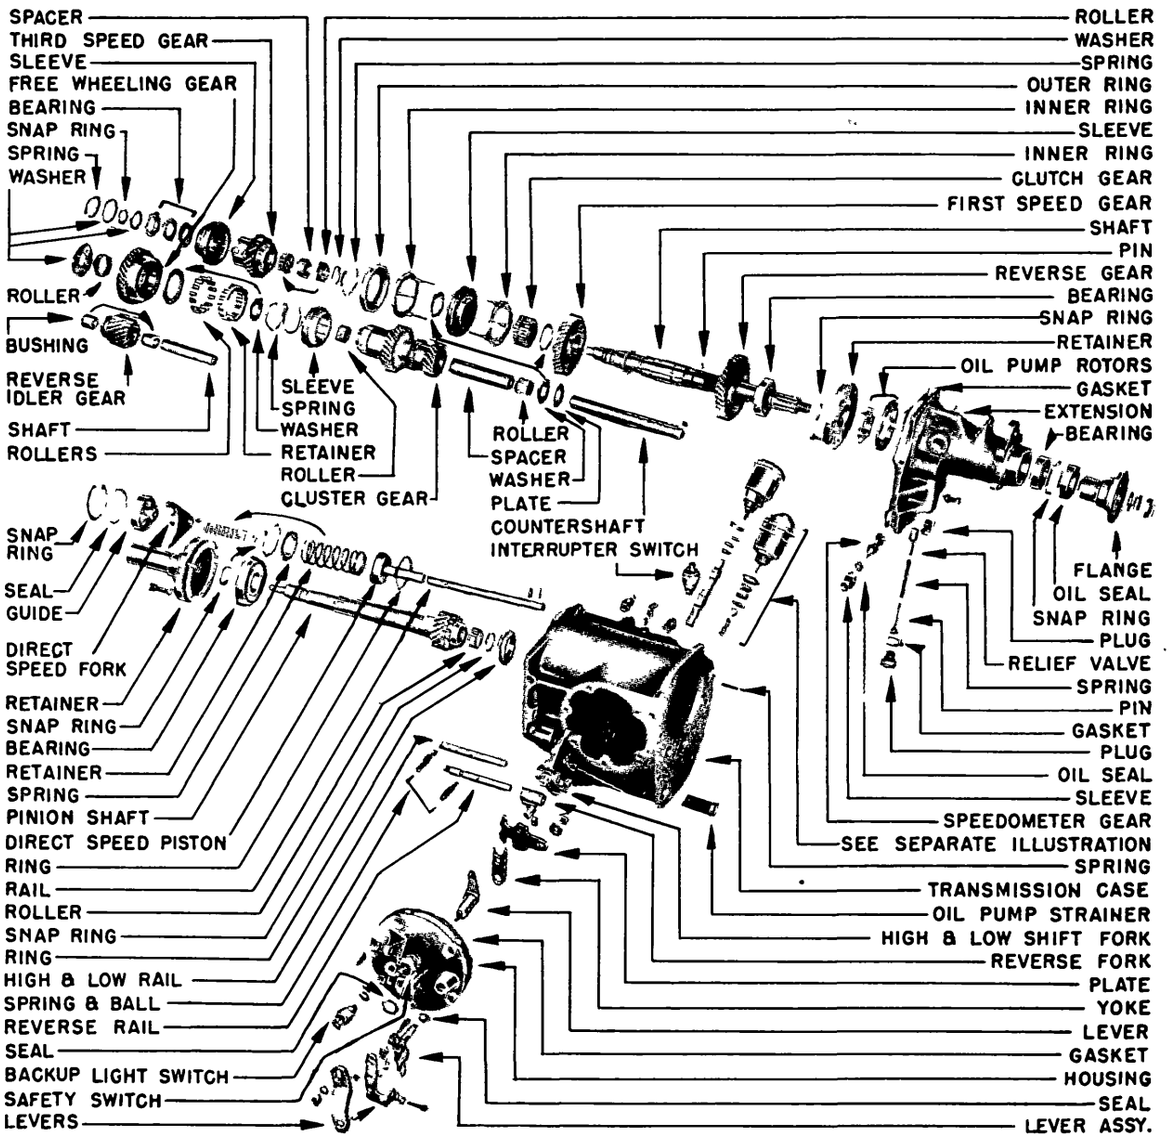
►**PARTS INTERCHANGE CAUTION**—Drive pinion and free wheeling gears in transmissions with Fluid-Matic are different than gears used in transmissions with Torque-Converter. Also the cluster gear and third speed gear is different in transmissions used with Fluid-Matic. DO NOT INTERCHANGE THESE PARTS.

►**STARTING ENGINE BY PUSHING OR TOWING CAR:** Turn ignition on, place gearshift lever in Low Range, disengage clutch and do not engage clutch until car speed is approximately 10 MPH. At this speed, transmission will automatically shift into 2nd Speed and engine will be cranked.

►**KICK-DOWN SWITCH CHANGE (For Improved Transmission Operation):** *See "Chrysler, DeSoto, Dodge Kick-down Switch" in Electrical Equipment Section.*

►**MANUAL CLUTCH GEAR SYNCHRONIZER PRODUCTION CHANGE:** "Plate Type" Synchronizer used on first transmissions, superseded by "Pin Type" Synchronizer on later transmissions. See illustrations and disassembly data for each type. *NOTE*—Transmissions with Pin Type Synchronizer marked by four-leaf clover on model number pad on transmission case cover face.

►**INTERRUPTER SWITCH MOUNTING PRODUCTION CHANGE:** On later transmissions, interrupter switch relocated toward rear of transmission and operated by pin located in rear end of direct speed rail (first type operated directly by piston skirt).



►*SWITCH TESTING CAUTION*—Manufacturer recommends that Interrupter Switch NOT BE REMOVED to check operation of hydraulic mechanism (new switch location may allow oil to spurt out over interior of car).

►*1952 PRODUCTION CHANGE (Direct Speed Clutch Sleeve Fork Engaging Spring)*—A new spring, Part No. 1530758 entered production to improve direct speed sleeve engagement. New spring can only be used on the later type transmissions having Ignition Interrupter Switch located near rear of transmission.

►*TRANSMISSION SELECTOR LEVER ADJUSTMENT (To correct difficult shifting): See "Transmission Selector Lever Adjustment" (below).*

DESCRIPTION

DESCRIPTION: Own make, semi-automatic, 4-speed transmission with hydraulic actuation and electrical control. Transmission is similar in design to transmissions used on corresponding previous models.

CHRYSLER, DESOTO, DODGE AUTOMATIC TRANSMISSION (WITH PIN TYPE SYNCHRONIZER)

LUBRICATION

LUBRICATION: Check oil level in transmission every 1,000 miles or 30 days, drain and refill every 10,000 miles or once a year, maintain oil level even with bottom of filler plug hole.

►*RECOMMENDED OIL CAUTION*—Lubricant installed at factory is special. Should it be ncessary to remove oil from transmission during first 10,000 miles of operation, the original oil should be saved, filtered and then used in the repaired or replacement assembly. Maintain proper level during the first 10,000 miles using SAE 10-W engine oil.

Recommended Oil—Use only SAE 10-W Engine Oil.
Capacity—3 pints (refill).

►*CAUTION—Add additional ½ pint (3½ pints total),*

C NTINUED ON NEXT PAGE

CHRYSLER PRESTOMATIC & FLUID-MATIC, DE SOTO TIP-TOE SHIFT, DODGE GYROMATIC (Cont.)

whenever transmission extension housing removed and drained (additional oil will work back into extension housing in service).

REMOVAL

See TRANSMISSION on individual car model pages.

TESTING

Ignition Switch to Circuit Breaker Check: Connect test light to coil side of circuit breaker, and the other wire of test light to ground. Turn ignition switch on. Test light should go on. If it does not, wires are faulty (loose or dirty). Correct as necessary.

Circuit Breaker Check: Connect test light to solenoid side of circuit breaker, and the other wire of test light to ground. Turn ignition switch on. Test light should go on. If it does not, circuit breaker connections are loose or dirty, or circuit breaker should be replaced. If circuit breaker is clicking, there is a short in the red solenoid wire or brown anti-stall wire. Determine cause and correct condition.

Circuit Breaker to Solenoid Check: Connect test light to red wire terminal of solenoid, and the other wire of test light to ground. Turn ignition switch on. Test light should go on. If it does not, the wire or corrections are faulty. Determine cause and correct.

Circuit Breaker to Anti-Stall Check: Connect test light to brown wire terminal of anti-stall control, and the other wire of test light to ground. Turn ignition switch on. Test light should go on. If it does not, the wire or connections are faulty. Determine cause and correct.

Anti-Stall Check: Turn igition switch on. Place a steel screw driver on the peened rivet head of coil which is located on top of anti-stall cover. A magnetic pull should be felt on screw driver (be sure screw driver has not been previously magnetized). If no magnetic pull felt, anti-stall control is at fault and should be replaced.

Solenoid Check: Hold a soft steel tool to solenoid body. Turn switch off and on. A definite magnetic pull should be left when ignition switch is on (be sure tool has not been previously magnetized). With ignition switch on, connect a test light across solenoid terminals. If no magnetic pull is felt, but light is on, the solenoid is at fault and should be replaced.

Governor & Kickdown Switch Check: Connect one wire of test light to governor terminal, and the other wire of test light to red wire terminal on solenoid. Turn ignition switch on. Test light should go on, indicating governor points are closed. If points are at fault, clean or replace them. Start engine and with transmission in neutral, accelerate engine speed to approximately 14 miles per hour. The test light should go out and then go on again when car speed is reduced to approximately 12 MPH., indicating governor is operating satisfactorily. If governor faulty remove and inspect. Clean points or replace parts as necessary. Accelerate car speed between 15 and 40 MPH., push in kickdown switch by hand. The test light should go on again, indicating kickdown switch operating satisfactorily.

Imterrupter Switch Check: With engine running, ground blue wire on the resistor or at interrupter switch. This should stall engine. If engine continues to run, either the blue wire from interrupter switch to resistor, or blue wire from resistor to coil is at fault.

▷*CAUTION—Do not remove interrupter switch with engine running. Oil may be forced out and damage car interior.*

Hydraulic Test: Make sure that transmission has correct amount and proper grade of lubricant.

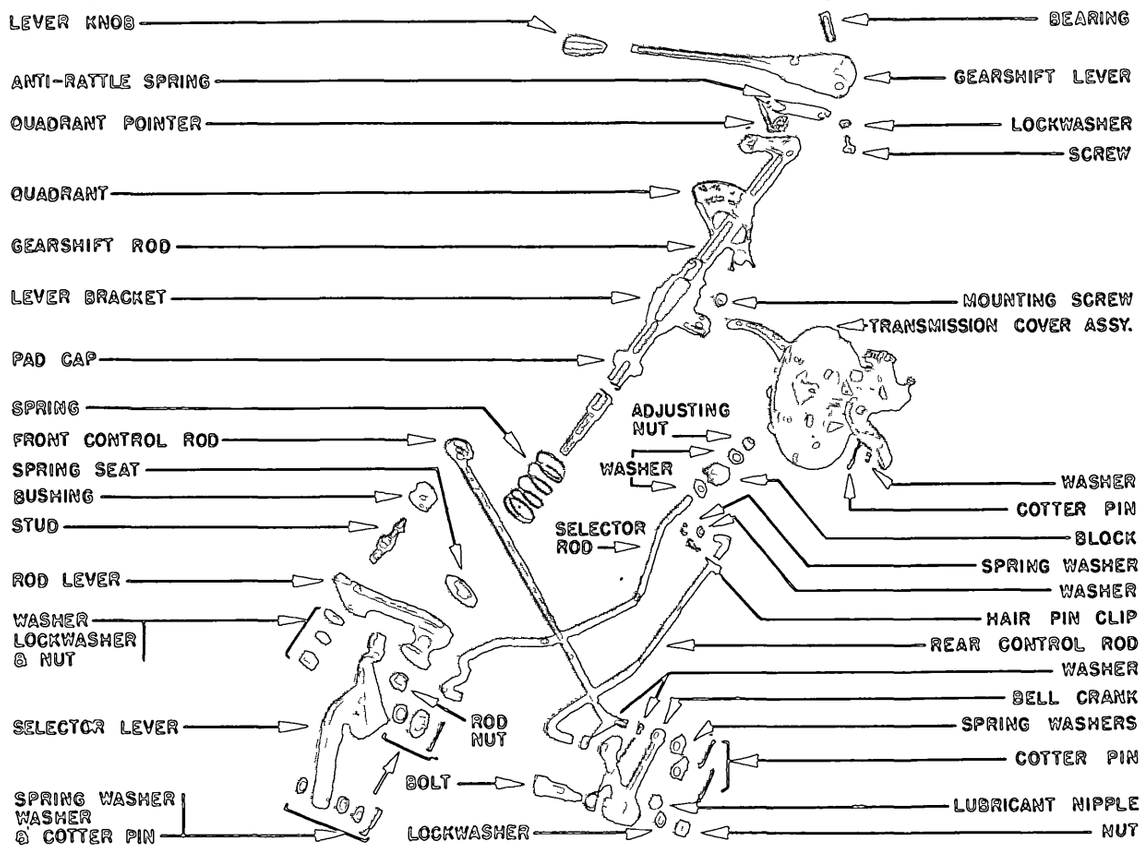
1) Jack up car so rear wheels are off floor. Then raise floor mat and remove floor board access cover.

2) Remove transmission case shifting fork lock screw plug. Start engine and engage the shift lever in forward speed (low range). Using the eraser end of a pencil, insert it in the shifting fork lock screw plug hole so it is resting against shifting fork. Accelerate engine to approximately 6 to 8 MPH. The pencil being positioned as described above will move forward as the direct speed shift rail and fork move forward, this can be readily felt while holding the pencil. This movement indicates hydraulic pressure is correct, which is 38 to 40 psi. If fork and rail does not move forward between the specified speeds, piston is either stuck, worn, or pump is faulty.

▷*CAUTION—It is no longer recommended to remove interrupter switch to make the above hydraulic check. Oil forced out under pressure may damage car interior.*

Governor Specification

Auto-Lite No.	Model Year
TG-4205R	1949-50
TGG-4001	1951-53



Contacts Open (On Acceleration)—575 RPM. max.
Contacts Close (On Deceleration)—390-455 RPM.
Range Between Opening & Closing—40-150 RPM.
Governor Endplay—.005-.010".

▷Replacement Governor Note—Cover and switch assembly furnished separately for replacement.

1952-53 TRANSMISSION CONTROL

▷*TRANSMISSION SELECTOR LEVER ADJUSTMENT (To Correct Difficult Shifting):* Disconnect selector rod from outer selector lever on transmission cover. Loosen the outer lever adjusting screw lock nut and back off adjusting screw as far as possible. Check tension of outer lever spring between inner and outer levers. Outer lever spring should have sufficent tension to hold outer lever firmly against inner lever. If tension not sufficent, replace spring. Reconnect selector rod to outer lever. Place transmission in high range position by moving gearshift control lever on housing to rear until gears are

CONTINUED ON NEXT PAGE

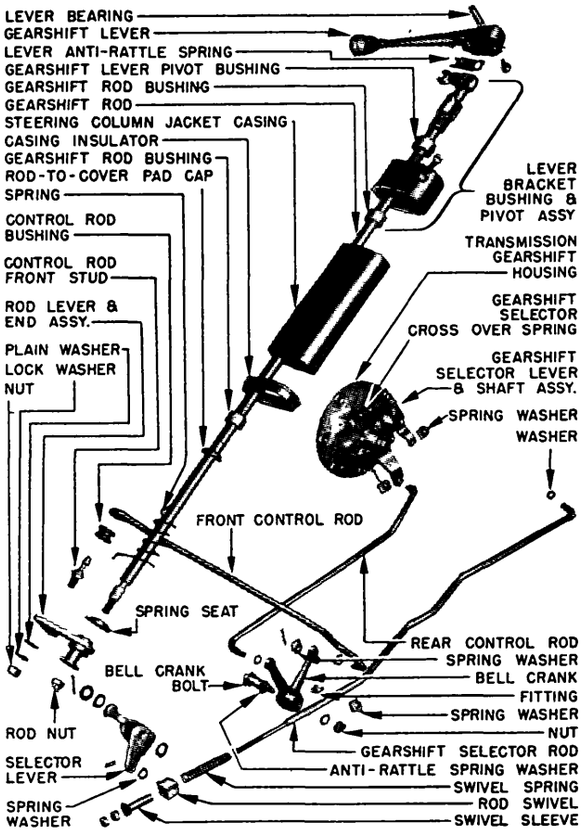
TYPICAL 1951-53 AUTOMATIC TRANSMISSION CONTROL

CHRYSLER PRESTOMATIC & FLUID-MATIC, DE SOTO TIP-TOE SHIFT, DODGE GYROMATIC (C nt.)

fully meshed. Thread outer selector lever adjusting screw inward until screw end just contacts inner selector lever pad. Lock adjusting screw with lock nut. ***(CAUTION—Do not turn adjusting screw inward beyond the point given above, or difficult shifting will result.)*** Hook both ends of outer lever spring over inner and outer selector levers in their respective positions. Check shifting operation, and if shifting is still difficult, see "Gearshift Lever Yoke" following.

►**Gearshift Lever Yoke Bushing Replacement**—If yoke or bushing is damaged, it will be indicated by a loose feeling at shift lever, and gear shifting may also be difficult.

1) Remove horn blowing ring and steering wheel. Remove transmission position indicator lamp housing by removing the two small crosshead screws. Remove snap ring retaining the turn signal housing to column jacket. Carefully work the turn signal housing upward until it is free of column jacket.



2) Remove the four crosshead screws retaining upper half of shifting yoke housing to jacket assembly and lift off upper half.

3) Very carefully remove the large diameter Oilite bushing from steering column tube. ***(CAUTION—Use care in removing bushing as it is easily broken.)*** Remove snap ring retaining shifting yoke and bushings in shifting tube.

4) Lift shifting tube upward and out of housing, using care not to drop bushings into tube, otherwise column jacket assembly must be disassembled to remove them.

5) Install new shifting yoke into position in housing with the lugged surface of yoke facing downward. Install the two Oilite bushings over shifting yoke pins with the flanged surface to the outside. Be sure bushings are properly positioned in shifting tube recess.

6) Install upper half of shift yoke retaining housing and tighten the four crosshead screws into position. Install bushing retaining snap ring with open ends away from shift yoke. After yoke bushing snap ring has been properly positioned, tap snap ring retaining lugs on tube downward slightly so ring will not become disengaged. Install turn signal housing and snap ring, steering wheel, and horn blowing ring. Install transmission position indicator lamp housing. Adjust transmission selector levers (above).

TYPICAL 1949-50 AUTOMATIC TRANSMISSION CONTROL

Gearshift Neutral Position Adjustment: Make certain transmission is in neutral position. Loosen remote control rod stud nut on shifting lever at base of steering column. Move gearshift lever until indicator pointer centers on "N" position on indicator dial. Retighten control rod stud nut securely.

►**Crossover Spring Installation (For Improved Operation of Selector Levers):** Crossover spring Part No. 1120874 can be installed to improve selector lever operation as follows. Hook large loop on end of spring over top of outer lever spring on transmission outer selector lever. If car does not have a torque converter, hook other end of spring through hole in lug on transmission cover. If equipped with torque converter, hook spring behind upper left hand cover attaching capscrew.

DISASSEMBLY

►*DISASSEMBLY CAUTION*—Before disassembling transmission, clean outside of transmission case thoroughly to prevent dirt and foreign material from entering case or getting on transmission parts.

DISASSEMBLY OF TRANSMISSION: With transmission off car and Governor, Solenoid, and Interrupter Switch removed, proceed as follows:

1) Make certain that governor drive pinion removed from case (can be lifted out with long-nosed pliers), remove speedometer drive gear and sleeve assembly.

2) Place gearshift control levers in neutral, remove gearshift housing assembly by taking out attaching capscrews.

3) If brake drum and propeller shaft flange not removed previously, lock mainshaft by moving the manual clutch gear sleeve and the reverse idler gear backward so that both gears are engaged, then remove nut, lockwasher, and plain washer from rear end of shaft, use Puller C-452 to remove propeller shaft flange and brake drum assembly.

4) Take out capscrews attaching extension housing on back of transmission case, remove extension housing and mainshaft as an assembly (Direct Speed Clutch will slide off Third & Direct Speed Gear and remain in case—note that sleeve and gear are paint-marked to insure correct reassembly), remove housing gasket.

5) Use Puller C-604 to remove reverse idler gear shaft through rear of case (CAUTION—do not lose shaft key), lift gear out.

6) Remove direct speed blocker ring from forward end of direct speed clutch sleeve. Remove snap ring in forward end of case retaining direct speed gearshift rail guide, remove guide and guide seal from case. Take out upper plug on right side of transmission case, insert a screwdriver in this hole and pry shifting fork backward just enough to allow direct speed clutch sleeve to be withdrawn through side opening in case.

7) Using screwdriver inserted through plug hole on right side of case, loosen locking screw in direct speed gearshift fork until the fork is forced forward by the engaging spring, then cock the fork on the shaft and pull the fork toward the rear of the case which will move the direct speed gearshift rail to the rear. Repeat this procedure (hold rail while moving fork forward for additional travel) until the rail is free, then remove rail, spring, and fork from the case using care not to lose interrupter switch operating pin (see Caution).

►***CAUTION—Later transmissions have loose fitting taper pin hole in rear end of direct speed gearshift rail for interrupter switch operation and this pin must not be lost when rail removed.***

8) Use Tool C-714 to compress direct speed piston spring (insert tool through gearshift rail hole from front of case), remove spring retaining snap ring (use long-nosed pliers inserted through guide hole in front of case), relieve spring tension, remove tool, withdraw spring retainer, spring, piston, and piston ring through front of case.

9) Drive countershaft out through rear of case using Arbor C-716 **leaving arbor within the countergear** cluster to retain the countergear bearing roller assemblies (CAUTION—do not lose woodruff key in rear end of shaft which locks shaft in case). This will allow countergear assembly to drop down in bottom of transmission case to allow main drive gear to be removed.

10) After countergear cluster lowered in case, take out attaching screws and remove drive gear bearing retainer and gasket on front end of transmission case. Use puller to remove drive gear and bearing assembly through front of case.

11) After drive gear removed, lift countergear cluster assembly up and remove from case using care not to lose thrustwashers (CAUTION—note location of bronze and steel washers to insure correct reinstallation), or disturb arbor within cluster which would allow bearing rollers to fall out.

12) Disassemble all sub-assemblies as follows:

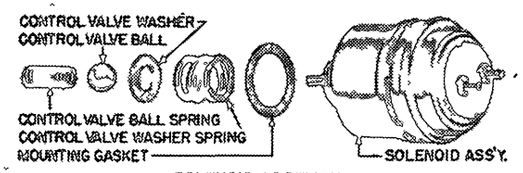
Extension Housing & Mainshaft Disassembly: Remove speedometer drive pinion and sleeve assembly. Use Puller C-748 to remove oil seal from rear end of housing. Press mainshaft assembly out of housing (see below for mainshaft disassembly).

Extension Housing—Remove capscrews holding mainshaft bearing retainer in front face of housing, lift off bearing retainer and oil pump inner and outer rotors. Remove shuttle valve retainer plug (on bottom of housing), withdraw valve parts

CONTINUED N NEXT PAGE

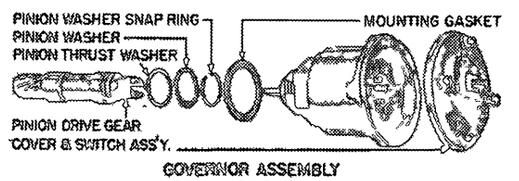
CHRYSLER PRESTOMATIC & FLUIDMATIC, DESOTO TIP-TOE SHIFT, DODGE GYROMATIC (Cont.)

(guide spring, pin, and valve). Remove oil seal, take out rear bearing snap ring, drive rear bearing out through rear of housing.



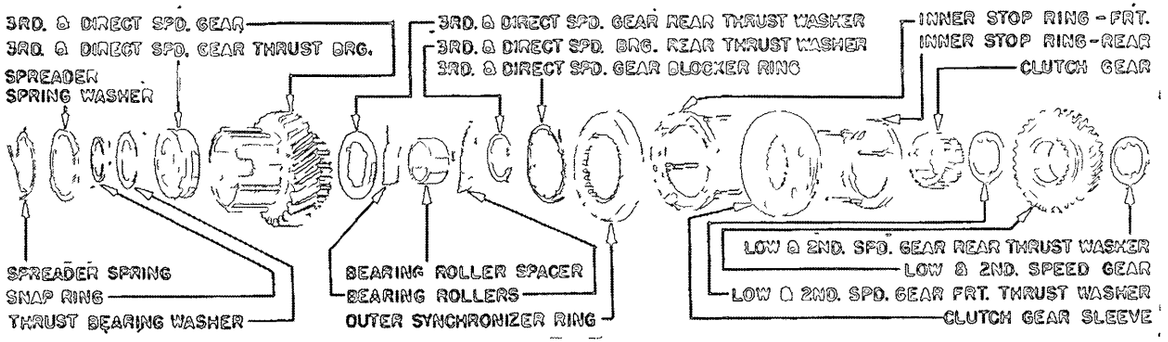
Mainshaft Disassembly: *CAUTION—Mainshaft with Plate Type Synchronizer serviced differently than later type with Pin Type Synchronizer:*

Mainshaft Disassembly (Plate Type Synchronizer Remove direct speed blocker spring and washer from forward end of shaft, remove snap ring, slide 3rd and direct speed gear off end of shaft (Caution —Use care not to lose bearing rollers, spacer, bearing front thrust washer, and needle bearing washer), remove rear thrust washer. Remove clutch gear synchronizer snap ring and front stop ring, remove clutch gear sleeve assembly as a unit, remove rear stop ring. Remove 1st speed gear front thrustwasher, slide gear off, remove rear thrustwasher. Remove oil pump drive pin from rear end of shaft, remove bearing snap ring from rear end of shaft, press bearing and reverse gear off rear end of shaft.



Mainshaft Disassembly (Pin Type Synchronizer): Remove 3rd and Direct speed gear blocker ring spreader spring, washer, snap ring, and the thrust bearing washer (CAUTION—this washer must be removed first or it will prevent removal of 3rd and direct speed gear). Use a clean pan to catch all parts when removing the 3rd and direct speed gear, remove the gear assembly (thrust bearing assembly, 72 bearing rollers, and bearing roller spacer). Remove the bearing roller steel thrustwasher and the thick direct speed rear thrustwasher. Remove outer synchronizer stop ring and front inner stop ring assembly (CAUTION—use care not to damage threads on either of the cone faces on this stop ring). Remove clutch gear sleeve and rear inner synchronizer stop ring (CAUTION—use care not to damage threads on either of the cone faces on this stop ring). Remove the clutch gear hub (may be tight enough to require a puller). Remove low and 2nd speed gear front thrustwasher, gear, and rear thrustwasher.

▷*CAUTION—Do not change relative position of these thrust washers. These washers are not identical and MUST BE REASSEMBLED IN THE SAME POSITION.*



Countergear Cluster Disassembly: Stand the assembly on end with free-wheeling gear upward. Remove bronze thrust washer and steel bearing washer. Slide free-wheeling control sleeve up and remove

SOLENOID ASSEMBLY

SOLENOID & GOVERNOR ASSEMBLY

PIN TYPE MANUAL CLUTCH GEAR SYNCHRONIZER

gear. Remove cam roller thrust washer, gear bearing rollers and free-wheeling cam rollers, cam roller retainer, and retainer springs *(CAUTION—*Use care not to distort springs), free-wheeling control sleeve and key. If countergear bearing rollers being replaced, remove arbor from within gear cluster, remove front and rear bearing rollers and bearing spacer.

REASSEMBLY

Reassemble all sub-assemblies as directed below and install these in transmission case in reverse order of disassembly procedure given above.

Countershaft Free-wheeling Gear Assembly: Install the key and free-wheeling control sleeve on forward end of gear cluster, hook anchor ends of both springs in holes in gear cluster so that springs wrap around in right hand direction from anchor end. Place roller cage over gear with lugs over spring anchors, rotate cage clockwise until lugs are over slots in control sleeve, make certain that spring ends have snapped into grooves in cage. Slide control sleeve forward until cage lugs fully engage sleeve. Install free-wheeling rollers (use cup grease to hold rollers in position), install thrustwasher, slide free-wheeling gear on gear cluster, install gear bearing rollers (45 rollers), install steel thrustwasher and bronze thrustwasher (steel washer next to gear).

Countergear Cluster Bearing Assembly—If bearing rollers removed from gear cluster, assemble bearings as follows: Install special arbor in gear cluster and stand assembly on bench with free-wheeling gear upward. Install several bearing rollers to position bearing spacer, install spacer, then install set of 27 bearing rollers, bearing washer (steel), and thrustwasher (bronze) in that order. Invert assembly and install 27 bearing rollers in opposite end of cluster, install steel and bronze thrustwashers in that order. Assembly is then ready for installation in case.

Countergear Cluster Installation: Place the assembly in bottom of case making certain that steel and bronze thrustwashers in place at each end of assembly (steel washer next to gear, bronze washer next to case). After main drive gear has been installed, lift assembly up and insert countershaft from rear (pushing arbor out through front of case), make certain that thrustwashers in place and that countershaft locking key installed in slot in rear end of shaft. Check gear cluster endplay which should be .002-.008". Adjust by installing bronze thrustwashers of correct thickness (furnished .097", .102", .107", .112", .117" thick).

Main Drive Gear Installation: Install the main drive gear assembly in case, then install bearing retainer without any gasket, tighten retainer capscrews. Measure clearance between retainer flange and face of case with a feeler gauge, select a gasket of same thickness as measured clearance (or nearest oversize), remove retainer and re-install with this gasket under the flange, use rubber gasket on each retainer capscrews, tighten these screws to 10-15 ft. lbs.

▷*CAUTION—Rubber gaskets must be used on retainer capscrews and these screws securely tightened to prevent oil leaks at this point.*

Mainshaft Assembly: Install all parts on shaft in following order:

Reverse Gear & Rear Bearing—Install reverse gear on rear end of shaft, press bearing in place, select and install thickest snap ring which will fit groove in back of bearing (furnished .088", .091", .095", .097" thick). Install oil pump rotor drive pin.

Low & Second Speed Gear—Install parts on front end of shaft in following order: Rear Thrustwasher, Low & Second Speed Gear, Front Thrustwasher.

Manual Clutch Gear Synchronizer—*CAUTION—First "Plate Type" and later "Pin Type" synchronizers are installed differently as follows:*

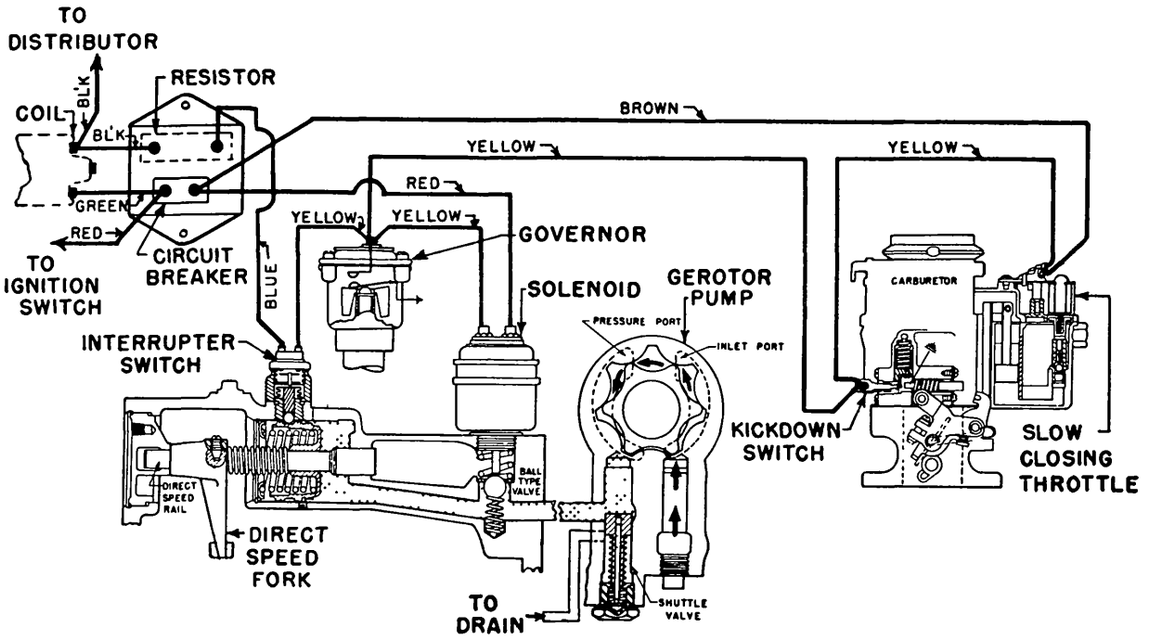
Plate Type Synchronizer Assembly—Clutch gear, sleeve, shifting plates (3), and springs (2) are removed and installed as an assembly (see illustration for assembly of these parts). First install rear synchronizer stop ring, then slide synchronizer assembly on shaft, install snap ring, then install front synchronizer stop ring.

Pin Type Synchronizer Assembly—Install inner (rear) synchronizer stop ring. Index the grind mark on the clutch gear teeth with paint mark on clutch gear teeth *(CAUTION—*this alignment necessary to insure free sliding fit between these parts), install this assembly on shaft with extended portion of sleeve hub and shoulder side of gear facing forward, install inner (front) synchronizer stop ring with the pins extending through the second set of three holes

CONTINUED ON NEXT PAGE

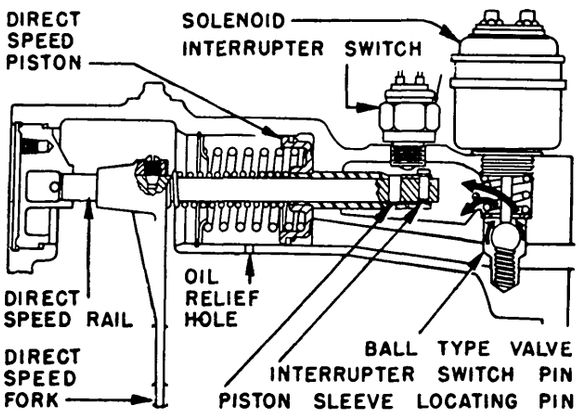
CHRYSLER PRESTOMATIC & FLUID-MATIC, DE SOTO TIP-TOE SHIFT, DODGE GYROMATIC (C nt.)

in the clutch sleeve. Install outer synchronizer stop ring. *NOTE*—Outer synchronizer stop ring spreader spring (blocker ring) should be assembled on rear of 3rd and direct speed gear and installed with the gear.



3rd & Direct Speed Gear Assembly—Install thick rear thrustwasher on shaft (recess side toward rear) and make certain that it is indexed with shaft splines. Assemble bearings in 3rd and direct speed gear as follows: Insert thrust bearing in forward end of 3rd and direct speed gear (end with largest hole first and grooved end toward front of gear), install one set of 36 bearing rollers (use cup grease to hold rollers in place), bearing spacer, second set of 36 bearing rollers, and bearing roller thrustwasher. Install this gear assembly on shaft (CAUTION—If Pin Type synchronizer used, make certain that synchronizer outer stop ring spreader spring is in place on rear end of 3rd and direct speed gear when gear installed). Install thrust bearing washer. Use thimble, Tool C-717, to install snap ring in shaft groove ahead of 3rd and direct speed gear (drive it into position with driver portion of tool and soft mallet). Check gear endplay (see Endplay note below) and adjust by selecting snap ring of correct thickness. On later transmissions with Pin Type synchronizer, install spreader spring washer and spreader spring on shaft using cup grease to hold these parts in place (*CAUTION*—these parts must not be allowed to drop down into case when installing mainshaft assembly). *NOTE*—On early transmissions with Plate Type synchronizer, blocker ring, blocker spring, and blocker spring washer are installed in direct speed clutch sleeve.

3rd.-&-Direct Speed Gear Endplay—Check clearance between bearing thrust washer and snap ring with a feeler gauge. If not within .003-.008", select snap ring of correct thickness to give this endplay. This snap ring furnished in thicknesses of .083", .088", .093", .098", .102".



Extension Housing Assembly: Make certain that small hole in top of shuttle valve is open, install shuttle valve assembly (valve, spring, guide pin), then install and tighten valve retainer plug and gasket. Install oil pump inner and outer rotors, mainshaft bearing retainer, extension housing bearing, and bearing snap ring. Use Driver C-850 to install oil seal in rear end of housing (leave 3/32" of seal protruding beyond rear machined face of housing). Install mainshaft assembly in extension housing (CAUTION—line up pump drive pin in shaft with slot in oil pump inner rotor before inserting shaft in housing), pressing the shaft bearing in the bearing retainer in the housing.

Propeller Shaft Flange Nut Note—When installing flange and brake drum assembly, tighten flange nut to 95-105 ft. lbs. torque.

Mainshaft & Extension Housing Installation: See that free-wheel control sleeve is back toward rear of case and engaged in groove of direct speed clutch sleeve. On first transmissions with Plate Type synchronizer, place blocker ring in direct speed clutch sleeve with large end of taper forward and anchor lugs back, install blocker spring and blocker spring washer (coat lightly with grease to hold in place). Insert mainshaft assembly through rear of case, align paint marks on clutch sleeve and gear (see Note below), and index teeth on gear hub with center tooth in sleeve. See that lugs on blocker ring are aligned with slots in gear hub. Tighten capscrews to 30-35 ft. lbs. torque.

TRANSMISSION CONTROL UNIT WIRING DIAGRAM (FIRST TYPE INTERRUPTER SWITCH)

CONTROL UNIT WITH LATER TYPE INTERRUPTER SWITCH

►*CAUTION—Do not force extension housing against transmission case, as blocker ring might become damaged. If housing does not move freely into position, the blocker ring is not indexed in 3rd speed gear slots. This ring should be properly indexed before housing is installed.*

►**Direct Speed Clutch Sleeve & Gear Marks—These marks are made in production after selective matching for approximately .005" min. backlash.**

NOTE—If new parts being installed, match parts for correct backlash and mark them to insure correct installation.

Direct Speed Gearshift Rail Installation: On early transmissions with Interrupter Switch mounted above hydraulic piston, install direct speed rail with offset screwdriver slot (in rear end of rail) horizontal and smallest shoulder toward side of case (this will position the setscrew hole for the gearshift fork properly in line with hole in case). On later transmissions with Interrupter Switch mounted to rear of hydraulic piston, make certain that loose taper pin in hole in rear end of shaft is in place and that pin points upward toward switch.

Gearshift Housing Installation: Before installing this assembly, position manual clutch gear sleeve in neutral and move reverse idler gear to fully disengaged position (*CAUTION*—shifting forks in housing assembly will not enter grooves properly unless parts positioned as above).

INSTALLATION

Install transmission assembly in car by reversing the removal instructions (see data on individual car model pages). Tighten transmission-to-clutch housing nuts and bolts to 45-50 ft. lbs. See control unit wiring diagram and individual car wiring diagrams for control unit wiring connections.

FLUID TORQUE DRIVE (COMBINED OIL SYSTEM)

Chrysler 6, C51 (1952) Optl.
Chrysler 6, C60 (1953) Optl.
DeSoto V8, S17 (1952) Optl.
DeSoto V8, S16 (1953) Optl.
Dodge D44, D48 (1953) Optl.
Plymouth, P24 (1953) Optl.

▷*IDENTIFICATION NOTE—This type Fluid-Torque Drive can be readily identified by absence of oil reservoir under clutch housing (plain lower pan used) and lack of oil cooler (at front of engine).*

DESCRIPTION: This Fluid Torque Drive (Torque Converter) consists of four basic elements—an impeller, turbine and two stators, which provide a maximum torque multiplication of 2.5-1 (Plymouth 2.6-1) starting torque to 1-1 driving torque. The oil system of the converter is COMBINED with that of the engine (see below). This method of circulating engine oil through the converter provides an adequate oil supply and efficient cooling without a separate oil pump and cooling system. On Plymouth cars the converter is used with a synchro-mesh transmission. On the others a modified hydraulically operated transmission is used.

Oiling System—Engine oil at normal pressure is fed through an opening in the engine main oil gallery at the rear of the block into the converter housing oil inlet passage and is routed through the reaction shaft and into the converter. Pressure is maintained at approximately 20 lbs. by a ball type regulator valve in the turbine shaft (excess oil flows through return passage in housing to an opening in the block through which it flows into the crankcase oil pan). Regulator valve also acts as a check valve to prevent oil in converter draining back into the crankcase when the engine is not running. *See LUBRICATION data below.*

OPERATION: *Similar to Fluid Torque Drive with SEPARATE oil system. See "Chrysler Fluid Torque Drive (Separate Oil System)" following.*

LUBRICATION: Check engine oil level in regular manner. Drain and refill twice a year or more often if required by seasonal temperatures (see Recommended Oil below).

▷*OIL FILTER CHANGE CAUTION*—Filter element should be changed at least every 5000 miles (or more often if required by operating conditions).

Capacity—(Plymouth) 10 qts. (Others) 12 qts. Add 1 additional quart if filter changed.

Recommended Oil—Use SAE grades of oil as follows:
Not Lower than +32°F.—SAE No. 30.
As Low as +10°F.—SAE No. 20-W.
As Low as —10°F.—SAE No. 10-W.
Below—10°F.—SAE No. 5-W.

Draining & Refilling—Drain crankcase by removing oil pan drain plug, drain torque converter by removing drain plug in converter housing (accessible through inspection hole in bottom of torque converter housing after removing inspection hole cover plate). Tighten both drain plugs and replace inspection hole cover plate. Install proper amount of oil through crankcase filler pipe. Run engine at moderate speed for approximately 5 minutes and check for oil leaks *(CAUTION*—Oil pressure should be higher than 20 lbs.). After 5 minutes run, stop engine, check oil level, add oil as required to bring level up to "Full" mark on indicator.

REMOVAL: Disconnect battery cable, then remove floor board solenoid cover, disconnect ignition interrupter, governor, solenoid lead wires, and safety or back up light switch (if so equipped). Raise car off floor and support it securely. Then proceed as follows:

1) Drain oil from engine crankcase and converter. See Draining data under LUBRICATION. *CAUTION—Oil in converter will be very hot if unit has been in operation.*

2) Remove transmission. *See Transmission Removal on individual car model pages.*

3) Remove clutch housing-to-exhaust pipe bracket bolt and shift bracket away from clutch housing. Disconnect and remove clutch fork pull-back spring and clutch fork rod assembly, *push pedal in until over-center spring holds pedal against floor board* (will prevent accidental movement of pedal during removal operation). Remove pivot bracket assembly and clutch release torque shaft. Remove release bearing but do not remove clutch fork *(CAUTION*—to avoid spreading the release bearing pull-back springs, pivot release bearing away from clutch fork enough to slide bearing off fork prongs—spreading of spring will cause lost motion between fork and bearing when unit reassembled).

4) Remove starter (turn wheels to extreme right for clearance).

5) Install engine support fixture Tool C-3162 to support rear end of engine (or use jack under engine with wood block approximately 12" square between jack and oil pan to prevent damage to pan).

6) Take out rear engine-to-cross-member support bolts, remove cross-member.

7) Lower engine approximately 3" for access to clutch housing upper attaching bolts.
CAUTION—DO NOT lower engine more than 3" to avoid damage to radiator hoses and other engine attachments.

8) Take out clutch housing-to-torque converter housing attaching bolts and remove clutch housing. *CAUTION—Do not use tools to pry or pound between clutch housing and converter housing flanges.*

9) Mark clutch cover and clutch driving plate to insure re-installation in same position, remove clutch assembly and driven member. *NOTE*—This will prevent getting oil or grease on clutch facings.

10) Take out converter housing-to-housing adapter bolts, remove complete assembly by pulling it straight back and away from converter unit *(CAUTION*—use extreme care not to damage flange surface of housing, torque converter impeller hub oil seal, or turbine shaft oil seal ring). Note "0" ring oil seals and sleeves in passages between the converter housing and engine adapter plate.

▷*CAUTION—Use care not to damage seal aligning sleeves in oil inlet and outlet passages in converter housing.*

11) Remove converter assembly from crankshaft by taking out attaching bolts in crankshaft flange.

12) Remove housing adapter plate from engine (three bolts on rear of plate, one bolt on front). Note "0" ring oil seals at oil inlet and oil return passages in engine block and in adapter plate. *NOTE*—Not necessary to remove adapter plate unless an oil leak is present between plate and cylinder block, or, the block is being changed.

DISASSEMBLY: *CAUTION—Crankshaft flange run-out and converter hub run-out must be checked whenever converter unit removed. See Installation data below.*

1) Take out capscrews in converter impeller hub oil seal retainer in converter housing, remove retainer and gasket.

2) Remove reaction shaft from converter housing by screwing two capscrews into threaded holes in shaft flange *(CAUTION*—pull shaft out evenly to prevent it binding in housing), remove gasket from beneath shaft flange and housing.

3) Remove snap ring from turbine shaft using pliers C-484, remove turbine shaft from bearing and housing using puller tool C-3182 *(CAUTION*—tighten side puller screws in housing thoroughly to prevent damaging threads).

4) Remove turbine shaft bearing from housing using tool C-3184 (insert puller body through inner diameter of bearing, then place cupped part of puller over outside of bearing and tighten puller nut to remove bearing).

5) Drive turbine shaft seal out of housing using a blunt drift *(CAUTION*—use care not to damage housing).

6) Remove turbine shaft-to-clutch drive plate capscrews and separate these parts. *NOTE*—This operation not necessary unless either part being replaced.

7) Take out regulator valve spring plug from clutch drive plate end of turbine shaft by screwing ¼" threaded part of tool C-3179 into plug and then installing puller cup and nut and tightening nut to remove plug from shaft. Remove regulator valve spring and ball from shaft.

INSPECTION: Inspect all parts for wear or damage. See that regulator ball in good condition and that valve seat smooth and free from nicks. Inspect spring for distortion and collapsed coils. Clean valve passage in shaft thoroughly. Thoroughly clean out all oil passages in converter housing, turbine shaft, and reaction shaft. Inspect oil seal rings on turbine shaft and reaction shaft and replace if worn or damaged (compare rings with new rings). Inspect mating surfaces of converter housing and adapter plate for nicks, burrs, or other damage which would prevent proper sealing at "0" rings.

OVERHAUL: *NOTE—except for items listed below, overhaul will be limited to replacement of worn or damaged parts when unit reassembled.*

▷*TORQUE CONVERTER UNIT REPAIR NOTE—Torque converter unit is sealed and no repair operations are required. Replace complete converter unit if repairs indicated.*

Starter Ring Gear Replacement (on Converter Drive Plate): With converter assembly removed from crankshaft, proceed as follows:

Removing Old Ring Gear—Remove staking lugs retaining ring gear on drive plate using a file. Use blunt chisel or drift to tap ring gear off drive plate. Use a file to remove all burrs and raised spots left on ring gear contact surface of drive plate.

Installing New Ring Gear—Heat new ring gear (see Heating Note below), place gear over flange surface of drive plate making certain that rear face

CONTINUED ON NEXT PAGE

FLUID TORQUE DRIVE (COMBINED OIL SYSTEM) (Continued)

of gear contacts drive plate flange evenly around entire circumference. Weld gear to drive plate spacing welds evenly and using approximately same amount of metal at each weld.

►**Ring Gear Heating Note**—Ring gear can be heated by any of the following methods: 1) Use C-794 Oven, setting temperature at 150°F. and allowing gear to remain in oven for 15-20 minutes, 2) Place ring gear in shallow container of water, allow it to remain in water for 8 minutes after water comes to a boil, 3) If steam used, direct steam flow around gear for approximately 2 minutes, 4) If direct flame used, direct slow flame around outer rim of gear using care to direct flame away from gear teeth, check heat with few drops of water on face of gear, gear should be hot enough when water boils.

Transmission Drive Pinion Pilot Bushing Replacement: Remove old bushing from turbine shaft by threading puller tool C-3185 into bushing. Clean all metal cuttings from shaft after removing bushing. Install new bushing with tool C-3181 as follows: Install spacer washer SP-1615 over drift, then slip new bushing over ground end of tool, use tool as a driver to install bushing in shaft *(CAUTION*—spacer washer is required to position bushing to proper depth). Install outer sleeve and nut on driver part of tool, tighten nut to withdraw tool which will BURNISH bushing to proper size.

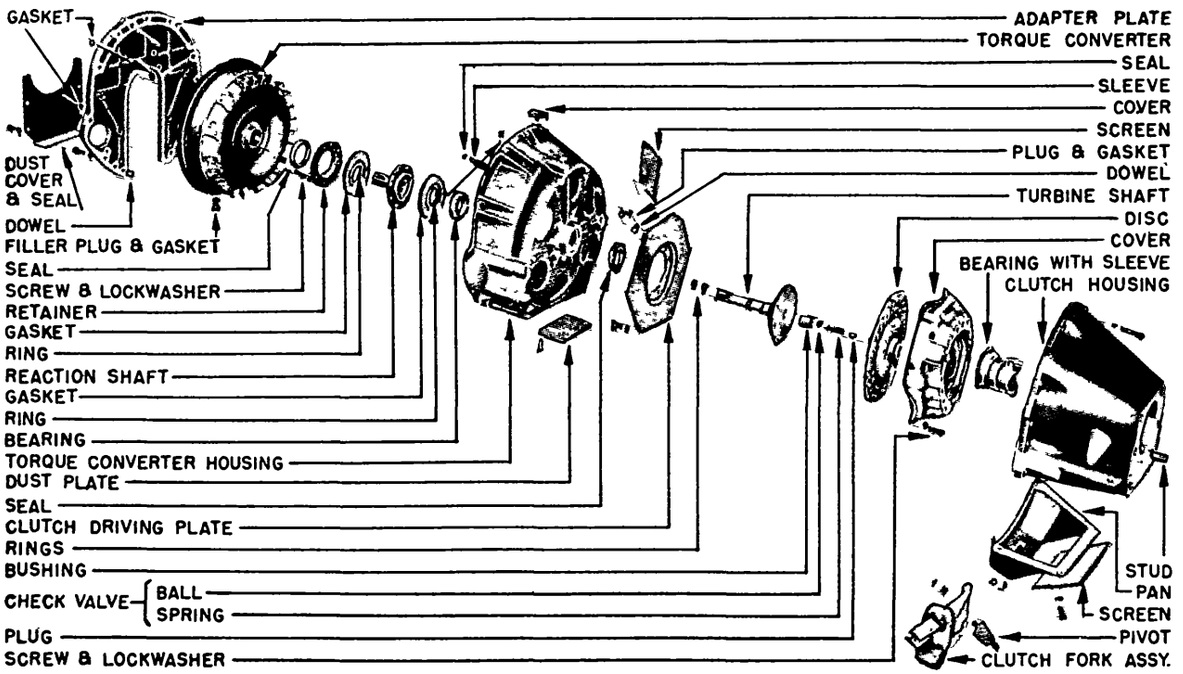
REASSEMBLY: *CAUTION—Use NEW shaft seals, "O" ring oil seals, gaskets, and snap rings when reassembling the unit.*

1) Install regulator valve ball and spring in turbine shaft, install NEW regulator valve plug using tool C-3178 to drive plug into shaft recess until tool bottoms on shaft.

2) Install turbine shaft on clutch drive plate (if these parts separated during disassembly).

3) Install turbine shaft bearing in converter housing using tool C-3186 to drive bearing in until it is seated in housing (insert guide portion of tool from rear of housing, place bearing in housing recess and insert driving tool). Install NEW turbine shaft seal in housing using tool C-3187.

4) Install converter housing and bearing assembly on turbine shaft using tool C-3183 to seat bearing on shaft *(CAUTION*—use care not to damage turbine shaft seal rings when installing tool). Install NEW turbine shaft snap ring using thickest ring possible to obtain zero backlash. *NOTE*—This snap ring is selective fit and furnished .086-.088", .089-.091", .092-.094", .095-.097".



5) Position NEW gasket in converter housing and install reaction shaft *(CAUTION*—use extreme care not to damage turbine shaft seal rings when sliding reaction shaft over turbine shaft). Align capscrew holes in reaction shaft flange with holes in converter housing, drive shaft into place using tool C-3192 *(NOTE*—These holes spaced so that they will line up in one position only, use two capscrews to maintain alignment while driving shaft into place).

6) Install NEW impeller hub oil seal in retainer plate using tool C-3180 *(CAUTION*—Install seal with rubber-coated end toward converter).

7) Position NEW gasket on reaction shaft flange, install impeller hub oil seal retainer plate, install capscrews and lockwashers, tighten screws evenly to 15 ft. lbs. torque.

8) Install clutch assembly and driven member on clutch drive plate *(CAUTION*—align marks on cover and driving plate as made during disassembly).

ASSEMBLY IS NOW READY FOR INSTALLATION ON ENGINE.

CHRYSLER, DESOTO, DODGE, PLYMOUTH FLUID TORQUE DRIVE (COMBINED OIL SYSTEM)

INSTALLATION: *CAUTION—Crankshaft flange run-out must be checked before converter installed, and converter hub run-out checked after converter installed. See installation data below.*

1) Check rear face of engine block and mating face of adapter plate for burrs or other foreign material which would prevent good contact between these parts. Install NEW "O" ring seals at oil passage holes in engine block (use heavy grease to retain seals), install adapter plate and tighten attaching bolts securely.

2) Check crankshaft flange run-out as follows: Mount dial indicator on adapter plate so that indicating button bears on outer machined surface of flange. Set dial indicator at zero and rotate crankshaft (will be facilitated by removing spark plugs). Run-out should not exceed .002".

3) Check mating surfaces of crankshaft flange and converter drive plate for burrs or foreign material. Install converter unit and tighten attaching bolts evenly and securely. Check converter hub run-out as follows:

Converter Hub Run-out Check—Mount dial indicator on adapter plate so that indicating button contacts outer surface of converter hub. Set dial indicator at zero and rotate converter to check run-out. Run-out should not exceed .004". Excessive run-out will probably be due to dirt or burrs at converter mounting face.

4) Make certain that mating surfaces of adapter plate and converter housing are free from burrs and foreign material, install NEW "O" ring seals on converter housing oil passage sleeves, install converter housing assembly on adapter plate using extreme care not to damage oil passage sleeves and reaction shaft seal rings or displace gaskets.

►*INSTALLATION CAUTION*—Make certain that reaction shaft aligned with converter hub opening, use only slight pressure to push assembly forward on converter until seal ring has entered hub. When housing flange is flush with adapter plate, install attaching bolts and tighten securely.

5) Install clutch housing, clutch release linkage, engine support cross-member, and other parts removed or disturbed during removal procedure by reversing the removal order (see Removal data above).

6) Fill engine and converter with oil. *See LUBRICATION data above.*

FLUID TORQUE DRIVE (SEPARATE OIL SYSTEM)

Chrysler 8, C52, C53, C54 (1951)
Chrysler 8, C52, C53, C54, C55 (1952)
Chrysler 8, C56, C58, C59 (1953)
DeSoto V8, S17 (1952)

▷*FLUID-TORQUE IDENTIFICATION:* This type Fluid-Torque Drive with SEPARATE oil system can be identified by presence of Oil Reservoir on bottom of clutch housing. Fluid-Torque Drive with COMBINED Engine oil system does not have this oil reservoir. *See separate data (preceding) for Fluid-Torque Drive with COMBINED Oil System.*

▷CHANGES, CAUTIONS, CORRECTIONS

▷*OIL PUMP RELIEF VALVE CHANGE* (To Improve performance and correct oil loss on first cars). New type Relief Valve (used in production beginning Eng. No. C51-8-19615) can be installed on earlier cars to correct loss of fluid due to one of the following causes: (1) First type valve sticking open, allowing oil to become overheated and expand out through vent to rear engine crankcase breather. (2) First type valve sticking closed, allowing pressure to develop within unit and causing noise in pump gears and displacing impeller hub seal and turbine shaft seal. (3) Leakage around holes in reservoir due to "O" rings on connectors between reservoir and torque converter not seating properly (will be corrected by installation of new rings furnished in Relief Valve Service Pkg. 1450072 containing all new relief valve parts). *See OVERHAUL data for Relief Valve Installation instructions.*

▷*RATCHETING & SIREN NOISE CORRECTION (Cars before Engine No. C52-8-3881):* On cars before No. C52-8-3178, improved Oil Pump Body, Pinion Gear, and Transfer Plate (as used in production on later cars—see Production Change Notes below) may be installed to correct a ratcheting sound in neutral or when driving car which may also be noted as a siren sound at higher speeds. On cars between No. C52-8-3178 and C52-8-3881, above condition can be corrected by installing later type Transfer Plate only (these cars have other later parts installed in production).

PARTS CHANGE NOTE—Parts required for above change are contained in Torque Converter Oil Pump Housing and Seal Service Package, No. 1450206. *See OVERHAUL data for disassembly and installation of these new type parts.*

▷*OIL PUMP BODY & PUMP PINION GEAR PRODUCTION CHANGE (Beginning Engine No. C52-8-3178):* Pinion gear changed to "Oilite" material with gear hub piloted in pump body. Body bore was increased to receive gear hub (no bushing required).

▷*TRANSFER PLATE PRODUCTION CHANGE (Beginning Engine No. C52-8-3881):* Transfer plate was revised and wall between inlet and outlet sides of plate reduced in thickness to approximately ¼". Internal passages were changed and steel valve sleeve and spacer eliminated (oil flow into converter controlled by metered passage cast in plate, and pressure relief ball seated directly on machined opening in plate). *NOTE*—Plate also has outlet (closed by ⅛" pipe plug) which can be used to check Oil Pressure. *See CHECKING OIL PRESSURE.*

DESCRIPTION: The "Fluid-Torque Drive" (Torque Converter) consists of four elements: an impeller (driving member), a turbine (driven member) and two reaction members (stators), which provide a maximum torque multiplication of 2.34-1 (starting torque) to 1.0-1 (driving torque). The converter housing is attached to the rear end of the crankshaft through a flexible steel disc which permits some flexibility. The starter ring gear is mounted on the rim of the flexible disc. The turbine shaft is connected through a splined shaft to the clutch driving plate.

Oiling System—SEPARATE type (self-contained). Oil from the reservoir is delivered to converter housing under approx. 30 lbs. pressure by a geared pump and control valve body mounted on the converter stationary support plate. The oil is drawn from the oil reservoir (mounted under clutch housing) and delivered to converter housing and then to the oil cooler (mounted at the water pump flange) where it is cooled by water from the radiator and an air blast from the fan, before its return to the reservoir.

OPERATION: The impeller being integral with the converter housing and driven by the engine forces oil toward the turbine causing it to rotate in the same direction. The turbine is mounted on a forged steel hub which is splined to the turbine shaft and clutch drive plate transmitting power to the transmission. The two stators are mounted between the impeller and turbine and are provided with overriding clutches that allow them to rotate only in the direction of impeller travel. At low car speeds (maximum torque) both stators remain stationary and control the direction of oil flow toward the turbine. When turbine speed approaches impeller speed (low torque) both stators 'free-wheel' in the direction of rotation and all elements in the converter rotate as a unit.

LUBRICATION: Check oil level in reservoir every 1000 miles, drain and refill unit every 20000 miles (see procedure below).

Capacity—10½ qts. Add 1 additional quart when filter changed.

Recommended Oil—Use "Mopar Fluid Drive Fluid" or high quality SAE. No. 10W Engine Oil.

Checking Oil Level—Oil level should be even with bottom of filler plug hole on left side of reservoir below clutch housing.

Draining—Drain reservoir by taking out drain plug in bottom. Drain Fluid-Torque unit by taking out converter oil plug (accessible after removing flywheel access plate). On engines without access plate, remove clutch pan and rotate converter until oil plug is accessible. Remove plug and drain oil.

Refilling—Replace plugs in converter. Fill oil reservoir to level of hole with MOPAR Fluid Drive Fluid. Start engine and run between 500 and 700 RPM. with transmission in neutral. With engine running, continue adding fluid to reservoir until oil level remains at bottom of filler opening. Replace filler plug in reservoir. To eliminate air bubbles from oil, shift transmission into high range and apply parking brake. Then run engine between 500 and 700 RPM. for not over two minutes. Check oil level and replenish to bring oil level up to bottom of filler hole.

CHECKING OIL PRESSURE: On cars after Engine No. C52-8-3881 (and earlier cars with later type transfer plate—See Production Change above), remove ⅛" pipe plug from support boss (above oil outlet and inlet to cooler lines) on transfer plate, connect pressure gauge C371 or equivalent at this point. Run engine until converter has been warmed to normal operating temperature. With engine running at 60 RPM pressure should be 30 lbs.±5 lbs.

TROUBLE DIAGNOSIS: Check as follows:

Car Creeps when idling—Throttle opening excessive. Check and adjust engine idle speed to 450-500 RPM.

Slippage—Check following conditions:

(1) With car parked, apply parking brakes, place transmission in direct speed, operate engine at 500-700 RPM. If slippage noted, check for oil leakage from converter onto clutch assembly. Correct oil leaks, clean oil from clutch assembly, replace clutch driven disc.

(2) If slippage noted with car in motion, check for low oil level in reservoir or low oil pressure. Overheating—Check for low oil level or lack of oil in converter, low water level or no water in radiator, fan belt loose or broken, water pump defective or water passages clogged, converter oil lines or cooler unit clogged, engine overloaded due to dragging brakes, etc.

REMOVAL & DISASSEMBLY: *For disassembly of Support Plate & Oil Pump (removed as an assembly), see OVERHAUL data below.*

1) Remove transmission. *See Transmission Removal on individual car model pages.*

2) Remove clutch housing-to-exhaust pipe bracket bolt and shift bracket away from housing. Remove breather oil line from right side of oil reservoir. Disconnect oil lines from torque converter support plate on left side of clutch housing.

3) Remove clutch release fork pull-back spring, remove clutch fork rod (disconnect front and rear ends of rod by removing cotter pins and washers), *push clutch pedal in until over-center spring holds pedal against floor board* (will prevent accidental movement of pedal during removal operations), remove pivot bracket assembly and clutch torque shaft, remove release bearing *(CAUTION*—to avoid spreading the release bearing pull-back springs, pivot release bearing assembly away from fork enough to slide bearing off fork prongs—spreading of spring will cause lost motion between fork and bearing when unit reassembled).

4) Remove starter (turn front wheels to extreme right), remove bracket holding oil cooler lines on cylinder block.

5) Remove rear engine-to-cross-member support bolts, install engine support fixture C-3082 and adjust to support weight of engine, take out cross-member attaching bolts and remove cross-member.

6) Remove torque converter oil reservoir from bottom of clutch housing.

7) Lower engine approximately 3" for access to clutch housing upper bolts *(CAUTION*—do not lower engine more than 3" without disconnecting radiator hoses and other engine attachments). Remove clutch housing using care not to damage inlet or outlet oil tubes (from converter plate to oil cooler).

▷*CLUTCH HOUSING REMOVAL CAUTION*—when removing lower half of clutch housing, install two of the flywheel housing bolts to hold the converter

CONTINUED ON NEXT PAGE

FLUID TORQUE DRIVE (SEPARATE OIL SYSTEM) (Continued)

plate in position while the lower half of the housing is being removed.

8) Drain oil from converter assembly by taking out drain plug *(CAUTION*—oil will be very hot if converter has been in operation).

9) Remove converter support plate-to-housing bolts, remove converter plate assembly by working assembly off dowel pins and lifting it **straight off converter hub to avoid damage to pump body oil seal.**

►*CAUTION—Use extreme care when removing converter plate from flywheel housing and DO NOT use tools to pry or pound between flange faces.*

10) If work to be performed on converter support plate, remove clutch cover and driven member assembly from clutch driving plate to avoid getting oil or grease on clutch facings.

INSPECTION: Examine hub of converter assembly. If hub deeply scored or burned, replace converter and drive plate as an assembly *(NOTE*—Light scuffing at base of drive lugs may be polished out with crocus cloth). *See Installation data for Converter replacement.*

OVERHAUL: *CAUTION—Converter hub run-out should be checked and corrected whenever any part of converter assembly has been removed from crankshaft drive flange. See Converter Hub Run-out data below.*

►*TORQUE CONVERTER UNIT REPAIR NOTE*—Torque converter unit is sealed and no adjustments or repairs are necessary except periodic draining and refilling. Replace complete converter unit if repairs are required.

Oil Pump Relief Valve Installation (New Type Relief Valve): Remove reservoir from bottom of clutch housing, take out three connectors in bottom of torque converter support plate. Remove relief valve plug and gasket from valve chamber in support plate. Withdraw and discard the **old type** relief valve assembly (valve, spring, spring damper, and horseshoe lock). Install new type relief valve (see note below). Re-install valve plug and gasket, connectors (CAUTION—use new rubber seal "O" rings furnished in valve package and lubricate seals with chassis lubricant), and reservoir. Refill torque converter (see LUBRICATION data).

Relief Valve Installation Note—New type valve should be installed in following order: Slide valve sleeve into valve chamber with slotted side first, slide valve spacer in with two tongues on end of spacer bearing against bottom of valve sleeve, install valve ball through spacer and follow with valve spring so that spring holds ball against its seat on bottom of valve sleeve, install retaining plug.

►*VALVE SPRING CAUTION*—Spring used in new type relief valve is longer but has less tension than first type valve spring. Old type spring MUST NOT BE USED with new valve assembly (valve could not open).

Pump Housing & Pinion Installation (New Type Parts furnished in Pkg. No. 1450206): *NOTE*—New type Pump Housing can be identified by larger diameter bore (1 7/8" O.D.) and fact that no bushing used, new type Pump Pinion can be identified by hub integral with gear (11/16" long) and "Oilite" material. Use new Transfer Plate No. 1323727 with above parts. *Install these parts as directed under Reassembly in "Support Plate & Oil Pump Overhaul" data below.*

Replacing Starter Ring Gear (on Converter Drive Plate): Remove converter and drive plate assembly from crankshaft (see Removal above). Take out six converter-to-drive plate bolts and separate drive plate from converter. Then service ring gear as follows:

Removing Ring Gear—Support the drive plate in vise and carefully remove staking lugs retaining ring gear with a file (CAUTION—use care not to distort drive plate when clamping it in vise). Support drive plate on 6" blocks of wood and use a blunt chisel or drift to tap ring gear off support plate. Use a file to remove all burrs or raised spots on gear contact surface of plate (CAUTION—do not remove any more metal than necessary to clean up this surface).

Installing Ring Gear—Heat new ring gear (see Heating Note below), place gear over flange surface of drive plate with rear face of gear contacting flange evenly around entire diameter. Weld gear to plate, spacing welds evenly and using same amount of metal at each weld to maintain balance. Clean surfaces of drive bosses on converter and mating surfaces on drive plate (CAUTION—Dirt or burrs on these surfaces will cause converter hub to run out of true and create converter unbalance). Install converter to drive plate bolts (CAUTION—check length of each bolt against bottoming in converter and use shorter bolts if bolts bottom before coming up against lockwashers). Check and correct converter hub run-out as directed below.

►**Ring Gear Heating Note**—Ring gear can be heated by any of the following methods: (1) Use C-794 oven, setting temperature at 150°F. and allowing gear to remain in oven for 15-20 minutes. (2) Place ring gear in shallow container of water and allow it to remain for 8 minutes after water has come to a boil. (3) If steam used, direct steam flow around gear for approximately 2 minutes. (4) If direct flame used, place support plate on flat surface with ring gear squarely on plate, direct slow flame around outer rim of gear using care to direct flame away from gear teeth and not at support plate, check heat with few drops of water on face of gear, gear should be hot enough when water boils.

Support Plate & Oil Pump Overhaul: *CAUTION—Support plate must be heated to remove or install oil pump in pump body recess (if not heated, recess will be scored or scuffed necessitating replacement of the support plate).*

Disassembly: Take out the six oil pump-to-support plate bolts. Place support plate on level surface with turbine and stator shafts upward, heat the plate (see Heating Note below). **After support plate heated** properly, install tools C-3126 (hex-head studs) in threaded holes in pump body until they bottom in support plate, turn these pulling tools in evenly until pump body is free of support plate. Grasp stator at splines and lift straight upward which will remove stator plate and shaft, transfer plate, and oil pump body and gears as an assembly. *CAUTION—DO NOT cock asembly and do not use excessive force in removing it.* Remove pump body and gears from stator plate and shaft. Take out turbine shaft snap ring (Tool C-484), install Tool C-3121 in pump recess and press shaft from bearing (leaving bearing in support plate). If bearing to be replaced, use Tool C-484 to remove snap ring and pull bearing out with Tool C-3138 *(CAUTION*—DO NOT drive bearing out of support plate—this would damage the plate). Remove turbine shaft seal from support plate using a suitable drift.

►**Support Plate Heating Note**—Support plate may be heated by any of the following methods: (1) Use three or four 125 watt or 250 watt infrared or heat lamps placed 2-3" from plate (not touching) and rotate plate to provide even heating. If four 250 watt lamps used, time required should be approximately 15 minutes. (2) If oven C-794 used, set temperature to 160-170°F. and heat plate for approximately 20 minutes. (3) If gas torch used, make certain all converter oil removed from support plate, direct flame at immediate area of pump body. Temperature when heated should be 160-170°F. (above that which can be held with bare hand).

Inspection—Inspect oil pump recess in support plate for scoring or scuff marks on inner diameter of recess *(NOTE*—light scuff marks may be polished out with crocus cloth, replace support plate if recess deeply scored to prevent oil leaks at pump body seal ring). Inspect oil pressure relief valve and make certain this is latest ball type valve (see Oil Pump Relief Valve Installation data). Check support plate-to-flywheel housing and support plate-to-clutch housing mating faces for burrs or uneven surfaces which would prevent securing oil-tight joint. Inspect turbine shaft oil seal ring and replace if broken or damaged. Clean support plate thoroughly and blow out all passages *(CAUTION*—protect bearing in support plate from dirt and foreign material during cleaning). Inspect oil pump outer gear (gear may be re-used if teeth not scored or chipped). Make certain that latest type oil pump body and pinion gear are used (see Pump Housing & Pinion Installation data above).

Reassembly—Position new bearing squarely over bore in support plate and drive bearing into position in housing using Drift C-3123 (CAUTION—plate must be supported on opposite side when driving bearing in place), install large turbine shaft bearing snap ring. Install new seal in opposite side of housing using Drift C-3122. Replace support plate and bearing on turbine shaft using Drift C-3124, install small turbine shaft bearing inner snap ring using ring which provides best fit in slot (this snap ring furnished in three thicknesses). Make certain that pump body recess free from scores and burrs and that recess and passages are clean. Install new impeller hub seal in pump body (Tool C-3125), install new seal ring on outer diameter of pump body. Install oil pump outer gear and inner gear (hub of inner gear entered in body) in pump body, use transfer plate as surface plate on face of pump body and check clearance between pump body face and face of gears. This clearance should be .001-.003". Install transfer plate on stator shaft and plate with large counterbore in transfer plate facing stator shaft plate. Hold pump body upright, pour fluid drive oil or SAE 10W engine oil in gear recess (to facilitate priming of pump), invert stator shaft and plate assembly and insert shaft through pump pinion gear hub, turn assembly over and align holes in pump body, transfer plate, and stator plate (holes will line up in only one position). Coat seal ring on pump body with SAE 10W engine oil. **After heating support plate** (see Heating Note above), position pump body and stator shaft assembly over support plate recess with the six holes in both parts aligned

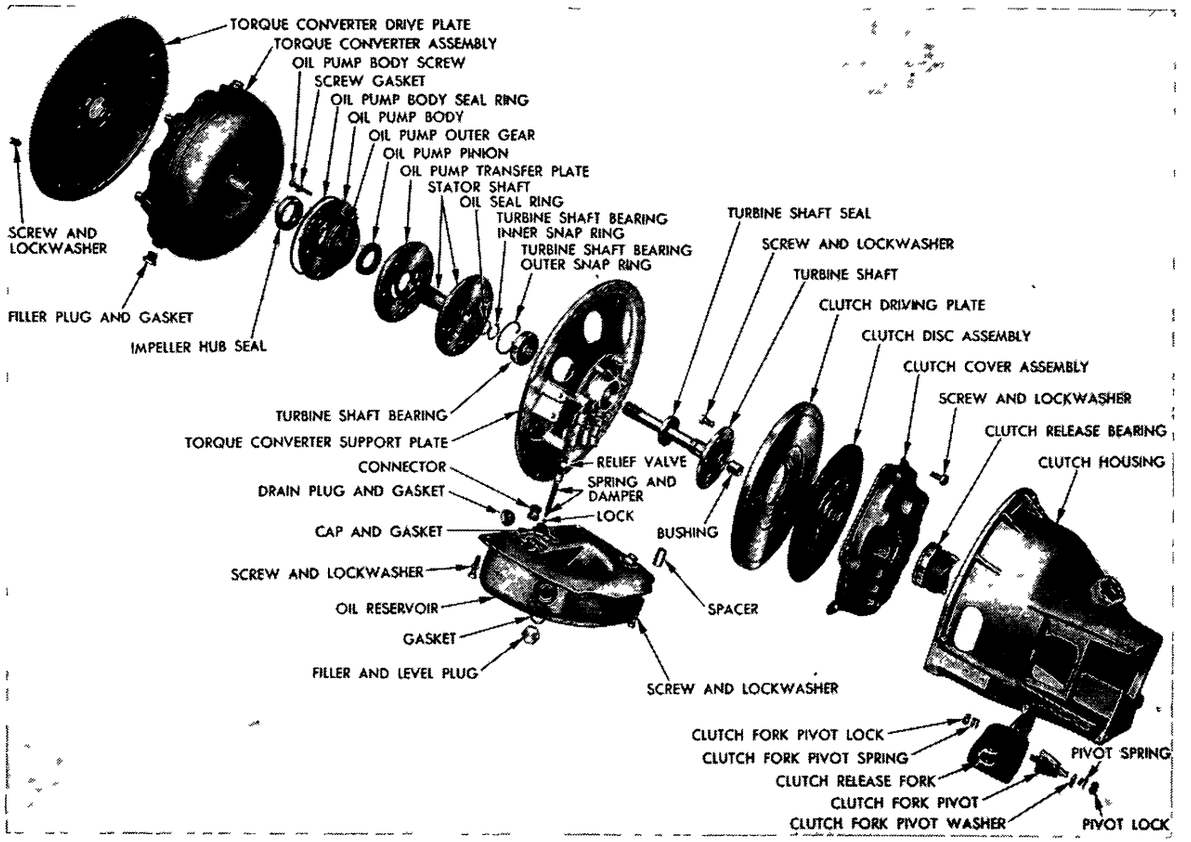
CONTINUED N NEXT PAGE

FLUID TORQUE DRIVE (SEPARATE OIL SYSTEM) (C ntinued)

and lower assembly into pump recess (CAUTION—use care to position oil seal ring on impeller shaft). Pump assembly should slip into recess easily, **if force required, oil seal ring on impeller shaft is not entering hub and stator shaft or support plate has not been heated sufficiently.** Start several of pump body-to-support plate bolts to serve as guides but **do not tighten** these bolts. Use light hand pressure to seat pump body in recess (only slight resistance of outer seal ring compressing against body in recess should be noted). Install all pump body-to-support plate bolts using **new** copper gaskets, tighten all bolts evenly to 17 ft. lbs. torque (CAUTION—make certain that bolts do not bottom in plate).

Converter Installation: Before installing converter, make certain that mating surfaces of crankshaft flange and drive plate are clean and free from burrs or rough surfaces. Tighten the six drive plate-to-converter capscrews to 17 ft.lbs. *(CAUTION*—make certain these screws do not bottom in converter before tightening against drive plate). Install converter and drive plate assembly and tighten the drive plate-to-crankshaft nuts evenly and securely. ***Check converter hub run-out as follows:***

Converter Hub Run-out: Check run-out after drive plate and converter assembly mounted on flywheel. Use dial indicator mounted on flywheel housing with plunger against converter hub (CAUTION—plunger must clear oil pump drive lugs). Rotate torque converter two complete turns while checking run-out. Maximum allowable run-out is .005". If run-out greater than .005", mark high point, turn converter until high point on same side of flywheel housing as dial indicator (to prevent damage to indicator) with one of the drive plate-to-converter bolts about 3" down from flywheel housing, use pry bar between flywheel housing and bolt to "flex" the drive plate sufficiently to reduce run-out (flexing the plate 7/64" will reduce run-out .001"). Recheck run-out and repeat this operation as necessary until run-out reduced to less than .005".



Transmission Drive Pinion Bushing Replacement: Use tool C-41 to remove bushing from turbine shaft. Check hole in shaft for metal chips and cuttings after bushing removed. Use tool C-3077 to install new bushing (tool will install and burnish bushing in one operation). Slip new bushing over ground end of tool (after removing outer sleeve and nut), use tool as driver to install bushing in shaft, then place outer sleeve and nut on tool and tighten nut to withdraw tool which will burnish bushing at same time.

Oil Cooler: ***NOTE—Cooler is mounted at front of engine and is serviced separately from torque converter.***

Removal—Drain radiator, remove battery and battery pan, remove lower radiator-to-oil cooler water hose. Remove inlet and oulet tubes from cooler. Take off nuts on oil cooler-to-water pump flange studs, remove cooler.

Installation—Clean mounting flange faces thoroughly, use new gasket, install cooler in reverse order of removal (above).

INSTALLATION: ***After converter assembly has been installed and converter hub run-out corrected (see above), install support plate assembly as follows:***

CHRYSLER & DE SOTO FLUID TORQUE DRIVE (SEPARATE OIL SYSTEM)

1) Carefully support the support plate assembly *(CAUTION*—weight of support plate assembly must not be allowed to rest on converter hub), enter the splined turbine and stator shafts into hub of converter (see Shaft Meshing Note below) and turn converter slowly to facilitate engaging pump gear on hub *(NOTE*—at point where dowel pins on flywheel housing enter support plate holes, driving lugs on converter hub should be entering driving surface of pump pinion gear). With all parts properly meshed, **face of support plate should be flush with face of flywheel housing.** ***CAUTION—DO NOT use force to bring support plate up to flywheel housing face.***

►***SHAFT MESHING NOTE***—When entering support plate assembly shafts into turbine hub, **three** distinct stages or mating of shaft splines will occur and following procedure should be used to accomplish these engagements: 1) Exert pressure on support and driving plate while rotating driving plate to allow external splines on turbine shaft to index with internal splines of turbine (when this occurs, a distinct forward give will be noted as the splines engage), 2) Turn entire assembly until splines on stator shaft index with internal splines of stator, 3) Position support plate so that dowel pin holes in plate line up with dowels on flywheel housing and rotate torque converter until driving sleeve indexes with oil pump pinion.

2) Install clutch assembly on clutch driving plate (if not installed previously).

3) Install clutch housing on support plate and flywheel housing, install attaching capscrews and tighten securely.

4) Install all clutch release parts and linkage by reversing removal procedure (see above).

5) Make certain that all burrs removed from holes in support plate and reservoir that might damage oil seals, install new "O" ring seals (Part No. 1323747) and connectors in holes in converter reservoir (lubricate seals with chassis lubricant), install reservoir on bottom of clutch housing (NOTE—install two short capscrews at front and two long capscrews with spacers at rear).

6) Connect oil cooler lines at rear support plate.

7) Re-install engine support cross-member and transmission, install and connect other parts disturbed during removal procedure (see Removal data above).

8) Fill converter and reservoir (see Lubrication data above).

POWERFLITE (CHRYSLER, DE SOTO, DODGE, PLYMOUTH)

Chrysler, DeSoto, Dodge, Plymouth (1954-55)

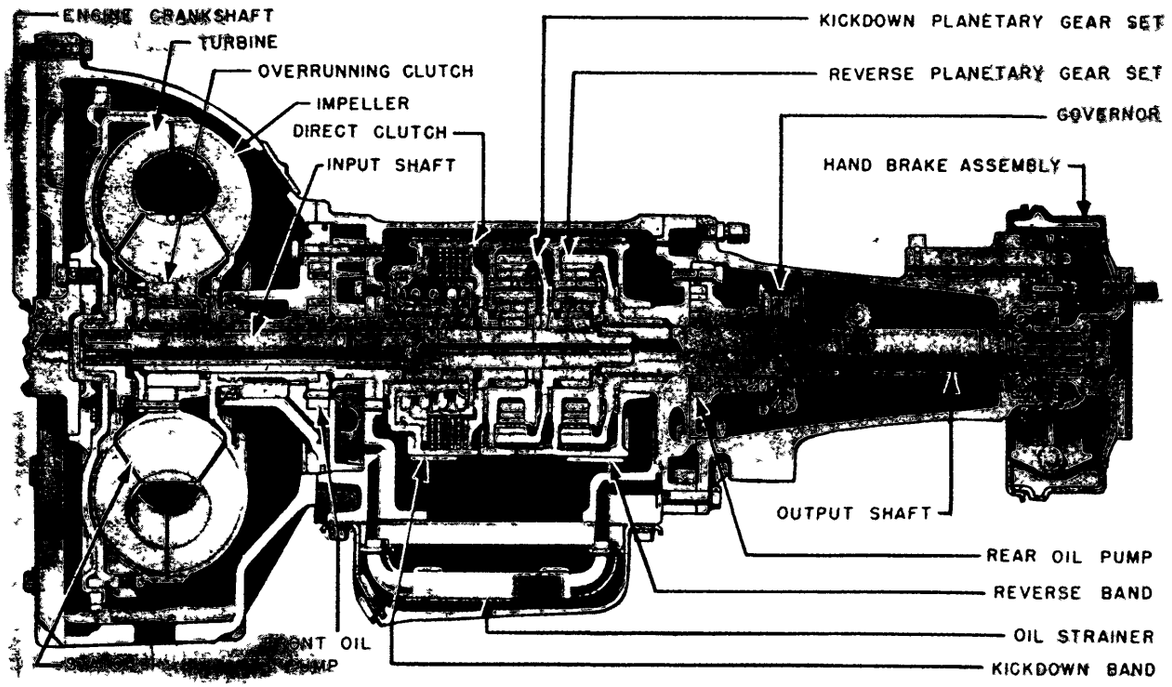
►CHANGES, CAUTIONS, CORRECTIONS

►***STARTING ENGINE BY PUSHING CAR:*** Pushing recommended rather than towing. Turn ignition switch "on," place selector lever in "N." When car speed of approximately 25 MPH. reached, move selector lever to Low "L" position and car will crank engine.

►***TOWING POWERFLITE CARS:*** Following procedure recommended:
Transmission Operating—Place selector lever in "N" and secure in this position by wiring lever in the gate on the lower end of the steering column. Tow car at moderate speeds. NOTE—For long distance towing (100 miles or over), propeller shaft should be removed.
Transmission Inoperative—Tow the car with rear end lifted or remove propeller shaft.

►***1953 MODEL NOTE: PowerFlite Transmission also used on late 1953 Chrysler Crown Imperial & Custom Imperial.***

►***1954 THROTTLE CONTROL CHANGE NOTE:*** Two types of throttle controls have been used and different throttle linkage adjustments are necessary. *See "Throttle Linkage Adjustment" below.*



►***1954 GOVERNOR PRODUCTION CHANGE:*** A later type governor which provides a lower wide open throttle upshift and lower kickdown limit entered production approximately April 26, 1954. Shift patterns with the new governor are changed as indicated in "Transmission Shift Pattern" tables below. The later type governor can be installed on earlier cars and is available in replacement kits, Part No. 1450993 (6 Cyl. Cars), No. 1450994 (8 Cyl. Cars). *NOTE—Also see "1955 Governor Production Change"*

►***1954 DIRECT CLUTCH PRESSURE TESTING POINT PRODUCTION CHANGE:*** a ⅛" take-off plug has been added to the bottom of the kickdown servo boss which can be used for checking direct clutch pressure. *See "Hydraulic Pressure Tests & Trouble Shooting" below.*

►***1954 SHUTTLE VALVE PRODUCTION CHANGE & SERVICE REPLACEMENT NOTE:*** A later type shuttle valve, Part No. 1643118 is used for production and can be used for service replacement. *CAUTION*—The adjustment screw is pre-set at the factory and MUST NOT BE CHANGED IN THE FIELD. *When replacing the older type valve with the later one, DO NOT install the old spacer and spring.*

►***1954 TRANSFER PLATE COVER PRODUCTION CHANGE:*** A cast iron cover replaces the aluminum cover formerly used. This change was made to prevent possible warpage due to heat. The new cover plate, Part No. 1559108 can be installed on all previous transmissions.

►***1955 TORQUE CONVERTER OUTLET VALVE PRODUCTION CHANGE (To prevent loss of torque converter pressure under severe operating conditions):*** A later type valve, Part No. 1630871 located in forward end of oil passage on left side of transmission case above line pressure take-off plug prevents loss of torque converter pressure. This valve can be installed on all early transmissions. *NOTE*—When installing the valve, make sure that the ball end of the valve is toward center of transmission. *Also see "Regulator Valve Body Production Change" below for later changes affecting the torque converter outlet valve.*

POWERFLITE TRANSMISSION SECTIONAL VIEW

►***1955 REGULATOR VALVE BODY PRODUCTION CHANGE (Converter pressure regulated at input, not at outlet):*** The torque converter outlet valve has been eliminated by a change in the regulator valve body, the torque converter control valve and spring. The later type regulator valve body is identified by a letter "D" at end of the part number. The later Regulator Valve Package, Part No. 1643243 can be installed on early transmissions. *CAUTION*—The Torque Converter Outlet Valve must be removed to insure proper lubrication when the later type Regulator Valve is installed.

►***1955 INPUT SHAFT PRODUCTION CHANGE (To provide better sealing and bearing support):*** A later type input shaft having a large area bushing (integral with shaft) replaced the former input shaft (three seal rings) at Transmission No. J-14-54 (stamped on lower right front corner of transmission case). The large area bushing is a press fit on the output shaft and is not serviced separately. When installing the later shaft in earlier transmissions, it will also be necessary to install a new reaction shaft.

►***1955 PLYMOUTH GOVERNOR PRODUCTION CHANGE (3-stage type replacing the 2-stage type):*** A later type governor, Part No. 1653463 (V8 Cars), 1653464 (6 Cyl. Cars) provides a closer control of shift speeds. The wide open throttle upshift limit is decreased and the low kickdown limit is increased (see "Transmission Shift Speeds" below). The later type governor can be used on earlier transmission for service replacement provided the complete package is installed. *NOTE*—Transmissions equipped with the new governor are identified by the letter "H" following the part number.

►***PLYMOUTH DIRECT CLUTCH DISC & PLATE REPLACEMENT CAUTION:*** Six discs and six plates are included in Disc & Plate Package, Part No. 1450209 (for use on all PowerFlite Transmissions). On Plymouth 6 Cyl. & V8 Models, use only 5 discs & 5 plates. Installation of six of each part will not provide adequate clearance and may burn the discs and plates.

DESCRIPTION

DESCRIPTION: PowerFlite transmission consists of a torque converter and a two-speed hydraulically controlled planetary gear type automatic transmission. The entire transmission has a single independent oil system (front and rear pumps in transmission circulating oil through transmission, converter, and oil cooler with oil carried in transmission case oil pan). Hydraulic control consists of valve assemblies in the transmission and a hydraulic governor on the output shaft within the transmission extension housing which control the operation of the planetary gear sets (see OPERATION following). Torque converter is similar to unit used previously in "Fluid-Torque" Drive and operates independently.

Torque Converter: Provides a torque converter ratio of 2.6-1 for starting, acceleration, or heavy pulling whenever a torque gain is required. At cruising speeds above 45-50 MPH., the torque converter acts

CONTINUED N NEXT PAGE

POWERFLITE (Cont.)

as a fluid coupling with no torque multiplication.

Planetary Gears: Consist of a "Kick-down" (Low Range) planetary gear set providing a gear ratio of 1.72-1, and a Reverse planetary gear set providing a reverse drive with a gear ratio of 2.39-1. The actual effective gear ratio depends on selector lever position and car speeds as follows:

OPERATION

OPERATION: Transmission operation in each position of the selector lever is outlined below. In Drive "D" position (normal driving position), operation varies in accordance with the car speed and operating conditions. *See Shifting Speed tables below.*

Drive "D" Position: This is normal driving position.

Breakaway (Starting & Accelerating)—Transmission is down-shifted so that kick-down (low range) planetary gear set is in operation. The car starts and accelerates with both the torque converter providing a torque increase of 2.6-1 and the gears providing a torque increase of 1.72-1 for a total ratio of 4.47-1. At a car speed of 15-75 MPH. (depending on throttle position), the transmission automatically upshifts (locking out the planetary gears) so that all torque multiplication is provided by the torque converter. See Direct Drive.

Direct Drive—After the transmission upshifts, the only torque multiplication is provided by the torque converter (2.6-1) and this gradually diminishes as the car speed increases until at approximately 50 MPH. the ratio is 1-1 and the torque converter operates as a fluid coupling.

Kickdown (Forced Downshift)—At car speeds below 45-60 MPH., depressing accelerator pedal to the wide-open position will cause the transmission to downshift and drive through the kick-down planetary gear set. This provides the same torque multiplication as in "Breakaway" above. When the accelerator pedal is partially released, or when the car speed reaches 60-75 MPH., the transmission automatically upshifts (kick-down not operative above 60-75 MPH.).

Low "L" Position: Operation is the same as in Drive "Breakaway" above except that no upshift occurs and the planetary gear ratio of 1.72-1 remains in action regardless of the car speed.

Reserve "R" Position: This engages the reverse band (kick-down band and direct clutch disengaged) so that the engine drives through the torque converter and the reverse planetary gear set to provide a reverse drive with a torque multiplication of 2.6-1 (torque converter) and 2.39-1 (reverse planetary).

Neutral "N" Position: The transmission is completely disengaged (both bands and direct clutch disengaged) so that there is connection between the engine and the rear wheels. The Starter Neutral switch contacts are closed which permits the starter to operate to crank the engine.

LUBRICATION

Checking Fluid Level (Engine Hot)—With engine idling oil level should not be above the "full" mark on dipstick after car has been driven sufficiently to bring engine and transmission up to operating temperature. If oil is slightly below desired level, add a little oil at a time and recheck. *Do not add a full quart unless check indicates that it is required.*

Checking Fluid Level (Engine Cold)—Start engine, set hand brake and shift selector lever through all ranges. Allow engine to run approximately two minutes. Move selector lever to "N" (neutral) and check oil level with engine idling. Oil level should not be higher than ½" above the "low" mark on dipstick, and it should not be below the "low" mark on dipstick.

Draining & Refilling—Drain transmission case by removing drain plug from oil pan. Drain torque converter by removing drain plug from converter housing (remove access plate from bottom of flywheel housing, rotate torque converter until drain plug is down). Replace both drain plugs using new gaskets, if necessary, tighten oil pan plug to 20-25 ft. lbs. and torque converter plug to 45-50 ft. lbs. Install 5 qts. new fluid through transmission filler tube. Start engine and add approximately four quarts more while engine is running. Allow engine to idle for two minutes, then shift selector lever through all positions and return it to neutral. Add sufficient fluid to bring fluid level to "low" mark on dipstick (approx. 1 quart).

Recommended Fluid—Automatic Transmission Fluid Type A.

LINKAGE ADJUSTMENT

1954 CHRYSLER, DESOTO, DODGE

Gearshift Linkage: Place manual control lever at the transmission in "D" position which is the third detent from front of car (Chrysler & DeSoto); "N" position which is the second detent from rear of car (Dodge). Check angle of gearshift control bellcrank upper lever in relation to frame line. This should be 24-29° (Chrysler & DeSoto); 40-45° (Dodge) to the horizontal above the frame line and pointing slightly toward rear of car. If not at the correct angle, adjust as follows:

1) Disconnect front and rear gearshift control rods at gearshift control bell crank. Locate gearshift control bell crank as described above and adjust the rear gearshift control rod to the required length for a free fit in the bell crank lower lever, reinstall rod.

2) Place selector lever pointer in the "N" (neutral) position on the indicator dial at the top of steering column. Check clearance between the gearshift tube lever gate neutral stop land at bottom of steering column and the gearshift tube lever. This clearance should be .015" to .017" with .015" to .030" clearance between the gate and the wide flat face portion of the lever (see illustration), with gearshift tube in its normal fully returned position. To adjust, loosen the three attaching screws (on Chrysler & DeSoto), clamp (on Dodge) and move the gate to the desired position for correct clearance. Tighten attaching screws or clamp.

3) Make sure selector lever is in "D" position (Chrysler & DeSoto); "N" position (Dodge) and adjust the front gearshift rod to the desired length for a free fit to the upper lever of bellcrank. Reinstall rod.

4) Operate lever through all detent positions and check position of pointer on indicator dial.

▷*CAUTION: If control does not operate properly or indicator does not indicate correctly, recheck the assembly and adjustment. DO NOT FORCE movement of selector lever.*

1954 PLYMOUTH

Gearshift Linkage: Measure distance between center of gearshift selector lever bearing bolt and gearshift rod bracket on steering column with a steel scale. Adjust to 49/64" (to get an accurate scale reading it may be necessary to force quadrant slightly away from rod bracket). Adjust as follows:

1) Remove steering column bracket assembly at selector lever and the bracket cap at the dash. Lower column enough to gain access to the cross head screw beneath selector lever. Remove lever, spring, and pointer.

2) Slide bracket assembly down on gearshift rod far enough to rotate and adjust bracket sleeve to 49/64" distance from center of hole to edge of bracket. This will provide approximately 3/16" minimum steering gear gearshift rod lever overlap on gate at lower end of steering column for "N" and "D" positions. Reinstall lever, spring, and pointer, then bracket assembly and bracket cap. Adjust gearshift rod lever stud to center of gearshift rod lever slot.

3) Raise car on hoist. Loosen the two nuts holding gearshift control rod to the swivel block attached to gearshift control bell crank mounted on transmission. Remove swivel block and control rod from bell crank. Move manual control lever on the transmission toward rear of car to place transmission in reverse gear, then move it one detent toward front of car which will place transmission in "N" (neutral). Reinstall swivel block in bell crank, leaving the control rod nuts still loose. Hold gearshift rod lever on steering column in "N" (neutral) position and draw up the front nut on the control rod to within 1/16" of the swivel block. Tighten nut to rear of swivel block, locking assembly in position.

4) Shift transmission through all gears and check for full engagement, making sure that the gearshift rod lever does not ride against control gate in any position. Readjust if necessary. Lower car and check position of selector lever pointer at "D" position. If necessary, bend pointer to locate it exactly at center of the letter.

1954 ALL MODELS

Throttle Linkage & Throttle Pressure: *CAUTION—Transmission throttle oil pressure must be checked and carefully adjusted when the throttle linkage is adjusted. This is important for proper operation.*

Chrysler, DeSoto & Dodge—

1) Check accelerator pedal released position. Included angle from face of pedal to floor at rear of pedal should be 118° (Chrysler & Dodge), 120° (DeSoto). Adjust length of accelerator bell crank to carburetor rod at carburetor throttle lever for correct pedal position.

Plymouth—

1) Measure distance between two anchor points of the throttle return spring. This distance should be 5⅝". To obtain the correct length, adjust throttle rod between carburetor lever and bell-crank.

All Models—Proceed as follows:

2) Operate linkage through entire travel to make certain there is no bind in any position, see that carburetor throttle valves closed with accelerator in released position and that pedal has sufficient travel to fully open throttle valves and operate

CONTINUED ON NEXT PAGE

POWERFLITE (C nt.)

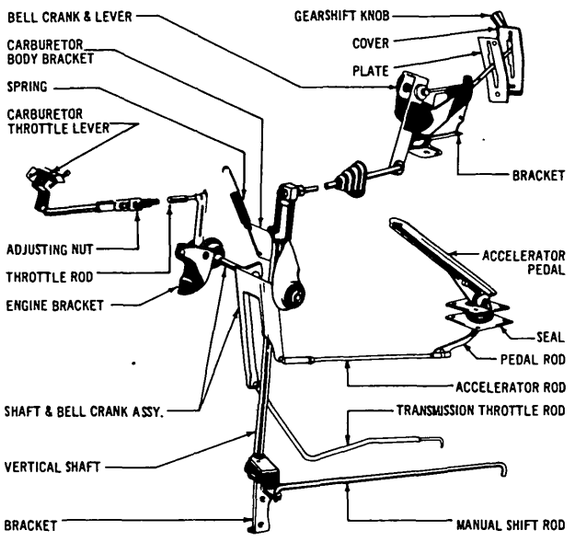
kick down valve (opening of valve should be felt just as the wide open throttle position is reached).

3) Set engine idle at 475-500 RPM., with engine at normal operating temperature and with selector lever in "N" (neutral) position. ***CAUTION—Correct engine idle speed setting is very important when adjusting linkage and accurate tachometer should be used.***

4) With engine not running, remove Throttle Pressure Take-off Plug on right side of transmission case (⅛" pipe plug between reverse and kick down servos), connect 100 P.S.I. Pressure Gauge (Tool C-3292) at this point.

5) Start engine and place selector lever in "D" position ***(CAUTION—Set hand brake firmly).*** Disconnect the throttle linkage at transmission throttle control lever and operate the throttle valve several times by hand. Observe pressure reaction to lever movement to make sure throttle valve is not sticking.

►***THROTTLE CONTROL CHANGE NOTE:*** Two types of throttle controls have been used. The first type has no return spring on throttle lever and no positive stop for the throttle valve cam. The second type has a return spring located on transmission throttle lever and a positive stop for the throttle valve cam. These two types are not interchangeable and different adjustment procedures are required as follows:



6) Position throttle control lever so it is approximately 30° toward front of car from a right angle to the transmission center line (this procedure is not necessary on the second type control valve having the return spring, as the positive stop within the transmission positions control valve at the closed throttle position). Check throttle oil pressure which should be 13-15 P.S.I. If not within this range, adjust throttle pressure by removing throttle valve adjusting screw plug (on left side of transmission slightly forward and below Back-Up Light Switch). ***Approximately one quart of fluid will drain out when plug removed.*** Using Throttle Screw Adjusting Wrench C-3279, adjust throttle pressure to 14 P.S.I. Turn screw counter-clockwise to increase pressure and clockwise to decrease pressure. Replace plug and tighten to 20-25 ft. lbs.

7) Reconnect throttle linkage to throttle valve lever on transmission. To check throttle linkage adjustment pull slightly on accelerator pedal lever from below car. The throttle pressure should read 14 P.S.I. at idle speed and **rise 8 P.S.I. immediately** when accelerator depressed. If pressure rise not immediate with throttle opening, proceed as follows:

►**Cars With First Type Control Valve—**

8) Loosen lock screw on throttle control rod swivel, disconnect clip from throttle control rod and move swivel and throttle lever as far forward as possible. Next, slowly move throttle and swivel rearward until a slight resistance is felt. At this point, with very slight additional travel of lever toward rear, the throttle oil pressure should suddenly rise 8 P.S.I.

9) Holding swivel and throttle lever at exact position where the slight resistance noted, push slightly forward on the throttle rod to remove free play in connections, and while holding the rod and swivel in this position, connect swivel clip and tighten lock screw, securing swivel to correct position on

1955 POWERFLITE LINKAGE (TYPICAL)

throttle control rod. Recheck adjustment as in (7) above. Remove pressure gauge, replace throttle oil pressure take-off plug and torque to 10-12 ft. lbs.

►**Cars With Second Type Control Valve—**

8) Disconnect throttle control linkage at transmission throttle lever. Operate lever several times by hand. With control lever pointing toward front of car, move it rearward until a slight resistance is felt. Pressure at this point should suddenly rise 6 to 8 lbs. Return lever to a position approximately 1/16" toward front of car. With lever held in this position, install control rod, clamp and nut. Tighten nut just enough so rod can be moved through the clamp by tapping the lever slightly. Pull the accelerator pedal lever until engine speed just begins to indicate rise on tachometer. At this point tap transmission throttle lever into position which will allow the throttle pressure to rise from the 14 lb. mark. With slight additional throttle lever travel, the oil pressure should suddenly rise approximately 8 lbs. When pedal lever is released the throttle pressure should return to 14 lbs. Tighten the nut at point where the pressure starts to rise.

1955 CHRYSLER, DESOTO, DODGE

Gearshift Linkage Adjustment: Hold lever in gate (between neutral "N" and drive "D" positions) under tension (which is adjustable by a bracket to which it is attached behind instrument panel). With spring scale, tool C-394, pull out from selector lever knob. This should require 1-2 lbs., pull to break contact between selector lever and gate. If it does not, then adjust by loosening bracket attaching screws and sliding bracket to obtain the proper tension. Tighten screws and recheck tension ***(NOTE*** —If correct tension cannot be obtained by adjusting bracket, it can be corrected by removing the selector lever and mounting bracket assembly and bending the tension spring. Bend tension spring away from gate to ***decrease*** and toward to ***increase*** tension). Raise hood and inspect selector lever to torque shaft rod for interference where it goes through firewall. If necessary, bend rod to provide clearance at this point. Disconnect selector lever to torque shaft control rod at upper torque shaft rod (adjustment end). Make sure manual control lever located on side of transmission is in the neutral detent position (second detent from rear, all the way to rear and then one notch forward) by shifting it out of neutral and in again. With selector lever in neutral "N" position, push control rod toward firewall until instrument panel selector lever strikes the neutral stop land on gate. Adjust control rod swivel to a free fit in torque shaft upper lever. Clamp swivel in place with the two locknuts and check for free fit. Shift selector lever through all ranges ***CAUTION—The selector lever must go into gate without interference when shifting. Do not use force. Recheck assembly and adjustment.***

►***EARLY 1955 DESOTO THROTTLE LINKAGE ADJUSTMENT CAUTION:*** Approximately the first 2000 cars had a throttle control the same as the late 1954 models, and requires a different throttle linkage adjustment than later cars. The first type control can be identified by throttle Control Lever (on transmission) not having a positive stop at 30° forward movement of throttle lever. Adjust throttle linkage and throttle pressure on early cars in same manner as for late 1954 models. *See "1954 Throttle Linkage Adjustment" above.*

Throttle Linkage & Throttle Pressure: ***CAUTION—Transmission throttle oil pressure must be checked and carefully adjusted when the throttle linkage is adjusted. This is important for proper operation.*** With engine at operating temperature, remove air cleaner and check choke valve for wide open position. Connect tachometer leads to coil and ground and adjust engine idle speed to 475-500 RPM, with selector lever in "N" (neutral). Stop engine. Loosen throttle linkage adjusting screw (located on accelerator-to-carburetor rod) and move rear portion of accelerator shaft shaft-to-carburetor rod rearward until it butts against stop. (Preload lightly.) With rods in line and rear portion of rod lightly preloaded, lock throttle linkage adjustment screw by tightening it to 10-15 ft. lbs. Start engine and recheck idle setting. With transmission in "N" (neutral) and hand brake set, raise car on hoist. Remove throttle oil pressure take-off plug (⅛" pipe plug) located between reverse and kick down servos on right side of transmission case. Connect 100 lbs., pressure gauge C-3292. Shift manual lever on left side of transmission case to "D" (drive) range and check throttle pressure which should be 13-15 lbs. (if necessary to readjust, set pressure to 14 lbs.). ***(NOTE—When manual control lever is moved into "D" range, the engine speed will drop approximately 50 RPM).*** If pressure is not within specifications remove throttle valve adjusting screw plug (⅜" pipe). ***(NOTE***—About one quart of transmission fluid will drain out). Insert adjusting screw wrench C-3279A or C-3279 and adjust throttle pressure to 14 lbs. Turn screw OUT to increase pressure and IN to decrease pressure. Open and release throttle several times to check for proper setting. Throttle pressure should return to 14 lbs. Replace throttle valve adjusting screw plug and tighten to 25 ft. lbs. With accelerator fully released and engine at 475-500 RPM, the pressure should read 14 lbs. Very slowly

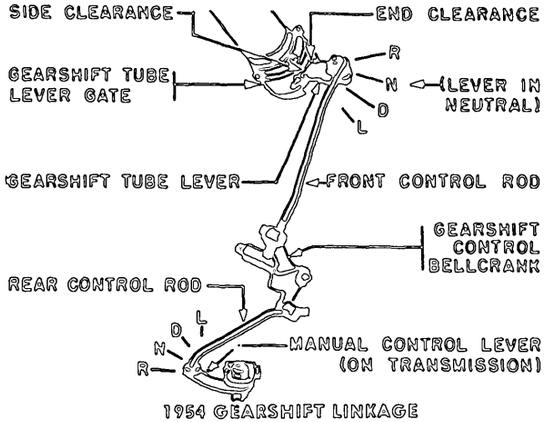
CONTINUED ON NEXT PAGE

POWERFLITE (Cont.)

move the accelerator pedal or lever from underneath. With throttle and pressure properly adjusted, the throttle pressure should rise immediately with an increase in RPM *(NOTE—Do not use throttle rod when making this check)*. Remove oil pressure gauge and install pipe plug. Tighten to 12 ft. lbs. *(CAUTION —Replace any fluid that drained out during the adjustment)*.

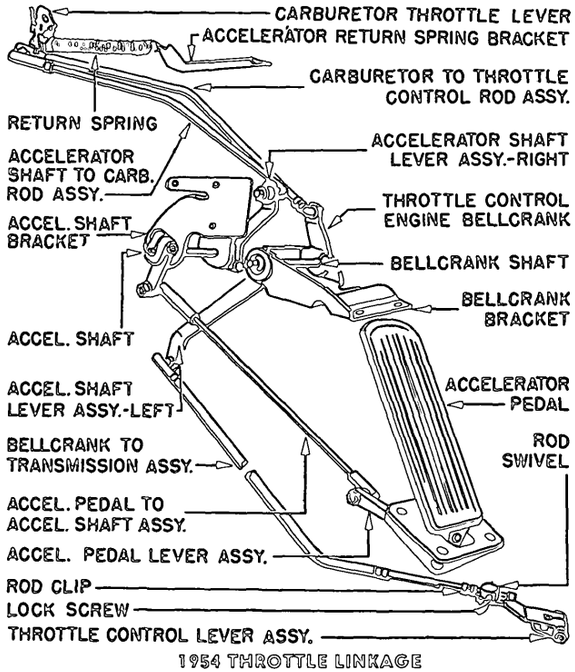
Checking & Adjusting Accelerator Pedal Height: At wide open throttle the tip of the pedal must be approximately ⅛" from the floor mat. To adjust, disconnect accelerator rod from bellcrank under the floor pan. Loosen locking nut and screw the connector counterclockwise on the shaft to raise pedal and clockwise to lower pedal. Reconnect rod to pedal bellcrank, lock with nut and turn down the connector nut.

1955 PLYMOUTH



Gearshift Linkage Adjustment: There should be 1/32" clearance between selector lever and the gate at instrument panel, with transmission in neutral. Adjustment is made at end of gearshift lever rod on engine side of firewall. Loosen adjusting nuts and place the transmission shift lever in neutral position. Tighten front adjusting nut to provide clearance on the instrument panel, then tighten rear nut. Check for full detent engagement at transmission.

Throttle Linkage & Pressure Adjustment: *(NOTE—To obtain correct relationship between throttle linkage and engine speed, throttle pressure as well as throttle linkage should be checked. Check linkage for possible binding and make sure lever returns to its stop)*. With selector lever in neutral "N" position, start engine and bring to normal operating temperature. Make sure carburetor is not on fast idle. Adjust engine idle speed to 475-500 RPM. in Neutral. Stop engine. Install tachometer leads for use under the car, start engine, then raise car on a hoist. Remove throttle oil pressure take-off plug (⅛" pipe plug) located between reverse and kickdown servos on right side of transmission. Connect the 100 lbs., pressure gauge C-3292. Move gearshift control lever on transmission one detent toward front of car to put transmission into "D" (drive) range. Disconnect throttle linkage at transmission throttle control lever and operate the throttle control lever several times by hand. Pressure should return to 13-15 lbs., with throttle lever returned to its stop. If it does not, adjust as follows: Remove the ⅜" pipe plug throttle valve adjusting screw plug on left side of transmission case (about one quart of fluid may drain out). Using throttle adjusting screw wrench C-3279A adjust the throttle pressure to 14 lbs. (Turn screw counterclockwise to increase pressure, clockwise to decrease). Shift transmission several times between "N" (neutral) and "D" (drive). Pressure should return to 14 lbs., when lever is returned to "D" (drive). Reinstall plug and tighten to 20-25 ft. lbs. *NOTE*—After throttle pressure is adjusted, adjust throttle control linkage:



V8 Engine Models—Loosen the clamp nut on throttle control rod (midway between carburetor throttle lever and cross shaft lever), and slide rear part of rod toward rear of car to take up all slack. Tighten clamp nut and make sure that carburetor is off fast idle.

6 Cyl. Engine Models—Loosen vertical clamp bolt at rear of engine and adjust the carburetor throttle lever rod to provide 5 7/16" distance between the anchor points of the throttle return spring. Then, with engine idling (off fast idle), take up slack at the vertical rod and tighten clamp nut.

On All Models—After adjustment is made, move gearshift control lever on transmission one detent toward rear of car to put transmission into "N" (neutral). Remove pressure gauge and reinstall plug. Tighten to 10-12 ft. lbs.

1954 GEARSHIFT LINKAGE

1954 THROTTLE LINKAGE

(CHRYSLER & DE SOTO SHOWN—DODGE & PLYMOUTH SIMILAR)

BAND ADJUSTMENT

BAND ADJUSTMENT: *Kick-down (Front) Band can be adjusted externally, Reverse (Rear) Band adjustment requires removal of transmission case oil pan.*

Kick-down (Front) Band: *NOTE—Some models do not have band adjusting access hole in front floor pan (on left side of tunnel adjacent to accelerator pedal) and adjustment must be made differently from beneath car.*

Adjustment using Tool C-3291 (Cars with access hole in front floor). Remove accelerator pedal from hinged section of accelerator assembly, remove floor mat and access hole cover (on left side of tunnel immediately adjacent to accelerator pedal location). Then proceed as follows: Use Tool C-3291 (combination wrench and counter) to loosen adjusting screw locknut, check to see that adjusting screw is free in transmission case. Use Inch-pound reading torque wrench (Tool C-3380 or C-685) to tighten band adjusting screw to 60-72 In. Lbs. torque, then using counter on tool, back off the adjusting nut exactly 3 turns, hold the adjusting screw stationary and tighten the locknut securely.

Adjustment (cars without access hole in front floor)—Tool C-3291 cannot be used. Working from underneath car use a box wrench to loosen the band adjusting screw locknut (adjusting screw located on upper left side of transmission case in front of control lever assembly), back off locknut 4 turns (Chrysler & DeSoto), 9 turns (Dodge & Plymouth). Check to see that adjusting screw is free in transmission case. Use Inch-Pound reading torque wrench (Tool C-3380 or C-685) to tighten band adjusting screw to 60-72 In. Lbs. torque, mark adjusting screw position for reference and back adjusting screw off exactly 3 turns, hold adjusting screw stationary and tighten locknut securely.

Reverse (Rear) Band: Drain transmission case and remove oil pan. Remove locknut from reverse band adjusting screw (in reverse band lever at right rear within transmission case). Use Inch-Pound reading torque wrench (Tool C-3380 or C-685) to tighten adjusting screw to 20-25 In. Lbs. torque, then back adjusting screw off 10 turns. Install adjusting screw locknut, hold adjusting screw stationary and tighten locknut to 30-35 Ft. Lbs. Replace oil pan and refill transmission with fluid (see LUBRICATION).

ROAD TESTING TRANSMISSION: If transmission operation not satisfactory, following complete procedure is recommended to check performance and diagnose trouble:

FIRST—Make certain that engine properly tuned, idle speed correctly set at 475-500 RPM. with engine at normal operating temperature and selector lever in Neutral "N" position, and that transmission fluid level is correct. *CAUTION*—If throttle linkage disturbed in tuning engine, linkage must be adjusted before making following tests.

1) Move selector lever through all positions and check pointer with reference to gate and transmission detent positions. See LINKAGE ADJUSTMENT.

2) Start engine. Increase engine speed up to 800 RPM. checking for gear noise and dragging.

3) Move selector lever to "R" and check the shift for speed and smoothness. Back the car and check

CONTINUED ON NEXT PAGE

POWERFLITE (C nt.)

for gear noise and dragging. ***CAUTION—do not use wide open throttle in Reverse.***

4) Make a Stall Test to check for band slippage (see STALL TEST below). If band slippage indicated, adjust bands before proceeding with the test (see BAND ADJUSTMENT).

NOTE—Refer to "Transmission Shifting Speed" data for correct upshift and downshift speeds when making the following tests:

5) Accelerate car with very light throttle. Note speed at which upshift occurs and check smoothness of the shift. Slow the car to approximately 15 MPH. and rapidly accelerate to wide-open throttle **without going into the kick-down position.** Check for clutch slippage. Transmission should not downshift.

6) With car operating 15-20 MPH., make a kick-down shift by opening throttle to kick-down position, then release accelerator to approximately the half-throttle position so that transmission upshifts. Check smoothness of each shift.

7) With car operating at 35-40 MPH., make a kick-down shift by opening throttle to kick-down position, then release accelerator to closed-throttle position. Check smoothness of each shift.

8) With car operating at 45 MPH., make a kick-down shift by opening throttle to kick-down position, then accelerate car with transmission kicked down until transmission upshifts. Check this shift speed and smoothness of both shifts.

9) Slow car speed to 65 MPH. (Chrysler & DeSoto), 50 MPH. (Dodge & Plymouth) and attempt to make a kick-down shift at this speed. Transmission should not downshift (this speed is above kick-down limit).

10) Slow car to 40-50 MPH., move selector lever to "L." Transmission should downshift. Check for gear noise.

11) Increase car speed to approximately 20 MPH. and move selector lever to "D." Transmission should upshift. Coast car to a stop and check speed at which transmission downshifts. Check smoothness of shift.

TESTING

①—See *1954 Governor Production Change* above.
②—With early type 2-stage governor. See *Production Change* above.
③—With later type 3-stage governor. See *Production Change* above.

STALL TEST: Use an accurate tachometer to check the engine speed. With engine idling, move selector lever to "D" and note smoothness and speed of the shift. Set hand brake firmly and apply foot brakes to hold car, accelerate engine to wide-open throttle and check engine speed. Speed in excess of maximum RPM as indicated below may be caused by band slippage See "Band Adjustment."

1954 Stall Performance ①

Car Model	②Engine RPM
Plymouth, Dodge 6, DeSoto 8	1275-1375
Dodge 8	1400-1500
Chrysler C-63-2 & C-64	1400-1500
Chrysler C-63-1	1450-1550
Chrysler 6	1200-1300
DeSoto 6	1150-1250

1955 Stall Performance ①

Car Model	②Engine RPM
Chrysler C-67	1380
Chrysler C-68, C-69, C-70, C-300	1540
DeSoto S-21	1585
DeSoto S-22	1490
Dodge 6 Cyl.	1330
Dodge Royal	1450
Dodge Custom Royal	1465
Plymouth 6 Cyl	1330
Plymouth 157 HP. V8	1395
Plymouth 167 HP V8	1435

①—Wide open throttle, selector lever in "D" range, at sea level
②—Plus or minus 50 RPM

►***CAUTION—When making stall test do not hold throttle wide-open for more than a few seconds. If engine speed excessive and is not corrected by band adjustment. make additional checks as listed below.***

If excessive engine speed not due to incorrect band adjustment, check for: incorrect Gearshift Linkage or Throttle Linkage Adjustment; leakage at Valve Body mating surfaces; defective Throttle Valve, Shuttle Valve, or Valve Body End Cover Plug; defective Kick-down Servo parts (piston, guide, band, lever, strut, etc.).

C NTINUED ON NEXT PAGE

POWERFLITE (Cont.)

HYDRAULIC PRESSURE TESTS & TROUBLE SHOOTING: *CAUTION—Pressure difference from 15 lbs. to 250 lbs., will be found in making following tests and correct pressure gauge must be used.*

C-3292 (100 P.S.I.) Gauge—Use for Throttle Pressure, Governor Pressure and Lubrication Pressure checks.

C-3293 (300 P.S.I.) Gauge—Use for Line Pressure check.

Line Pressure: Remove ⅛" pipe plug from line pressure take-off hole (front left side of transmission case), install C-3293 (300 P.S.I.) pressure gauge at this point. Check Reverse oil pressure first (brakes off), then apply brakes to hold car and check the other points. Run engine at speed indicated in table below, check line pressure for each selector lever position as indicated.

Line Pressure

Gearshift Position	Engine RPM.	Pressure (P.S.I.)
R	1600	225-275
N	800	85-95
D	800	85-95
L	800	85-95

If line pressure not correct, check for: Low oil level or clogged oil strainer; defective Regulator Valve and Spring, Manual Valve and Lever, Throttle Valve, Cam, and Spring; Oil Leakage at Valve Body or Regulator Body mating surfaces; defective Kick-down Piston and related parts; defective Reverse Piston and related parts; Worn Front Pump or defective pump drive sleeve or pinion.

Direct Clutch Pressure: *(NOTE—Check line pressure before checking direct clutch pressure as any deviation in line pressure will affect direct clutch pressure).* Remove ⅛" pipe plug from direct clutch pressure take-off hole located at bottom of kickdown servo boss on right side of transmission (directly above filler tube connection on side of transmission). Connect a 300 lb. pressure gauge at this point. With rear wheels raised and free to turn, accelerate engine slowly until an upshift occurs. During the upshift, the pressure should rise rapidly from 0 to 90 lbs. pressure in 1½-2 seconds. With an engine speed of not less than 650 RPM, and transmission upshifted, the direct clutch pressure should read within 10 lbs. of line pressure. *If direct clutch pressure not correct*, refer to "Shift Quality", and "Excessive Engine Speed on Upshifts" in "Trouble Shooting & Diagnosis" below.

Throttle Pressure: Remove ⅛" pipe plug from throttle pressure take-off hole (right center of transmission case between the servos), install C-3292 (100 P.S.I.) gauge at this point. Apply brakes to hold car, place selector lever in "D" position, run engine at speed indicated in table below and note throttle pressure at each speed.

Throttle Pressure

Throttle Opening	Engine RPM.	Pressure (P.S.I.)
Closed	Idle	13-15
Wide-open	Stall	80-90

▷*CAUTION—When making above test do not hold throttle wide-open for more than a few seconds. If engine speed exceeds 1500 RPM. (indicating band slippage), refer to STALL TEST above for recommended checks.*

If throttle pressure not correct, check Line Pressure (above), and also check for: incorrect Throttle Linkage adjustment; leakage at Valve Body mating surfaces; defective Throttle Valve, Cam, and Spring; defective Throttle Pressure Check Ball or Kick-down Valve Ball and Rod; defective kick-down piston or related parts.

Governor Pressure: Remove ⅛" pipe plug from governor pressure take-off hole on lower left side of output shaft support (plate between transmission case and extension housing), install C-3292 (100 P.S.I.) gauge at this point. Support car securely with rear wheels off the floor so that they are free to turn, place selector lever in "D" position, run engine at car speed indicated (as noted on speedometer), note governor pressure in each speed range.

Governor Pressure

1955 Plymouth 8

Car Speed (MPH)	Pressure P.S.I.
13-16	15
23-26	45
55-62	60

If governor pressure not correct, check for: leakage at Valve Body mating surfaces or Output Shaft Support gaskets, defective Governor assembly, defective Rear Pump.

Lubrication Pressure: Check only when there is reason to suspect that it is incorrect. Connect gauge in oil cooler return line as follows: Disconnect cooler return line from flared tube connector fitting at upper left side of output shaft support (between transmission case and extension housing), install a ⅛" short pipe nipple and ⅛" pipe tee at this point, connect the flared tube connector fitting which was removed from the transmission into the tee, connect C-3292 (100 P.S.I.) gauge to the other side of the tee, connect oil cooler return line to the flared tube fitting *(CAUTION—always place a flared tube nut in the flared tube fitting when screwing it in or out to prevent crushing the fitting).* Run the engine at 800 RPM. with selector lever in "N" and note lubrication pressure which should be 10-20 P.S.I.

If lubrication pressure is not correct, check for: leakage at Regulator Body mating surfaces or at Output Shaft Support gaskets; defective Converter Control Valve; defective Front Pump Drive Sleeve; defective Reaction Shaft seals or worn reaction shaft bore; defective Input Shaft seal rings; plugged lubrication holes

TROUBLE SHOOTING & DIAGNOSIS

EXCESSIVE SLIPPAGE:

All Ranges—Inspect oil level. Adjust gearshift linkage Check oil pressure; if low, inspect regulator valve and torque converter control valve for sticking Inspect valve body in transmission case mating surfaces for evidence of oil leakage

Kickdown—Readjust throttle linkage and kickdown band Inspect valve body to transmission case mating surfaces for evidence of oil leakage. Check operation of throttle valve and note wear of valve bore and cam Check spring. Check valve body end cover for oil leakage Check shuttle valve for free movement. Inspect kickdown piston and guide for binding Inspect spring Inspect band lining for wear and band lever for free movement

Kickdown (Over 25 MPH)—Inspect valve body end cover for oil leakage. Inspect shuttle valve and plug for free movement. Inspect spring

Direct—Inspect valve body to transmission case mating surfaces for evidence of oil pressure leakage. Check kickdown piston for binding. Check shaft seal rings and clutch retainer bushing for wear. Check clutch discs, piston and clutch check valve

Reverse—Check reverse band adjustment Inspect transmission case to valve body mating surfaces for evidence of oil pressure leakage. Inspect

CONTINUED ON NEXT PAGE

POWERFLITE (C nt.)

reverse servo assembly for wear or binding Inspect reverse lever and linkage for free movement

Hill Climbing—Insufficient oil will result in low pressures to kickdown servo or direct clutch if oil level is low

SHIFT PATTERN:

No Upshift—Check oil level and gearshift linkage adjustment Check governor and throttle pressure If there is no pressure rise when accelerating engine in direct drive, governor valve may be stuck closed Check valve body to transmission case for parallelism Check manual valve and lever for correct detent engagement Check shift valve for free operation and shift valve spring for breakage Check kickdown piston assembly Check rear pump drive pinion Drive pinion ball may be cracked or broken, permitting pinion gear to slip Inspect clutch ball check for proper operation Ball check valve must operate freely and seat properly

No Shift in "D" (Drive) Range and an Upshift In Low Range—The cause is the governor valve sticking open This can be verified by checking governor pressure (see "Governor Pressure Test" above) If governor pressure exceeds the pressures indicated in table, governor valve is possibly stuck and in most cases can be corrected in the following manner Clean off area around governor pressure take-off plug and remove plug Cover oil filler tube with a cloth or plug and hold firmly to prevent air from forcing transmission oil out through filler tube Screw a piece of ⅛" pipe into hole to help direct air into unit Apply clean filtered air to pipe in short blasts, tapping parking brake drum at same time with a rubber hammer just enough to jar governor After applying air pressure, recheck governor pressure and see if valve has been freed up In cases where governor pressure is still to high, it will be necessary to remove transmission extension case for further inspection

Low Upshift Pattern—Readjust throttle linkage Check governor pressure Governor valve may be binding or sticking Inspect the rear pump assembly Check valve body to transmission case for parallelism Check operation of throttle valve and inspect cam and spring Check shift valve for free operation and spring for breakage

Low Upshift Pattern at Heavy Throttle—Inspect regulator valve, throttle valve, and governor for burrs or dirt which may cause binding or sticking Inspect the regulator spring

High Upshift Pattern—Readjust throttle linkage and check both throttle and governor pressures Adjust throttle pressure if necessary If throttle pressure does not rise according to speeds on chart (see "Throttle Pressure" above), throttle valve may be sticking Inspect for dirt or burrs Inspect throttle cam for wear Check valve body to transmission case for parallelism Check shift valve spring If governor pressure does not correspond to pressures indicated in "Governor Pressure" table above, remove governor and inspect valve for sticking Check rear pump gears for wear, broken teeth or excessive clearance Inspect pump drive pinion ball

All Upshifts Below 14 MPH—Inspect throttle valve, cam and spring Check throttle pressure check ball Check governor valve for sticking

Erratic Shifting—Check oil level Inspect valve body to transmission case for parallelism Check action of shift valve Inspect governor support gaskets for oil leakage

No Downshift—Check governor pressure High initial pressure indicates valve is stuck open Remove governor and inspect Inspect shift valve action, check spring

Low Downshift Speed—Governor valve is stuck open Remove and clean and check for burrs and dirt

High Downshift Speed—Readjust gearshift linkage Inspect valve body to transmission case for parallelism Inspect manual valve and lever Inspect kickdown valve and ball

No Kickdown—Adjust throttle linkage Inspect valve body to transmission case for parallelism Inspect throttle valve, cam and spring Also inspect kickdown valve and shift valve components

Low Kickdown Limit—Check governor pressure Governor valve may be sticking due to dirt Inspect regulator valve and spring for proper operation Inspect rear pump gears and drive pinion ball Check valve body cover plate for parallelism

SHIFT QUALITY:

Harsh Shift from Neutral to Reverse—Adjust engine idle speed Readjust rear band Inspect condition of the reverse band, strut and linkage Inspect the reverse servo piston, spring valve and rings

Harsh Shift from Neutral to Drive—Adjust engine idle speed Adjust throttle linkage Inspect kickdown servo pistons, springs, guide, rod and piston rings

Delayed Shift from Neutral to Drive—Adjust kickdown band Inspect condition of band, strut, lever and lever shaft

Excessive Engine Speed Increase on Upshifts—Check oil level and adjust throttle linkage Inspect regulator valve and spring and check operation of valve in regulator body Check valve body mating surface for parallelism Inspect throttle valve, cam and spring Check operation of valve in valve body Inspect kickdown piston components Check mating surfaces of regulator valve body and transmission for parallelism Inspect reaction shaft seal ring for deterioration Inspect input shaft oil seal rings for wear or breakage and condition of reaction shaft bore Inspect clutch retainer bronze bushing If worn below bronze surface, replace retainer Inspect condition of reaction shaft oil seal rings for wear or broken ends Inspect condition of clutch plate and condition of friction material on seal ring Check clutch check valve ball

Excessive Engine Speed Increase on Upshifts at Light Throttle—Check line pressure Inspect front oil pump gears for wear and excessive clearance

Harsh Upshift—Adjust throttle linkage Inspect regulator valve and spring Check for sticking shuttle valve Check valve body mating surfaces for parallelism Inspect throttle valve, cam and spring Inspect kickdown piston components Check regulator valve body mating surfaces for parallelism Inspect direct clutch spring, spring retainer, and snap ring

Harsh Lift Foot Shift—Adjust throttle linkage Check valve body mating surface Check operation of throttle valve Inspect valve, valve bore, cam and spring Inspect servo pressure bleed valve for dirt Check operation of shuttle valve Inspect shuttle valve, plug, inner and outer springs, and guide pin

Excessive Engine Speed Increase on Downshift at Part Throttle—Check oil level and adjust throttle and gearshift linkage Check valve body mating surface Check operation of manual valve and valve lever Inspect servo restrictor valve and operating plug Check plug for free operation Check valve spring for distortion or looseness

Harsh Downshift—Adjust engine idle speed and throttle linkage Inspect valve body mating surface Inspect throttle valve, cam and spring for proper operation Inspect for dirt, burrs or wear, or breakage Inspect servo restrictor valve for proper operation Inspect clutch plates and disc friction material Inspect the piston for wear or scoring Check seal for wear or deterioration which would result in leakage Inspect thrust washers for excessive wear

Excessive Increase in Engine Speed on Kickdown—Readjust kickdown band Check regulator valve and spring for proper operation Inspect for dirt wear or breakage Check valve body mating surface for nicks, burrs and trueness, which would cause leakage Check operation of servo restrictor valve and shuttle valve Inspect valve and plug for dirt, burrs or wear Inspect all parts of kickdown piston assembly Inspect piston rings for excessive wear or broken ends Check governor valve for wear, dirt binding or sticking Inspect rear pump gears for excessive wear or broken teeth Check pump clearance, drive pinion gear and pinion ball

Harsh Kickdown—Adjust kickdown band Inspect regulator valve and spring Inspect for dirt burrs or breakage Inspect servo pressure bleed valve for dirt Check operation of shuttle valve Check valve and plug for burrs, dirt or excessive wear Inspect all parts of kickdown piston assembly Inspect piston rings for scoring, wear or broken ends Inspect regulator valve body mating surface for nicks, burrs and trueness which would cause leakage Inspect reaction shaft neoprene seal for deterioration Inspect governor valve for free operation Check for dirt which would cause sticking Inspect rear pump gears for excessive clearance, worn or chipped teeth Inspect drive pinion gear and drive pinion ball Inspect the input shaft seal rings for excessive wear or broken ends and reaction shaft bore for scoring Inspect all parts of the direct clutch assembly

OIL PRESSURE:

No Governor Pressure—Governor valve may be stuck in closed position due to dirt To free valve, apply a short spurt of high air pressure (90 lbs) to governor pressure take-off hole and at same time tap transmission extension housing with a rubber mallet Before applying air pressure, cover filler tube with a cloth In addition, drain two or three quarts of oil from transmission oil pan After air is applied, reinstall governor pressure take-off plug and run transmission in Reverse a few seconds Recheck governor pressure This corrective procedure may not be permanent If valve becomes stuck again, remove governor for servicing If pressures do not correspond to those indicated in "Governor Pressure" table above, the governor may need service However, before servicing governor, check the other points in the transmission that could

CONTINUED ON NEXT PAGE

POWERFLITE (Cont.)

cause low pressure as follows: Check the valve body mating surface for trueness, nicks or burrs. These could cause oil leakage. Check both output shaft support gaskets for evidence of internal leakage. Check operation of governor valve and inspect for foreign matter. Check the rear pump gears for broken teeth, wear, and excessive clearance. Check the mating surface of output shaft for trueness, burrs or nicks.

High Initial Governor Pressure—High governor pressure at low engine speeds is due to the governor valve being stuck in the open position, usually caused by dirt *(see "No Governor Pressure" above)*, for clearing with air pressure.

Line Pressure—If line pressure does not correspond to pressures indicated in "Line Pressure" table above, it will be necessary to investigate and make the following adjustments or corrections: Check transmission oil level. Inspect regulator valve for free operation, dirt or burrs, and condition of valve spring. Check valve body mating surface for trueness, nicks or burrs. Check operation of manual valve and lever. Inspect front pump gears for worn or chipped gears. Check clearance between gears and face of housing.

Throttle Pressure—If throttle pressures do not correspond to pressures indicated in "Throttle Pressure" table above, check line pressure and make the following adjustments and corrections: Adjust throttle linkage. Inspect operation and condition of regulator valve and spring. Check valve body mating surfaces for nicks, burrs and trueness. Check operation and condition of throttle valve, cam and spring. Check throttle pressure check valve ball for nicks and dirt. Inspect condition of kickdown rod and ball.

Direct Clutch Pressure—Direct clutch pressure should be approximately 10 lbs. lower than line pressure with transmission upshifted and engine speed not lower than 650 RPM. If not, refer to "Excessive Engine Speed on Upshifts" above. A pressure drop between line pressure and direct clutch pressure as high as 25 lbs. may be due to broken or damaged seal rings in the direct clutch circuit. These are: three interlocking type input shaft seal rings; the direct clutch piston retainer seal ring, direct clutch piston neoprene seal ring, the neoprene reaction shaft seal ring, and the two interlocking type reaction shaft seal rings.

Lubrication Pressure—Lubrication pressure is checked at the upper left side of the output shaft support, Remove the ⅛" pipe plug and use 100 lbs., pressure gauge C-3292 to check pressure. Lubrication pressure should be 35 to 50 lbs. pressure with transmission in neutral and engine speed at fast idle. If pressure readings are incorrect, check line pressure and inspect torque converter control valve. Low pressures may be due to internal oil leakage at the following points: drive sleeve seal ring, regulator valve body mating surface, reaction shaft seal ring, output shaft support gaskets, input shaft seal rings, and reaction shaft bore. Low oil pressure may also be caused by plugged lubrication lines.

IMPROPER RESPONSE TO GEARSHIFT SELECTOR LEVER POSITIONS:

Moves Forward in "N" (Neutral)—Adjust gearshift linkage. Adjust kickdown band. Inspect manual valve lever assembly. Check valve body mating surface for nicks, burrs and trueness which would cause leakage. Check operation of manual valve. Inspect all parts of kickdown piston. Check regulator body mating surface for nicks, burrs and trueness. Check clutch discs and plates for warpage which would cause dragging. Inspect clutch ball check.

Car Moves Forward in "N" (Neutral) at High Engine Speed—Clutch check valve ball bleed hole may be plugged causing centrifugal oil pressure to partially engage the direct clutch. A slight surge which is not continuous is normal.

Car Moves Backward in "N" (Neutral)—Readjust gearshift linkage and inspect manual valve and valve lever for proper engagement. Adjust reverse band, levers, strut, and shaft. Check for binding, dirt, excessive wear.

MISCELLANEOUS DIAGNOSIS PROCEDURES:

Starter Will Not Energize—Adjust gearshift linkage. Test neutral starter switch. Inspect manual valve lever for proper engagement.

Hard Shifting Into "N" (Neutral)—Check operation of neutral starter switch and inspect manual valve lever.

Hard Shifting Into "R" (Reverse)—Check operation of backup light switch and manual valve lever.

Oil Foams From Filler Tube—Check fluid level in transmission. Inspect transmission breather vent.

PARTS REMOVAL & INSTALLATION (TRANSMISSION IN CAR)

▷*NOTE: Transmission must be removed from vehicle for the removal and replacement of parts other than those listed below.*

Oil Pan: Remove oil pan filler tube, drain transmission and remove oil pan attaching screws and oil pan. When installing pan, tighten screws evenly and torque to 12-17 ft. lbs.

Governor Servicing: *NOTE—It is necessary to remove transmission extension to remove governor assembly. See "Transmission Overhaul" below for Extension Housing Removal, Governor Removal, Overhaul & Installation.*

Valve Body & Transfer Plate Assembly (Removal): Remove oil pan and disconnect throttle and manual control lever linkage from levers. Loosen throttle and manual control lever assembly locking screws. Slide throttle valve operating lever assembly off shaft and remove throttle valve camshaft felt retainer and felt. Slide manual valve lever assembly off shaft and remove valve lever shaft seal cover. Remove the two oil strainer support screws and washers and take the strainer assembly off valve body and plate assembly. Remove transfer plate screws and lock washers and remove valve body and transfer plate assembly. For overhaul. *See "Valve Body Overhaul" below.*

Installation—Clean mating surfaces and check for burrs on both transmission case and valve body transfer plate. Place valve body and transfer plate assembly into position and install plate screws and lockwashers *(CAUTION—The two 1⅝" screws go through transfer plate cover on valve body. The three 1⅛" are used in the other holes)*. Tighten evenly to 12-17 ft. lbs. torque. Make sure the two oil strainer tube seals are in position over oil strainer and place oil strainer assembly into position on transfer plate. *(CAUTION—Check to see that oil tubes on strainer properly enter valve body)*. Install the two oil strainer support screws and torque to 12-17 ft. lbs. Place manual lever shaft seal cover over manual valve lever shaft and slide into position on transmission case. Install manual lever (arm side of lever against cover) on manual valve lever shaft, and tighten locking screw. Place throttle valve camshaft felt and retainer over throttle valve shaft. Install throttle valve lever assembly on throttle camshaft and tighten locking screw. Check operation of control by shifting into all positions. Check kickdown operation and manual lever contact on neutral safety and back-up light switches. Install oil pan and adjust throttle linkage and gearshift linkage.

Manual Control Valve Lever Shaft Oil Seal Removal & Installation: Remove oil pan, valve body and transfer plate assembly. Using a suitable brass drift, drive seal out of transmission case from below. To install, use tool C-3277. Start seal squarely into bore and tighten tool C-3277 until it is flush with the case. This properly positions seal. Install valve body and plate assembly and oil pan.

Kickdown Piston (Removal): Remove oil pan, valve body and transfer plate assembly. Loosen kickdown band adjusting screw locknut and back adjusting screw out sufficiently to permit kickdown band strut to be removed by compressing band ends. With kickdown band lever hanging down, install tool C-3289 on transmission case. Apply sufficient pressure on kickdown rod guide to permit easy removal of the snap ring. Loosen compressing portion of tool and remove piston rod guide, piston spring and kickdown piston rod assembly (the kickdown piston cushion spring will fall out of piston when rod assembly is removed). Using snap ring pliers, inserted inside of kickdown piston, remove piston from transmission case. *See "Overhaul" below, for disassembly and inspection.*

Installation—Make sure the two interlocking seals are locked in position and all seals are coated with Lubriplate, then place kickdown piston into transmission case. With one hand apply pressure to piston and at the same time carefully compress bottom seal and push piston into case. *(CAUTION—*After bottom seal has entered, piston will seem to hang at two different locations while being pushed into case. This is due to seals entering cylinder, do not use extreme force. If any rings should be broken when piston assembly is being installed, transmission will not operate properly.) Slide piston spring over kickdown piston rod assembly then balance piston cushion spring on rod assembly (Lubriplate may be used to help hold cushion spring in position on rod assembly), and install in piston. Holding it in this position, install kickdown piston rod guide assembly on piston rod assembly. Using tool C-3289, and extreme care, compress the kickdown piston spring to the point that piston guide seal slightly binds on transmission case. Work seal into position and gradually compress spring until seal enters case and snap ring can be installed. Install kickdown piston rod guide snap ring, making sure it is properly seated. Loosen compression portion of tool and remove tool from transmission case.

CONTINUED ON NEXT PAGE

POWERFLITE (Cont.)

With one end of band fit over adjusting screw, compress the other end sufficiently to install the kickdown band strut between kickdown band and band lever *(CAUTION—Make sure band strut slot engages with kickdown band strut pin in band end)*. Install valve body, plate assembly and oil pan. Adjust kickdown band.

Reverse Servo (Removal): Remove oil pan, valve body and transfer plate assembly. Loosen reverse servo adjusting screw locknut and back adjusting screw out sufficiently to permit reverse band strut to be removed by compressing band ends. Remove reverse servo piston sleeve. Mount tool C-3289 on transmission case and compress reverse piston spring retainer. Using a screwdriver, remove the reverse servo piston and valve assembly spring retainer snap ring and loosen compressing part of tool (Spring retainer may require guiding out of transmission case). Remove spring retainer, spring, reverse servo piston and valve assembly from transmission case. Using C-3229 pliers, remove the reverse servo piston valve spring snap ring, and remove spring and valve from piston. *See "Overhaul" below, for disassembly and inspection.*

Installation—Place reverse servo piston valve and spring in reverse servo piston (shaft on valve protruding through hole in bottom of piston). Using snap ring pliers C-3229, install reverse servo piston valve spring snap ring, making sure it is properly seated. Coat reverse servo piston ring (neoprene) with Lubriplate. Insert reverse servo piston and valve assembly into transmission case in a cocked position, then by rotating piston, the ring will enter case without being damaged. Place reverse servo piston spring over piston and position spring retainer over spring. Using tool C-3289, compress spring sufficiently to install snap ring. Make sure retainer is correctly installed, and snap ring seated. Remove tool C-3289 from transmission case and install reverse servo piston sleeve. Make sure piston sleeve slides freely on piston by working it up and down. Hook one end of reverse band assembly in reverse link assembly, compress other end sufficiently to install reverse strut in slots of reverse band assembly and reverse band lever assembly. Adjust reverse band. Install valve body, transfer plate and oil pan.

Speedometer Pinion (Removal & Installation): Disconnect speedometer cable and housing from sleeve assembly on transmission, and remove speedometer pinion and sleeve. When installing sleeve and pinion assembly, torque it to 40-45 ft. lbs.

Neutral Safety and Back-Up Light Switch Removal & Installation Note: It is not necessary to drain transmission to remove these switches. A small amount of lubricant will drain from transmission when these switches are removed. When installing, tighten switches to 15-20 ft. lbs.

Transmission Output Shaft Rear Bearing Oil Seal (Removal): Disconnect the front universal joint and secure shaft to frame out of the way. Apply hand brake and remove propeller shaft flange nut and washers. Release hand brake and install puller C-452. Remove propeller shaft flange and drum assembly. Remove transmission support grease shield spring (small one). Remove brake support grease shield from extension housing *(CAUTION—If screwdriver or sharp instrument used to remove shield, do not damage the neoprene sealing surface at bottom of shield)*. Install puller C-748 and remove rear bearing oil seal.

Installation—Install rear bearing oil seal with tool C-3205. Install brake support grease shield on extension housing *(CAUTION—Indent on grease shield must match groove in housing for correct positioning. Install grease shield far enough on housing to permit installation of spring)*. Install brake support grease shield spring with opening in spring toward adjusting sleeve. Make sure spring is properly seated in groove. Make sure brake adjustment is backed off and install drum assembly (In some instances it may be necessary to use tool C-496 to press drum assembly on output shaft). Install propeller shaft flange washer, shakeproof washer and nut. Adjust hand brake. Apply hand brake and torque propeller shaft flange nut to 140-160 ft. lbs. Connect front universal joint.

Transmission Regulator Valve Assembly (Removal): Remove transmission regulator valve spring retainer, gasket, and spring. Using a mechanical retriever or a piece of welding rod inserted in end of valve, remove valve.

Installation—Place valve in position in valve body. Install regulator valve spring, gasket, and retainer and tighten to 45-50 ft. lbs. torque.

Torque Converter Control Valve Assembly (Removal): Remove control valve spring retainer, gasket, and spring. Using a mechanical retriever or a piece of welding rod inserted in end of valve, remove valve.

Installation—Reverse removal procedure.

Oil Cooler (Removal): Drain radiator, remove battery and battery pan. Remove lower radiator-to-cooler hose. Remove inlet and outlet oil tubes. Remove oil cooler to water pump flange bolts.

Installation—Clean mating flanges thoroughly and install new flange gasket. Install cooler to water pump and tighten flange bolts. Install inlet and outlet oil tubes. Install lower radiator-to-cooler water hose. Install battery and battery pan. Refill radiator and start engine. Check carefully for water and oil leaks.

TRANSMISSION REMOVAL

1) Disconnect battery and raise car off floor. Drain transmission and torque converter. When fluid has drained, replace drain plug. Disconnect oil pan filler tube from oil pan. Disconnect front universal joint and secure shaft to frame out of the way.
2) Remove adjusting screw cover plate and cable clamp bolt from hand brake support. Disconnect speedometer cable from transmission extension. Disengage ball end of cable from hand brake operating lever and remove cable from brake support.
3) Disconnect neutral safety and back-up light switch wires at switches and unclip wires from crossmember. Disconnect manual and throttle control linkage from levers. If car equipped with oil cooler, disconnect cooler lines from transmission case and remove bracket holding lines to cylinder block. On all models remove screws holding exhaust pipe bracket to transmission case.
4) Remove bracket holding oil cooler lines to cylinder block. Remove nuts and lockwashers holding engine rear support insulator to cross-member, leaving insulator attached to transmission.
5) Install engine support fixture tool C-3245, insert hooks of fixture firmly into holes in side of frame member with support ends up; against the underside of oil pan flange. Adjust fixture to support weight of engine. Raise engine slightly, remove cross-member to frame bolts and remove crossmember.

▷*CAUTION—When using tool C-3245, do not lower engine more than three inches from floor boards to avoid disrupting the set position of water hoses and other engine attachments.*

6) Remove the two upper transmission-to-adapter screws and lockwashers and install guide studs C-3276. Remove the lower screws and slide transmission straight back to avoid damage to converter driving sleeve, then lower transmission to floor.
7) If front oil pump drive sleeve remained in the torque converter hub when transmission removed, remove the sleeve and inspect. Check driving lugs and machined surfaces for burrs and wear. Check ring for broken ends and freeness in ring groove.

TRANSMISSION INSTALLATION

1) Install guide studs C-3276 in the two upper transmission case-to-adapter screw holes. Lubricate front oil pump drive ring sleeve and bearing surface with Lubriplate and install in torque converter hub making sure drive lugs are properly engaged. Note position of driving lugs on front oil pump drive sleeve, then position front oil pump pinion in same way to aid in proper engagement when transmission installed.

2) Slide transmission over guide studs and into position. Make sure drive lugs on front oil pump drive sleeve properly engage front oil pump pinion. *(CAUTION—To avoid damage to front oil pump, do not attempt to use transmission-to-adapter screws to bring transmission and adapter together. If oil pump drive sleeve and input shaft have been properly aligned, the transmission should slide into position relatively easy. DO NOT FORCE.)*
3) Install the two lower transmission-to-adapter screws and lock washers, do not tighten. Remove guide studs and install the two upper transmission case-to-adapter screws and lock washers, then draw all four down evenly and tighten to 45-50 ft. lbs. torque.
4) Place cross-member into position and install crossmember-to-frame bolts, tightening them to 50-55 ft. lbs. torque. Lower engine and at same time align mounting holes in extension of transmission with holes in crossmember. Install the two nuts and lockwashers that hold engine rear support insulator to crossmember and tighten to 30-35 ft. lbs. torque. Remove support fixture from side of frame member.
5) From this point, reverse the removal procedure as indicated above. Refill transmission and adjust manual and throttle control linkage. *See "Manual & Throttle Control Linkage" above.*

TORQUE CONVERTER REMOVAL

1) With transmission removed, turn front wheels to extreme right and remove starter motor. Remove the transmission case adapter screws and lockwashers and remove transmission from car. Remove Remove lower half of flywheel housing.

CONTINUED ON NEXT PAGE

POWERFLITE (C nt.)

►*NOTE*: If torque converter being removed because of excessive runout damage, check by using dial indicator on hub and mark the highest point of runout on both converter and crankshaft flange. The reason for this is so it may be determined later if runout was caused by the converter or crankshaft, after crankshaft has been checked in the same manner.

2) Using tool C-811, remove the eight torque converter stud nuts and lockwashers from crankshaft flange. Remove torque converter from crankshaft.

►*NOTE*—Check crankshaft flange runout. Maximum is .002".

STARTER RING GEAR REPLACEMENT (REMOVAL): Support torque converter assembly in a vise and carefully remove staking lugs, retaining ring gear to torque converter, with a file *(CAUTION*—Be careful when supporting torque converter in vise to avoid distortion). Place torque converter on blocks of wood, and using a blunt chisel or drift, tap around ring gear until it comes off converter.

Installation of Ring Gear—Remove burrs or raised spots on torque converter with a file, being careful not to remove more metal than is necessary. Any of the following methods for expanding the ring gear can be used in the manner outlined.

Oven—Set temperature at 150° and allow ring gear to remain for 15 to 20 minutes.

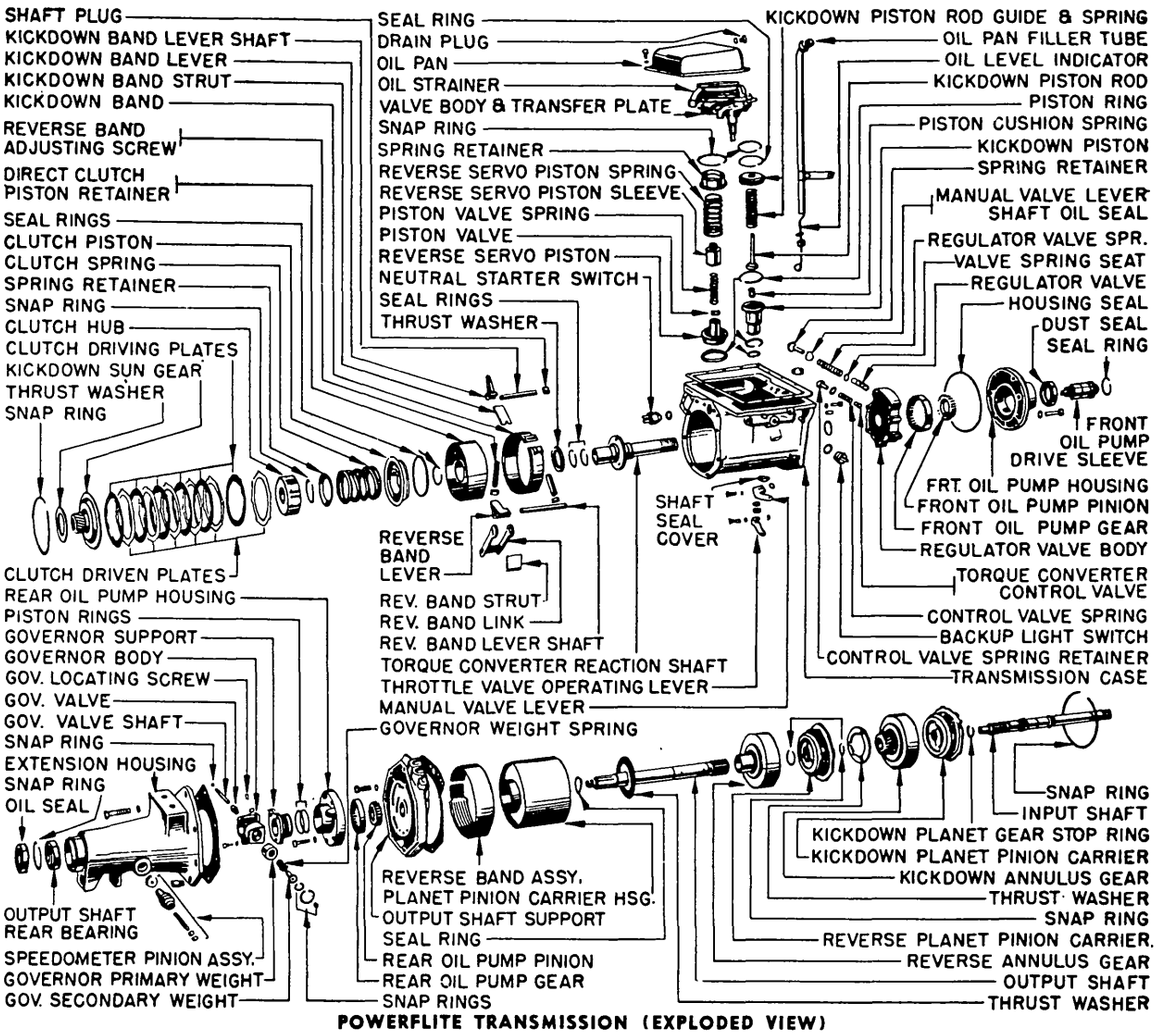
Boiling Water—Place ring gear in shallow container, add water and heat for approximately two minutes.

Flame—Place ring gear on a flat surface. Using a medium size tip, direct a slow flame around inner rim of gear, being careful not to direct flame onto teeth of ring gear. Place a few drops of water on face of gear at short intervals during heating process. When gear is hot enough to boil the drops of water, installation of gear to torque converter can be made.

When gear properly expanded, proceed as follows: Place starter ring gear over flange surface of torque converter, making sure that rear face of gear contacts flange on torque converter evenly around the entire diameter. Reweld ring gear to torque converter, *using extreme care to place as nearly as possible the same amount of metal in exactly the same locations as original assembly.* This is necessary to maintain proper balance of the unit. Place weld alternately on opposite sides of the converter to mimimize distortion. Clean thoroughly before installing in car.

►*RING GEAR WELDING NOTE:* Use a welding current of 200 amps. and 5/32" Fleet-Weld No. 27, or General Electric No. W28 rod, or their equivalent.

►*WELDING CAUTION:* To prevent burning through the torque converter, the arc should be directed at the intersection of gear and housing from an angle of approximately 45° from the face of the gear. DO NOT GAS WELD.



TORQUE CONVERTER INSTALLATION

►*TORQUE CONVERTER HUB RUNOUT NOTE:* When torque converter assembly is removed for any reason from crankshaft drive flange, the converter assembly runout should be checked when reinstalled. There are two methods for adjusting the hub runout. *See "Torque Converter Hub Runout Adjustment" below.*

1) Inspect mating surfaces of torque converter and crankshaft flange for burrs and dirt. Install torque converter on crankshaft flange. Install eight torque converter stud nuts and draw down evenly and tighten. Install lower half of flywheel housing and starter motor.

2) Install transmission case adapter on flywheel housing and tighten to 25-30 ft. lbs. torque. Install transmission (see above). Refill torque converter as follows:

3) Fill transmission with Automatic Transmission Fluid (Type A) to "full" mark on dipstick. This will take approximately 5 qts. Run engine at idle speed in neutral for approximately two minutes, then add 8 qts. of fluid to bring oil level to "full" mark on dipstick. Allow engine to run until normal operating temperature is reached. Set handbrake and shift selector lever through all ranges and return it to "N", recheck level and add fluid to bring level to "full" mark. *CAUTION—Fluid should NOT BE ABOVE THE FULL MARK.*

POWERFLITE TRANSMISSION (EXPLODED VIEW)

TORQUE CONVERTER RUN-OUT ADJUSTMENT

►*NOTE—Two methods, as follows, can be used to adjust torque converter run-out.*

Heat Method: *(CAUTION—When using this method, extreme caution must be used to prevent burning the metal and causing irreparable damage. Sufficient heating of this unit, to cause the necessary drawing of metal required, is accomplished in just a few seconds. DO NOT OVERHEAT).* Remove transmission, torque converter housing and dust shield. Mount Torque Converter Hub Alignment Indicator C-430 on adapter plate. Rotate converter through 360° and mark high point on converter with chalk, then rotate converter to move the high point to the top. Apply heat 180°

CONTINUED N NEXT PAGE

POWERFLITE (C nt.)

from the high point at opposite side of converter shell at **high point of radius**. Use a No. 3 acetylene torch burner, moving the flames at all times in a circular motion about the size of a dime. When the spot begins to change color remove the flame and quench the converter with a water soaked rag. Change rags several times (the more quickly converter is cooled, the greater the drawing on the metal). Before checking hub runout make certain that both sides of the converter are the same temperature. If runout exceeds .004" at the same point, repeat operation. *(CAUTION—*It is possible to draw the metal excessively, thus causing runout at opposite side. If this occurs, reheat converter 180° from original point).

Shim Method: Determine hub runout in the same manner as for "Heat Method" above. Loosen converter drive flange nuts sufficiently to insert shims of proper thickness 180° from indicated high point. The thickness of shims used should equal half the total indicator reading, shim thickness not exceeding .008". New shims are furnished in the following sizes. Part No. 1610442 (.002"), 1610443 (.003), No. 1610444 (.005").

TRANSMISSION OVERHAUL DISASSEMBLY

1) Place transmission assembly in stand C-3280 and turn upside down. Remove oil pan and gasket. Loosen throttle and manual control lever locking screws and slide levers off shafts. Remove throttle valve camshaft felt retainer and felt and manual valve lever shaft seal cover. Inspect these parts for wear.
2) Remove oil strainer support screws and remove oil strainer assembly. Inspect ring seals located at both outlet sides of strainer. Remove transfer plate screws and take off valve body and transfer plate assembly. *See "Valve Body & Transfer Plate Overhaul" below.*

►*CAUTION: Mating surfaces are machined and extreme care must be used to avoid damage to these parts.*

3) Remove neutral safety switch and back-up light switch and gaskets.
4) Check transmission end clearance with a dial indicator or feeler gauge by prying direct clutch assembly toward rear and measuring the distance between direct clutch and carrier housing. Pry direct clutch forward and again measure the distance between direct clutch and carrier housing. Clearance should be .043-.069". If not within limits, record the measurement for reference at reassembly.

Hand Brake Assembly: Using tool C-3281 to hold transmission to flange, remove transmission flange nut and washers. Attach puller C-452 and remove brake drum assembly. Inspect oil sealing surfaces, and lining surfaces on drum for scoring or wear. Remove transmission brake support grease shield spring (NOTE—this spring acts as a guide for the brake shoes and retains the brake support grease shield to transmission extension housing). Place a rubber band around brake shoes to hold them in position and remove brake shoe return spring. Remove brake anchor shoe washer and brake shoe guide. Remove both brake shoe assemblies, adjusting sleeve, nut, screw and brake shoe operating lever link. Remove brake support grease shield from extension housing. *(CAUTION—*If a screwdriver or sharp instrument is used to remove the shield, care must be taken not to damage neoprene sealing surface at bottom of shield). Slide brake support assembly from rear extension housing and anchor. Inspect neoprene spacer for deterioration and note the steel sleeve used between spacer and extension housing.

Transmission Extension: Remove speedometer drive pinion. *(CAUTION—Nylon gear can be damaged if extension housing is removed without first removing the speedometer drive pinion).* Using puller C-748, remove the output shaft rear bearing oil seal and remove any burrs from counterbore of extension housing. Remove the transmission-to-extension screws and lockwashers. Install guide studs C-3283 and attach puller C-3282. Pull extension housing from output shaft support assembly and remove extension gasket. *(CAUTION—*Use care when removing extension housing to prevent damage to governor housing). Inspect extension housing for cracks in casting and remove burrs from gasket surface. Clean output shaft rear bearing and dry with compressed air. Check bearing for rough spots but do not remove from housing unless it is found to be defective. Using a pair of long nose pliers, remove output shaft rear bearing snap ring. Using driver C-3275, drive output shaft rear bearing out rear of extension housing. Remove vent from top of extension housing and make sure it is clear of foreign matter and is open.

Governor: Using a sharp instrument, remove either of the governor valve snap rings. Remove governor valve shaft and valve from governor body. With snap ring-pliers, remove governor weight assembly snap ring (large), and remove governor weight assembly from governor body. Using C-3229 pliers, remove governor secondary weight snap ring. *(CAUTION—*Keep thumb pressure against secondary weight when removing snap ring as it is spring loaded). Remove secondary weight and spring. Inspect all parts for burrs or wear. Check secondary weight for free movement in primary weight by placing secondary weight in primary weight without spring. Primary weight should fall freely when both parts are clean and dry. Check spring for distortion. Remove governor locating screw from governor body and output shaft *(make sure that screwdriver used fits slot in screw perfectly to avoid damage to governor body).* Slide governor body and support from output shaft. Remove the two governor support piston rings and inspect closely. *(CAUTION—*Governor support has pressed in steel sleeve which routes oil through the support. Make sure these passages are open. Do not attempt to replace sleeve if damaged, replace support). Clean passages with air and inspect valve and governor body for slight scores. Remove the four governor body-to-support screws and lockwashers and separate body from support.

Rear Oil Pump: Remove oil pump housing-to-output shaft support screws and lockwashers and remove housing and oil pump gear. Use prussian blue to mark front side of gear in housing *(DO NOT USE A SCRIBE).* Inspect machined surfaces for nicks and burrs, oil pump gear and housing for being scored or pitted, and pump housing plug for leaks. Remove rear oil pump pinion from output shaft and mark front side with prussian blue *(CAUTION—*Oil pump pinion keyed to shaft by a small ball. Use care when removing pinion not to lose ball). Check pinion keyway and ball pocket for pitting or scoring. Using tool C-3335 and feeler gauge, check clearance between pump housing face and face of gears. Clearance limits are from .001-.003".

Center Assembly (Output Shaft Support, Planet Pinion Carriers, and Direct Clutch Assemblies): Remove output shaft support-to-transmission case screw and washer. With one hand, work output shaft up and down, and at the same time apply pressure with the other hand to the input shaft. Slide output shaft rear support assembly, planet gear housing assembly and gasket from rear of transmission case. If rear support is stuck to transmission case and cannot be removed as just described, then proceed as follows: Install one of the oil pan screws into transmission case and with the aid of a pry bar, pry against support sufficiently to separate support from case. Remove direct clutch piston retainer assembly from torque converter reaction shaft. Remove direct clutch piston retainer thrust washer from torque converter reaction shaft. This washer is a select fit and controls end clearance between direct clutch assembly and carrier housing. Inspect washer for cracks, burrs and wear.

►*1955 INPUT SHAFT PRODUCTION CHANGE: Seal rings not used in late production. See Production Change above.*

Planet Pinion Carrier Removal from Housing Assembly: Place unit in an upright position in tool C-3285. Using a feeler gauge, check clearance between kickdown planet pinion carrier housing snap ring and kickdown planet pinion carrier assembly. This clearance should be .012-.038". If within these limits, then identify each thrust washer as it is removed. Using a screwdriver, remove transmission kickdown planet pinion carrier housing snap ring. Identify snap ring to aid in assembly (ring is not a selective fit). Proceed as follows:
1) Remove input shaft, kickdown planet pinion carrier assembly and kickdown annulus gear from carrier housing. Remove reverse planet pinion carrier thrust washer and inspect for cracks, burrs and wear. Remove kickdown annulus gear snap ring. Remove kickdown annulus gear from input shaft and inspect for worn, cracked or broken teeth.
2) Remove kickdown planet pinion carrier assembly from input shaft and carefully inspect stop ring on end of shaft which controls position of annulus gear on input shaft. Check all oil passages in both gear and shaft for obstructions. Inspect splines and bearing surfaces for burrs and wear. On early cars, inspect the three seal rings on input shaft for broken ends and make sure they are free to rotate in grooves.
3) Inspect planet pinion carrier for scores on thrust surfaces, broken and worn teeth. Using a feeler gauge, check end clearance on individual planet gears, clearance should be .006-.017". Inspect pinion shafts for tight fit in carrier and make sure pinions are free to rotate on shafts. Check oil holes in gears and shafts for obstructions. Inspect oil holes in the thrust washer of the kickdown carrier to make certain they are open *(NOTE—Do not replace planet pinion carrier assembly unless the above inspection indicates that it is necessary. This assembly is serviced only as a complete unit).*
4) Remove reverse planet pinion carrier assembly from planet pinion carrier housing. Inspect in the same manner as for planet pinion carrier (3 above).

CONTINUED N NEXT PAGE

POWERFLITE (Cont.)

Remove output shaft and reverse annulus gear assembly from carrier housing and output shaft support. Remove reverse annulus gear snap ring and remove annulus gear from shaft. Inspect thrust surfaces, journals and inner bushings for scores. Check annulus gear for worn or broken teeth. Inspect ring grooves for burrs and ring for broken ends. Inspect splines on both shaft and gear for burrs and wear. Check speedometer pinion gear and gear output shaft, and shaft bushing for burrs, wear and scoring.

5) Remove planet pinion carrier housing thrust washer and check for cracks or wear. Remove planet pinion carrier housing from output shaft support and inspect driving lug slots inside of housing for wear. Inspect bearing and thrust surfaces for scores and burrs. Closely inspect band contacting surface for burned spots and scoring, especially if lining has worn excessively. Inspect all oil passages in output shaft and support for obstructions. Check rear oil pump mating surface for burrs and scores, and check for stripped threads in support.

Direct Clutch Piston Retainer: 1) Using a screwdriver remove kickdown sun gear snap ring. Identify this ring so it can be returned to the same position (selective fit). Lift out sun gear assembly. Check for clutch material obstructing oil passages and slinger and remove any metal pickup which might have accumulated on front side. Inspect for cracked or broken teeth.

2) Lift out direct clutch hub from center of direct clutch piston retainer. Inspect driving lugs for wear and remove any metal pickup accumulated on either side of hub. Invert the direct clutch piston retainer and remove clutch plates (steel) and driving disc assemblies (five or six of each used, depending on car model), noting position in which these parts were assembled. *(CAUTION*—If assembly was started with cork portion on outer top, the same sequence will follow all through the assembly and when unit is reassembled the same sequence should be followed to assure smooth operation). Inspect driving discs for evidence of wear, burning, glazing, and flaking off of facing material. Check discs by scratching with finger nail and if material collects under nail, replace discs. Inspect splines in discs, replacing any that are damaged. Inspect steel plates for burning, scoring, or damaged splines.

3) Using tool C-3302, compress direct clutch spring sufficiently to unseat clutch spring retainer snap ring. Release tool C-3302, and remove direct clutch spring retainer snap ring, spring retainer and spring from direct clutch piston retainer. Using a twisting motion remove direct clutch piston assembly from clutch retainer. Air pressure may be used to blow piston out if it is tight.

4) Inspect ball check in clutch retainer housing to make sure it is free. The bearing used in direct clutch piston retainer is a steel back bronze type and is not replaceable. If torque converter reaction shaft seal rings have worn or grooved the bearing so that bronze is no longer visible at that point replace the direct clutch piston retainer. Inspect band contacting surfaces for deep scores and burns, especially if band lining is worn to point where steel band has been contacting direct clutch piston retainer. *(CAUTION—Do not turn clutch piston retainer in lathe to remove score marks).* Inspect steel clutch plate contacting surfaces for deep scores, replace as needed. Make sure clutch driving lugs will slide freely into retainer. Inspect inside bore for score marks, and if light, remove with crocus cloth, if heavy, replace piston.

5) With tool C-3286, unlock direct clutch piston retainer seal ring and remove from retainer. Inspect for wear and broken ends. Remove direct clutch piston seal ring (neoprene) from piston. Inspect for deterioration and hardness.

Reverse & Kickdown Band Assemblies: Mark reverse band for installation purposes, then compress ends of band sufficiently to remove reverse band strut. Unhook reverse band assembly from link assembly and remove by rotating band ends through rear opening in transmission case. Repeat with kickdown band, noting that strut is grooved to act as a guide to strut pin on band end. Remove from case in same manner as for reverse band. Inspect linings for wear and bonding to metal band. If lining is worn to point where grooves are no longer visible, replace band. *(CAUTION—Do not attempt to reline bands.)* Check bands for distortion and cracked ends.

Reverse & Kickdown Band Lever Assemblies: *(CAUTION—Inspect these link assemblies and levers for cracks or wear, making sure they have side clearance and are free to turn on shafts. Do not remove these assemblies unless inspection reveals that it is necessary).* If necessary to remove, proceed as follows: Insert finger in back of reverse band and link assembly lever shaft, and holding the reverse band lever and link assembly with the other hand, push shaft out rear opening in transmission case. Remove kickdown band lever shaft plug in front of transmission case and remove kickdown band lever in same manner as for reverse band, except that shaft is removed from front of transmission case.

Front Oil Pump: 1) Remove transmission regulator valve spring retainer, spring, gasket and valve. Remove torque converter control valve spring retainer, spring, gasket and valve.

2) Remove front oil pump-to-transmission case screws and washers (discard aluminum or copper sealing washers, new ones must be used at reassembly). Remove housing by tapping gently with a fibre hammer (if front pump housing has two threaded holes, attach puller C-3287 and guide studs C-3288 and pull housing and gears from transmission case). Use prussian blue to mark front side of gears *(CAUTION—Do not scribe gears for identification).*

3) Remove front oil pump housing seal (large neoprene) from housing, and inspect for deterioration and hardness. Using a brass drift, drive housing dust seal out front of housing. Inspect housing bushing for scores. Remove light scores with crocus cloth and if bushing scored heavily, replace housing (bushing is not replaceable). Check housing and gears for scores.

4) Using tool C-3335 and feeler gauge, check clearance between pump housing face and face of gears. Clearance limits are from .0012-.0022". Make sure all oil passages are clear by blowing out with compressed air.

Regulator Valve Body: Using the two holes provided in regulator valve body, attach puller C-3287, and install guide pins C-3288. Pull regulator body off torque converter reaction shaft. Place body and both valves in pan containing clean solvent, wash thoroughly and dry with compressed air. Check valves for free movement in body, these valves should fall in and out of bores when both valves and body are dry. *(CAUTION*—If crocus cloth is used to polish valves, care must be taken not to round off the sharp edges of valve.) Check for all passages for obstructions and all mating surfaces for burrs or distortion. If body has a slight nick or raised portion on a mating surface, it can be removed with a surface plate and crocus cloth. Check regulator valve spring seat (snap ring) for proper seating. Wrap valves and body in separate cloths until ready for installation.

Reverse Servo Piston: Lift out reverse servo piston sleeve. Inspect inside bore, lever, and contacting surface on piston sleeve for scores and wear. Make sure the two bleeder holes are open. Install tool C-3289 on transmission case and compress reverse piston spring retainer. Using a screwdriver, remove the reverse servo piston and valve assembly spring retainer snap ring, and loosen compressing portion of tool. Remove spring retainer, spring, servo piston and valve assembly. Remove servo piston ring (lip type neoprene) from piston and inspect for distortion and hardness. Remove reverse servo piston valve snap ring. Remove spring and valve from piston. Inspect servo bore for scores and remove light scores with crocus cloth.

Kickdown Piston: Using tool C-3289, apply sufficient pressure on kickdown piston rod guide and remove the snap ring. Loosen compressing portion of tool and remove tool from transmission case. Remove piston rod guide, piston spring, kickdown piston rod assembly, and kickdown piston cushion spring. Inspect riveting of kickdown piston rod to kickdown piston spring retainer. Remove seal ring from guide and inspect for light scores and wear on piston rod and guide. Using C-484 pliers, remove kickdown from transmission case. Remove the three snap rings (two locking and one open type) from kickdown piston. Inspect rings for scores or broken ends, and piston for wear.

Torque Converter Reaction Shaft: *(CAUTION—Inspect shaft seal rings (interlocking type) for broken ends and make sure they are free to rotate in grooves. Inspect inside of shaft for burrs, and splines for burrs and wear. Check thrust surfaces for wear and slight scores. Do not remove reaction shaft from case unless inspection reveals that it is necessary).* If shaft must be removed, proceed as follows: Remove shaft seal (neoprene). Using a suitable brass drift, remove shaft dowel pin from shaft flange and transmission case. Remove transmission case-to-reaction shaft screws and using tool C-3297, press shaft out of transmission case. Remove the two shaft seals (interlocking).

Manual Control Valve Lever Shaft Oil Seal: Drive seal out of case with a suitable drift.

Kickdown Band Adjusting Screw: Loosen locking nut and remove kickdown band adjusting screw and locknut. *CAUTION—When locknut is loosened, the adjusting screw must be finger free. If not, inspect screw and nut for pulled threads or foreign material on threads. Freeness of this screw is very important to adjustment.*

Transmission Case Inspection: Inspect case for cracks, sand holes and stripped threads. Check for burrs on mating surfaces. Blow compressed air

CONTINUED ON NEXT PAGE

POWERFLITE (Cont.)

through all passages to make sure they are open. Check oil hole plugs for tightness.

REASSEMBLY

Kickdown Band Adjusting Screw: Install adjusting screw in transmission case until there is approximately 1" of screw left outside case. Do not lock screw into position at this time.

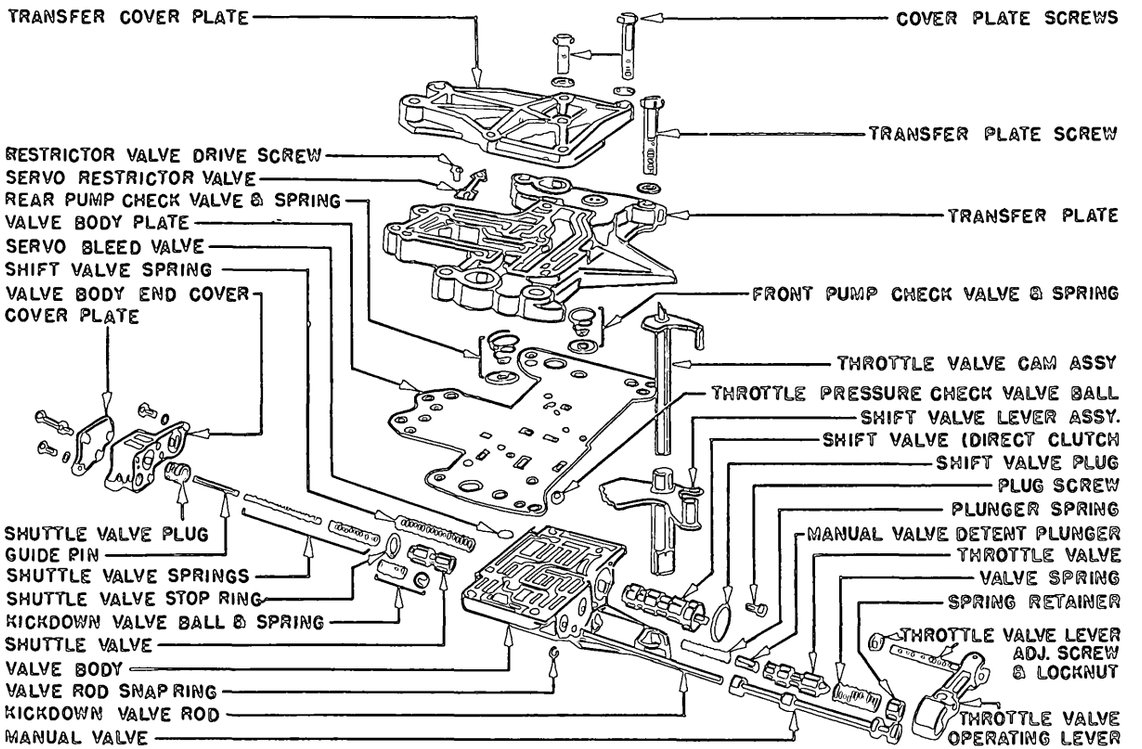
Manual Control Valve Lever: Using tool C-3277, start seal squarely and tighten until seal is flush with case.

Torque Converter Reaction Shaft: *(NOTE—Reaction shaft should only be removed if inspection indicates that it is faulty).* Heat front face of transmission case to 170-190°, using sun lamps for the purpose.

1) Coat the two shaft interlocking seal rings with Lubriplate and install on shaft and lock in place. Make sure the rings are free to rotate in lands. Coat the portion of shaft that presses into case with Lubriplate and position shaft into front of transmission so holes in shaft line up with screw holes in case.

2) Place a 5/16" (.308-.311" outside diameter in unthreaded section), 2¼" long bolt through dowel guide pin holes in case and reaction shaft to act as guide, install nut. Using tool C-3297 press shaft into place. Do not remove 5/16" bolt at this time. Start the three transmission case-to-reaction shaft screws and washers and tighten slightly, but do not torque.

3) Remove 5/16" bolt from dowel hole and install the reaction shaft dowel from inside case. Torque the case-to-reaction shaft screws to 10-15 ft. lbs. Coat neoprene reaction shaft seal and install on shaft.



Kickdown Piston: 1) Coat the three kickdown piston rings (two locking and one open type) with Lubriplate and install on piston. Lock into position and make sure they are free to rotate in lands. Place kickdown piston assembly into transmission case, compress bottom ring with a brass rod (flatten end), and push piston into place.

▷*CAUTION: After bottom ring has entered, piston will seem to hang at two different locations while being pushed into case. This is due to rings entering cylinder. If any of the rings should be broken when piston assembly is being installed, transmission will not operate properly.*

2) Place cushion spring in piston and install tool C3289 on transmission case. Place piston rod assembly in piston and slide piston spring over piston rod assembly. Coat piston rod guide seal ring with Lubriplate and install on rod guide. Make sure ring rotates in groove.

3) Place piston rod guide assembly on piston rod assembly and using extreme care, compress the kickdown piston spring to the point where piston guide seal ring slightly binds on case. Using a piece of brass rod (flattened on end), work seal into position, gradually compressing spring until seal ring enters case and snap ring can be installed. Install snap ring, making sure it is properly seated.

Reverse Servo Piston: 1) Place reverse servo piston valve and spring in reverse servo piston, with shaft protruding through hole in bottom of piston. Using pliers C-3229, install reverse servo piston valve spring snap ring and make sure it is seated.

EARLY 1954 POWERFLITE VALVE BODY & TRANSFER PLATE ASSEMBLY

2) Coat servo piston ring with Lubriplate and install on piston. Insert piston and valve assembly into transmission case in a cocked position, then by rotating piston, the piston ring will enter case without damage.

3) Place servo piston spring over piston and position spring retainer over spring. Compress spring with tool C-3289 sufficiently to install snap ring, making sure it is seated. Inspect interior of servo sleeve for burrs, then place sleeve over piston, making sure sleeve slides freely on piston by working it up and down. Remove installing tool from transmission.

Regulator Valve Body: 1) Inspect regulator valve body and valves to make sure that no damage has occurred since disassembly and blow out passages with air.

2) Coat reaction shaft seal (neoprene) with Lubriplate if not already done, and place regulator valve and torque converter control valve in regulator valve body. Install guide studs C-3288 in front transmission case.

3) Place regulator valve body assembly, with oil passages to rear, over reaction shaft and onto guide studs *(CAUTION—When reaction shaft seal enters regulator body use care to prevent shaft screws damaging passages on regulator body)*, seat firmly to front of transmission case.

Front Oil Pump: 1) Position front oil pump housing dust seal in oil pump housing with metal portion of seal down. Using driver C-3278, bottom seal in housing. Coat housing seal (large neoprene seal) with Lubriplate and install on housing.

2) Place front oil pump gear and pinion (driving lugs on pinion facing up, and prussian blue marks made at time of disassembly toward front) in pump housing. *(CAUTION—Oil pump pinion must be installed correctly or damage will result when installed in transmission.)* Lubricate pump gears with transmission fluid.

3) Place pump housing assembly over reaction shaft and slide into position over guide studs until pump housing seal is flush with transmission case. Using new aluminum or copper washers on screws, start five of the screws and draw housing down evenly until it is seated into transmission case. Remove guide studs and install two remaining screws and washers. Torque all screws to 12-17 ft. lbs. *NOTE—After all screws have been installed and torqued, engage driving lugs of oil pump pinion to determine if pinion turns freely. Use the oil pump drive sleeve for this check. If not free, remove pump and check for foreign matter between gears and housing.*

4) Using a new gasket, install torque converter control valve spring and retainer. Torque to 35-40 ft. lbs. Install regulator valve spring and retainer, using a new gasket, and torque to 45-50 ft. lbs.

Reverse Band, Kickdown Band & Lever Assemblies: *NOTE—If lever assemblies were not removed, omit the operations covering their installation.*

1) Place kickdown band lever assembly in trans-

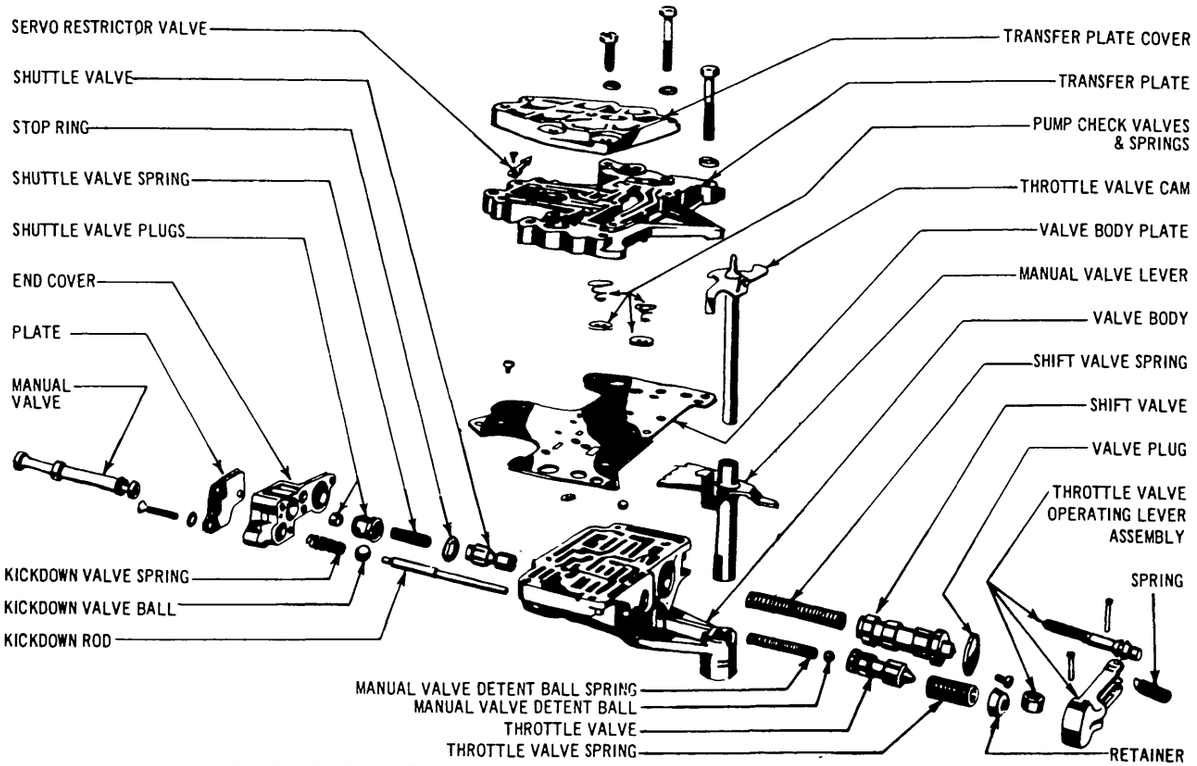
CONTINUED ON NEXT PAGE

POWERFLITE (C nt.)

mission case and slide band lever shaft into position from front of case, making sure it operates freely. Install band lever shaft plug and torque to 30-35 ft. lbs. Place kickdown band assembly into transmission case by rotating ends of band through opening in case. Fit proper end of band over adjusting screw and compress band sufficently to install band strut between other band end and band lever. ***CAUTION—Make sure band strut slot engages with kickdown band strut pin in band end.***

2) Place reverse band lever assembly in reverse band link assembly and position into transmission case, aligning holes in lever and link assemblies to holes in transmission case. Slide band lever shaft into position from rear of transmission case. Shaft is held in position by rear output shaft support.

3) ***(NOTE—If new reverse band is to be installed, back adjusting screw out until approximately 1" of screw is above lever on locknut side.)*** Place reverse band assembly into transmission case by rotating ends of band through rear opening in case. Hook correct end of band (previously identified when band removed) in link assembly. Compress band sufficiently to install band strut in slots of reverse band and band lever assembly.



Direct Clutch Piston Retainer: 1) Coat direct clutch seal ring with Lubriplate and install on piston, with lip of ring facing away from the flange. Coat clutch piston retainer seal ring with Lubriplate and install on retainer hub. Using tool C-3286, lock seal into position and make sure it is free to rotate in lands. Place piston assembly in clutch retainer, and with a twisting motion, seat piston in bottom of retainer, being careful not to damage lip of seal.

2) Seat clutch spring into piston retainer and position spring retainer and snap ring on spring. Using tool C-3302, compress clutch spring sufficiently to seat the snap ring. *NOTE*—Piston spring retainer may require guiding past the snap ring grooves. Make sure snap ring properly seated.

3) Place clutch hub in center of clutch piston retainer. Lubricate all clutch plates and driving discs with automatic transmission fluid and assemble by placing one of the clutch plates in clutch piston retainer, followed by a driving disc. ***(NOTE—Install discs in the same manner they were removed. If first driving disc was installed with cork portion on outer top, then the remaining discs must be installed in the same manner, or vice versa. Repeat this procedure until all six discs and plates have been installed.)***

4) Place kickdown sun gear assembly in direct clutch piston retainer and install snap ring (this ring is a selective fit and must be checked as follows): Using a feeler gauge, check clearance under kickdown sun gear snap ring. Clearance limits should be as close to zero as possible. Rings are furnished in three sizes for selective fitting. Part No. 1327729 (.059-.061"), No. 1327730 (.062-.064"), No. 1327731 (.065-.067").

Planet Pinion Carriers: 1) Place output shaft support in tool C-3285 with bearing surface up. Lubricate bearing surface of planet pinion housing and place bearing surface of housing over output shaft support bearing surface. Place reverse annulus gear on output shaft and install snap ring. (Output shaft may be placed in vise, providing vise is clean and equipped with brass jaws). ***(CAUTION—Reverse annulus gear must be tight fit on shaft. End clearance is controlled by various snap rings which are furnished in the following three thicknesses: Part No. 1329608 (.078-.080"), No. 1329609 (.082-.084"), No. 1329610 (.086-.088"). Make sure that snap ring is properly seated.)***

LATE 1954 & 1955 POWERFLITE VALVE BODY & TRANSFER PLATE ASSEMBLY

2) Coat output shaft seal ring with Lubriplate and install on shaft. Lock into position and make sure ring rotates freely in groove. Coat planet pinion carrier housing thrust washer with Lubriplate, slide over output shaft and into position in reverse annular gear. Place output shaft and reverse annulus gear in position in carrier housing and through output shaft support, being careful not to damage shaft seal ring as it enters shaft support. ***Check to see that planet pinion carrier thrust washer seats properly between annular gear and carrier housing.***

3) Lubricate thrust surfaces and gear teeth of reverse planet pinion gear and carrier assembly, and place carrier assembly in reverse annulus gear. ***(CAUTION—Make sure driving lugs on carrier assembly properly engage slots in planet pinion housing.)***

4) On early cars, coat input shaft seal rings with Lubriplate and lock into position, making sure rings rotate freely in lands. (Later cars have a large bearing area (bushing) on shaft replacing the three seal rings. ***See "Input Shaft Production Change" above for installation of later type shaft in early cars). (CAUTION—Inspect stop ring for proper position in input shaft groove).*** Lubricate thrust surfaces and gear teeth on kickdown planet pinion gear and carrier assembly. Slide assembly with collector ring up, carefully down on rear end of input shaft and over stop ring. Lubricate teeth and thrust surfaces and install kickdown annular gear onto input shaft, down to stop ring. Install kickdown annulus gear snap ring and make sure it is seated (Input shaft can be installed in vise providing it is clean and equipped with brass jaws).

5) Engage teeth of kickdown planet pinion gears with teeth on kickdown annulus gear. Slide pinion gear and carrier assembly into position in kickdown annulus gear. Coat reverse planet pinion carrier thrust washer with Lubriplate and install on kickdown annulus.

6) Place kickdown planet pinion carrier assembly, annulus gear and input shaft into position in planet carrier housing. Make sure planet pinion carrier thrust washer remains on annulus, and driving lugs on carrier assembly properly engage slots in planet pinion housing. Install planet pinion housing snap ring (not selective fit), making sure it is positioned and seated properly. Lubricate gears and splines.

7) Using a feeler gauge, check clearance between kickdown planet pinion carrier housing snap ring and the kickdown planet pinion carrier assembly. Limits are .012-.038". If not within these limits disassemble and recheck reverse planet pinion carrier and planet pinion carrier housing thrust washers.

Center Assembly (Output Shaft Support, Planet Pinion Carriers, and Direct Clutch Assemblies): 1) Coat kickdown planet pinion thrust washer with

CONTINUED ON NEXT PAGE

POWERFLITE (C nt.)

Lubriplate, place over kickdown sun gear and on to thrust surface of direct clutch piston retainer assembly. Place direct clutch piston retainer assembly over input shaft, engaging sun gear with kickdown planet pinion gears and engaging splines of input shaft with direct clutch hub. Make sure kickdown planet pinion carrier thrust washer remains in position.

►*DIRECT CLUTCH PISTON RETAINER THRUST WASHER CAUTION:* This thrust washer controls transmission endplay clearance and is a selective fit. After transmission is reassembled, except for hand brake assembly, the endplay clearance must be checked and corrections made in the washer thickness as necessary. *See "Checking Transmission Endplay" below.*

2) Coat direct clutch piston retainer thrust washer with Lubriplate and install on torque converter reaction shaft inside transmission case. Use care when sliding washer over rings to prevent damage.

3) Install guide studs C-3283 in rear of transmission case, position new output shaft support gasket over guide studs and on to case. Place tool C-3306 over splines on front of input shaft.

4) Insert input shaft, with direct clutch assembly, planet pinion carrier housing, output shaft support and output shaft attached, through rear of transmission case and through transmission reaction shaft. Then guide assembly through bands and over guide studs into position in transmission case. Remove tool C-3306 from front of input shaft.

►***CAUTION: Do not force assembly into case. Avoid damage to seal rings on torque converter reaction shaft.***

5) Install one output shaft support-to-transmission case screw and lockwasher finger tight.

Rear Oil Pump: 1) Coat oil pump pinion ball with Lubriplate and insert in ball pocket in output shaft. Lubriplate oil pump drive pinion, place over shaft and slide into position, aligning keyway in pinion with ball in shaft. ***Make sure pinion is installed with side marked with prussian blue at disassembly, is toward front.***

2) Slide pump housing assembly over output shaft and into position against output shaft support. Install five rear oil pump housing-to-output shaft support screws and lockwashers. ***(CAUTION—There are two extra holes in housing which are used for vents. Make sure screws are not installed in these holes. Check each screw hole before installing screws).*** Draw screws down evenly and tighten to 15-20 ft. lbs. torque. When screws have been properly tightened, check output shaft for free rotation of pump gears. If not free, disassemble pump to determine cause.

Governor: 1) Coat the two governor support piston rings with Lubriplate and install on governor support. Stagger rings and make sure they are free. Position governor body on support, install the four screws and lockwashers ***but do not tighten at this point.***

2) Slide governor support and body assembly over output shaft and into position in rear pump housing, compressing governor support piston rings with fingers as support enters oil pump housing.

3) Align locating hole in output shaft to locating screw hole in governor body and install governor locating screw, tighten to 3½-4 ft. lbs. torque. ***NOTE—Holes can be easily aligned by turning output shaft and holding governor body. Make sure screw driver attachment fits the screw slot when tightening locating screw.***

4) Tighten the four governor body screws to 5-10 ft. lbs. torque.

5) Dry governor parts with compressed air but do not lubricate when assembling. Place governor weight spring over secondary weight and position both in primary weight, making sure springs seat properly. Guide secondary weight, and compress governor weight spring sufficiently to install snap ring. Make sure ring is properly seated. Place governor weight assembly, with secondary weight snap ring up, into governor body and install snap ring, making sure it is seated.

6) Slide governor valve, with small end up, over governor valve shaft. Slide governor shaft into governor body through output shaft and governor weight assembly, at same time positioning valve into body. Install governor shaft snap ring and make sure it is securely locked to shaft. Check operation of governor weight assembly and valve by turning output shaft. Both should fall freely in body.

Transmission Extension: ***NOTE—If output shaft rear bearing was not removed, omit operation covering its installation.***

1) Using driver C-3204, install output shaft rear bearing in extension housing. Make sure it is properly seated then lubricate with automatic transmission fluid. Install output shaft bearing snap ring, bevel side up, making sure it is properly seated.

2) Replace extension breather and tighten to 10-12 ft. lbs. torque. Install new transmission extension gasket over guide studs and into position against output shaft support. ***Do not use sealing material on gasket.*** Using care not to damage governor housing, place extension housing over output shaft and onto guide studs. Using tool C-496 with adapter C3284, press extension housing into position against output shaft support.

3) Start the seven transmission extension-to-case screws and lockwashers, then draw down evenly and tighten to 25-30 ft. lbs. torque. Tighten output shaft support-to-case screw to 25-30 ft. lbs. torque. ***Check to see that output shaft turns freely.***

4) Coat nylon gear and threads on speedometer drive pinion with Lubriplate and install in extension. Tighten to 40-45 ft. lbs. torque.

Checking Transmission Endplay: Using dial indicator C-430 or feeler gauge, measure the distance between direct clutch assembly and carrier housing when clutch is in **rearward** position. Using a screwdriver inserted between the direct clutch assembly and carrier housing, carefully pry direct clutch **forward.** Remove screwdriver and measure again. The difference in measurements is the end clearance and must be .043-.069". If it does not fall within these limits, proceed as follows:

1) Remove the seven screws and lockwashers from transmission extension and install guide studs C-3283. Then remove the one output shaft support-to-case screw and washer, and remove extension housing, output shaft, support, and planet pinion carrier housing assembly as a unit.

2) Slide direct clutch piston retainer from torque converter reaction shaft and remove direct clutch piston thrust washer. Using a micrometer, measure thickness of the washer and then select a washer to give correct clearance. These washers are available in the following five thicknesses: Part No. 1406442 (.125-.130"), No. 1406443 (.135-.140"), No. 1406444 (.145-.150"), No. 1406445 (.155-.160"), No. 1406446 .164-.170").

3) To install, reverse removal procedure. Using driver C-3205, install output shaft rear bearing oil seal.

Hand Brake Assembly: 1) With brake support spacer in position on back of brake support and spacer sleeve in center of support, slide brake assembly over rear extension housing and anchor pin. Make sure spacer sleeve remains in center of support. Install brake support grease shield on extension housing. ***NOTE—Indent in shield for correct positioning on extension housing. Shield must be located on housing far enough to permit installation of spring later.***

2) Place both anchor brake washers on brake shoe anchor and install locking washer. Place both shoe assemblies with adjusting sleeve nut and screw into position on anchor. Make sure brake shoes are between the anchor washers. Use a rubber band around shoes to help hold them in position.

3) Install operating link (marked for correct installation), and brake shoe support grease shield spring (with opening in spring toward adjusting sleeve). Make sure spring is properly seated in groove. Slide brake shoe return spring behind grease shield spring and hook into position in holes in brake shoes.

4) Make sure adjustment is loose enough and install brake drum assembly. If necessary, use tool C-496 to press brake drum on output shaft. Install transmission flange washer, shakeproof washer and nut, and tighten to 140-160 ft. lbs. torque.

Kickdown Band Adjustment: Turn transmission on side and using tool C-3291, loosen locknut and tighten kickdown adjusting band adjusting screw to 60-72 inch lbs. torque. With the counter on C-3291, **back adjusting screw out 3 turns,** then holding adjusting screw stationary with short handle, tighten locknut securely. ***Use extreme care to assure correct adjustment.***

Reverse Band Adjustment: Remove reverse band adjusting screw locknut and tighten adjusting screw to 20-25 inch lbs. torque, then back out adjusting screw 10 turns. Holding adjusting screw in this position, replace adjusting screw locknut and tighten to 30-35 ft. lbs.

Valve Body & Transfer Plate: 1) Install neutral safety switch, back-up light switch and gasket, and tighten to 15-20 ft. lbs. torque. Clean mating surfaces and check for burrs on transmission case and valve body. Place valve body and transfer plate into position on transmission case and install five transfer plate screws and lock washers ***(Install the two 1⅝" long screws through transfer plate cover on valve body),*** tighten to 12-17 ft. lbs. torque. Make certain the two oil strainer tube seals are in position on oil strainer, and place oil strainer in position on valve body. Install oil strainer support screws and lock washers and tighten to 12-17 ft. lbs.

2) Place manual valve lever shaft seal cover over manual shaft and install manual control lever with arm side of lever against cover, on manual valve shaft. Tighten locking screw. Place throttle valve camshaft felt and retainer over throttle valve shaft. Install lever assembly on throttle camshaft, and

CONTINUED ON NEXT PAGE

POWERFLITE (Cont.)

tighten locking screw. Check operation of controls by shifting manual control into the four operating positions.

3) Check throttle cam position in throttle operating lever assembly and throttle camshaft assembly for kickdown operation. Visually check manual lever contact on neutral safety and back-up light switches.

4) Install oil pan, using a new gasket, and tighten attaching screws to 12-17 ft. lbs., drawing screws down evenly. Tighten drain plug to 20-25 ft. lbs. torque.

VALVE BODY OVERHAUL

Valve Body & Transfer Plate Disassembly: *(NOTE—Two different throttle valve assemblies used in production. Overhaul procedures are the same except as noted below).*

▷*1954 SHUTTLE VALVE PRODUCTION CHANGE & SERVICE REPLACEMENT NOTE:* A later type shuttle valve, Part No. 1643118 is used for production and can be used for service replacement. *CAUTION—* The adjusting screw on the later type shuttle valve is pre-set at the factory and *MUST NOT BE CHANGED IN THE FIELD.* When replacing the older type valve with the later one, DO NOT install the spacer and spring.

▷*OVERHAUL CAUTION:* Place valve body and plate assembly in holding fixture C-3294. *DO NOT USE VISE TO HOLD TRANSFER PLATE ON VALVE BODY.*

1) Remove two of the long transfer plate cover screws and lock washers and install guide studs C-3295. Keeping finger tight pressure against transfer plate, remove the three remaining transfer plate cover screws, (two long & one short), and remove transfer plate cover. Using care not to lose the servo restrictor valve operating plug from transfer plate, remove transfer plate from valve body plate. *NOTE—Rear pump check valve has metering hole in it. Note position of this valve in relation to the front pump check valve (without metering hole).*

2) Remove valve body plate from valve body, noting position of throttle pressure check valve ball, and servo bleed valve (servo bleed valve may stick to valve body plate). Remove these parts and place in clean container. On later type valve assemblies remove throttle valve cam spring from cam and operating lever. On early and later type assemblies, compress the throttle valve operating lever assembly against throttle valve spring and slide throttle valve cam assembly from manual lever assembly. *(CAUTION—Remove any burrs from throttle valve camshaft and manual valve lever shaft before sliding them from valve body).*

3) Swing throttle valve operating lever out of way and remove throttle valve spring and retainer from throttle valve. Remove throttle valve from valve body core. Check distance from valve body to end of throttle valve operating lever adjusting screw. This distance should be 1 11/16". Using tool C-3279, remove throttle valve adjusting screw, lock nut and throttle valve operating assembly. *NOTE—It is not necessary to remove throttle valve operating assembly unless parts are to be replaced.*

4) Remove the four (three long and one short) valve body end cover plate screws and lock washers and remove valve body end cover plate. Remove valve body and cover screw, keeping pressure against cover to avoid losing the four springs (early type), three springs (late type) behind it. Carefully remove valve body cover so as not to lose any of the springs or kickdown valve ball. Remove shuttle valve plug *(CAUTION—Later type shuttle valve assembly has an adjustment screw. DO NOT CHANGE THIS ADJUSTMENT as it is pre-set at the factory).* Remove kickdown valve ball from body. Remove shuttle by using shuttle valve spring, and related parts (see illustration for parts in early and late type assemblies).

5) Remove direct clutch shift valve spring from valve body. Mark the direct clutch shift valve plug with prussian blue (in order to reinstall with right side out), then loosen plug screws sufficiently to allow removal of plug by pushing on open end of shift valve with finger. Remove shift valve, and remove valve body from tool C-3294. Place valve body on clean paper. On early type assemblies, remove kickdown rod snap ring and kickdown rod from valve body. On later type assemblies, remove kickdown rod from cover end of valve body.

▷*MANUAL VALVE AND LEVER ASSEMBLY NOTE—It is not necessary to remove this assembly unless damaged parts are to be replaced. If assembly must be removed, proceed as follows:*

6) Place manual control valve lever on lever assembly and turn it counter-clockwise until manual control valve is in low range position (last detent). Using a screwdriver, compress detent plunger and spring and continue to turn manual valve lever assembly until manual valve becomes disengaged from manual valve lever assembly. Remove manual valve from valve body bore. Remove manual control lever and slide manual lever assembly from valve body. Remove manual valve lever detent plunger and spring from valve body.

Valve Body & Transfer Plate Inspection: Wash all parts in clean solvent and dry with compressed air. Check all passages for obstructions and check for porous coating. Inspect all mating surfaces for burrs and scratches. Light scratches and burrs can be removed with crocus cloth. With a light, check bores in valve body for pits and scores. Check springs for distortion and collapse. Check mating surfaces on a surface plate for distortion. Check all moving parts for free operation, and valves for freeness in body bores. Inspect servo restrictor valve in transfer plate to make sure it is seating properly. If valve is defective, carefully remove drive screw. Install new valve and new drive screw, making sure drive screw is tight, and being very careful not to distort transfer plate when installing drive screw. Check all points in valve for wear and replace defective parts.

Valve Body & Transfer Plate Reassembly: *CAUTION—When assembling valve body and transfer plate assemblies, handle parts carefully to avoid damage, such as nicks, etc., to mating surfaces. Use a twisting motion when placing valves in their respective bores.*

1) Place manual valve lever detent plunger spring and plunger into place in valve body. Slide manual valve lever assembly into valve body. Using a twisting motion place manual valve into valve body sufficiently to engage manual valve with manual valve lever pin. Then using valve lever assembly, turn slowly in clockwise direction and at the same time using a twisting motion, guide manual valve into valve body to low range position. Make sure detent plunger is seated.

2) Place kickdown rod (small end toward end cover) into valve body, making sure it is properly seated. Place valve body in tool C-3294 and install direct clutch shift valve. Place direct clutch shift valve into position (same as when removed, and with marks made at disassembly in correct position) in valve body. Draw the two screws down evenly and torque to 24-30 inch lbs. Install direct clutch shift valve spring in valve.

3) Install shuttle valve in valve body. Coat stop ring lightly with Lubriplate and place into recess in valve body. On early type assemblies place shuttle valve spring guide pin in shuttle valve and install both inner and outer spring over guide pin. On later type assembly place shuttle valve spring in valve. On both assemblies, install kickdown valve ball into valve body.

4) Place valve body end cover plate on end cover. Install one short screw and lock washer. Tighten securely. Place shuttle valve plug into position in end cover, and install kickdown valve spring. Install valve body end cover onto valve body. *CAUTION—* Make sure direct clutch shift valve, shuttle valve and kickdown valve spring are in correct position and properly seated when cover is being installed. Install valve body end cover screw and lock washer, but do not tighten.

5) Install the three (long) valve body end cover plate screws and lock washers. Draw down evenly and tighten to 24-30 inch lbs. Tighten valve body end cover screw and the remaining end cover plate screw to 24-30 inch lbs.

6) Using tool C-3279, install throttle valve adjusting screw, locknut and throttle valve lever assembly. Adjust to where there is approximately 1 11/16" distance between valve body and end of throttle valve operating adjusting screw. Install throttle valve (point outward) in valve body. Place throttle valve spring and retainer over throttle valves. Swing throttle valve operating lever over spring and retainer. Compressing the throttle valve lever assembly against throttle valve spring, slide throttle valve cam assembly into manual lever assembly, indexing cam portion on throttle valve in slot of operating lever. On later type assemblies, install throttle valve cam spring to cam and operating lever.

7) Install servo bleed valve and throttle pressure check valve ball into position in valve body and install guide studs. Position transfer plate cover on transfer plate and install the center screw (short) and lock washer finger tight. Install the servo restrictor valve operating plug (long end first) into transfer plate.

8) Make sure pump check valves and springs are properly positioned in transfer plate. The pump check valve with the metering hole should be toward the rear of transmission. Place valve body plate flush into position on transfer plate by compressing pump check valve springs. *CAUTION—Be sure pump check valves enter transfer plate, otherwise valve body plate will be damaged when assembly drawn down.*

9) Keep sufficient pressure on transfer plate and valve body to hold them together. Place over guide studs and into position on valve body, and install two of the transfer plate cover screws and lockwashers (one on each side) finger tight. Recheck to see that pump check valves remained in position in valve body plate. Remove guide studs and install two remaining transfer plate cover screws and lock washers. Draw transfer plate down evenly and torque all five screws to 45-50 inch lbs. torque.

FORDOMATIC & MERCOMATIC TRANSMISSION

Ford 6 & 8 Cyl. (1951-53)
Mercury V8 (1951-53)
Ford Truck, F-100 (1953)

▷CHANGES, CAUTIONS, CORRECTIONS

▷TRANSMISSION IDENTIFICATION NOTE: Transmission Model No. and Serial No. on name plate on left side of case must be used to identify individual units for parts replacement etc.

Model No.—On left hand boss on plate (prefix indicates year and model).

Serial No.—On right hand boss on plate (prefix indicates manufacturing plant).

▷STARTING ENGINE BY TOWING OR PUSHING CAR: Pushing is recommended. Place selector lever in Neutral "N" position. When car speed reaches 20 MPH., turn on ignition, move selector lever to "LO", depress accelerator pedal to half-throttle position until engine begins to run. *NOTE*—In ice or snow where traction not good, move selector lever to "DR" position to crank engine.

▷TOWING CAR: *Do not tow car at speed greater than 40 MPH. and observe following precautions:*

If Transmission Operating Properly—Place selector lever in Neutral "N" position. Car can be towed normally for distances not to exceed 3 miles. For greater distances, use same procedure as for inoperative transmission.

If Transmission Inoperative—Tow car with rear wheels lifted off road, or disconnect and remove propeller shaft and protect rear end of transmission from entry of dirt (U-joint Knuckle 1M-4841 can be installed and wired in place for this purpose).

▷*1951 MERCURY ENGINE STALLING AT IDLE SPEED (After Engine Idle Speed and Anti-Stall Dashpot properly adjusted):* May be caused by excessive tension of torsion spring on accelerator cross-shaft (Z-bar) preventing proper operation of dashpot which should retard closing of the carburetor throttle to prevent stalling. Correct by bending tail or straight portion of torsion spring DOWN (at point midway between spring coil and bracket on firewall) to lessen spring load. NOTE—Spring can be bent UP to increase spring load if tension not sufficient to return cross-shaft to off position when accelerator released (see rattle correction following).

▷*1951 MERCURY ACCELERATOR SHAFT RETRACTING SPRING RATTLES:* If cross-shaft spring rattles (see stalling correction above), correct by lifting spring tail from notch in bracket on firewall and position it on left side of bracket. This will place enough tension on spring to prevent rattles.

1951 MERCURY ENGINE REAR LEFT SUPPORT BOLT CHANGE (to correct loosening of bolt in service): Where loose bolt is encountered, check for use of first type 1" long bolt (which may bottom in hole) and replace with later type ¾" long bolt No. 24348-S8 (use with ⅜" external tooth lockwasher). NOTE—This ¾" long bolt used in production after Sept. 1951.

▷*1951 FORD THROTTLE LINKAGE PRODUCTION CHANGE:* Original design throttle linkage has been revised to provide quieter and more efficient operation. *New design throttle linkage requires different adjustment procedure. See Linkage Adjustment.*

▷*1952 FORD PRESSURE REGULATOR CHANGE (New Front Pump Check Valve to prevent valve sticking):* Regulator Cover Assembly, No. 1P-77451-C, used with new Front Pump Check Valve, No. 1P-77709-B, and Check Valve Spring, No. 1P-77455-A. The valve is piloted by the spring and the staked pin which served as a pilot in previous type No. 1P-77450-B Regulator cover is not used.

▷*FORD SHIFT TUBE VIBRATION DAMPER (Installation on 1952 & early 1953 Cars):* This damper used in production on later 1953 cars and can be installed on earlier cars to reduce selector lever shake. Install as follows: Loosen two nuts on selector tube bracket "U" bolt on steering column, raise gear shift tube bracket assembly, "U" bolt, and lower end of gear shift tube and socket asembly away from steering column. Coat top and bottom of spring damper with lubricant and insert damper between shift tube and steering column tube. Reposition bracket and tighten "U" bolt. Check and adjust linkage. *NOTE*—If interference noted where gear shift tube and socket assembly passes through steering column to instrument panel bracket, enlarge hole in bracket for clearance.

▷*1953 FORD SHIFT LEVER ASSEMBLY PRODUCTION CHANGE & LINKAGE ADJUSTMENT CAUTION:* New Gearshift Lever Assy. No. AB-7302-D (with nylon bushing in insulator) used on later cars and furnished as service replacement to supersede previous type lever No. AB-7302-C. New type insulator and nylon bushing are furnished separately and can be installed in previous type lever in the field. *WHENEVER NEW LEVER (or new insulator and nylon bushing) USED, SPECIAL LINKAGE SETTING REQUIRED. SEE LINKAGE ADJUSTMENT.*

▷*1953 FRONT DRUM AND SECONDARY SUN GEAR ASSEMBLY PRODUCTION CHANGE:* New assembly No. 1P-77530-C used in production and is available for service replacement of previous types. This new assembly has a needle bearing in place of front bushing used on previous types and MUST BE USED WITH NEW TYPE PRIMARY SUN GEAR SHAFT (see below).

▷*1953 PRIMARY SUN GEAR SHAFT PRODUCTION CHANGE:* Primary Sun Gear Shaft Assembly Part No. 1P-77530-C used in production and can be used to replace previous types in service. The later type shaft can be identified by groove machined in center of front clutch hub section of shaft and MUST BE USED WITH NEEDLE BEARING TYPE FRONT DRUM AND SECONDARY SUN GEAR ASSEMBLY (See Production Change above). This new shaft assembly can also be used with previous bushing type Front Drum and Secondary Sun Gear assembly.

CAUTION—Previous type Primary Sun Gear Assemblies Nos. 1P-77530-A or 1P-77530-B should only be used with bushing type Front Drum and Secondary Sun Gear Assembly.

▷*1953 REAR CLUTCH PISTON SPRING & SEAT PRODUCTION CHANGE & SERVICE REPLACEMENT:* New Spring No. 1P-77515-B and spring seat used in later transmissions provides greater clearance between spring and clutch cylinder and these parts SHOULD BE USED IN ALL TRANSMISSIONS WHENEVER TRANSMISSION DISASSEMBLED (NOTE—Old spring seat may be used with new spring if new type seat not available).

Spring Identification—New spring No. 1P-77515-B is .050" smaller diameter and has left-hand coils (reversed from previous type 1P-77515-A).

▷*1952 CONVERTER COVER, GASKET, & IMPELLER PRODUCTION CHANGE:* Converter cover and impeller changed from 34 bolt type with flat gasket to an 18-bolt type with "O" ring type seal (see Impeller Note—below). Correct type parts must be used together as listed below and converter drive plate must be properly installed to maintain balance. *See "Converter Overhaul" and "Installation in Car" data.*

Impeller Note—Revised type impeller is also 34-bolt type (to facilitate lining up balance marks) but is used with 18-bolt cover. Impellers can be identified by the absence of sealing lands on revised type (first type had three lands formed by two concentric grooves in raised section on inner edge of cover mounting face).

Ford 6 Cyl.

Part & No.	①First Type	②Later Type
Converter Cover	1P-7950-B	1P-7950-D
Impeller	1P-7908-B	1P-7908-D
Gasket	1P-7963-C③	1P-7963-B
Bolts	1P-7964-E③	1P-7964-E

Ford V8 & Mercury

Part & No.	①First Type	②Later Type
Converter Cover	1P-7950-A	1P-7950-C
Impeller	1P-7908-B	⑤1P-7908-D, C
Gasket	1P-7963-C③	1P-7963-B
Bolts	1P-7964-D④	1P-7964-D

①—34-bolt type. ②—18-bolt type.
③—Supersedes Gasket No. 1P-7963-A.
④—New "Coned" head type (superseding previous type bolts).
⑤—1P-7908-D (Ford). 1P-7908-C & D (Mercury).

▷*CONVERTER COVER & IMPELLER HOUSING BOLT CHANGE ("Coned" bolts to eliminate possibility of leakage):* These bolts No. 1P-7964-D (Ford V8 & Mercury), 1P-7964-E (Ford 6 Cyl.) used on later transmissions will retain tightness more effectively and prevent leakage at converter cover flange. These bolts can be identified by slight "coning" on bottom face of head (this surface .007-.012" concave —previous bolts were flat). *See "Overhaul—Torque Converter" for bolt installation.*

CAUTION—Old and new type bolts must not be used together.

▷*CONVERTER COVER LEAKAGE CORRECTION:* If leakage not corrected by proper tightening of converter cover bolts, install new type "coned-head" bolts (see above), and tighten bolts as directed in "Overhaul—Torque Converter."

▷*FRONT PUMP & IMPELLER HUB PRODUCTION CHANGE:* Front Pump Assembly No. 1P-77820-D with bushing in front pump drive gear (bearing on stator support assembly) has been released and is interchangeable with previous type pump except that it MUST BE USED WITH NEW SHORTER CONVERTER HUB as follows:

Part & No.	First Type	Later Type
Front Pump Assy.	1P-77820-A,B,C	1P-77820-D
Converter Hub Assy	1P-7915-B①	②1P-7915-C

①—Length 2.06" (used with 1P-7908-C impeller).
②—Length 1.66" (used with 1P-7908-D impeller).

▷*1952 FRONT CLUTCH PLATE PRODUCTION CHANGE & EARLIER MODEL SERVICE REPLACEMENT CAUTION*—Current type Front Clutch Plates No. 1P-77519-C (supersedes previous type 1P-77519-B) should be used for all front clutch service replacements. These plates have improved friction material bonding and should be installed in all trans-

FORDOMATIC & MERCOMATIC
►CHANGES, CAUTIONS, CORRECTIONS (C ntinued)

missions not so equipped whenever transmission being overhauled. Discard previous type plates.

Front & Rear Clutch Plates

Type of Spline	Front	Rear
External (Steel)	1P-77573-A	①1P-77518-A
Internal (Bronze)	1P-77519-C②	1P-77519-A

①—CONED type (.010" minimum).
②—Superseding Nos. 1P-77519-A & 1P-77519-B.

Clutch Plate Identification—

No. 1P-77518-A (Rear Clutch Steel Plates): Are coned and have four teeth omitted at two points diametrically opposite.

No. 1P-77519-B—Have two partially removed teeth 180° apart and letter "R" stamped on one tooth midway between these two teeth.

No. 1P-77519-C—Same as above except letter "C" stamped on tooth midway between the two partially removed teeth.

NOTE—These new 1P-77519-C clutch plates used in production beginning Trans. Serial No. 3-48845 and 4-43004.

►*1951 REAR PUMP PRODUCTION CHANGE & REPLACEMENT CAUTION (Transmissions beginning Nos. 1-84567 and 2-83007):* Cast iron type oil pump used optionally on these transmissions and is interchangeable with previous type aluminum pump but **correct type pump cover and output shaft thrustwasher must be used** with each type as follows:

	Rear Oil Pump	
	Aluminum Pump	Cast Iron Pump
Pump Body	1P-77850-A	1P-77850-C
Pump Cover	①1P-77860B	②1P-77860-C
Thrustwasher	1P-77066-A	1P-77066C-

①—Phosphate-coated.
②—Plain (not phosphate-coated).
See Rear Oil Pump Reassembly data for correct use and installation of above parts.

►*1951 CONTROL VALVE PRODUCTION CHANGE & REPLACEMENT CAUTION:* First type 1P-77700-A control valve body superseded by later 1P-77700-C which has changes to insure smoother performance and lessen possibility of leakage. Later type control valve body can be used to replace first type by reworking front servo release tube as follows:

Installation of 1P-77700-C Control Valve Body (when replacing first type 1P-77700-A body): Cut 7/32" off end of longer (4 21/32") front servo release tube, remove all burrs, chamfer cut end to 1/64" x 30°, make certain that all chips removed before installing tube and control valve body. *NOTE*—After this rework, both tubes will be same length (4 7/16").

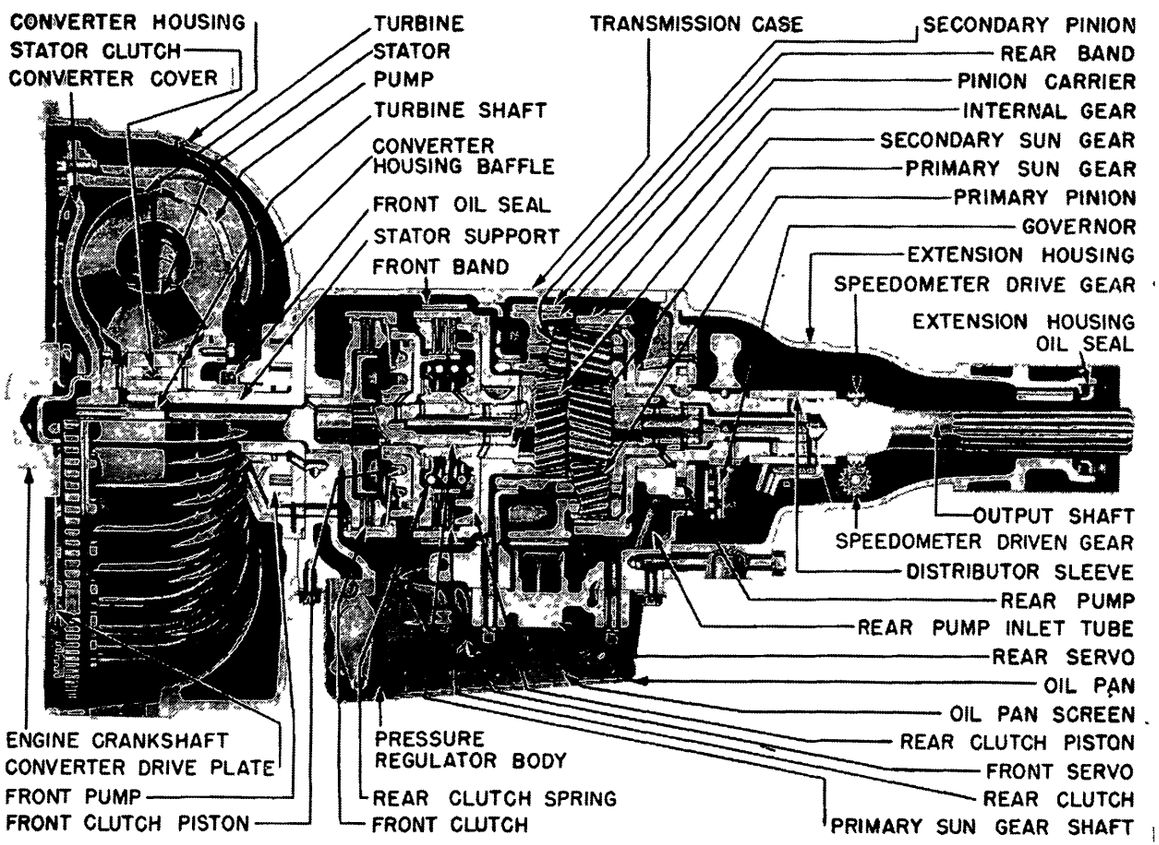
►*FORD 6 CYL. THROTTLE LINKAGE BIND (Causing faster-than-normal engine idle speed): See Ford 6 Cyl. Throttle Linkage Adjustment for possible causes and corrective procedure.*

►*FORD ANTI-STALL DASHPOT PRODUCTION CHANGE FOR IMPROVED PERFORMANCE:* Late 1952 cars have new dashpot assembly with neoprene boot type dust shield to protect control rod and prevent sticking due to dirt or foreign material. These new dashpot assemblies interchangeable with previous type and will be furnished for service as follows:

Dashpot Assembly	First	Later Type
Ford 6 Cyl.	1BA-99560-A	EAA-99560-A
Ford V8	1BA-99560-A	EAB-99560-A

►*MERCURY DASHPOT ASSEMBLY PRODUCTION CHANGE (for improved Performance):* Late 1952 cars have new type Dashpot Assembly No. EAC-99560-B which has nylon check ball and spring in dashpot body. (This check ball and spring located in carburetor with previous type dashpot). *CAUTION*—When this new EAC-99560-B dashpot installed to replace previous type, CHECK BALL, SPRING, AND RETAINER MUST BE REMOVED FROM CARBURETOR AND DISCARDED.

►*FORD 1951-52 TRANSMISSION CASE REPLACEMENT OIL PAN CAUTION:* 1953 type Oil Pan No. 1P-77472-B (with outlet for under-hood filler) furnished for these models. When installing this pan on 1951-52 cars, use plug No. 1P-77492-A to close this pan opening.



►*FORD 1951-53 REPLACEMENT TRANSMISSION CASE CAUTION:* 1953 type Transmission Case No. 1P-7005-C furnished for these models. This case has two plugged holes on right side (for oil cooler connections when used on 1953 Ford F-100 Truck) and these PLUGS MUST BE TIGHT TO PREVENT OIL LEAKAGE. This case also has provision for underhood oil filler tube. *See REPLACEMENT OIL PAN CAUTION above.*

►*TRANSMISSION "BUZZING" SOUND:* May be caused by undersize or worn bleed flats on Main Oil Pressure Regulator Valve Assembly. Correct by rotating the valve 90° in its bore. *See "Minor Repairs (Transmission in Car)" for disassembly directions.*

►*CONVERTER INSTALLATION CAUTION (To Prevent Damage to Front Pump):* Converter pilot bore in crankshaft must be clean and relatively free of lubricant and without burrs or scratches which would prevent pilot entering bore freely (lubricate pilot with Lubriplate). If converter does not have slight endplay (before drive plate connected), converter assembly may be forced back so that converter hub presses against front pump drive gear causing damage to front pump. *See Transmission & Converter Installation data.*

►*MERCURY INABILITY TO SECURE FORCED 3-2 DOWNSHIFT: See Mercury Throttle Linkage Adjustment for recommended change in carburetor rod assembly setting to correct this condition.*

FORDOMATIC & MERCOMATIC TRANSMISSION (SECTIONAL VIEW)

FORDOMATIC & MERCOMATIC
(Continued)

DESCRIPTION

The Ford and Mercury automatic transmission consists of a hydraulic torque converter and an automatic transmission which provides automatic operation in the "Dr" range and additional Low, Reverse, Neutral and Parking positions controlled manually.

Torque Converter: Mounted in a housing and connected to rear end of crankshaft in place of the conventional flywheel, and consists of the Torque Units listed below Torque converter is fully automatic in its operation, acting as torque converter for low speed and starting operations (when input torque is less than output torque), and as a fluid coupling at higher car speeds (when input and output torque are equal) The change from torque converter to fluid coupling and the operating phases of the torque converter unit is governed by the car operating conditions and do not occur together or at any particular time

Pump (Driving Member)—Mounted on engine crankshaft and bolted to converter cover Pump rotates at engine speed to transmit engine power to turbine thru the medium of converter oil

Turbine (Driven Member)—Splined to output shaft forward of converter pump and driven by oil flow from converter pump Turbine transmits power to the planetary gears (Low, Intermediate & Reverse) and to the propeller shaft (Driving Range)

Stator—Consists of reaction blades and a one way clutch mounted on the converter cover hub The stator redirects the fluid flow to turbine, increasing torque for low and starting speeds (when input torque is less than output torque) being held from rotating in a direction opposite to pump and turbine by the one way clutch At higher speeds (when input torque equals output torque) the Stator rotates in the same direction and at the same speed as the pump and turbine causing the torque converter to automatically become a fluid coupling

Planetary Transmission: Hydraulically controlled planetary transmission employs a gearset of the compound type consisting of long and short pinions, two sun gears and a single internal gear, providing three forward speeds and one reverse Controlling bands, multiple disc clutches and servo mechanisms are within the transmission case

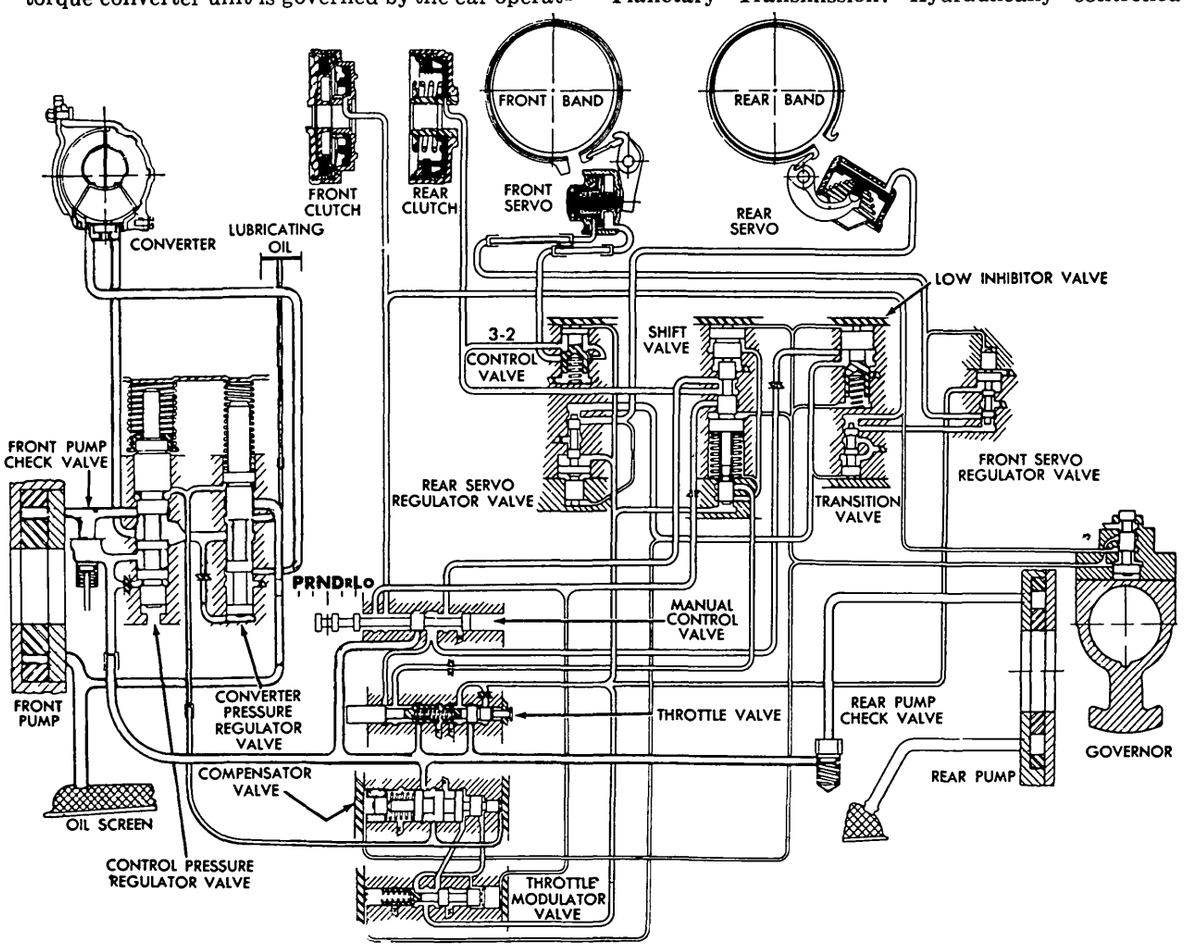
Planetary Pinion Assembly—Consists of three Primary Pinions (short) and three Secondary Pinions (long) mounted in a pinion carrier The Primary Pinion is driven by the Primary Sun Gear and drives the Secondary Pinion which is meshed with the Secondary Sun Gear and the Internal Gear The pinion carrier is controlled by the Rear Servo and the Rear Band

Primary Sun Gear—Integral with Primary Sun Gear shaft which is splined to the driven flange of the Front Clutch unit Power is transmitted thru this gear to the Pinion assembly (Low & Intermediate Range)

Secondary Sun Gear—Located forward of the Primary Sun Gear and in mesh with the Secondary (Long) Pinions Mounting is on a hub connected to the driven flange of the Rear Clutch Power transmitted from the Rear Clutch to Secondary Pinions (Reverse)

Front Clutch—Front (input) member of clutch is integral with Turbine Shaft and is splined to Front Clutch drum The Front Clutch drum is formed so that it is also the inner (input) member of the Rear Clutch Front Clutch hub (output) is splined to the Primary Sun Gear Shaft The Front Clutch is engaged by a hydraulic piston within the clutch drum and locks the Primary Sun Gear Shaft to the Turbine Shaft Clutch is engaged for all forward speeds and is disengaged by an internal spring for neutral and reverse

Multiple Rear Clutch—Clutch Drum (output) is integral with the Secondary Sun Gear and is provided with a brake band and operating servo Clutch Hub (input) member is integral with the front clutch drum When clutch is engaged, the Secondary Sun Gear is locked to the Turbine Shaft Clutch engagement is by a hydraulic piston within the unit A coil spring between the hub and the drum provides the release



Front Brake Band and Servo Assembly—Band holds the Secondary Sun Gear stationary when it is applied on the clutch drum by the Servo which consists of a hydraulic piston linked to band One end of the band is held stationary by a strut and anchor which has an adjusting screw for band adjustment Servo is fluid applied and spring released

Rear Brake Band and Servo Assembly—Band holds planet carrier stationary when it is applied by the rear Servo which consists of a hydraulic piston linked to one end of the brake band The opposite end is held stationary by a strut and anchor

Oil Pumps: Two pumps used to supply oil pressure for hydraulic controls, oil supply for converter and transmission lubrication

Front Pump—Internal-External gear type mounted between the transmission and torque converter and driven by the converter pump through a tongue and slot coupling This pump has a large capacity and begins to operate as soon as the engine is started, supplying oil to the torque converter and for transmission lubrication and hydraulic controls

Rear Pump—Internal-External gear type mounted

FORDOMATIC & MERCOMATIC TRANSMISSION HYDRAULIC CIRCUITS

CONTINUED ON NEXT PAGE

FORDOMATIC & MERCOMATIC (Continued)

at the rear of transmission and driven by the output shaft. Pump operates whenever rear wheels are turning and supplements the front pump volume. When car reaches sufficient speed, two ball check valves open and allow the oil from the rear pump to enter the hydraulic system.

Hydraulic Controls: Consist of manual and automatic valves, controlling the operation of the transmission servos and clutches.

Control Pressure Regulator—As pump speed varies, spring loaded valve maintains constant pressure. Excess volume is returned to oil pan.

Manual Valve—Control pressure is directed to manual control valve for proper distribution to accomplish the performance desired. Valve is actuated from the selector lever on the steering column.

Throttle Valve—Actuated by the accelerator through linkage. Control Pressure is directed to the throttle valve from the Control Pressure Regulator Valve. As the accelerator is depressed, moving the Throttle Valve towards the open position modifies the Control Pressure in proportion to the degree of throttle opening.

Shift Valve—Automatically changes the speed from Intermediate to High. Valve is spring loaded and is controlled by Governor Pressure and Throttle Pressure.

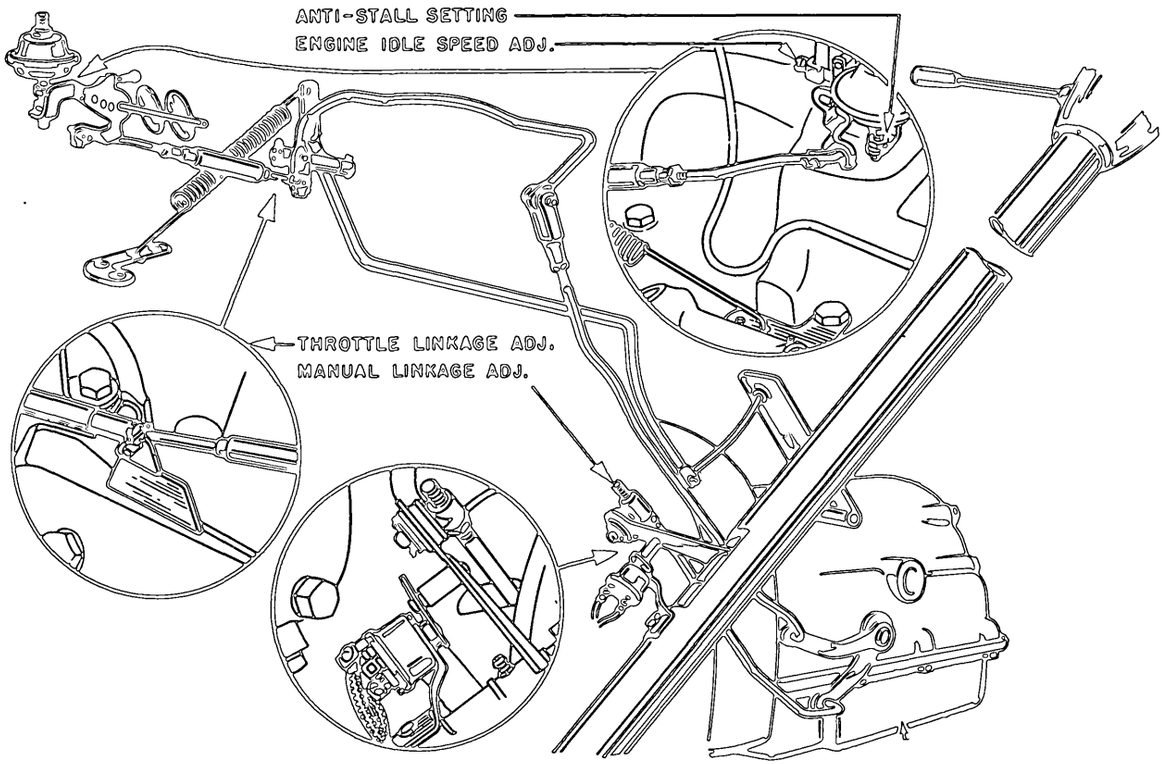
Hydraulic Governor—Mounted on output shaft at rear of transmission. Rotation of the Governor Valve causes centrifugal force to act on the valve plunger and regulate the pressure in direct proportion to the car speed.

Front Servo Apply Regulator Valve—Provides for smooth changes between Intermediate and High speed, by controlling the flow of oil to the Front Servo. Valve is controlled by throttle pressure.

3-2 Control Valve—Provided for Down-Shifting from High to Intermediate on either open or closed throttle.

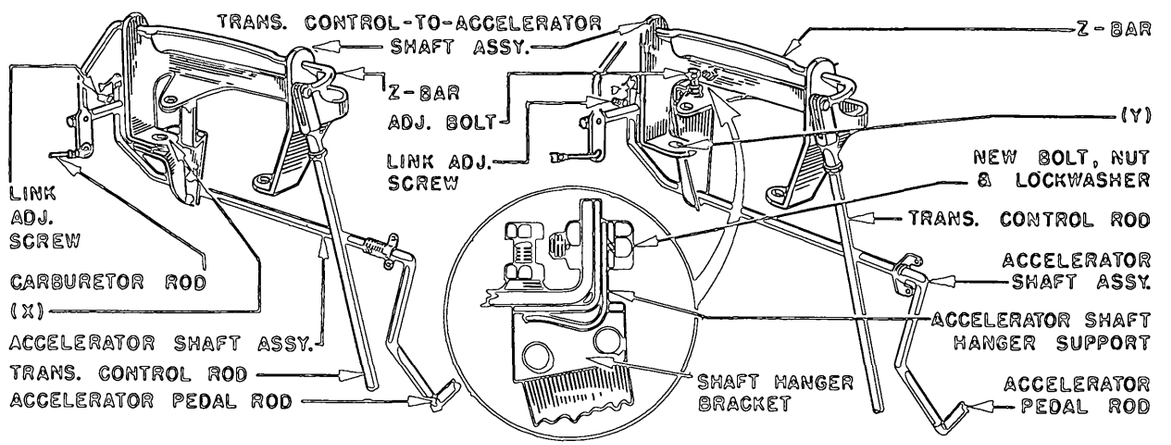
Down-Shift Valve—Operated by accelerator pedal. Allows speed change from High to Intermediate by depressing the accelerator pedal past it's fully open position.

OPERATION



Torque converter automatically provides a torque multiplication ranging from 2.1-1 (maximum for starting and acceleration) to 1.0-1 (normal driving range with torque converter acting as fluid coupling) This torque multiplication is supplemented by the planetary gears when selector lever placed in "Drive," "Low" and "Reverse" Range. Transmission operates in each range as follows:

Neutral Range—Front and Rear Clutches fully released, and Front and Rear Brake Bands fully released so that gears are free to turn. Drive is not transmitted through transmission and this "N" position can be used to start and warm up engine.



Drive Range—Car starts in Intermediate Gear with Front Clutch applied locking the Primary Gear to the Turbine Shaft and the Front Band applied, holding Secondary Sun Gear stationary, the power flow is from the Turbine Shaft through the Front Clutch to the Primary Pinion to the Secondary Pinions to the Internal Gear to the Output Shaft. As car speed is increased to a certain point, the Front Band is released and the Rear Clutch is applied automatically causing the transmission to change to direct (1.0—1) drive. The power flow in "High" is from the Turbine Shaft through the Front and Rear Clutches to the Planetary Gear which are locked together and rotates as a unit, causing the Output Shaft to rotate at engine speed.

Low Range—Front Clutch applied, locking the Turbine Shaft to the Primary Sun Gear, and the Rear Band applied, holding the Pinion Carrier sta-

8 CYL. FORDOMATIC TRANSMISSION CONTROL LINKAGE

EARLY 1951 THROTTLE LINKAGE

LATE 1951-53 THROTTLE LINKAGE

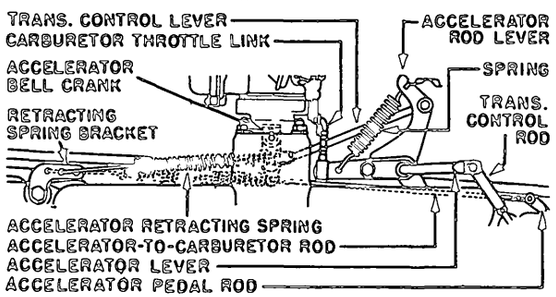
FORD V8 THROTTLE LINKAGE

FORDOMATIC & MERCOMATIC (Continued)

tionary, the flow of power is from the Turbine Shaft through the Front Clutch to the Primary Pinions, to the Secondary Pinions, to the Internal Gear and out the Output Shaft at the ratio of 2.44-1.

Reverse Range—Rear Clutch applied, locking the Turbine Shaft to the Secondary Sun Gear and the Rear Band applied, holding the Pinion Carrier stationary, the flow of power is from the Turbine Shaft through the Rear Clutch to the Secondary Sun Gear, to the Secondary Pinions, to the Internal Gear. The Secondary Pinions acting as idlers on stationary axis, drive the Internal Gear in a reverse direction.

LUBRICATION



▷*CAUTION:* Transmission oil level should be checked at 1000 mile intervals and should be changed at 15000 mile intervals.

Recommended Oil—Part No. 8L-19582-C, Automatic Transmission Oil "A", in sealed containers.

Capacity—Approximately 9 qts.

Checking Fluid Level—Apply hand brake, place selector lever in Neutral "N" position, run engine at idle speed for approximately four minutes, then move selector lever to Park "P" position. When engine and transmission have reached normal operating temperature, move selector lever through all positions to assure fluid distribution throughout transmission, return lever to "P" position. Raise engine hood, clean all dirt from around filler cap at right rear corner of engine. Check fluid level on dipstick in filler tube (*CAUTION*—make certain dipstick pushed all the way down in the filler tube when checking fluid level). Add fluid as necessary to bring level up to "F" full mark on dipstick.

▷Check for Oil Leaks—Inspect the bottom of the floor pan at the rear of the transmission for evidence of fluid. If fluid is found here, the rear extension housing seal is leaking between the two sections of the telescopic shield. Replace the seal. Check the speedometer cable connection at the transmission and replace the rubber seal if necessary. Check the governor inspection plate and install a new gasket if necessary. Leaking around the oil pan gasket generally can be stopped by tightening the attaching screws to proper 10-13 ft. lbs. torque. If necessary install a new gasket. Check filler tube connection at transmission oil pan. If leakage is evident, tighten the connection. If leakage is evident at either the throttle lever shaft or manual lever shaft, replace either of the seals. Inspect the two hexhead pipe plugs at each side of the transmission case at the front. If either plug shows leakage, tighten to 7-15 ft.lbs. torque. Inspect the discharge air duct for evidence of fluid. If transmission fluid is found, make certain that converter cover bolt nuts tightened to 25-28 ft. lbs. torque, and drain plugs tightened to 7-10 ft. lbs. torque.

FORD 6 CYL. FORDOMATIC LINKAGE

▷*CAUTION—Fluid found in the discharge air duct may be engine oil that has leaked past the rear main bearing. Be sure to determine which type of leak exists.*

Drainage and Refilling—Remove converter housing lower plate and drain converter by removing one drain plug, then rotate the engine 180° and remove the second drain plug. Disconnect filler tube from transmission oil pan to drain fluid from transmission. Tighten converter drain plugs to 7-10 ft. lbs. Tighten filler tube connection. Install 5 quarts of automatic transmission fluid, start engine and allow to idle two minutes. Add 4 qts. of fluid and bring transmission to operating temperature. Place selector lever in parking (P) position and check oil level. If level is not up to dip stick level mark, add additional fluid as required.

▷*TRANSMISSION CASE VENT CHANGE NOTE:* New type Vent Assembly No. 1P-7034-B (identifed by rounded cap) used on later 1953 transmissions and can also be installed on 1951-52 transmissions to provide faster filling when changing transmission fluid.

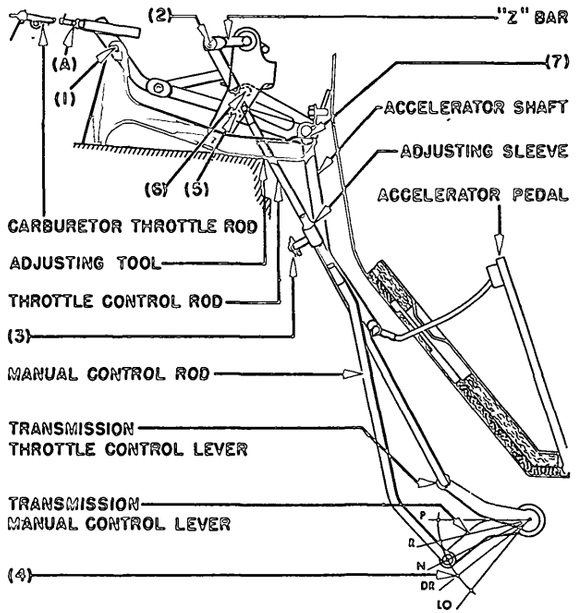
▷*CAUTION—Correct fluid level should be determined by dipstick reading rather than actual number of qts. installed.*

LINKAGE ADJUSTMENT

▷*FORD THROTTLE LINKAGE ADJUSTMENT CAUTION: Different type linkage used on 6 and V8 cars. See special procedure for each model below.*

MAKE ADJUSTMENTS IN FOLLOWING ORDER:

CARBURETOR IDLE SPEED: With engine at normal operating temperature (choke valve wide open and fast idle inoperative) and selector lever in Neutral "N" position, set throttle stopscrew for idle speed 440-460 RPM. (6 Cyl. Cars), 415-425 RPM. (Ford V8 and Mercury. Shut off engine for Dashpot adjustment.



ANTI-STALL DASHPOT: *CAUTION—Ford and Mercury adjusted differently as follows:*

Ford 6 Cyl. & V8—After engine idle speed correctly set (above), loosen the dashpot adjusting screw locknut (on throttle lever), hold throttle lever in closed position, turn adjusting screw out (counter-clockwise) until the screw causes the dashpot rod to bottom in the dashpot (additional movement of screw will cause throttle valve to open), then turn the adjusting screw in 1½-2 turns and tighten the locknut. This will provide correct clearance of .045-.064" between dashpot rod and adjusting screw (apparent only when rod bottomed in dashpot).

Mercury Adjustment—After engine idle speed correctly set (above) and with engine at normal operating temperature so that fast idle cam in slow idle position, first make certain that dashpot adjusting screw does not contact dashpot rod, then loosen locknut and turn adjusting screw until gap between head of screw and dashpot rod is .020" (check with a feeler gauge), tighten locknut and recheck for .020" gap.

THROTTLE LINKAGE: *CAUTION—Each model adjusted differently as follows:*

Ford 6 Cyl. (1952-53) Throttle Linkage: *CAUTION—Check linkage for free operation and correct any binding BEFORE making adjustments—*

MERCURY MERCOMATIC LINKAGE

▷*LINKAGE BINDING CORRECTION*—If engine idles at faster-than-normal speed, check accelerator pedal rod for interference with floor mat or at floor pan opening, check all linkage pivot points and carburetor Dashpot shaft for binding. Correct any binds, lubricate all pivot points with engine oil and recheck linkage for free operation. If engine does not return to normal idle speed after Linkage Adjustments properly made, increase accelerator retracting spring tension by hooking forward end of spring in front hole of spring bracket and hook rear end of spring to end of accelerator rod at accelerator bellcrank. *CAUTION—Changing spring location without removing all binding from linkage will result in excessive pedal pressure.*

Linkage Adjustment: Adjust in following order:

1) Measure distance from top surface of accelerator pedal to FLOOR PAN (not floor mat) which should be 4 5/16" (necessary to insure correct kickdown). If distance not correct, adjust threaded trunnion at rear end of carburetor throttle rod (at accelerator pedal rod connection) for correct pedal height.

2) Disconnect transmission throttle rod by removing clevis pin at forward end (at lever on left side of cylinder head), pull upward gently but firmly on rod to insure transmission lever being against its stop, adjust clevis on rod until clevis pin freely enters holes in clevis and lever, then lengthen rod by turning clevis 2½ turns, connect rod and tighten clevis locknut.

3) Assemble throttle control rod to accelerator assembly shaft with the clevis pin and cotter pin, then tighten locknut. Lubricate throttle linkage, and check and relieve any binding conditions. Road test car. If band or clutch slippage is evident, increase length of rod to 3 turns but do not exceed 3½ turns.

CONTINUED ON NEXT PAGE

FORDOMATIC & MERCOMATIC (Continued)

Ford V8 (Early 1951), Mercury (1951) Throttle Linkage Adjustment: *CAUTION—On Mercury, Z bar-to-Carburetor rod must be connected at FORWARD hole in carburetor throttle lever. If rod connected at rear hole, disconnect and lengthen rod as necessary to connect at forward hole when making the linkage adjustment.*

1) Disconnect rod and remove the clip from the carburetor to Z-bar rod at the Z-bar end. Reinsert the rod in the Z-bar lever, place tool No. 77230M (Mercury), tool No. 77230F (Ford), on the end of the rod. With the tool resting on the finished surface of the cylinder block (CAUTION—tool must rest on clean finished surface of block, not on manifold gasket or foreign material), adjust the rod length so that carburetor throttle lever is held against the idle stop. Remove the tool and assemble the rod to the Z-bar with the clip.

▷*CAUTION*—If above setting results in insufficient accelerator pedal travel and prevents high-to-intermediate kick-down with normal throttle linkage setting (2 below), adjust carburetor-to-Z-bar rod so that tool is .125" away from surface of engine block and adjust linkage to 2½-3½ turns off stop (below).

2) At the Z-bar, remove cotter pin and clevis pin from the upper end of the Z-bar-to-transmission rod and pull upward gently but firmly on the rod from the transmission throttle lever to hold the lever against the stop. Adjust the clevis so that the clevis pin will freely enter the clevis and Z-bar hole. Lengthen the rod by turning the clevis counter-2 full turns (Mercury), 2½ full turns (Ford) except as noted in CAUTION below, then assemble the rod to the Z-bar with the clevis pin and cotter pin. Lock the clevis on the rod with the locknut while holding the clevis in alignment (necessary to prevent binding of the linkage).

▷*CAUTION*—If clutch or band slippage noted with above setting, or if setting in (1) above varied to secure correct kick-down operation, the rod setting should be lengthened to 3 full turns but must not exceed 3½ turns.

Ford V8 (Late 1951-53) Throttle Linkage Adjustment *NOTE—Adjusting Tool 77230-FA must be modified for use in adjusting 1952-53 Models (Slot in tool should be used only when adjusting 1951 linkage). Make adjustments in following order.*

1) Check position of accelerator Z-bar-to-carburetor connecting link. If link is not parallel to centerline of engine, loosen locknut and turn link adjustment screw (see illustration) until link position is correct, tighten locknut while holding the screw.

2) Check position of accelerator shaft hanger support in relation to accelerator shaft. If support is not perpendicular to shaft, loosen bolt securing support to engine bracket and move top of support to correct position, tighten the bolt while holding two horizontal legs of bracket together with vise-grip pliers.

3) Late 1951 Cars Only—Install special adjusting tool 77230-FA (Either Modified as noted below, or not modified) on rear end of carburetor-to-Z bar rod with SLOT in tool engaging end of rod and leg at rear of tool behind accelerator shaft and make certain that tool rests on finished surface of cylinder block (CAUTION—See that block is clean and that gauge is not resting on manifold gasket). Hold the rod at the bottom of the slot in the gauge, loosen locknut on adjustment bolt in Z-bar bracket, turn adjusting bolt until tool leg just touches accelerator shaft, tighten locknut.

3) 1952-53 Cars Only—Install modified Adjusting Tool 77230-FA (see Tool Modification Note below) on rear end of carburetor-to-Z-bar rod with end of rod resting in adapter on tool and leg at rear of tool behind accelerator shaft. Make certain that tool rests on clean finished surface of cylinder head (CAUTION—tool must not rest on manifold gasket). Hold rod against adapter on tool, loosen locknut on adjusting bolt in Z-bar bracket, turn adjusting bolt until tool leg just touches accelerator shaft, tighten locknut.

4) With tool in place on carburetor-to-Z-bar rod, loosen the locknut on the rod, turn barrel on rod until idle adjustment screw (throttle stopscrew) just touches its stop when rod is held against adapter on tool, then tighten the locknut. Remove the adjusting tool.

5) Remove cotter pin and clevis pin from upper end of Z-bar-to-transmission rod, pull gently but firmly upward on rod to hold transmission lever against its stop, adjust clevis on rod until clevis pin freely enters holes in clevis and Z-bar, then lengthen rod by turning clevis 2½ full turns counter-clockwise (off) rod. Assemble rod to Z-bar with clevis pin and cotter pin, tighten clevis locknut.

6) Lubricate all bearing points in linkage and check for free operation throughout entire range without binding. Check and reset engine idle speed.

Check operation of car after all adjustments completed. If clutch or band slippage occurs at part throttle, increase transmission-to-Z-bar rod adjustment (5 above) to 3 full turns but do not exceed 3½ turns. If accelerator pedal height not sufficient for correct kick-down operation with above settings, adjust carburetor rod length with rod end positioned in top of slot of adjusting tool (step 3 above).

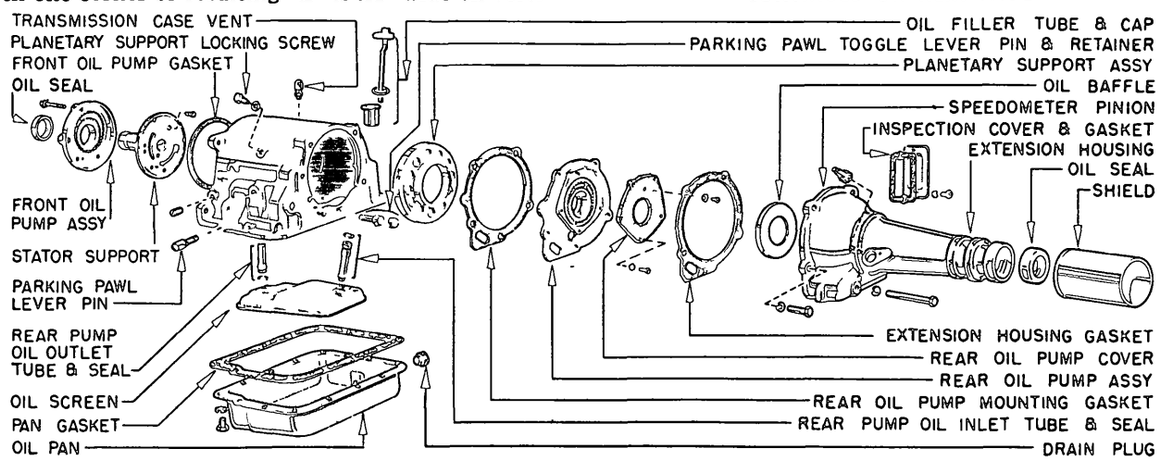
▷*ADJUSTING TOOL 77230-FA MODIFICATION (for use on 1952-53 Ford V8 Cars)*—Special adapter must be sweated on side of gauge to provide lower adjusting point for carburetor-to-Z-bar rod. Make up adapter from ⅛" flat stock .44" square with cutout in one corner so resulting "L" is .12" wide on vertical leg and .25" wide on horizontal leg with .03" radius in corner. Position adapter on right side of gauge with vertical leg .12" to rear and horizontal leg .12" below lower end of gauging slot in tool (this will provide new gauging point .12" below and to rear of slot).

Mercury (1952-53) Throttle Linkage Adjustment: See illustration for adjustment points. Adjust as follows:

1) Disconnect transmission throttle rod by taking out clevis pin at forward end of rod (point "2"), loosen two bolts in accelerator rod link bracket (points "5" and "6").

2) Position Tool 77230-MAA on finished face of engine block (see illustration). Adjust accelerator shaft so that it contacts upper face of rear end of tool (point "7"), then tighten the two bolts (points "5" and "6").

3) Make certain that engine idle speed correctly set at 425 RPM. maximum slow or hot idle speed, adjust accelerator shaft-to-carburetor rod (point "A") so that rod enters carburetor throttle arm freely, connect rod. *See "No 3-2 Forced Downshift Correction" below.*



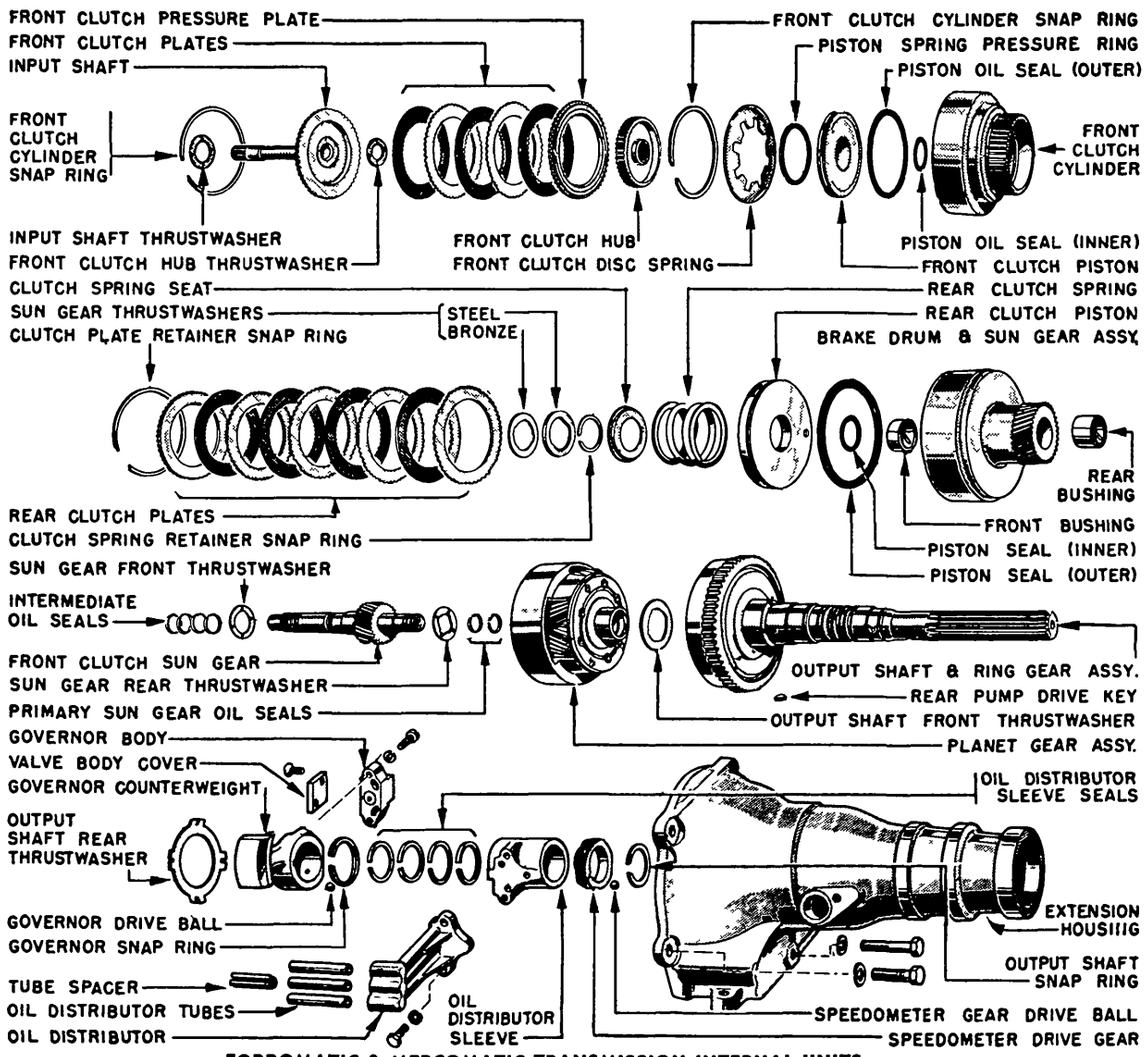
4) Hold carburetor throttle lever in slow idle position, pull transmission throttle lever rod upward gently but firmly so that lever is in the "stop" position, adjust clevis at upper end of rod (point "2") so that clevis pin enters clevis and control shaft freely, then lengthen rod by turning clevis 2½ turns counter-clockwise, connect rod.

NOTE—If above setting does not give satisfactory operation, rod can be lengthened ½ turn for 3-turn setting. DO NOT exceed 3½ turns from the stop position.

▷*NO 3-2 FORCED DOWNSHIFT AFTER COMPLETING ADJUSTMENT:* If forced 3-2 downshift cannot be secured after linkage has been properly adjusted (above), disconnect accelerator shaft-to-carbureor rod and shorten the rod one complete turn (see step 3 above). *CAUTION*—Over-run spring in assembly must allow for free movement of the ball in its socket.

Ford Truck (1953): Throttle and Manual Control Linkage Adjustment same as for corresponding Pass. Car Models except that distance between ac-

CONTINUED ON NEXT PAGE



TRANSMISSION CASE AND EXTENSION HOUSING ASSEMBLY

FORDOMATIC & MERCOMATIC (Continu d)

celerator pedal pivot point (where accelerator cross shaft connects to pedal) and floor pan (not mat) is 2⅝". Adjust carburetor connecting link to obtain correct height of pedal.

MANUAL LINKAGE: Disconnect the manual rod from the transmission selector arm at the upper end. Position the selector lever so that the indicator at the steering wheel is down against the stop in the drive position. Position the transmission manual lever in the drive (Dr) position (second position from the bottom). Adjust the rod length so that the sleeve trunnion freely enters the grommet in the selector arm. Lengthen the rod by turning the sleeve one full turn counter-clockwise (except on later 1953 Fords with new type Gear Shift Lever Assembly—see Changes & Corrections) or earlier cars with the same new Insulator and Nylon Bushing in the old arm in which cases rod should be lengthened two full turns. Reassemble rod to selector arm and tighten the locknut to hold the adjustment. Check alignment of the pointer for all positions of the selector lever.

STARTER NEUTRAL SWITCH: Loosen the neutral switch to steering column attaching screws. Position the switch so that the starter circuit is closed when the selector lever is in the neutral (N) position. Check the starter circuit in all selector lever positions. NOTE—The circuit must be open in all positions except neutral.

FORDOMATIC & MERCOMATIC TRANSMISSION INTERNAL UNITS

BAND ADJUSTMENT

►*Band Adjustment is recommended to be made at 15000 mile intervals when transmission fluid is changed (pan should be removed and cleaned at this time).*

FRONT BAND ADJUSTMENT: Drain fluid from pan using a drain can with a fine mesh screen, remove pan. Remove fluid screen from transmission and loosen the front servo adjusting screw locknut TWO FULL TURNS, using a 11/16" wrench. Using front band adjusting tool No. 7225, insert gauge block between servo piston and adjusting screw and tighten adjusting screw until wrench overruns. Back off adjusting screw exactly ONE COMPLETE TURN and remove gauge block. While holding adjusting screw stationary, tighten locknut clockwise (20-25 ft.lbs.). Install fluid screen and install pan using new gasket. Install the drain plug and refill transmission to "Full" mark using fluid drained from transmission unless fluid being changed. Check fluid level (see LUBRICATION).

►*CAUTION—Severe damage may result if adjusting screw not backed off exactly 1 full turn.*

REAR BAND ADJUSTMENT: Fold back floor mat to expose right side of floor pan and remove access hole cover on right side of transmission floor pan. Using rear band adjusting tool No. 7195, loosen rear band adjusting screw locknut. Using "T" handle of tool No. 7195, tighten rear band adjusting screw until wrench overruns. (If screw was found to be tighter than wrench capacity (10 ft. lbs.), loosen several turns and retighten until wrench overruns). Back off adjusting screw exactly 1½ COMPLETE TURNS. While holding adjusting screw stationary, tighten adjusting screw locknut to 35-40 ft. lbs.

►*CAUTION—Severe damage may result if adjusting screw not backed off exactly 1½ turns.*

TESTING & TROUBLE SHOOTING

►*CAUTION—While making the test never hold the throttle open longer than 5 seconds and RELEASE THROTTLE IMMEDIATELY if speed exceeds 1565 RPM. (indicating band or clutch slippage).*

STALL TEST: The stall test is made in the drive range and the reverse range. The test determines whether the bands and clutches are holding properly. Connect a tachometer to read on the high scale, and make sure the engine is idling properly (425 RPM) at normal operating temperature. Firmly apply the brake pedal with the left foot, place the selector lever in drive (Dr) range, and press the accelerator all the way down to the floor. The engine speed should be 1365-1565 RPM. (Ford), 1400-1600 RPM. (Mercury). If engine speed is below this lower RPM., tune up the engine and repeat test. If engine speed exceeds the higher figure, release the accelerator immediately because it indicates the front band or clutch is slipping. Repeat the test with the selector lever in reverse (R) position. If slippage occurs, it is the rear band or rear clutch. Release the accelerator immediately. If the stall test shows proper band and clutch operation, proceed with the shift point test. If slippage is evident, make a pressure test.

SHIFT TEST: Select a smooth level road for the test. First check the shift from intermediate to high with a light throttle. Place the selector in drive (Dr) position and starting from a standstill, apply the accelerator lightly but steadily. The shift from intermediate-to-high should occur at the correct

CONTINUED ON NEXT PAGE

FORDOMATIC & MERCOMATIC (Continued)

MPH. Allow the car to decelerate until downshift from high-to-intermediate occurs. See table for correct shifting speeds. With the selector lever still in drive (Dr) position, press down hard on the accelerator until the car shifts from intermediate to high. See table for correct shifting speeds. Reduce the car speed to a point below 50 MPH., then press the accelerator pedal quickly to the floor. This action engages the kickdown valve which shifts the transmission from high to intermediate. The kickdown shift occurs only with the car in high gear and at a speed below the full throttle (kick-down) point as shown in the table below.

FORD & MERCURY SHIFT SPEEDS

	Min. Throttle	Full Throttle
Automatic Shifts		
2-3 Upshift	14-19 MPH	64-69 MPH.
3-2 Downshift	7-3 MPH	①Below 55 MPH.
Manual Shift ("Dr" to "Lo")		
3-2 (Intermediate)		Above 23-27 MPH.
3-1 (Low)		Below 23-27 MPH.

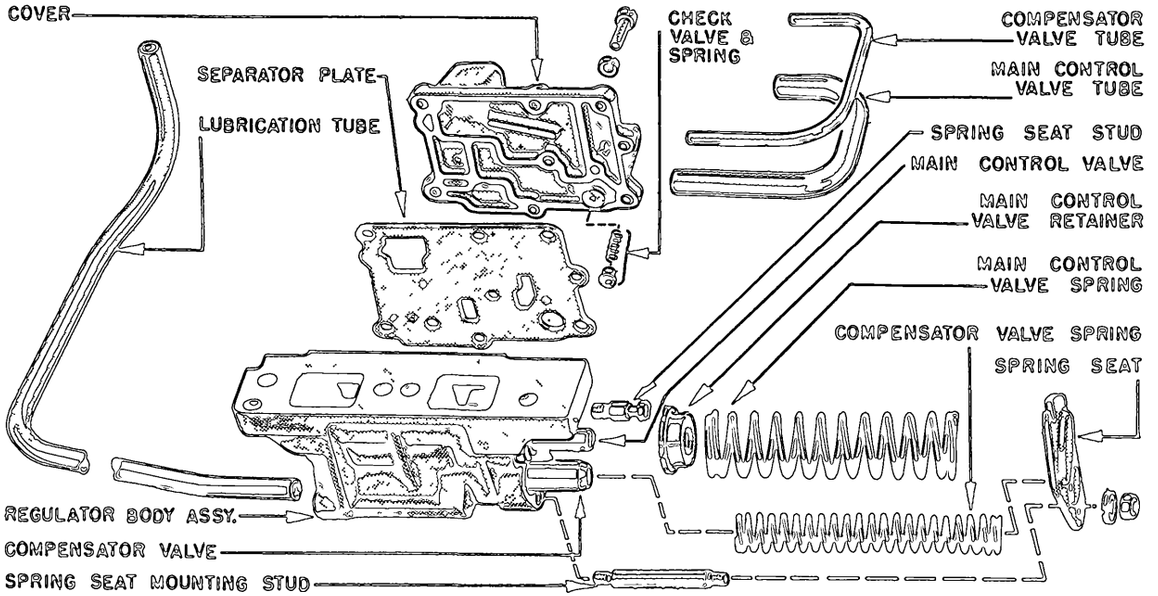
①—Forced downshift or "kick-down."

OPERATING PRESSURE TEST: Set the parking brake firmly and hoist the car until the rear wheels clear the floor. Remove the converter air intake duct and screen. Disconnect the throttle linkage at the outer throttle lever. Remove the ¼" pipe plug located near throttle levers, then connect pressure gauge No. 77820 and mount gauge so that it can be read under the car. Position the throttle lever protractor gauge No. 77270A (Ford), 77270 (Mercury) on the throttle lever shaft (see Gauge Note below if gauge will not fit over shaft), locating large elongated hole in gauge over the large shaft to rear of control lever. Set gauge indicator to 0° and lock in place with knurled thumbscrew. Hold throttle lever against stop (up), insert gauge pin 7000-B-1 through the small elongated hole in the gauge and the hole in the throttle lever. If the gauge pin enters these two holes freely the throttle mechanism has not been distorted and need not be replaced. Replace the throttle control mechanism if it is distorted. With the throttle lever still held against the stop (up), lock the throttle lever to the gauge by tightening the thumb screw on the gauge. Remove the gauge pin, then loosen the knurled screw and advance the lever fully (down). The lever should travel 28°-33°. Use an engine tachometer and set the engine idle speed to 600 RPM. by adjusting the idle adjusting screw. Make tests in Reverse "R" and Drive "DR" positions as directed below.

▷Protractor Gauge Installation Note—If gauge can not be installed on shaft due to flow of brazing metal on end of shaft, remove this metal by reducing shaft to original diameter for distance of ¼" from end. Do not rework the gauge.

Reverse Test—With engine idling at 600 RPM., place selector lever in Reverse "R" position. Observe the pressure at 0° throttle lever position. The pressure should be 60-80 p.s.i. From underneath the car advance the throttle lever slowly and observe the angular reading at the point the pressure begins to rise. Pressure rise should begin between 3½-4½° throttle advance. Continue to advance the throttle lever slowly until maximum pressure is indicated (should be 140-165 lbs.) and observe angular reading which should be 4½-7½°. If above points not correct, adjust by changing throttle valve stop position (see Throttle Valve Stop Adjustment below).

Drive Test—Place selector lever in Drive "Dr" position and repeat above test procedure. Maximum pressure should be 120-145 lbs. with angular reading of 7-10½°. If above points not correct, adjust by changing throttle valve stop position.



Throttle Valve Stop Adjustment—This adjustment requires draining transmission and removing oil pan. Use Bending Tool No. 77763 to bend the throttle valve stop within transmission case as follows:

If Pressure Rise Start is over 4½° (in Reverse "R" Range)—Hold outer throttle lever against its stop, clamp protractor gauge on lever and set to read 0°, then advance lever to maximum travel. Install bending tool over throttle valve stop, bend stop TOWARD valve body to advance the stop position the required number of degrees to bring the pressure rise start to 4° in "R" range. Check by returning the lever to stop position and reading protractor gauge (reading will indicate change in stop position).

If Pressure Rise Start is under 3½° (in Reverse "R" Range)—Bend stop AWAY from valve body, following same procedure as above except that protractor gauge must be set at some positive reading such as 5° (instead of zero). Final gauge reading subtracted from initial gauge reading will indicate change in stop position.

After making above adjustment, re-install oil pan, fill transmission with fluid, recheck pressure rise start in "R" range.

After completing above tests—Remove protractor gauge and pressure gauge, re-install pipe plugs and tighten to 7-15 ft. lbs. Connect link to throttle lever using a new cotter pin. Install converter air intake and duct. Reset engine idle speed to 425 RPM. Adjust throttle linkage. *See Linkage Adjustment.*

FORDOMATIC & MERCOMATIC PRESSURE REGULATOR ASSY.

MINOR REPAIRS (TRANSMISSION IN CAR)

The following transmission units can be removed for repairs while the transmission remains in the car. Raise car on hoist for these operations.

▷NOTE: For disassembly and overhaul of the following units, see "Overhaul (All Transmission Units)."

Governor Removal: Remove governor inspection cover from extension housing. Rotate the drive shaft to bring governor body in line with inspection hole. Remove the two screws that secure governor body to sleeve. Remove governor.

▷*CAUTION—Use care not to drop balls or governor valve into housing.*

Installation—Lubricate governor valve with transmission fluid and install valve in governor body (CAUTION—valve must move freely in body). Install governor body on counterweight with the side plate forward (CAUTION—fluid passages in governor body and counterweight must be aligned), install governor body attaching screws. Install inspection cover with NEW gasket, tighten cover screws to 4-6 ft. lbs. torque.

▷NOTE: For the following operations, remove transmission fluid level indicator. Remove transmission filler tube and drain the fluid into clean container using a fine mesh wire screen for straining. (fluid may be re-used). Then remove transmission oil pan and screen.

Front Servo Removal: Loosen lubrication tube from pressure regulator and rear pump and remove. (NOTE—If necessary, tap tube with soft hammer to remove—*CAUTION*—Do not bend or distort tube). Loosen control valve body attaching bolts. Remove servo attaching bolt and while holding servo strut with fingers, remove servo assembly.

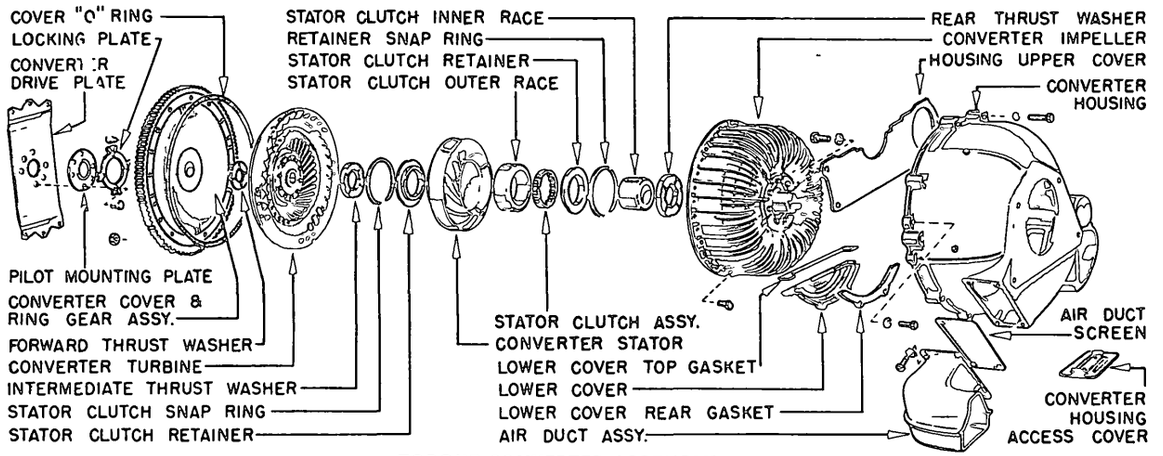
Installation—Position servo band forward in case with band ends down. Position servo strut with

CONTINUED ON NEXT PAGE

FORDOMATIC & MERCOMATIC (Continued)

large end indexing with servo actuating lever and small end indexing with band end. Rotate band, strut and servo into position, indexing tubes from valve body to servo, and anchor end of band with anchor in case. Install attaching bolt, tightening to 30-35 ft.lbs. Tighten control valve attaching bolts to 8-10 ft.lbs. Install lubrication tube and adjust servo band. See "Front Band Adjustment." Install screen, install oil pan using NEW gasket, tighten oil pan screws to 10-13 ft.lbs. Connect filler tube. Fill transmission to correct level (old fluid can be re-used), recheck fluid level with transmission at operating temperature.

Rear Servo Removal: Remove lubrication tube from rear pump and regulator. (NOTE—If necessary tap tube with soft hammer to remove). Remove rear pump intake tube. Remove front servo (see above). Take out rear servo attaching bolts, hold actuating and anchor struts with the fingers, remove rear servo assembly.



Installation—Position servo anchor strut and rotate servo band to engage strut. Hold in position with fingers. Position actuating lever strut and install servo and install servo attaching bolts, tightstall servo, install servo attaching bolts (CAUTION—Longer attaching bolt must be installed in forward bolt hole), tighten attaching bolts to 40-45 ft. lbs. torque. Install front servo (see above). Install rear pump intake tube and lubrication tube. Adjust rear band (see BAND ADJUSTMENT). Install oil pan with NEW gasket, tighten oil pan screws to 10-13 ft.lbs. Connect filler tube. Fill transmission to correct level (old fluid can be re-used), recheck fluid level with transmission at operating temperature.

Control Valve Body Removal: Remove two "U" tubes from pressure regulator and control valve body. Loosen front servo attaching bolt three turns. Take out three valve body attaching bolts, lower the valve body and pull it off the servo tubes.

▷*CAUTION—Use extreme care when removing valve body to prevent damage to body and attached parts.*

Installation—Align servo tubes with holes in control valve body, position manual lever in neutral, position inner throttle lever between stop and downshift valve and at the same time push the throttle valve in to clear the transmission case making certain that manual valve engages actuating pin manual detent lever. Install control valve body attaching bolts but do not tighten the bolts. Install two "U" tubes in pressure regulator and control valve body. Tighten control valve body attaching bolts to 8-10 ft. lbs. torque. Tighten front servo attaching bolt to 35-40 ft. lbs. torque. Adjust front and rear bands (see BAND ADJUSTMENT). Install oil screen, install oil pan using NEW gaskets, tighten oil pan screws to 10-13 ft.lbs. Connect filler tube. Fill transmission to correct level (old fluid may be re-used), recheck fluid level with transmission at normal operating temperature.

Pressure Regulator Removal: Remove lubrication tube. Remove control pressure tube and compensator tube from valve body and regulator. Remove pressure regulator spring retainer. *(CAUTION—Maintain pressure on retainer to prevent springs flying out).* Remove the control pressure and converter pressure valves. Take out pressure regulator attaching bolts and washers, remove regulator.

TORQUE CONVERTER ASSEMBLY

▷*MAIN OIL PRESSURE REGULATOR VALVE INSTALLATION CAUTION:* If regulator removed to correct transmission "buzzing" noise, examine valve for undersize bleed flats and rotate valve 90° in bore from original position when re-installing it. This should correct the noise.

Installation—Install regulator body and attaching bolts and tighten to 17-22 ft.lbs. Install converter pressure and control pressure valves and make certain valves operate freely in bore, then install valve springs and retainer. Install large control pressure tube, small compensator tube, and lubrication tube. Install oil screen, install oil pan using NEW gaskets, tighten pan screws to 10-13 ft.lbs. Connect filler tube. Fill transmission to correct level (old fluid may be re-used), recheck fluid level with transmission at normal operating temperature.

Manual & Throttle Lever Seal Replacement: Remove control valve body (see above), disconnect manual and throttle linkage rods at transmission levers. Remove nut on inner throttle lever shaft and remove inner throttle lever. Remove outer throttle lever and shaft, remove throttle shaft seal from counterbore in manual lever shaft. Take out cotter pin in each end of parking pawl torsion lever rod and remove the rod, rotate manual lever shaft until detent lever clears detent ball (CAUTION—do not allow detent ball to fly out), remove detent ball and spring. Remove manual lever shaft nut, remove detent lever, remove outer manual lever and shaft assembly. Remove manual shaft seal.

Installation—Coat outer diameter of new seal with Permatex #3, install seal in case using tool No. 77288. Install outer manual lever and shaft, rotate shaft until manual lever points downward, place detent lever on inner end of shaft, install attaching nut and tighten nut to 35-40 ft. lbs. torque. Place detent spring and ball in hole in case (use piece of thin wall tubing to depress ball and spring), rotate detent lever until detent ball is held in place. Install parking pawl torsion lever rod and cotter pins. Install new throttle shaft seal, outer throttle lever and shaft, inner throttle lever and attaching nut, tighten nut to 25-28 ft. lbs. Connect manual and throttle rods to outer levers. Check linkage for free movement. Install control valve assembly and other parts. *See Control Valve Assembly Installation (above).*

REMOVAL FROM CAR

▷*TRANSMISSION OR CONVERTER REMOVAL NOTE:* Transmission and converter can be removed as an assembly, or transmission can be removed separately (without disturbing converter) as follows:

TRANSMISSION & CONVERTER ASSEMBLY REMOVAL:

▷*FORD 6 CYL. TRANSMISSION REMOVAL CAUTION:* The procedure below is recommended by manufacturer and requires modification of transmission jacks as explained below. *This procedure will allow transmission to be removed without removing engine from chassis.*

Ford 6 Cyl. Transmission & Converter Removal: Place car on hoist or support car on jack stands with tires at front and rear at least 10" above floor. Then proceed as follows:

1) Fold back front floor mat, remove rubber plugs in dash panel assembly, work through these holes, remove two top converter housing-to-engine bolts.
2) Remove all lower converter housing-to-engine bolts EXCEPT one located over starter and one located over exhaust pipe. DO NOT remove these bolts until later.
3) Remove transmission linkage splash shield, and converter air duct assembly, then disconnect rods from both levers on transmission case. Disconnect speedometer cable assembly. Remove starter.
4) Disconnect propeller shaft at rear universal joint flange, remove shaft by pulling it to rear to disengage forward end from transmission.
5) Drain transmission case fluid by disconnecting filler tube at transmission oil pan connection.
6) Remove two transmission housing-to-engine rear support bolts.
7) Position transmission jack under transmission (see Fordomatic Transmission Jack Note below), raise transmission slightly to remove load from rear support.
8) Disconnect and remove engine rear support.
9) Remove converter housing lower access cover and oval cover on engine rear plate. Disconnect

CONTINUED ON NEXT PAGE

FORDOMATIC & MERCOMATIC (Continued)

driving flex plate from converter cover, position flex plate horizontally.

CONVERTER DRAINAGE NOTE—Converter can be drained after transmission removed from car, or it can be drained at this point as follows: Remove one converter housing drain plug, then rotate converter 180°, remove second drain plug and allow converter to drain.

10) Install engine support bar to support engine weight and adjust tightly to engine oil pan flanges.

11) Remove two remaining converter housing-to-engine attaching bolts (2 above), slide transmission assembly to rear sufficiently to disengage it from engine. Wedge converter assembly in place (piece of strap iron can be bolted across lower part of converter housing) to prevent assembly sliding out when transmission tipped. Lower transmission assembly slightly and tilt front end downward and toward the right. Raise engine rear plate and move it forward, then continue to lower and tilt the transmission until it clears the engine rear plate. Remove transmission from beneath car.

▷*FORDOMATIC TRANSMISSION JACK NOTE—Jacks must be modified for above use as follows:*

Lo-Jack 5000-304—Set of spacing bars, No. 30403, should be installed to move Fordomatic Adapter 2½" to rear to relocate center of balance and provide better tilting action as required for transmission removal on 1952 cars.

Hi-Jack 3000-304 & 3200-304—Install set of spacing bars (as for Lo-Jack above) and also install new Tilt Screw Assy. No. 7036 to allow for greater tilting angle required for 1952 transmission removal.

Ford V8 & Mercury Transmission & Converter Removal: Place car on hoist or support it on jack stands with all four wheels at least 10" above the floor. Then proceed as follows:

1) Fold front floor mat back, remove two rubber plugs in toepan, work through these openings and remove two top converter housing-to-engine bolts.

2) Remove starter. Remove converter housing front plates. Drain converter if desired (converter can be drained after assembly removed from car).

CONVERTER DRAINAGE NOTE—Remove one converter drain plug, rotate converter 180° and remove second drain plug, allow converter to drain.

3) Drain transmission case by disconnecting filler tube at oil pan connection.

4) Remove converter housing lower access cover, remove six converter-to-flex drive plate bolts, position flex plate horizontally for clearance, replace lower converter housing front plate (to prevent converter sliding out of housing during removal).

5) Position Engine Support Bar under rear end of crankcase so that engine can be lowered ¾" below normal position.

6) Disconnect manual control rod and throttle control rod from levers on transmission case. Disconnect speedometer cable. Disconnect accelerator pedal shaft at accelerator cross-shaft.

7) Disconnect propeller shaft at rear axle, remove shaft assembly by pulling it to rear to disengage forward end from transmission.

8) Disconnect parking brake assembly at cross-member and move cable and equalizer to one side and out of the way.

9) Remove two engine rear support-to-transmission bolts. Position transmission jack under transmission case and raise transmission just enough to remove weight from cross-member. Remove attaching bolts at each end of cross-member and remove cross-member.

10) Lower transmission until engine is supported by support bar (at point approximately ¾" below normal height).

11) Remove all remaining converter housing-to-engine bolts. Move transmission straight back far enough to clear converter pilot, then lower transmission and remove from beneath car.

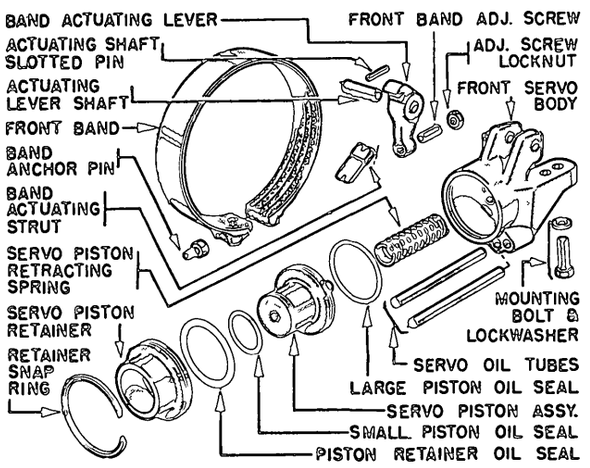
TRANSMISSION REMOVAL (WITHOUT DISTURBING CONVERTER ASSEMBLY): Place car on hoists or support car securely on jack stands with all wheels approximately 12" above floor. Then proceed as follows:

1) Drain transmission case by disconnecting filler tube at transmission oil pan connection.

2) Disconnect manual control rod and throttle control rod from levers on transmission case. Disconnect speedometer cable. Disconnect parking brake cable assembly at cross-member and move cable and equalizer to one side out of the way.

3) Disconnect propeller shaft at rear universal joint flange, remove shaft assembly by pulling it to rear to disengage forward end from transmission.

4) Remove engine rear support-to-transmission bolts, install transmission jack under transmission, raise engine and transmission just enough to install engine support bar under rear end of crankcase.



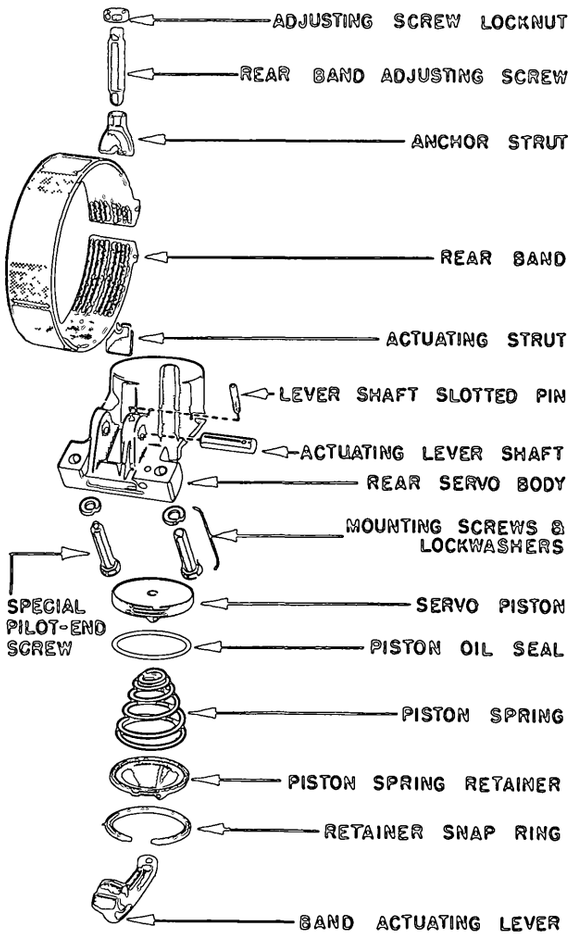
5) With engine weight on support bar, raise transmission just enough to remove weight from cross-member, take out attaching bolts at each end and remove the cross-member.

6) With transmission securely supported by jack, remove four transmission-to-converter housing bolts.

7) Slide transmission straight back to disengage the turbine shaft, then lower transmission and remove it from beneath car.

OVERHAUL—TORQUE CONVERTER

▷*DISASSEMBLY & REASSEMBLY CAUTION: CLEANLINESS IS EXTREMELY IMPORTANT WHEN OPENING UP TRANSMISSION. Thoroughly clean outside of case first, clean each part as removed.*



FRONT SERVO & BAND ASSY.

TORQUE CONVERTER REMOVAL (From Transmission): Grasp converter cover with both hands and pull straight out. *(CAUTION*—To prevent damage to front seals, do not rock assembly from side to side). Remove converter housing attaching bolts and remove housing from transmission.

DISASSEMBLY: Remove converter cover attaching bolts and nuts. Remove cover and gasket. Remove bronze thrust washer from turbine and lift turbine out of pump housing: Lift stator out of pump housing. *(CAUTION*—Note position of stator when removing so that it can be installed in the same manner). Remove thrust washers from pump hub and from turbine hub. Remove the one way clutch inner race from stator and take out the snap ring retaining outer hub to stator. *(CAUTION*—Do not burr snap ring groove). Remove outer hub, sprag assembly and outer race. Remove snap ring retaining inner hub to stator and remove inner hub. Take

CONTINUED ON NEXT PAGE

REAR SERVO & BAND ASSY.

FORDOMATIC & MERCOMATIC (C ntinu d)

out bolts attaching pump hub to pump and remove hub. Remove seal from groove in hub.

INSPECTION: Inspect converter blades for looseness, and check thrust surfaces for scores and splines for burrs and wear. Inspect seal surfaces and front pump driving lugs for wear. Inspect sprag assembly for worn or broken sprags or broken or distorted spring. Inspect bushings for wear or scoring (if bushings worn, polish bearing surface of journal with crocus cloth to eliminate possibility of wear having been caused by rough bearing surface). Wear limits for bushing inside diameters are: Stator Support Assy. Bushing .906-.910", Stator Clutch Retainer Assy. Bushing 2.1573-2.1603".

►*REPLACEMENT PARTS CAUTION: See "Changes, Cautions, Corrections" for production changes and revised design parts which must be used together.*

REASSEMBLY: Install stator inner hub and snap ring. Turn assembly over, install outer race in stator. Install sprag assembly in the outer race (*CAUTION*—Make sure sprags are pointed in the right direction). Install outer hub and outer hub snap ring. Insert the tool 7946, tapered side first, into sprag assembly while rotating tool counterclockwise to position sprags. Install inner race with spline section up. Guide tool IP-7946 with hand while pushing inner race into position. Check stator for clockwise rotation while holding the inner race. Install new seal in pump hub, install hub in pump, tighten hub capscrews to 8-10 ft. lbs. torque. Install thrust washer into hub of converter pump and install stator with "Front" (Stamped into face of stator) up. Install thrust washer into hub of turbine and install turbine. Install bronze thrust washer on turbine hub. Position converter cover on pump housing with new gasket, properly align balance marks on cover and housing (see Converter Balance Mark Caution below), install all converter bolts (see Cover Bolt Installation Caution below for proper location of several types used), tighten bolt nuts evenly to 25-28 ft. lbs. Install converter housing on transmission case and tighten attaching bolts to 40-45 ft. lbs. Install converter assembly and press it firmly in position on turbine shaft.

►*CAUTION—Do not "rock" converter assembly while installing it on shaft (will damage oil seals).*

►**Converter Balance Mark Caution**—Converter cover stamped with "0" at point directly below one of the drain plugs, pump housing stamped similarly between cooling vanes on outer diameter of housing. When installing cover, these marks must be lined up with each other to maintain balance.

►*CONVERTER COVER PRODUCTION CHANGE & INSTALLATION CAUTION: See "Changes, Cautions, Corrections" for cover and gasket change and note the following cautions when installing each type:*

34-Bolt Cover used with FLAT Gasket—Inspect flange faces of converter cover and impeller for smoothness and freedom from deep nicks or scratches. Make certain that sealing lands (between concentric grooves) on impeller flange are free from nicks and are continuous without any breaks. Lands must have minimum width of 1/32" at top and must have minimum height of .008". Remove any burrs by light stoning. Use only improved gasket No. 1P-7963-C (13 27/32" O.D., 12 1/8" I.D.) and do not remove gasket from waterproof envelope until ready for use (if gaskets oversize due to moisture absorption, dry out in oven at 150-200°F). Tighten bolts in sequence noted below. *THIS PROCEDURE IMPORTANT TO PREVENT LEAKS AT COVER FLANGE.*

18-Bolt Cover used with "0" Ring Seal—Always use NEW "0" ring seal. Tighten bolts in sequence noted below. *THIS PROCEDURE IMPORTANT TO PREVENT LEAKS AT COVER FLANGE.*

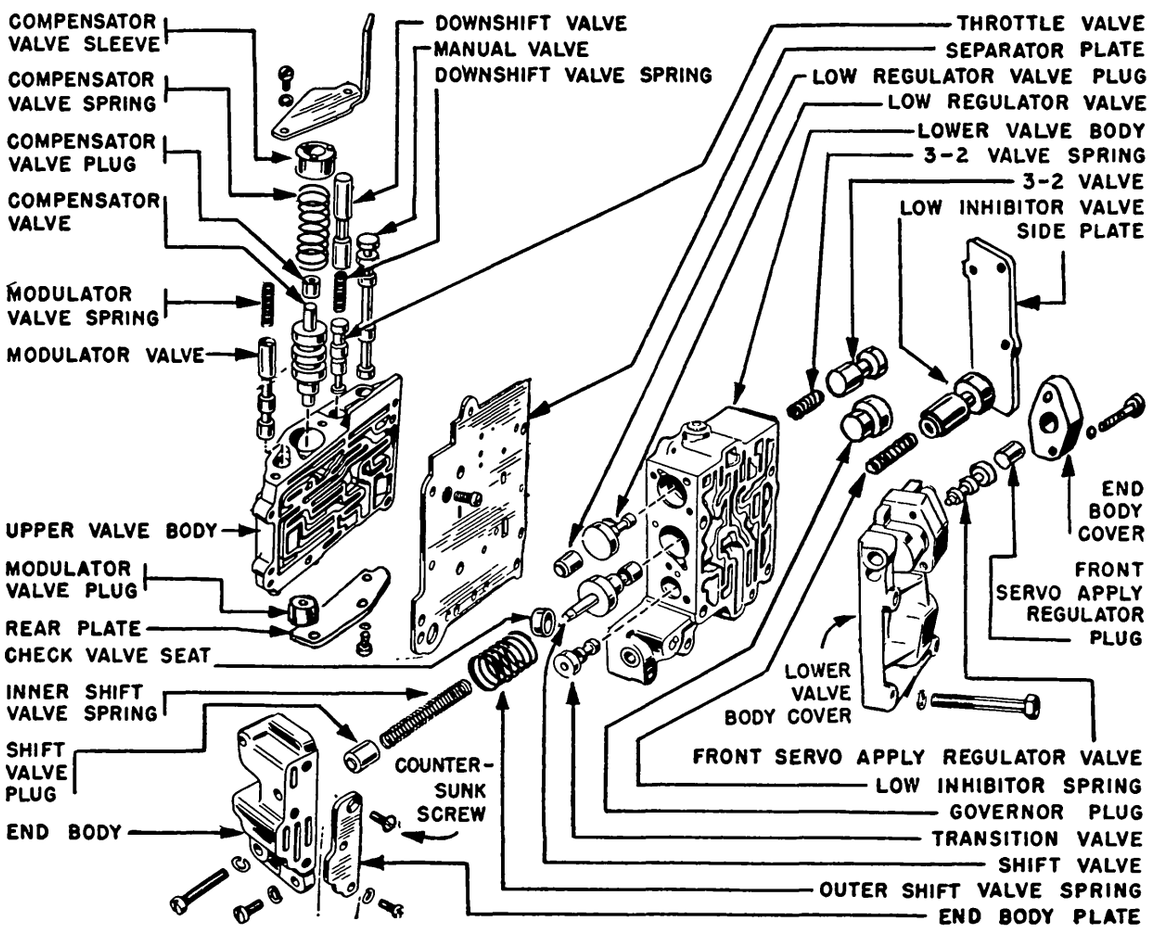
►*"CONE HEAD" COVER BOLTS: See "Changes, Cautions, Corrections" for cone-head bolts (used on later transmissions, can be installed on earlier models). These bolts retain tightness more effectively than previous type flat-head bolts.*

►*COVER BOLT TIGHTENING SEQUENCE (To prevent leaks):* Tighten two nuts directly opposite each other just snug, tighten two nuts 90° from first two similarly, tighten two nuts 45° from first four nuts similarly. Continue this sequence until all nuts have been tightened just snug, then torque all nuts in same sequence to 25-28 ft. lbs. torque.

DISASSEMBLY—TRANSMISSION

►*DISASSEMBLY & REASSEMBLY CAUTION: CLEANLINESS IS EXTREMELY IMPORTANT WHEN OPENING UP TRANSMISSION. Thoroughly clean outside of case first. CLEAN each part as removed with cleaning fluid or gasoline and dry with air—wiping cloths will leave lint on parts.*

DISASSEMBLY OF TRANSMISSION (Into Maj r Units): With transmission on bench fixture, (tool No. 7000-C-D recommended for holding transmission), remove all transmission units as follows:



1) Remove pan and gasket and take out fluid screen.

2) Remove pressure regulator spring retainer, regulator springs, control pressure and converter pressure regulator valves.

►*CAUTION—Maintain pressure on retainer to prevent valve springs from flying out.*

3) Loosen pressure regulator and valve body attaching bolts, and remove lubrication tube from pressure regulator and rear pump. NOTE—If necessary tap

CONTINUED ON NEXT PAGE

FORDOMATIC & MERCOMATIC CONTROL VALVE ASSEMBLY

FORDOMATIC & MERCOMATIC (Continued)

tube with soft hammer. *CAUTION—do not bend or distort tube.*

4) Remove rear pump intake tube, being careful not to bend or distort it.

5) Remove compensator pressure tube (small) and control pressure tube (large) from pressure regulator and valve body. NOTE—If necessary, tap tube with a soft hammer. *CAUTION—do not bend or distort tube.*

6) Loosen front and rear servo band adjusting screws five turns and loosen front servo attaching bolt three turns. Remove valve body attaching bolts and raise valve body to clear case and disengage valve body servo tubes. Remove valve body.

7) Remove regulator body attaching bolts and washers, remove regulator body from case. Insert control pressure valve and regulator valve in regulator body bore to prevent damage to valves.

8) Remove front servo apply and release tubes by twisting and pulling on tubes. Take out front servo attaching bolt, hold front servo strut with the fingers, lift servo assembly out.

9) Remove rear servo attaching bolts and while holding actuating and anchor struts with fingers, lift servo from case. *(CAUTION—Do not permit struts to drop into case).*

10) CHECK TRANSMISSION ENDPLAY before proceeding with disassembly: Remove one front pump attaching bolt and mount Dial Indicator & Support Tool 77067 in this bolt hole so that contact button rests on end of turbine shaft. Install Extension Housing Seal Replacer Tool 7657 on output shaft to provide support for shaft. Pry front clutch cylinder toward rear of transmission using a large screwdriver and set dial indicator at Zero while maintaining silght pressure on clutch cylinder. Then remove screwdriver and pry units toward front of transmission by inserting screwdriver between large internal gear and case. Record indicator reading (endplay) for use in step 17 (below). This endplay should be .010-.029". Remove dial indicator and support, remove tool from output shaft.

11) Remove front pump attaching bolts and remove front pump assembly. (NOTE—If pump is tight in case, use soft hammer to loosen pump). Remove pump to case gasket. *CAUTION—Pull pump off shaft carefully to avoid damaging oil seal.*

12) Remove five extension housing-to-transmission bolts (these bolts also hold rear oil pump on case), withdraw extension housing carefully while holding rear pump in place. *CAUTION—pull housing off output shaft carefully to avoid damaging rear oil seal.*

13) Remove speedometer drive gear snap ring from output shaft and take off the speedometer drive gear. *(CAUTION—Do not lose drive ball).*

14) Remove fluid distributor attaching bolts and slide distributor and tube from transmission. Remove distributor sleeve from output shaft. Carefully remove the four seal rings from the output shaft with the fingers *(CAUTION—use care not to damage these rings).*

15) Remove governor snap ring from shaft and slide governor assembly from output shaft. *(CAUTION—Use care so as not to damage seal rings on output shaft. Do not lose governor drive ball).*

16) Remove rear pump discharge tube using tool IP-77869 and remove pump from case. Remove extension housing and pump gaskets. Remove rear pump drive key from output shaft. Remove bronze thrust washer from output shaft. (NOTE—Washer may come off with pump). Hold rear drum forward and remove the output shaft.

17) Remove selective thrust washer from rear of pinion carrier. If endplay as recorded in step 10 (above) was not within limits of .010-.029", replace this washer with one of proper thickness to give desired endplay. This washer furnished in following sizes: .063-.061", .069-.067", .076-.074", .083-.081".

18) Remove two seal rings from primary sun gear shaft. *CAUTION—use care not to distort rings.*

19) Remove pinion carrier from case and remove bronze thrust washer from sun gear shaft.

20) Mark rear band position so that it can be assembled in the same position. Remove band by squeezing ends together and tilting band forward.

21) Remove two center support bolts (on outside of case—one on each side). Press on end of turbine shaft to force clutch units toward rear of transmission and remove center support from case.

22) Remove rear and front clutch assemblies from transmission case as a unit. Install clutch assembly into bench fixture, tool No. IP-77530 and remove thrust washer from front of turbine shaft. Remove the front band from case. Lift front clutch assembly from primary gear shaft. *(CAUTION—Do not rock assembly while lifting to prevent damage to seal rings).*

23) Remove bronze and steel thrust washers from primary sun gear shaft and then remove the front clutch seal rings from primary sun gear shaft. Lift rear clutch assembly from shaft. *(CAUTION—Do not rock assembly while lifting to prevent damage to seal rings).* Remove rear clutch seal rings and thrust washers from shaft.

OVERHAUL (ALL TRANSMISSION UNITS)

▷*DISASSEMBLY & CLEANING CAUTION:* Handle all parts carefully to avoid nicking or burring bearing surfaces and mounting faces. Clean all parts with clean solvent and dry with air. DO NOT use wiping cloths which may leave lint which would interfere with proper operation. Minor scores or burrs may be removed with crocus cloth. *CAUTION*—when polishing valves, use extreme care not to round edges of valve lands.

▷*REPLACEMENT PARTS CAUTION: See "Changes, Cautions, Corrections" for production changes and revised design parts which must be used together.*

▷*REASSEMBLY CAUTION:* Use all NEW gaskets when assembling units or installing units in transmission. Lubricate all internal parts with TRANSMISSION FLUID TYPE A (vaseline can be used to retain gaskets and thrustwashers). Tighten all bolts and screws to correct torque as listed.

Primary Sun Gear Shaft: Remove rear clutch seal rings (see Note below) from shaft, then remove thrustwasher from thrust face of primary sun gear. Seal Ring Note—New "hooked type" seal rings used on later transmissions. To remove these rings, apply pressure on one end and at back of ring forcing ring into groove at these two points, other end of ring will spring out and free the hook. Ring can then be removed from shaft. Install rings similarly, pressing free end in to engage hook and releasing pressure at back of ring first which will prevent hook disengaging.

Inspection—Inspect all thrust surfaces and journals for wear or scores. Inspect sun gear for broken, chipped, or worn teeth. Inspect shaft splines and ring grooves for wear or burrs. Check all fluid passages for evidence of leakage and make certain passages are clean and free from obstructions. Check seal rings for wear by installing rings in bore and measuring end gap which should be .002-.009", check rings for free fit in groove (must not bind).

▷*REPLACEMENT PARTS CAUTION: See "Changes, Cautions, Corrections" for production changes and revised design parts which must be used together.*

▷*CAUTION—Latest type Primary Sun Gear Shaft requires use of NEEDLE BEARING type Front Clutch Drum. See "Front Clutch" data below.*

Assembly—Install bronze thrustwasher against thrust face of primary sun gear, install seal rings in shaft grooves (see Seal Ring Note above).

Rear Clutch Disassembly. Use an arbor press and tool 77515 to compress clutch release spring, remove release spring snap ring. Relieve spring pressure *(CAUTION*—guide spring retainer while releasing press to prevent retainer interfering with snap ring groove). Remove retainer, release spring, pressure plate snap ring, and pressure plate. Remove the four bronze and four steel clutch plates from the drum. Place splined end of primary sun gear shaft in clutch piston bore, entering it as far as it will go, apply air pressure to hole in end of shaft which will force clutch piston out of cylinder *(CAUTION*—hold hand over piston to prevent it flying out and being damaged). Remove outer seal ring from groove in piston and inner seal ring from clutch drum. Discard these seals (do not re-use).

Inspection—Inspect clutch cylinder, thrust surfaces, piston bore and clutch plate serrations for scores or burrs. Check fluid passages for obstructions. Check clutch release spring for distortion and cracks. Inspect bronze clutch plates for scored bearing surfaces, and fit on clutch hub serrations. Inspect steel plates for scored surfaces, and fit of serrations in the clutch drum. Check pressure plate for scored bearing surfaces. Check clutch hub thrust surfaces and bronze thrust washers for scored surfaces. Check clutch hub splines and turbine shaft splines for wear. Inspect clutch cover bearing surfaces and bushings for wear and scoring. Wear limit for bushing inside diameters are Rear Drum & Planetary Gear Assy. Bushing 1.000-1.004". These bushings are serviced and can be replaced as follows:

▷Rear Clutch Drum & Sun Gear Bushing Replacement: Bushings furnished for service (No. 1P-77507-B Front, No. 1P-77508-B Rear) and can be renewed if oil seal ring bore between bushings not worn excessively (if bore between bushings shows heavy wear or ring wear grooves, replace assembly). Remove and install bushings as follows:

Rear Bushing Removal—Use Tool 77508-A. Place tool mandrel in counterbore, install Truarc Retaining Ring behind bushing, press bushing out in an arbor press. DO NOT drive bushing out.

Front Bushing Removal—Use Tool 77507-A. Place tool mandrel in counterbore, install Truarc Retaining Ring behind bushing, press bushing out in an arbor press. DO NOT drive bushing out.

CONTINUED ON NEXT PAGE

FORDOMATIC & MERCOMATIC (Continued)

Bushing Installation—Use special installing Tool 77507-B in an arbor press to press new bushing into place. Tool is double-ended and will install both bushings to proper depth. Inspect bushings for chips, burrs, or other foreign material after installation and clean assembly thoroughly in solvent.

►**Rear Clutch Plate Checking (External Spline Steel Plates)**—These clutch plates are "coned" or dished on one side. Check plates for correct coning by placing each plate on flat surface with dished side down. Clearance between inner edge of plate and flat surface should be .010" minimum measured with a feeler gauge. Discard plates if not sufficiently coned, if badly scored, or if not free on hub serrations.

►*REPLACEMENT CLUTCH PLATE CAUTION: See "Changes, Cautions, Corrections" for clutch plate changes and identification of various types used.*

►*REAR CLUTCH PISTON SPRING & SEAT RECOMMENDED CHANGE: See "Changes, Cautions, Corrections" for new type spring and seat which should be installed in all transmissions not so equipped.*

Assembly—Install inner seal ring in groove in drum and outer seal in groove in piston. Install piston in clutch drum using automatic transmission fluid as a lubricant to facilitate assembly. *(CAUTION*—Make sure seals are not twisted or distorted during assembly). Install four steel and four bronze clutch plates alternately, starting with a steel plate convex side up. (NOTE—Lubricate plates as they are installed). Install clutch pressure plate with bearing surface down. Install snap ring making sure it is fully seated in groove. Install clutch release spring and position retainer on spring. Using tool IP-77515 in arbor press, compress clutch spring and install snap ring. *(CAUTION*—While compressing spring, guide retainer to avoid interference of retainer with snap ring groove). Make sure snap ring is fully seated in groove.

Front Clutch: Disassembly. Remove clutch cover snap ring and remove turbine shaft (input shaft) from clutch drum. Remove thrustwasher and clutch hub. Remove three bronze and two steel clutch plates and pressure plate. Using arbor press and tool IP-77565 depress clutch release spring and remove snap ring. Release spring pressure, remove clutch release disc spring from drum. Install special nozzle tool 7000-DD on an air hose and place nozzle against one clutch apply hole in front clutch housing and cover the second hole with a finger so that air pressure forces piston out of housing. (NOTE—if nozzle not available, place splined end of primary sun gear shaft in clutch piston bore, entering shaft as far as it will go, apply air pressure to opposite end of primary shaft which will force piston out). Remove piston inner seal from clutch housing and outer seal from groove in piston.

Inspection—See "Rear Clutch Inspection" above. Follow same procedure except that all front clutch plates are FLAT (not coned). Wear limits for bushing inside diameters are: Input Shaft Assembly Bushing 0.875-0.879", Front Drum & Secondary Sun Gear Assy. Bushings 1.062-1.068" (front—first type only, needle bearing used at this point on later transmissions), 1.2495-1.2555" (rear).

►*REPLACEMENT PARTS CAUTION: See "Changes, Cautions, Corrections" for production changes and revised design parts which must be used together.*

Assembly—Install a NEW piston inner seal ring in clutch cylinder, and NEW outer seal ring in piston groove, install piston in clutch housing *(CAUTION*—make certain steel bearing ring is in place on piston). Position release spring in cylinder with **concave side up**, place spring compressor tool on spring and compress spring in an arbor press to enable snap ring to be installed *(CAUTION*—see that snap ring fully seated in its groove).

Primary Sun Gear Shaft & Clutch Reassembly: After individual units assembled (see above), complete reassembly of this sub-assembly as follows: Place primary sun gear shaft assembly in bench fixture, install rear clutch assembly on the shaft *(CAUTION* —center seal rings on shaft to prevent breakage as clutch assembly installed). Install steel and bronze thrustwashers on shaft in that order. Install two seal rings in shaft grooves. Install front clutch housing on primary gear shaft while rotating clutch units to mesh rear clutch plates with serrations on clutch hub *(CAUTION*—use care to avoid breaking seal rings when installing clutch assembly). Install clutch hub in clutch cylinder with deep counterbore down. Install bronze thrustwasher on clutch hub. Install pressure plate in clutch cylinder with bearing surface up, then install three bronze and two steel clutch plates alternately starting with a bronze plate and lubricating all plates as they are installed *(CAUTION*—See "Front & Rear Clutch Plate Caution" for identification of plates and various types used). Install turbine shaft in clutch cylinder, install snap ring (CAUTION—make certain snap ring fully seated in its groove). Install bronze thrustwasher on turbine shaft. Assembly is then ready for installation in transmission case. *See "Reassembly—Transmission."*

Front Pump Disassembly: Remove pump cover attaching screws and remove cover with stator support. Mark the driven gear with Prussian Blue to assure correct assembly and remove drive and driven gears from pump body. To remove seal from pump body, mount the pump body on transmission case, use puller Tool 1175-AE to remove seal.

►*CAUTION*—Extreme care must be taken not to scratch or mar pump gears or bearing surfaces.

Inspection—Inspect bushing, gear pockets and crescent for scores. Inspect front cover, pump body, gear teeth and stator support splines for burrs. Check pump for evidence of contact between outside diameter of drive gear and crescent. Replace pump if such contact noted. Check bushing for wear and scoring. Wear limits for bushing inside diameters are: Pump Drive Gear Bushing 1.812-1.815" (Later type pump only—this bushing not used on first type pump), Pump Body Assy. Bushing 1.940-1.943". *CAUTION*—Check pump for evidence of contact between outside diameter of drive gear and crescent in pump and REPLACE PUMP if such contact noted (even if pump bushings within service limit).

►*REPLACEMENT PARTS CAUTION: See "Changes, Cautions, Corrections" for production changes and revised design parts which must be used together.*

Assembly—Use tool 1P-77837 to install new seal in pump body (CAUTION—coat outside diameter of seal with Permatex No. 3 before installation to prevent fluid seepage). Install pump driven gear in pump body in accordance with marks made before disassembly, install drive gear. Install pump cover and attaching screws **without** lockwashers, tighten cover screws evenly to 25-35 **In.lbs.** Check pump for free movement after assembly completed.

Rear Pump Disassembly: Remove screws and lockwashers securing pump cover to pump body and remove cover. Using Prussian Blue, mark pump drive and driven gears to assure correct assembly, and remove gears from body.

►*CAUTION—Handle pump parts with care to avoid scratching or marring.*

Inspection—Inspect all pump parts for excessive wear, scores or burrs. Check fluid passages for obstructions. Check pump for evidence of contact between outside diameter of drive gear and crescent, replace pump if such contact noted. Check bushing for wear and scoring. Wear limit for bushing inside diameter is: Rear Pump Body Assy. Bushing 2.061-2.065". *CAUTION*—Check pump for evidence of contact between outside diameter of drive gear and crescent in pump and REPLACE PUMP if such contact noted (even if pump bushings within service limit).

►*REPLACEMENT PARTS CAUTION: See "Changes, Cautions, Corrections" for production changes and revised design parts which must be used together.*

Assembly—Install pump driven gear into pump body, positioning gears as marked on disassembly. Install drive gear into position as marked. Install pump cover (see Pump Change Caution Note below), install cover screws with lockwashers, tighten screws evenly to 80-90 **In. lbs.** (¼" type), 25-35 **In.lbs.** (#10-24 type). Check pump for free movement after assembly completed.

►**Pump Change Caution**—Two different types of interchangeable pumps used (aluminum & cast iron) and **correct type cover must be used with each type pump** as follows: Phosphate coated cover (Aluminum Pump), Plain cover (Cast Iron Pump).

Pressure Regulator Body Disassembly: Remove valves from regulator body. Take out cover attaching screws, remove cover, remove separator plate.

Inspection—Inspect regulator body and cover mating surfaces. Check fluid passages in body and fluid passage holes in separator plate for obstructions. Inspect valves and valve bores for scoring and check freedom of valves in valve bores. Check regulator valve springs for distortion. Wash thoroughly in clean solvent and blow dry with air.

Assembly—Position separator plate on regulator body, install regulator cover and attaching screws, tighten screws evenly to 20-30 **In.lbs.** Insert valves.

►*CAUTION*—If regulator valve disassembled to correct "buzzing" noise, inspect main oil pressure regulator valve assembly for undersize bleed flats and install valve in a position rotated 90° from original position which should correct this condition.

Control Valve Disassembly: Remove manual valve. Take out one screw attaching separator plate to valve body. Remove upper body front plate. (NOTE —Plate is spring loaded, apply pressure to plate while removing attaching screws). Remove compensator sleeve, plug, compensator spring, compensator valve, modulator valve spring and valve, downshift valve and spring. Take out two screws

CONTINUED ON NEXT PAGE

FORDOMATIC & MERCOMATIC (Continued)

attaching throttle valve return spring to upper body, remove the spring. Take out remaining screw attaching upper valve body rear plate and remove the plate *(CAUTION—*Plate is spring loaded—apply pressure to plate while removing screws). Remove 3-2 control valve and spring, low inhibitor valve and spring, and governor plug. Remove the end body. *(CAUTION—*End body is spring loaded—apply pressure while removing screws.) Remove low regulator plug and shift valve plug from end body, then remove end body plate. Remove shift valve outer and inner springs and shift valve, low regulator valve, and transition valve. Remove attaching bolts and separate valve bodies. Remove cover end body. Remove front servo apply regulator valve from cover. Remove separator plate from upper body. Remove check valve seat.

Inspection: *CAUTION—Handle all parts carefully to avoid scoring, burrs, and distortion.* Clean all parts thoroughly in clean solvent and blow dry with air. DO NOT USE CLOTH FOR WIPING PARTS (lint left by a cloth may cause poor valve operation). Inspect all mating surfaces for burrs, scratches, and flatness. Check all passages for obstructions. Inspect all valves and valve bores for scoring and check valves for free movement in bores (valves should slide in bore of own weight). Valves can be polished with crocus cloth.

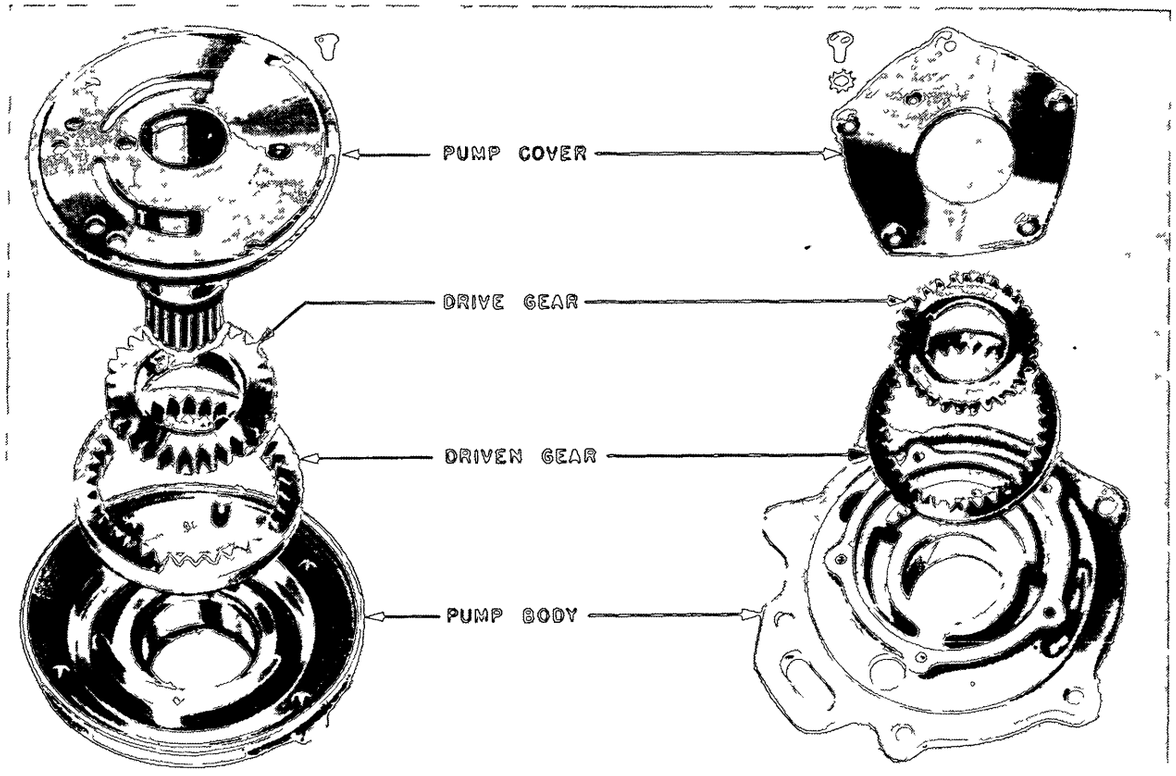
▷*CAUTION—Do not round the sharp edges of valves and plugs.*

▷*REPLACEMENT PARTS CAUTION: See "Changes, Cautions, Corrections" for production changes and revised design parts which must be used together.*

Assembly: *CAUTION—Use care when installing valves and plugs in their bores not to shear soft body castings* (rotate valves and plugs as they are entered so that sharp edges will not be damaged or cut into the valve body castings). Install the separator plate on upper valve body, install but do not tighten separator plate screws. Install check valve seat in lower valve body, install front servo apply regulator valve in cover and plug in cover end body. Install cover end body on cover but do not tighten attaching screws. Position lower body on upper body, install lower body cover and attaching bolts. Tighten the bolts evenly to 4-6 ft. lbs. torque, tighten separator plate screws to 20-30 in. lbs. torque. *(CAUTION—*excessive tightening of these bolts may distort valve body and cause valves and plugs to stick). Tighten cover and body screws to 20-30 in. lbs. torque. Check for free movement of front servo apply regulator valve by shaking valve body. Install plate on lower end body and make certain that countersunk head screw installed in correct hole. Install low regulator and shift valve plugs in end body. Install transition valve, low regulator valve, and shift valve in lower body. Install shift valve inner and outer springs. Install end body on lower body, install governor plug in lower body. Install low inhibitor valve spring and valve, 3-2 control valve spring and valve, then install lower body side plate. Install modulator plug in upper body, install throttle valve, position upper body rear plate on upper body with plate between end lands of throttle valve, install one screw in hole next to throttle valve, position throttle valve return spring on plate and install remaining plate-to-valve body screws. Install compensator valve and spring, downshift spring and valve, and modulator valve and spring. Install plug in compensator valve sleeve (castellated end out) and install assembly in body. Install upper body front plate, install separator plate-to-lower body screw, install manual valve.

Governor Disassembly: Remove governor body side plate attaching screws, remove plate. Remove governor body attaching screws and remove body from counterweight. Remove governor valve from body.

Inspection—Inspect valve and valve bore for scores and check free movement of valve in bore Inspect all fluid passages for obstructions. Inspect mating surfaces for burrs and distortion.



Assembly—Install governor valve in bore of governor body and install body cover plate and attaching screws. Mount governor body on counterweight. (NOTE—Make sure fluid passages in body line up with passages in counterweight). Install body attaching screws. Tighten body-to-counterweight screws to 50-60 In.lbs. and valve body cover screws to 20-30 In.lbs.

Front Servo Disassembly: Remove servo piston guide snap ring. *(CAUTION—*Servo piston is spring loaded, apply pressure to piston when removing snap ring). Remove servo piston and guide from servo body. (NOTE—If necessary, tap servo piston guide slightly with soft hammer to remove from servo body). Remove servo spring, servo guide and seal rings from piston and guide.

Inspection—Inspect servo body for cracks. Inspect piston and piston bore for scores. Check fluid passages for obstructions. Check actuating lever for free movement and inspect for wear. (NOTE—If necessary to replace actuating lever or shaft, remove retaining pin and push shaft out of bracket). Inspect threads in lever and on adjusting screw. Check servo spring and servo band for distortion. Inspect servo band lining for excessive wear and bond to metal band. (NOTE—Band should be replaced if worn to a point where grooves are not evident). Inspect bands for cracks and distortion.

Assembly—Install servo spring in body. Install new, large and small seal rings on servo piston and new seal rings on servo guide. Install guide on servo piston. *(CAUTION—*Use care not to distort seals). Install piston and guide assembly into piston body. (NOTE—Lubricate parts to facilitate assembly). Install adjusting screw and locknut in actuating lever if previously removed. Press cover down and then install snap ring. *(CAUTION—*Make sure snap ring is fully seated in groove).

CONTINUED ON NEXT PAGE

FORDOMATIC & MERCOMATIC HYDRAULIC PUMPS

FORDOMATIC & MERCOMATIC (Continu d)

Rear Servo Disassembly: Using ⅛" pin punch, remove servo actuating lever shaft retaining pin and remove shaft and actuating lever. While pressing down on servo spring retainer, remove snap ring. NOTE—Release pressure on retainer slowly, to avoid snap ring from flying out. Remove retainer and servo spring. Use air pressure to force piston out of servo body. *(CAUTION*—Hold hand over piston to prevent damage). Remove piston seal ring.

Inspection—See "Front Servo Inspection."

Assembly—Install new seal ring on servo piston and install piston into servo body. (NOTE—Lubricate parts to facilitate assembly). Install servo spring with small coiled end against servo piston. Install spring retainer and compress spring and install snap ring. *(CAUTION*—Make sure snap ring is fully seated in groove). Install actuating lever with socket in lever bearing on piston stem and install lever shaft, aligning the retainer pin holes, and install pin. Check actuating lever for free movement.

Distributor Sleeve Inspection—Inspect all passages for obstructions. Inspect sleeve bore for scores or excessive ring wear. Inspect mating surfaces for burrs and flatness. Check fit of fluid tubes. NOTE—Make sure spacer is on center tube.

Pinion Carrier Inspection—Inspect servo band surface for scores. Inspect inner bushing for scores. Check free movement of pinions on pins and inspect for worn or broken teeth. Check pinion end play. Should be .010 to .020". Pinion pins should be a tight fit in carrier. NOTE—The planet carrier is serviced as an assembly.

Output Shaft Inspection—Inspect external parking gear teeth for damage. Inspect ring grooves and splines for burrs and wear. Inspect all thrust surfaces, journals, and inner bushing for wear or scores. Inspect aluminum sleeve for leakage or scores and for correct position in shaft *(NOTE*—On later transmissions, sleeve is staked in place in shaft to eliminate possibility of it rotating out of position). Inspect ring grooves, keyway, and drive ball pocket for wear and burrs. Wear limit for bushing inside diameter is: 1.500-1.505".

NOTE—Output shaft is two-piece assembly but is serviced as a unit.

Extension Housing Inspection—Inspect housing for cracks and inspect drive shaft slip yoke bearing surface for scores. Inspect gasket surfaces for burrs. To remove rear seal, use Tool 1175-AE *(NOTE*—Rear seal may be replaced without removing the transmission from car). Use Tool 7657 to install new seal in extension housing, coating outer diameter of seal with Permatex No. 3 (to prevent fluid seepage around seal), and positioning seal with felt side to rear. Remove inspection cover and gasket and inspect fluid baffle for tight fit in housing.

►**Extension Housing Change Note**—Two optional types of extension housings used: 1P-7650-A (aluminum) and 1P-7650-B (cast iron). Later type cast iron housing requires bushing No. 8M-7041-B (same as type used in standard transmission). Bushing wear limit (inside diameter) is 1.4995-1.5045".

Transmission Case Linkage Disassembly: Remove throttle lever nut and take off inner and outer throttle levers. Remove throttle lever shaft seal from counterbore in manual lever shaft. Remove parking mechanism actuating rod, detent ball and spring. Remove manual lever shaft nut, detent and outer manual lever and shaft. Remove torsion lever retainer clip and take off torsion lever assembly. Disassemble torsion lever assembly by rotating lever while holding spring. Disengage pawl return spring from toggle link pin and remove pin. Remove pawl pin by working pawl fore and aft until pin protrudes from case. Remove toggle pin retainer clip, toggle pin, pawl return spring, spring retainer and link. Remove toggle lever pin by tapping lever toward rear of case, then remove plug, toggle lever pin and lever (NOTE—toggle lever pin is held in place by the plug). Remove manual shaft seal and transmission vent from case.

Inspection—Inspect each part of parking mechanism for wear, distortion, or other damage.

Assembly—Assemble toggle lever, link, pawl return spring and pawl and install assembly in transmission case. Install toggle lever and pawl pins. Install torsion lever assembly. (NOTE—Use screwdriver to position spring on torsion lever). Install washer and retainer clip. Coat outer diameter of new manual shaft seal with Permatex #3 and use Tool 77288 to install seal in case. Install manual lever and shaft in case, mount detent lever and tighten attaching nut to 35-40 ft. lbs. torque. Install detent spring and ball *(NOTE*—use a piece of thin tubing to depress ball and spring while rotating detent). Position ends of parking pawl torsion lever rod in detent lever and torsion lever and secure with cotter pins. Install new seal on throttle lever shaft, install outer throttle lever and shaft in case, install lever on inner end of shaft and tighten attaching nut to 17-20 ft.lbs. torque. Check linkage for free operation without binding.

Transmission Case Inspection: Inspect case for cracks and stripped threads. Inspect all gaskets and mating surfaces for burrs. Inspect all bearing surfaces for wear, scores, and burrs. Wear limit for bushing inside diameters are: Front Bushing 1.375-1.379", Center Support Assy. Bushing 3.1795-3.184".

►*REPLACEMENT CASE & OIL PAN CAUTION: See "Changes, Cautions, Corrections" for 1953 type parts and necessary cautions when these parts used on earlier transmissions.*

REASSEMBLY—TRANSMISSION (AFTER OVERHAUL OF UNITS)

►*REASSEMBLY CAUTION—Use Automatic Transmission Fluid Type A only to lubricate parts on assembly. DO NOT use any other lubricants. Use all new gaskets on assembly and tighten all bolts and screws to correct torque specifications. DO NOT USE FORCE WHEN ASSEMBLING PARTS. If parts do not assemble freely, examine parts for cause of difficulty.*

Clutch & Shaft Assembly and Front Servo Band: Install front servo band in transmission case indexing anchor end with index in case. Insert front and rear clutch assembly into transmission case from the rear while positioning servo band on drum. *(CAUTION*—Hold units together while making installation). Install center support into case, aligning the support with the mounting bolt holes in right and left side of case, install special support bolts and lockwashers from outside of case *(CAUTION*—rolled edge of lockwashers must be toward case to insure a tight seal). Tighten bolts evenly to 20-25 ft.lbs. torque.

Rear Servo Band: Position rear servo band in case, according to indicating mark made at disassembly, with strut ends up. Install bronze thrust washer behind primary sun gear.

Pinion Carrier: While meshing planet pinions on sun gears, position rear band over carrier drum. Install two seal rings on sun gear shaft and check for free movement. Install selective thrust washer (see note) on rear of pinion (hold in place with fluid).

►**Thrust Washer Note**—This selective thrust washer controls endplay (.010-.029") and should be selected during transmission disassembly (see step 10 of "Disassembly of Transmission into Major Units."

Output Shaft: Install output shaft, carefully meshing internal gears with pinions. *(CAUTION*—Position seal rings on primary shaft with gaps up to prevent breakage during installation of output shaft).

Rear Pump: Install four rings into distributor sleeve and check ring gap. Position rear pump drive key in keyway on output shaft. Position new front and rear gaskets on pump body. Install thrust washer on pump body with bronze side up. Make sure to index thrust washer tangs with bosses on pump body (see Pump & Thrust Washer Change Caution below). Install rear pump (CAUTION—use care to index drive key with keyway in pump drive gear).

►**Pump & Thrust Washer Change Caution**—Two types of pumps used which require **different thrust washers.** Thrust washer used with first type aluminum pump has four sets of lugs on outer diameter which engage four lugs on pump cover, thrust washer for second type cast iron pump has two lugs on outer diameter which engages recesses in cover.

►*CAUTION—Correct type thrust washer must be used with each type pump cover.*

Governor: Position governor drive ball in pocket in output shaft. Retain in place with fluid. Install governor assembly, indexing groove with ball in output shaft. (NOTE—Governor installed with body plate toward front of transmission). Install snap ring.

Distributor: Install rings in grooves of output shaft and make certain rings rotate freely. Install distributor sleeve on output shaft with chamfer forward. Install distributor and tubes on distributor sleeve *(CAUTION*—make certain that fluid passages in sleeve and distributor are aligned). Install attaching bolts and lockwashers and tighten finger-tight. Insert distributor tubes into transmission case until spacer on center tube is against case, then tighten distributor attaching bolts to 8-10 ft. lbs. torque.

Extension Housing: Place speedometer drive gear ball in pocket of output shaft, install speedometer drive gear with chamfered side toward front of transmission, install snap ring to retain gear. Position Extension Housing Oil Seal Replacer & Pilot Tool 7657 in extension housing, then install housing on transmission. Install attaching bolts and external-tooth lockwashers *(CAUTION*—lockwashers must be installed with rolled edge toward case to insure a tight seal), tighten bolts finger-tight. Install new seal ring on rear pump discharge tube and install tube using Tool 77869 *(CAUTION*—make certain tube is correctly positioned and below upper surface of transmission case). Tighten extension housing

CONTINUED ON NEXT PAGE

FORDOMATIC & MERCOMATIC (Continued)

attaching bolts evenly to 28-33 ft.lbs. torque. Install governor inspection cover on housing using a new gasket, tighten cover screws to 50-60 In.lbs.

Front Pump: Install new front pump gasket into counterbore in transmission case and install front pump. Line up dowel hole in pump with dowel in case. Install three pump attaching bolts and lockwashers (do not install fourth bolt until endplay has been checked as directed below), tighten bolts evenly to 17-22 ft. lbs. *Check Transmission Endplay before proceeding with assembly.*

Transmission Endplay Check & Adjustment: Mount extension tool 1P-77067 and dial indicator on front pump (use hole from which pump attaching bolt omitted for this purpose) with dial indicator resting on end of turbine shaft. Insert tool 1P-7657 in end of transmission extension housing. Use large screwdriver to pry front clutch drum toward rear of transmission, set dial indicator at zero. Remove screwdriver and pry units toward front of transmission (insert screwdriver between large internal gear and transmission case). Indicator reading will be the endplay and should be .010-.029". If reading within these limits, proceed with reassembly. If endplay not within limits, it will be necessary to change selective thrust washer on rear of planetary pinion (see Pinion Carrier assembly above). Remove checking tools, install remaining front pump attaching bolt and tighten to 17-22 ft. lbs.

Front Servo: Position front band forward in case with band ends up. Position servo strut with slotted end indexing with servo actuating lever and small end indexing with band end. Rotate band, strut and servo into position engaging anchor end of band with anchor pin in case. Locate servo on dowel in case and install attaching bolt. (NOTE—tighten bolt only two or three threads). Install servo tubes.

Rear Servo: Position servo anchor strut and rotate rear band to engage strut. Hold in position with fingers. Position servo actuating lever strut and install servo, tighten bolts to 40-45 ft. lbs.

Pressure Regulator Body: Install pressure regulator body and attaching bolts. Tighten to 17-22 ft.lbs. Install control and converter pressure regulator valves in valve body. Install control and converter valve springs, retainer and retainer attaching nut and lockwasher, tighten nut to 40-50 In.lbs. Install new seal ring on rear pump intake tube and install tube in case.

Control Valve: Install control valve assembly using care to index servo tubes with control valve (see Control Valve Body Change note below), also index inner throttle lever between throttle lever stop and downshift valve—and at the same time push throttle valve in to clear transmission case. *(CAUTION*—Make sure manual valve indexes with actuating pin in manual detent lever). Install large tube into valve body and regulator. Install control pressure compensator tube and lubrication tube. Install control valve body attaching bolts. Tighten to 8-10 ft.lbs. Tighten front servo attaching bolts to 30-35 ft. lbs. torque. Adjust both bands. *See BAND ADJUSTMENT.*

▷Control Valve Body Note—See "Control Valve Body Production Change & Replacement Caution" for instructions on reworking Front Servo Release Tube required when installing later type 1P-77700-C Control Body to replace first type No. 1P-77700-A.

Fluid Screen and Pan: Position fluid screen over inlet tubes of front and rear pumps. Mount pan on transmission case using a new gasket and tightening attaching bolts to 10-13 ft.lbs. NOTE—1953 type oil pan does not have drain plug (transmission is drained by disconnecting oil filler tube from oil pan connection). This opening must be closed by plug when pan used on earlier transmission without under-hood filler tube, and drain plug on earlier type oil pan should be tightened to 20-25 ft.lbs.

INSTALLATION IN CAR

▷*INSTALLATION CAUTION:* Rotate converter until flex driving plate bolt holes are horizontal, wedge converter in place so that it will not slip out during installation. Clean out all dirt, grease, and burrs from pilot bore in crankshaft, lubricate converter pilot bearing surface with heavy film of special lubricant M-4648-A.

▷*CAUTION*—Excess lubricant or foreign material in pilot bore may force converter assembly back so that converter hub presses against front pump drive gear causing damage to front pump.

1) Mount transmission and converter assembly on a lift, under the car, raise assembly and carefully move it forward into position *(CAUTION*—guide assembly to avoid damage to flexible drive plate and converter pilot).

2) Install four lower converter housing bolts, tighten evenly to 40-45 ft. lbs. torque.

3) Check converter endplay to make certain that pilot is free in bore by moving converter back and forth before flexible drive plate is bolted to converter. This endplay should be 1/32" minimum.

4) Raise the engine and replace the cross-member, tighten cross-member attaching bolts to 25-32 ft.lbs. Tighten rear support-to-crossmember bolts to 40-45 ft.lbs., then lower engine and transmission onto rear support and tighten support-to-transmission case bolts to 20-25 ft.lbs. Remove engine support bar.

5) Position the flex drive plate correctly for each model (see Notes below), install flex plate attaching bolts, tighten bolts evenly to 25-28 ft.lbs. torque.

▷*FLEX DRIVE PLATE POSITIONING CAUTION*—Plate must be correctly positioned on converter cover to maintain balance and avoid interference with ring gear welds on cover. Position plate so that center bolt hole at end of plate is lined up with following bolt hole on cover:

Ford 6 Cyl. (First 34-Bolt Converter Cover)—Center hole at either end of plate exactly 10 bolt holes in either direction from bolt hole in line with drain plug on converter cover (sides of plate will be approximately parallel to ring gear retainers on cover).

Ford 6 Cyl. (Later 18-bolt Converter Cover)—Same as first type except center hole at end of plate should be 6 bolt holes from bolt hole in line with drain plug.

Ford V8 & Mercury (First 34-Bolt Converter Cover)—Center bolt hole at either end of plate exactly 6 bolt holes in either direction from bolt hole in line with drain plug on converter cover.

Ford V8 & Mercury (Later 18-Bolt Converter Cover)—Center bolt hole at either end of Plate exactly 3 bolt holes from bolt hole adjacent to drain plug on cover (drain plugs are midway between two bolt holes).

6) Coat universal joint knuckle with transmission fluid, install driveshaft assembly.

7) Install parking brake assembly, connect speedometer cable.

8) Connect manual and throttle linkage rods to transmission levers.

9) Install converter housing lower plates and tighten bolts to 10-15 ft.lbs. Install starter and tighten attaching bolts to 15-20 ft.lbs.

10) Install remaining converter housing to engine bolts and tighten evenly to 40-45 ft. lbs. torque (install two upper bolts through access holes in front compartment and close these holes with the rubber plugs).

11) Connect filler tube at oil pan connection, fill transmission and check for leaks. Adjust linkage. Recheck fluid level after transmission reaches normal operating temperature.

TRANSMISSION (Converter in Car): Install two guide pins, ST-0711, into top transmission-to-converter housing attaching bolt holes. Mount transmission on lift and position under car. Rotate engine to position front pump drive lugs, on converter pump housing in a vertical position. Rotate transmission front pump to position slots in pump drive gear in a vertical position. Apply lubriplate to seal surface on converter pump cover hub and raise transmission and move towards front of car. *(CAUTION*—Use care to index turbine shaft splines with splines in turbine hub, and lugs on converter pump with slots in front pump drive gear). Install two lower transmission to converter housing attaching bolts, then remove guide pins and install two upper bolts, tighten all four bolts to 40-45 ft. lbs.

REMAINDER OF INSTALLATION PROCEDURE IS SAME AS FOR "TRANSMISSION & CONVERTER ASSEMBLY above beginning with step (6).

1954-55 FORDOMATIC, MERCOMATIC & TURBO-DRIVE

Ford Pass. Cars, All Models (1954-55)
Ford Thunderbird (1955)
Ford Trucks F-100, F-250, F-350, P-350 (1954-55)
Lincoln, All Models (1955)
Mercury, All Models (1954-55)

►CHANGES, CAUTIONS, CORRECTIONS

►*TRANSMISSION IDENTIFICATION NOTE:* Transmission Model No. and Serial No. on name plate on left side of transmission case must be used to identify individual units for parts replacement etc.

►*STARTING ENGINE BY TOWING OR PUSHING CAR:* Pushing is recommended. Place selector lever in Neutral "N" position. When car reaches 20 MPH speed, turn on ignition, move selector lever to "LO", depress accelerator pedal to half throttle position until engine begins to run. *NOTE–On ice or snow where traction not good, move selector lever to "DR" position to crank engine.*

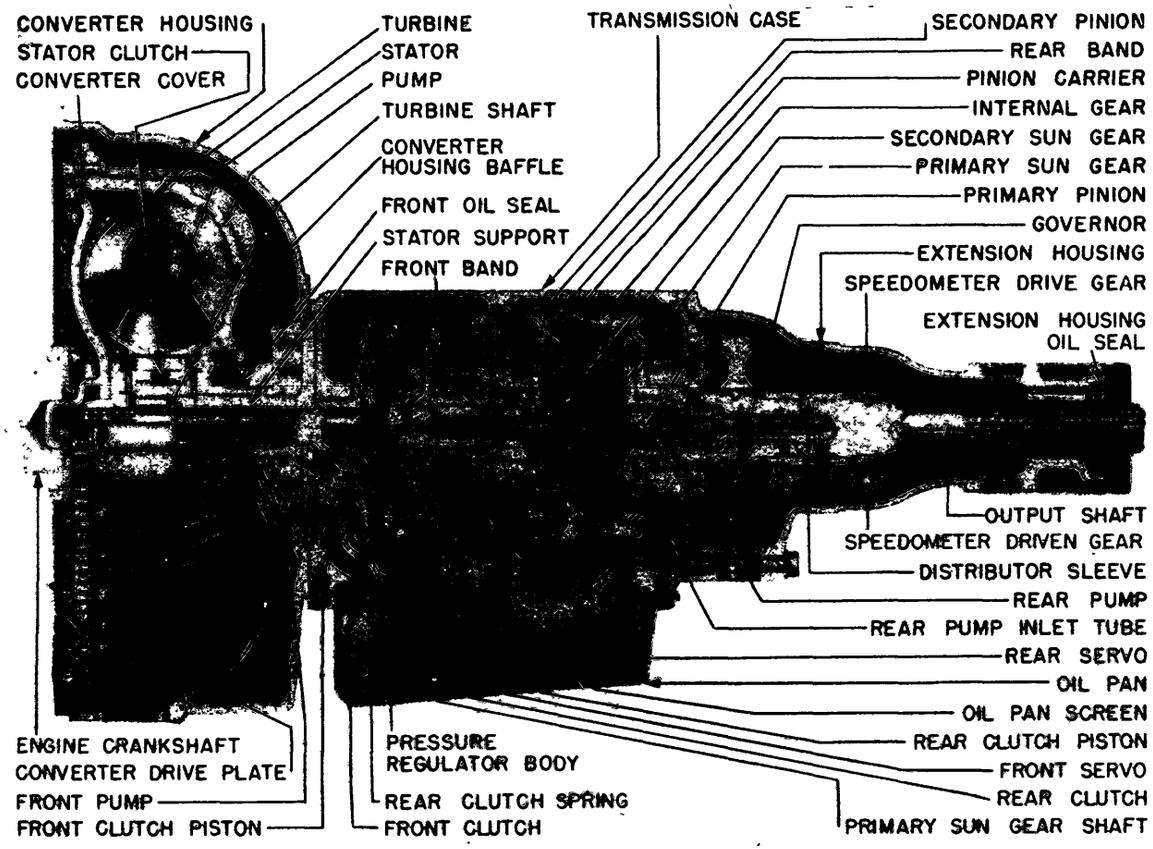
►*TOWING CAR CAUTIONS: Do not tow at speed greater than 40 MPH and observe following precautions:*
If Transmission Operating Properly–Place selector lever in Neutral "N" position. Car can be towed normally for distances not to exceed 12 miles. **For greater distances, use same procedure as for inoperative transmission.**
If Transmission Inoperative–Tow car with rear wheels lifted off road, or disconnect and remove propeller shaft and protect rear end of transmission from entry of dirt (U-joint Knuckle, Part No. 1M-4841 can be installed and wired in place for this purpose).

►*TRANSMISSION "BUZZING" SOUND:* May be caused by undersize or worn bleed flats on Main Oil Pressure Regulator Valve Assembly. Correct by rotating the valve 90° in its bore. *See "Minor Repairs (Transmission in Car)" for disassembly directions.*

►*1954 FORDOMATIC PRODUCTION CHANGE (PARTIAL PRODUCTION) & PARTS INTERCHANGEABILITY CAUTION:* Special transmission assemblies were installed in some production cars manufactured at the Dearborn Plant starting in August 1954. These assemblies are identified by the Model No. IP-7003-T and Serial No. Prefix 23D. A black stripe, 1" wide, located 4¾" from end of extension housing shield also identifies the assembly. The following parts are NOT INTERCHANGEABLE with parts in the regular production transmission: Primary Sun Gear Assembly (B5A-77530-C); Planet Assembly (B5A-77162-C); Output Shaft Thrust Washer (B5A-77067-E,F,G,H); Output Shaft Assembly (B5A-77059-C); Drum & Secondary Sun Gear Assembly (B5A-77502-A).

►*1954 FORDOMATIC WHISTLING NOISE CORRECTION:* This whistling noise may be noticed during normal operation and can be corrected as follows: Inspect converter housing casting for metal flash at junction of inner surface of housing with exhaust air passage. Grind metal flash from casting until surface is smooth. Check diameter of front opening on casting against specified diameter of 15.13". If diameter is less, grind front of opening adjacent to lower cover plate and air inlet on right side, smoothly to specified diameter. Check lower left inspection cover retaining bolt hole. In some cases this hole has been drilled completely through the housing where it should actually be a blind hole. Correct by replacing the ½" long screw with a 1" long screw. In some cases it may be necessary to run a 5/16" tap through to clean the threads.

►*1954 FORDOMATIC INDICATOR DIAL BREAKAGE CORRECTION:* This breakage may be due to a binding condition between selector lever tang and plastic indicator dial. Correct by grinding approximately 1/16" off tang at point on corner of tang nearest pivot pin. Length of grind should be approximately halfway between lower edge of tang and shift lever. Check for clearance between tang and indicator dial.



►*1954 FORDOMATIC BINDING OR STICKING IN "PARK" POSITION CORRECTION:* Check for a burr or step in the park detent of manual control detent lever assembly (located inside transmission). To correct, remove detent lever from transmission and grind or hone burr or step from lever *(CAUTION–Lever is case hardened to a depth of .008-.012" and care must be taken when grinding or honing).* Check the surface finish of the parking pawl and if found to be rough, grind or hone to a smooth finish.

►*1955 FORDOMATIC LOW SPEED (UNDER 28 MPH) LOW & HIGH "LOCK-UP" CORRECTION:* May be caused by improper torquing of control valve body bolts. *See "Control Valv " in Transmission Overhaul.*

►*1955 F-100 TRUCK FORDOMATIC OIL COOLER PRODUCTION CHANGE:* The oil cooler assembly and attaching parts have been discontinued on later 1955 production trucks. A by-pass tube is being used in place of the oil cooler.

►*1955 FORDOMATIC MAIN CONTROL ASSEMBLY PRODUCTION CHANGE-EXC. POLICE INTERCEPTOR & SPECIAL 8 CYL. CARS–(To eliminate "slipping" or "long servo fill-up time" in manual shift from Drive or Neutral to Low):* A new Main Control Assembly, Part No. B5A-77700-E, incorporating a new transition valve spring, replaced the early assembly, Part No. B5A-77700-C. *NOTE*–Control Assembly, Part No. B5A-77700-C will continue to be used on the Police Interceptor and the Special V8, and for identification

CONTINUED ON NEXT PAGE

FORDOMATIC, MERCOMATIC, & TURBO-DRIVE (SECTIONAL VIEW)

FORDOMATIC, MERCOMATIC & TURBO-DRIVE (C nt.)

purposes, the part number will be changed to B5A-77700-D, with the letter "M" stamped on the lower valve body cover

►*1955 FORDOMATIC "SLIPPING" IN MANUAL SHIFT FROM "N" OR "D" TO "LOW" CORRECTION (EXCEPT POLICE INTERCEPTOR & SPECIAL V8)*· On cars and trucks having the early type Main Control Assembly Production Change above), a new transition valve spring, Part No B5A-77741-A has been released for service replacement (this spring is incorporated in later type main control assembly, Part No B5A-77700-E) If changing the main control assembly or installing the later type transition valve spring does not correct the "slipping" condition, check the main pressure regulator spring free length of 4 08", and spring shut length of 1 84" with a 20 75 to 21 75 pound load

►*1955 FRONT CLUTCH ASSEMBLY PRODUCTION CHANGE (ALL TRANSMISSIONS)* To prevent gear noise or clutch "roll over" during manual shift from "D" to "N" Front Clutch Plate (Bronze) Part No B5A-77519-A is used to replace two of the original four bronze plates Install one later type plate, identified by additional grooves on both sides, next to clutch pressure plate and the other installed on top of the balance of plates These later type plates can be used to correct the above condition in early 1955 transmissions

►*1955 FORDOMATIC SELECTOR LEVER INDICATOR VISIBILITY IMPROVEMENT* Cover front edge and both sides of indicator with red reflective tape Align indicator in "LO" range, adjusting position of indicator as necessary to provide clearance between it and the dial

►*1955 MERCOMATIC & TURBO-DRIVE BAND OR CLUTCH FAILURE CORRECTION (When caused by improper control valve assembly operation)* Thoroughly clean and inspect control valve assembly making sure that all passages and orifices are clean and free of foreign material Check length of Shift Valve which should be 3 3/16" long Check Transition Valve and be sure that hole in valve is deep enough to accomodate entire spring when compressed *See "Trouble Shooting" for other possible causes*

►*1955 MERCOMATIC THROTTLE LINKAGE ADJUSTMENT CHANGE (To improve the 2-3 upshift in the 20-30 MPH range)*· The Mercomatic Throttle Linkage has been changed and is recommended for all 1955 cars, superseding the previous specifications *See "Throttle Linkag Adjustment" below*

►*1955 MERCOMATIC & TURBO-DRIVE PRESSURE REGULATOR VALVE SPRING SEAT & SPACER INSTALLATION CAUTION* It is extremely important that the spring seat and spacer be installed so that the cupped end fits over the end of the control pressure valve, and the stem fits down through the control pressure spring Two types of spacers are used in production, one having the small diameter end closed, and the other with the end open Install either spacer as indicated above

►*1955 MERCOMATIC & TURBO-DRIVE ROUGH 3-2 DOWN SHIFT AT CLOSED THROTTLE CORRECTION & PRODUCTION CHANGE*· A lighter Shift Valve Outer Spring, Part No B5A-77721(Mercury), B5A-77721-A (Lincoln) is used in production and for service replacement The new spring is identified by a wire thickness of 042" (earlier spring had a wire thickness of 049").

►*1955 MERCOMATIC & TURBO-DRIVE MAIN CONTROL ASSEMBLY PRODUCTION CHANGE & SERVICE REPLACEMENT NOTE (To eliminate slip in manual shift from "Drive" to "Low")*: A new Main Control Assembly, Part No. B5A-77700-F which has a new Transition Valve Spring, Part No. B5A-77741-A is used in production and for service replacement on early 1955 transmissions. The later type Transition Valve Spring can also be used to service early 1955 Main Control Assemblies to eliminate complaints of this slipping condition.

►*1955 MERCOMATIC TRANSMISSION THROTTLE CONTROL INNER LEVER PRODUCTION CHANGE & SERVICE REPLACEMENT NOTE (To eliminate excessive endplay)* Throttle Control Inner Lever, Part No. B5A-77283-A, identified by the letter "0" stamped on lever is used in production and can be used for service replacement on 1954-55 transmissions. When installing the later type lever, the letter "0" must be installed toward inside of transmission.

DESCRIPTION

Fordomatic, Mercomatic, & Turbo-Drive Automatic Transmissions consist of a hydraulic torque converter and an automatic transmission which provides automatic operation in "DR" range, and additional "LO", "R", & "P" ranges which are controlled manually

Torque Converter: Mounted in a housing and connected to rear end of crankshaft in place of the conventional flywheel, and consists of the Torque Units listed below Torque converter is fully automatic in its operation, acting as torque converter for low speed and starting operations (when input torque is less than output torque), and as a fluid coupling at higher car speeds (when input and output torque are equal) The change from torque converter to fluid coupling and the operating phases of the torque converter unit is governed by the car operating conditions and do not occur together or at any particular time

Pump (Driving Member)—Mounted on engine crankshaft and bolted to converter cover Pump rotates at engine speed to transmit engine power to turbine through the medium of converter oil

Turbine (Driven Member)—Splined to output shaft forward of converter pump and driven by oil flow from converter pump Turbine transmits power to the planetary gears (Low, Intermediate & Reverse) and to the propeller shaft (Driving Range).

Stator—Consists of reaction blades and a one way clutch mounted on the converter cover hub. The stator redirects the fluid flow to turbine, increasing torque for low and starting speeds (when input torque is less than output torque) being held from rotating in a direction opposite to pump and turbine by the one way clutch . At higher speeds (when input torque equals output torque) the Stator rotates in the same direction and at the same speed as the pump and turbine causing the torque converter to automatically become a fluid coupling

Planetary Transmission: Hydraulically controlled planetary transmission employs a gearset of the compound type consisting of long and short pinions, two sun gears and a single internal gear, providing three forward speeds and one reverse. Controlling bands, multiple disc clutches and servo mechanisms are within the transmission case.

Planetary Pinion Assembly—Consists of three Primary Pinions (short) and three Secondary Pinions (long) mounted in a pinion carrier The Primary Pinion is driven by the Primary Sun Gear and drives the Secondary Pinion which is meshed with the Secondary Sun Gear and the Internal Gear The pinion carrier is controlled by the Rear Servo and the Rear Band

Primary Sun Gear—Integral with Primary Sun Gear shaft which is splined to the driven flange of the Front Clutch unit Power is transmitted through this gear to the Pinion assembly (Low & Intermediate Range)

Secondary Sun Gear—Located forward of the Primary Sun Gear and in mesh with the Secondary (Long) Pinions Mounting is on a hub connected to the driven flange of the Rear Clutch Power transmitted from the Rear Clutch to Secondary Pinions (Reverse)

Front Clutch—Front (input) member of clutch is integral with Turbine Shaft and is splined to Front Clutch drum The Front Clutch drum is formed so that it is also the inner (input) member of the Rear Clutch. Front Clutch hub (output) is splined to the Primary Sun Gear Shaft The Front Clutch is engaged by a hydraulic piston within the clutch drum and locks the Primary Sun Gear Shaft to the Turbine Shaft Clutch is engaged for all forward speeds and is disengaged by an internal spring for neutral and reverse.

Multiple Rear Clutch—Clutch Drum (output) is integral with the Secondary Sun Gear and is provided with a brake band and operating servo Clutch Hub (input) member is integral with the front clutch drum When clutch is engaged, the Secondary Sun Gear is locked to the Turbine Shaft Clutch engagement is by a hydraulic piston within the unit A coil spring between the hub and the drum provides the release

Front Brake Band and Servo Assembly—Band holds the Secondary Sun Gear stationary when it is applied on the clutch drum by the Servo which consists of a hydraulic piston linked to bank One end of the band is held stationary by a strut and anchor which has an adjusting screw for band adjustment Servo is fluid applied and spring released

Rear Brake Band and Servo Assembly—Band holds planet carrier stationary when it is applied by the rear Servo which consists of a hydraulic piston linked to one end of the brake band The opposite end is held stationary by a strut and anchor

Oil Pumps: Two pumps used to supply oil pressure for hydraulic controls, oil supply for converter and transmission lubrication

Front Pump—Internal-External gear type mounted between the transmission and torque converter and

CONTINUED ON NEXT PAGE

FORDOMATIC, MERCOMATIC & TURBO-DRIVE (C nt.)

driven by the converter pump through a tongue and slot coupling This pump has a large capacity and begins to operate as soon as the engine is started, supplying oil to the torque converter and for transmission lubrication and hydraulic controls

Rear Pump—Internal-External gear type mounted at the rear of transmission and driven by the output shaft Pump operates whenever rear wheels are turning and supplements the front pump volume When car reaches sufficient speed, two ball check valves open and allow the oil from the rear pump to enter the hydraulic system

Hydraulic Controls: Consist of manual and hydraulic valves, controlling the operation of the transmission servos and clutches

Control Pressure Regulator—As pump speed varies, spring loaded valve maintains constant pressure Excess volume is returned to oil pan

Manual Valve—Control pressure is directed to manual control valve for proper distribution to accomplish the performance desired Valve is actuated from the selector lever on the steering column

Throttle Valve—Actuated by the accelerator through linkage Control Pressure is directed to the throttle valve from the Control Pressure Regulator Valve As the accelerator is depressed, moving the Throttle Valve towards the open position modifies the Control Pressure in proportion to the degree of throttle opening

Shift Valve—Automatically changes the speed from Intermediate to High Valve is spring loaded and is controlled by Governor Pressure and Throttle Pressure

Hydraulic Governor—Mounted on output shaft at rear of transmission Rotation of the Governor Valve causes centrifugal force to act on the valve plunger and regulate the pressure in direct proportion to the car speed

Front Servo Apply Regulator Valve—Provides for smooth changes between Intermediate and High speed, by controlling the flow of oil to the Front Servo Valve is controlled by throttle pressure

2-1 Shift Valve (1955 Models)—Provided for starting in "Low" ratio for rapid acceleration, with selector lever in "DR" position. This shift will occur only with car speed below approximately 16 MPH., and with accelerator pedal fully depressed

3-2 Control Valve (1954 Models)—Provided for downshifting from "High" to "Intermediate" on either open or closed throttle.

Downshift Valve (1955 Models)—Operated by accelerator pedal Allows for speed change from "High" to "Intermediate" ratio by depressing the accelerator pedal past its fully open position with car speed above approximately 16 MPH.

OPERATION

Torque converter automatically provides a torque multiplication ranging from 2 1-1 (maximum for starting and acceleration) to 1 0-1 (normal driving range with torque converter acting as a fluid coupling) This torque multiplication is supplemented by the planetary gears when selector lever placed in "DR", "LO", and "R" ranges Transmission operates in each range as follows

Neutral Range—Front and Rear Clutches fully released, and Front and Rear Brake Bands fully released so that gears are free to turn Drive is not transmitted through transmission "N" range is used to start and warm up engine

Drive Range—Car starts in Intermediate Gear (except when accelerator pedal depressed to floor when car will start in Low gear) with a gear ratio of 1.48-1 (1954 Models), 1.467-1 (1955 Ford), 1 46-1 (1955 Mercury & Lincoln), with Front Clutch applied locking the Primary Gear to the Turbine Shaft, and the Front Band applied, holding Secondary Sun Gear stationary. The power flow at this point is from Turbine Shaft through Front Clutch to Primary Pinion, to Secondary Pinion, to Internal Gear, to Output Shaft. As car speed increases (depending on throttle pressure) to a certain point, the Front Band is released and the Rear Clutch is applied, automatically causing transmission to change to direct (1.0-1) drive. The power flow in "High" gear is from the turbine shaft through the Front and Rear Clutches to the Planetary Gears which are locked together and rotate as a unit, causing the Output Shaft to rotate at engine speed.

Low Range—Front Clutch applied, locking the Turbine Shaft to Primary Sun Gear, and the Rear Band applied, holding Pinion Carrier stationary The flow of power is from the Turbine Shaft through the Front Clutch, to Primary Pinions to Secondary Pinions, to Internal Gear and out the Output Shaft at a ratio of 2.44-1 (1954). 2.40-1 (1955).

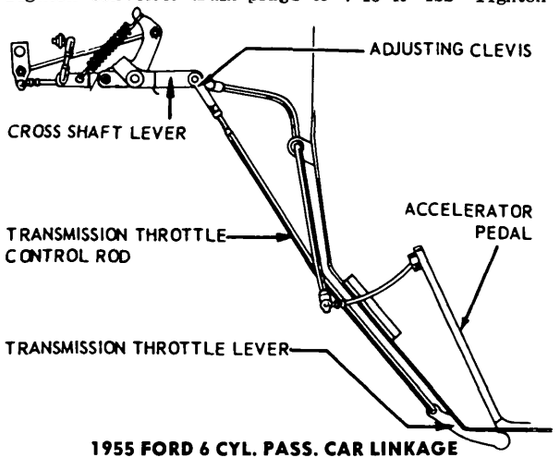
Reverse Range—Rear Clutch applied, locking the Turbine Shaft to Secondary Sun Gear, and the Rear Band applied, holding the Pinion Carrier stationary The flow of power is from the Turbine Shaft through the Rear Clutch, to Secondary Sun Gear, to Secondary Pinions, to Internal Gear The Stationary Pinions acting as idlers on a stationary axis drive the Internal Gear in a reverse direction at a ratio of 2 0-1

LUBRICATION

►*CAUTION Transmission oil level should be checked at 1000 mile intervals and should be changed at 15,000 mile intervals*

Recommended Oil—Automatic Transmission Fluid Type "A" only

Capacity—Approximate capacities are as follows



1954 Ford & Mercury (All Models)—9 qts.
1955 Ford (6 Cyl Pass. Cars & All Trucks)—9 qts.
1955 Ford 8 Cyl Pass. Cars exc those listed below)—9½. qts.
1955 (Ford Thunderbird & Police Interceptor)—10½ qts.
1955 Lincoln (All Models)—10 qts.
1955 Mercury (All Models)—10½ qts.

Checking Fluid Level—Apply hand brake, place selector lever in Neutral "N" position, run engine at idle speed for approximately four minutes, then move selector lever to Park "P" position When engine and transmission have reached normal operating temperature, move selector lever through all positions to assure fluid distribution throughout transmission, return lever to "P" position Raise engine hood, clean all dirt from around filler cap at right rear corner of engine. Check fluid level on dipstick in filler tube *(CAUTION—make certain dipstick pushed all the way down in the filler tube when checking fluid level)* Add fluid as necessary to bring level up to "F" full mark on dipstick

►**Check for Oil Leaks**—Inspect the bottom of the floor pan at the rear of the transmission for evidence of fluid If fluid is found here, the rear extension housing seal is leaking between the two sections of the telescopic shield Replace the seal Check the speedometer cable connection at the transmission and replace the rubber seal if necessary Check the governor inspection plate and install a new gasket if necessary Leaking around the oil pan gasket generally can be stopped by tightening the attaching screws to proper 10-13 ft lbs torque If necessary install a new gasket Check filler tube connection at transmission oil pan If leakage is evident, tighten the connection If leakage is evident at either the throttle lever shaft or manual lever shaft, replace either of the seals Inspect the two hexhead pipe plugs at each side of the transmission case at the front If either plug shows leakage, tighten to 7-15 ft lbs torque Inspect the discharge air duct for evidence of fluid If transmission fluid is found, make certain that converter cover bolt nuts tightened to 15-28 ft lbs (Fordomatic), 25-28 ft lbs (Mercomatic & Turbo-Matic), and drain plugs tightened to 7-10 ft lbs torque.

►*CAUTION Fluid found in the discharge air duct may be engine oil that has leaked past the rear main bearing Be sure to determine which type of leak exists*

Drainage and Refilling—Remove converter housing lower plate and drain converter by removing one drain plug, then rotate the engine 180° and remove the second drain plug Disconnect filler tube from transmission oil pan to drain fluid from transmission Tighten converter drain plugs to 7-10 ft lbs Tighten

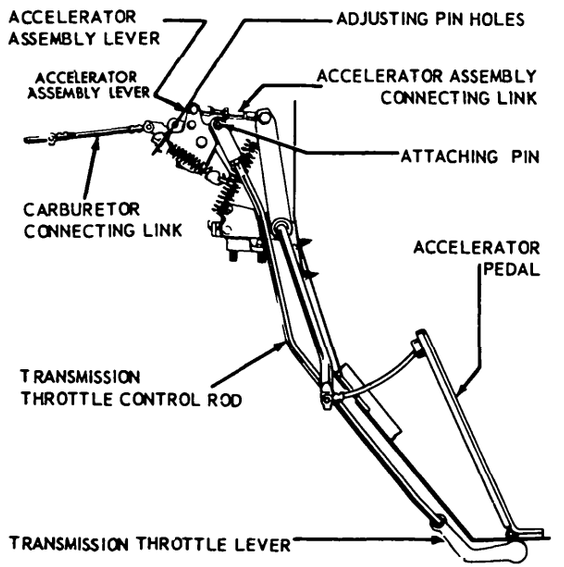
1955 FORD 6 CYL. PASS. CAR LINKAGE

filler tube connection Install 5 quarts of automatic transmission fluid, start engine and allow to idle four minutes Add 4 qts, of fluid and bring transmission to

CONTINUED ON NEXT PAGE

FORDOMATIC, MERCOMATIC & TURBO-DRIVE (C nt.)

to operating temperature. Place selector lever in parking (P) position and check oil level. If level is not up to dip stick level mark, add additional fluid as required.



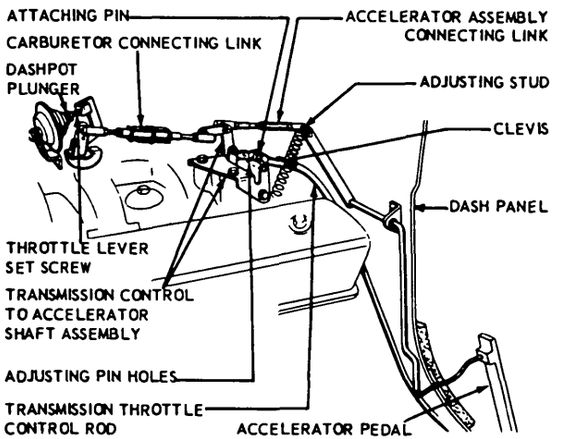
►*CAUTION–Correct fluid level should be determined by dipstick reading rather than actual number of qts. installed.*

LINKAGE ADJUSTMENT

►*FORD THROTTLE LINKAGE ADJUSTMENT CAUTION: Different type linkages used on the various models. See sp cial procedure for each model.*

ANTI-STALL DASHPOT ADJUSTMENT (ALL CARS & TRUCKS): After engine idle speed adjusted and with engine at normal operating temperature and with transmission selector lever in "N" (Neutral) position, loosen dashpot adjusting screw locknut. Hold throttle in closed position and turn dashpot adjusting screw out (counterclockwise) until head of screw pushes dashpot rod up to the end of its travel. Turn dashpot adjusting screw in (clockwise) 1½-2 turns to obtain a clearance of .045-.064" between rod and screw head. Tighten adjusting screw locknut.

►*1955 FORD INTERCEPTOR & SPECIAL 8 CYL. FORDOMATIC CONTROL LINKAGE CHANGE (To improve "kickdown" from "High" to "Intermediate" and from "Intermediate" to "Low"):* New Shaft & Bracket Assembly, Part No. B5A-77230-G; Bellcrank-to-Carburetor Rod, Part No. B5A-9772-C; and Accelerator-to-Transmission Rod, Part No. B5A-9784-G are being used in production and can be used for service replacement on earlier cars. *NOTE–When using these parts on cars b fore May 1955, all the parts listed must be used.*



1955 FORD V8 PASS. CAR LINKAGE

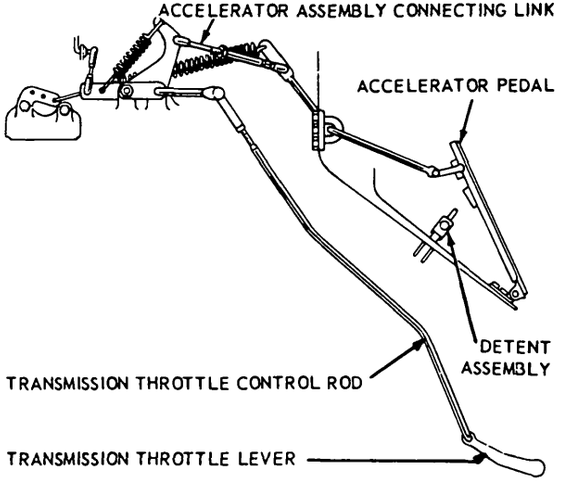
Ford 6 Cyl. Pass. Cars (1954-55) Throttl Linkage: With selector lever in "N" and engine at normal operating temperature, set engine idle speed to 440-460 RPM (1954); 450-475 RPM (1955). Adjust Anti-Stall Dashpot, then turn engine off. Remove clevis pin from upper end of transmission throttle control rod (at cross shaft). Pull upward gently on throttle control rod to hold transmission lever against its internal stop. Rotate rod clevis for free entry of clevis pin into holes in clevis and cross shaft lever. Lengthen control rod by rotating clevis 2½ turns (1954); 3 turns (1955) counter-clockwise. Connect control rod to cross shaft lever. Road test car and if band or clutch slippage is evident, **increase rod length to 3 turns (1954); 3½ turns (1955) of clevis but do not exceed 3½ turns (1954); 4 turns (1955).** Check transmission for kickdown action and if found to be incorrect, disconnect accelerator connecting link from cross shaft lever and adjust pedal height by turning the threaded trunnion on connecting link until top surface of accelerator pedal is 4 5/16" (1954); 4 9/16" (1955) from floor pan.

Ford 8 Cyl. Pass. Car (1954) Throttle Linkage: Adjust engine idle speed to 445-455 RPM with engine at normal operating temperature and transmission selector lever in "N". Adjust Anti-Stall Dashpot, then turn engine off. Position Throttle Lever Adjusting Tool T54L-77230-A on surface of accelerator shaft and bracket assembly (on engine). The upper pin of the tool should enter gauge hole (a hole directly below connecting hole for accelerator link on flat accelerator lever). If pin does not enter hole in lever, loosen the carburetor connecting link barrel lock nut. Rotate barrel until pin enters hole freely (make sure carburetor idle adjustment screw is against its stop). Tighten connecting link barrel locknut and remove adjusting tool. Remove clevis pin from upper end of throttle control rod and accelerator assembly lever, then pull up gently on rod to hold transmission lever against its internal stop. Rotate clevis until clevis pin freely enters holes in clevis and accelerator assembly lever. **Lengthen the throttle control rod by rotating the clevis 2½ turns counter-clockwise.** Assemble throttle control rod to accelerator assembly lever and tighten locknut. Road test car and if clutch or band slippage evident, increase length of throttle rod to 3 turns, but do not exceed 3½ turns. Check transmission for kickdown action and if found to be incorrect, loosen accelerator cross shaft-to-accelerator assembly lever connecting link locknut and rotate barrel as necessary to provide a distance of 3 13/16" from floor pan to center of accelerator pedal rod ball.

Ford 8 Cyl. Pass. Cars (1955), (Except Thunderbird) Throttle Linkage: With selector lever in "N" position and engine at operating temperature, set idle speed to 450-475 RPM (Exc. Interceptor), 475-500 RPM (Interceptor). Adjust Anti-Stall Dashpot, then turn engine off. Disconnect transmission throttle control rod from accelerator assembly lever on engine and insert a locking pin (¼" drill rod) through adjusting holes in lever and assembly. Adjust length of link between assembly and carburetor throttle valve lever to close lever against its stop. Adjust accelerator assembly connecting link (assembly-to-cross shaft link) to obtain a pedal height of 3 11/16" (Exc. Interceptor & Special), 3 9/16" (Interceptor & Special). Remove locking pin and pull up gently on transmission throttle control rod to hold transmission lever against its internal stop. Rotate clevis on upper end of rod until clevis fits freely on pin on accelerator assembly lever, then lengthen rod by turning clevis 3 turns counter-clockwise. Install throttle control rod on lever. Hold lever in alignment to prevent binding, and tighten locknut. Road test car and if band or clutch slippage evident, **increase rod length to 3¼ turns of clevis but do not exceed 4 turns.** *NOTE–* Connecting link between cross shaft and lever must be parallel to centerline of engine. Adjust as necessary by rotating adjusting screw in lever.

Ford Thunderbird Throttle Linkage: With selector lever in "N" position and engine at normal operating temperature, set engine idle speed at 475-500 RPM. Adjust Anti-Stall Dashpot, then turn engine off. Disconnect

1955 THUNDERBIRD LINKAGE

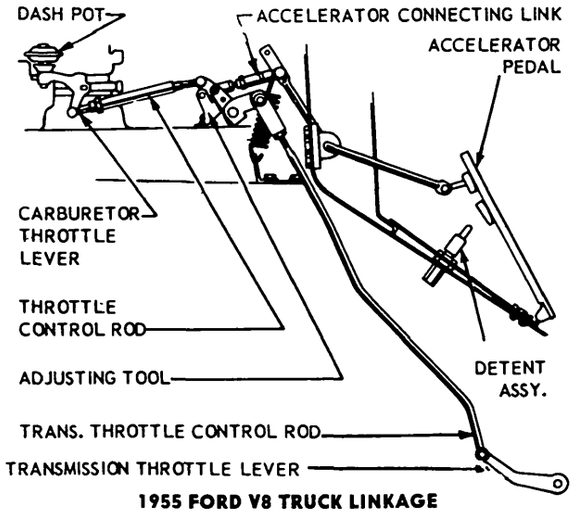


transmission throttle control rod from accelerator assembly lever on engine and insert a lock pin (¼" drill rod) through adjusting holes in lever and assembly. Adjust length of link between assembly and carburetor throttle valve lever to close lever against its stop. Adjust accelerator assembly connecting link (assembly-to-cross shaft link) to obtain a pedal height of 4¼". Remove lock pin and pull up gently on transmission throttle control rod to hold transmission lever against its internal stop. Rotate clevis on upper end of rod until clevis fits freely on pin on accelerator assembly lever, **then lengthen rod by turning clevis 3 turns counter-clockwise.** Install throttle rod on lever. Hold lever in alignment to prevent binding and tighten locknut. Road test car and if band or clutch slippage evident, **increase rod length to 3¼ turns of clevis but do not exceed 4 turns.** *NOTE–*Connecting link between cross shaft and lever must be parallel to centerline of engine. Adjust as necessary by rotating adjusting screw in lever.

Ford 6 Cyl. Truck (1955) Throttl Linkag : With selector lever in "N" position, engine at operating temp-

CONTINUED ON NEXT PAGE

FORDOMATIC, MERCOMATIC & TURBO-DRIVE (C nt.)

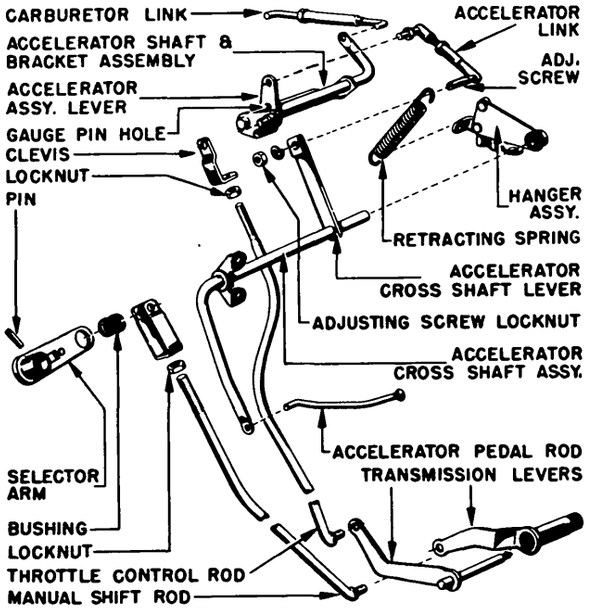


erature, set engine idle speed at 450-475 RPM. Adjust Anti-Stall Dashpot, then turn engine off. Remove clevis pin from upper end of transmission throttle control rod (at cross shaft). Pull gently upward on throttle control rod to hold transmission lever against its internal

1955 FORD 6 CYL. TRUCK LINKAGE

stop. Rotate rod clevis for free entry of clevis pin in holes in clevis and cross shaft lever. **Lengthen control** rod by rotating clevis 3 turns counter-clockwise.

Connect control rod to cross shaft. Adjust accelerator pedal height so that pedal just touches detent stem on floorboard when throttle lever on carburetor hits its wide open stop. Road test car and if band or clutch slippage is evident, **increase rod length to 3½ turns of clevis, but do not exceed 4 turns.**

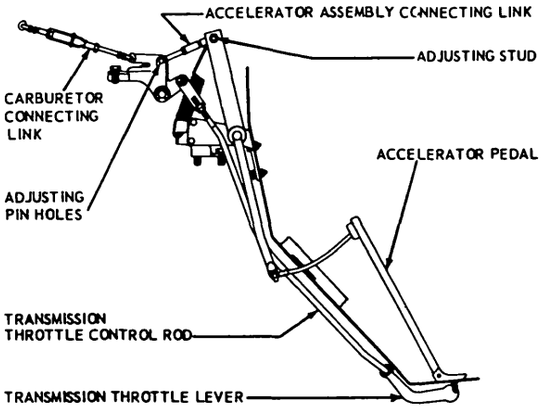


1955 FORD V8 TRUCK LINKAGE

Ford 6 & 8 Cyl. Trucks (1954) Throttl Linkage: The throttle linkage adjustment is the same as for passenger cars except as noted below:

Accelerator Pedal Height—Check transmission for kickdown action. If there is no action, loosen the accelerator stop bolt lock nut located under the accelerator pedal and adjust the stop bolt height until kickdown action is obtained.

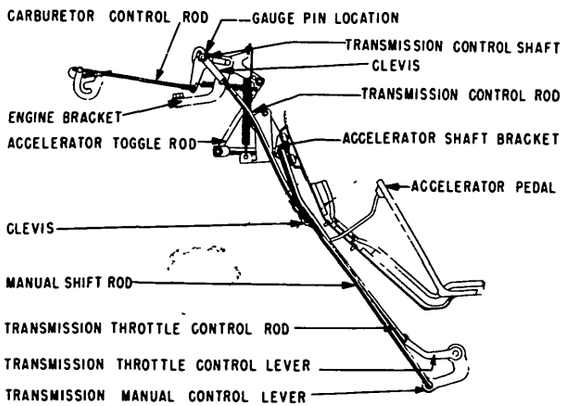
See MANUAL LINKAGE ADJUSTMENT below.



Ford 8 Cyl. Trucks (1955) Throttle Linkage: Adjust idle speed and Anti-Stall Dashpot. Position Throttle Linkage Adjusting Tool T54L-77230-A on surface of accelerator mounting bracket. Lower pin of tool should freely enter hole in accelerator assembly lever. If pin does not enter hole in lever, loosen carburetor connecting link barrel locknut and rotate barrel until pin enters hole freely (with carburetor throttle valve lever

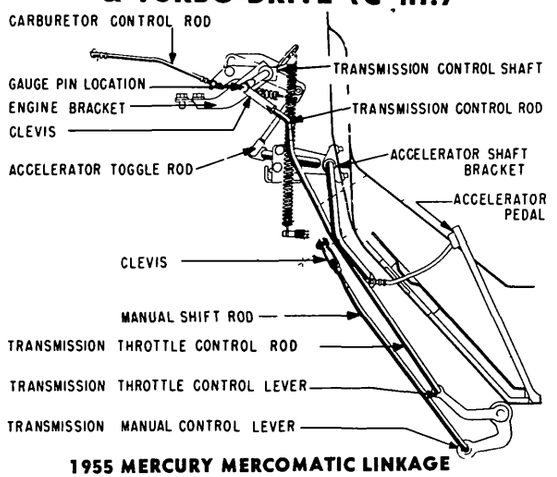
1954 FORD V8 THROTTLE LINKAGE

against its stop). Tighten link barrel locknuts. Remove clevis pin from upper end of transmission throttle control rod at cross shaft. Pull gently upward on throttle control rod to hold transmission lever against its internal stop. Rotate rod clevis for free entry of clevis pins into holes in clevis and cross shaft lever. **Lengthen control rod clevis 3 turns counter-clockwise.** Connect control rod to cross shaft. Road test car and if band or clutch slippage evident, **increase rod length to 3½ turns of clevis but do not exceed 4 turns.** *NOTE*—Connecting link between cross shaft and lever must be parallel to centerline of engine. Adjust as necessary by rotating adjusting screw in lever.



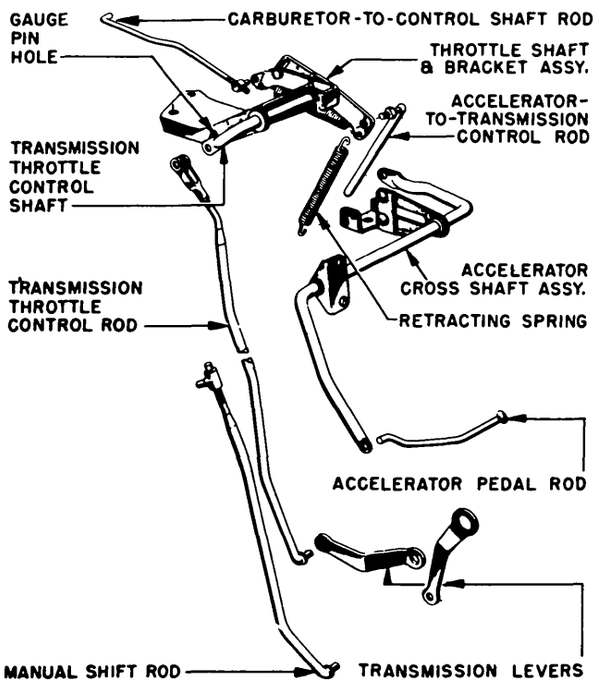
Linc ln Throttl Linkag : Disconnect carburetor to throttle rod at carburetor. Adjust engine idle speed to 425-450 RPM with selector lever in "DR" position then turn ignition off. Adjust Anti-Stall Dashpot. Re-

1955 FORD V8 INTERCEPTOR & SPECIAL LINKAGE



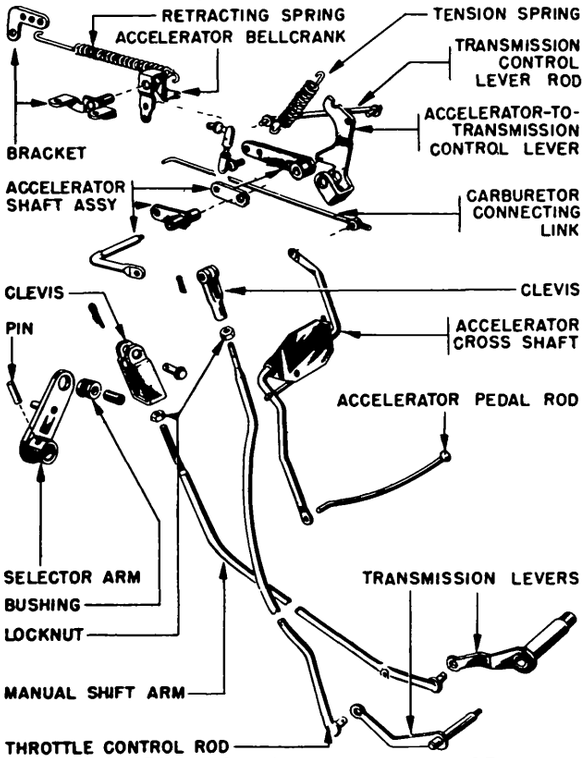
move clevis pin securing transmission control rod to transmission control shaft. Insert gauge pin Tool 77230-MB through control rod and shaft bracket. With engine at operating temperature and on slow idle, adjust carburetor to control shaft rod so that it enters hole in carburetor freely. If rod is too long shorten one full turn and assemble into hole in carburetor. Remove positioning gauge pin. While holding carburetor throttle in slow idle position, hold the control shaft to transmission rod up against its stop, and adjust length of rod to allow a free entry of clevis pin in hole in shaft of transmission control shaft, **th n l ngth n rod by turning clevis three compl t turns in ac unt r-cl ckwise direction.** Install clevis pin and tighten locknut. *(NOTE*—If, after making this adjustment, clutch or band slippage is still indicated, the rod may be lengthened another complete turn, **but th c mplet adjustm nt must never exceed a total of four turns fr m "St p" p siti n).** With ignition off and accelerator pedal depressed, adjust the length of the toggle rod assembly so that nylon bushing has a clearance of .100" from top of slot in accelerator shaft assembly (see Throttle Linkage illustration).

CONTINUED ON NEXT PAGE



1955 LINCOLN TURBO-DRIVE LINKAGE

FORDOMATIC, MERCOMATIC & TURBO-DRIVE (C nt.)



1955 MERCURY MERCOMATIC LINKAGE

Mercury (1954-55 Thr ttle Linkage): Disconnect carburetor-to-control shaft rod at carburetor. Adjust engine idle speed to 425-450 RPM with selector lever in "Dr" position, then turn engine off. Adjust Anti-Stall Dashpot. Remove clevis pin securing transmission control rod to transmission control shaft. Insert Gauge Pin Tool 77230-MB through control rod and shaft bracket. With engine at normal operating temperature and on slow idle, adjust carburetor-to-control shaft rod so it enters hole in carburetor rod freely. On 1955 Models, **lengthen th rod two full turns.** Remove positioning pin. While holding carburetor throttle in the slow idle position, hold control shaft-to-transmission rod up against its stop and adjust length of rod to allow free entry of clevis pin in hole in clevis and hole in transmission control shaft. **Lengthen rod by turning clevis three full turns in a counter-clockwise direction.** If it is not possible to obtain a forced downshift with this adjustment, control shaft should be lengthened an additional 1½ turns. Install clevis pin and tighten clevis locknut.

1954 MERCURY MERCOMATIC LINKAGE

1954 FORD 6 CYL. FORDOMATIC LINKAGE

Manual Linkage Adjustment (All Models): Disconnect upper end of manual shift rod from selector arm. Position selector lever, with the indicator in the quadrant down against its stop in the "DR" position Place manual lever at transmission in the drive "DR" detent (second from bottom) Rotate manual shift rod clevis until clevis pin fits freely into holes in clevis and selector arm Lengthen rod assembly 2 complete turns (Ford, All Models), 1 complete turn (Lincoln & Mercury), counter-clockwise Install clevis pin and check pointer alignment in all positions.

STARTER NEUTRAL SAFETY SWITCH: *(NOTE–Neutral Safety Switch is located at lower end of steering column (1954-55 Ford, 1954 Mercury), on steering column, inside passenger compartment (1955 Lincoln & Mercury).*

BAND ADJUSTMENT

►*Band Adjustment is recomm nded to be made at 15000 mile intervals when transmission fluid is changed (pan should be removed and cleaned at this time)*

FRONT BAND ADJUSTMENT: Drain fluid from pan using a drain can with a fine mesh screen, remove pan. Remove fluid screen from transmission and loosen the front servo adjusting screw locknut TWO FULL TURNS, using a 9/16" wrench Using front band adjusting tool No. 7225, insert gauge block between servo piston and adjusting screw and tighten adjusting screw until wrench overruns. Back off adjusting screw exactly ONE COMPLETE TURN and remove gauge block. While holding adjusting screw stationary, tighten locknut clockwise (20-25 ft lbs) Install fluid screen and install pan using new gasket Install the drain plug and refill transmission to "Full" mark using fluid drained from transmission unless fluid being changed Check fluid level (see LUBRICATION).

►*CAUTION–Severe damage may result if adjusting screw not backed off exactly 1 full turn*

REAR BAND ADJUSTMENT: Fold back floor mat to expose right side of floor pan and remove access hole cover on right side of transmission floor pan Using rear band adjusting tool No. 7195, loosen rear band adjusting screw locknut Using "T" handle of tool No. 7195, tighten rear band adjusting screw until wrench overruns. (If screw was found to be tighter than wrench capacity (10 ft lbs), loosen several turns and retighten until wrench overruns). Back off adjusting screw exactly 1½ COMPLETE TURNS. While holding adjusting screw stationary, tighten adjusting screw locknut to 35-40 ft. lbs

►*CAUTION–Severe damage may result if adjusting screw not backed off exactly 1½ turns.*

TESTING

►*1955 FORD INTERCEPTOR & THUNDERBIRD, MERCURY & LINCOLN PRESSURE TAKE-OFF HOLE RELOCATION* Later cars will have the pressure take-off hole located on the rear face at the left hand corner near bottom of case (looking toward front of case).

►*CAUTION: While making the Stall Test never hold the throttle open longer than 5 seconds*

STALL TEST: The stall test is made in "D", "LO" & "R" ranges to determine if bands or clutches are slipping Connect a tachometer to engine and set it to read on the "high" scale Make sure engine is idling properly at normal operating temperatures. Start engine, then firmly apply parking brake and service brake. Place selector lever in "D" range, then press accelerator slowly all the way to the floor without going into "low gear" kickdown. The engine speed should be as indicated in the "Stall Speed Table" below. If engine speed is below minimum limit, tune the engine and repeat test If engine speed exceeds maximum limit, release accelerator immediately because front band or clutch slippage is evident. To determine whether the front band or front clutch is causing slippage, move lever to "LO" range and repeat the test. If slippage

CONTINUED ON NEXT PAGE

FORDOMATIC, MERCOMATIC & TURBO-DRIVE (Cont.)

is evident in "LO" range also, the front clutch is slipping If slippage is found in "DR" range, but not in "LO" or "R" ranges, the front band is causing the the slippage If engine exceeds the maximum limit with selector lever in "R" range, the rear band or rear clutch is slipping To determine which of the two is faulty, move selector lever to "LO" range If slippage is evident in "LO" and "R" ranges, but not in "D" range, the rear band is slipping When slipping is noted in "R" range but not in "LO" or "D", the rear clutch is causing the slippage

ENGINE STALL SPEEDS

Car Model	Low Limit - Engine RPM -	High Limit
1954 Ford, All Models	1365	1565
1954 Mercury, All Models	1400	1600
1955 Ford 6 Pass. Car	1380	1580
1955 Ford V8 Pass. Car①	1450	1650
1955 Ford Thunderbird	1550	1750
1955 Ford Interceptor	1510	1710
1955 Ford 6 Truck	1380	1580
1955 Ford V8 Truck	1440	1640
1955 Lincoln	1525	1725
1955 Mercury②	1510	1710
1955 Mercury Montclair	1550	1750

①—Special 182 HP V8 Engine included.

②—Except Montclair.

SHIFT TESTS: Select a smooth road for tests. Make tests as outlined below and see 1954 or 1955 "Shift Point Table" for correct speed where shifts should occur.

2-3 Upshift (Minimum Throttle): Place selector lever in "DR" range, and starting from a standstill, apply accelerator lightly but steadily

3-2 Downshift (Minimum Throttle): Permit car to decelerate (from speed attained in above test) until downshift occurs from high to intermediate

3-2 Downshift (Forced): Reduce car speed below 45 MPH (Ford), 50 MPH (Mercury & Lincoln) Press accelerator pedal to floor Transmission should shift from high to intermediate This shift should occur only with car in high gear

2-3 Upshift (Maximum Throttle): Place selector lever in "DR" range, and starting from a standstill, press accelerator to the floor Full throttle upshift should occur as indicated in 1954 or 1955 "Shift Point Table".

2-1 Downshift (Forced)—1955 Models Only: With selector lever in "DR" range and car speed below 18 MPH (Ford), 19 MPH (Mercury & Lincoln), quickly press accelerator fully to floor. This action shifts transmission from high, to intermediate, or low.

1-2 Upshift (Maximum Throttle)—1955 Models Only: With accelerator pressed to floor for above test (2-1 Downshift, Forced), transmission should upshift from low to intermediate when car speed indicated in 1955 "Shift Point Table" is reached. The 2-3 Upshift will occur at the speed indicated in table.

"DR" to "LO" Manual Shift: With car speed between 40-45 MPH (Ford), 45-50 MPH (Mercury & Lincoln), Manually shift selector lever from "DR" to "LO" Instead of shifting to low gear, the transmission should shift from high to intermediate When car speed is reduced within the range indicated in 1954 or 1955 "Shift Point Table", the transmission should shift into low range.

"R" Shift: Bring car to a stop and place selector lever in "R" range The car should move in reverse direction smoothly, upon light throttle pressure

OPERATING PRESSURE TEST: Set parking brake firmly and raise rear wheels off floor Disconnect throttle at outer throttle lever on transmission

Pressure Gauge Installation: *NOTE—See "1955 Ford Interceptor & Thunderbird, Mercury & Lincoln Pressure Take-off Hole Relocation" above.* Remove pipe plug from side of transmission near throttle lever (or on rear face of transmission case), then connect pressure gauge No. 77820 so it can be read from under car.

Throttle Lever Protractor Gauge Installation (1954 Models): Position throttle lever protractor gauge No. 77270-A (Ford), 77270 (Mercury) on the throttle lever shaft, locating the large elongated hole in gauge over the large shaft to rear of control lever. Set gauge indicator to 0° and lock in place with knurled thumbscrew Hold throttle lever against stop (up), insert gauge pin 7000-B-1 through the small elongated hole in gauge and the hole in throttle lever If gauge pin enters these two holes freely the throttle mechanism has not been distorted and need not be replaced **Replace the throttle control mechanism if it has been distorted.**

Throttle Lever Protractor Gauge Installation (1955 Models): Position gauge T55L-77270-C (Ford), 77270-C (Mercury & Lincoln) over throttle lever shaft Rotate gauge on shaft until gauge pin passes through hole in oil pan flange and contacts bottom machined surface of transmission case Tighten gauge set screw to hold gauge firmly on throttle lever shaft Rotate throttle lever up against its internal stop in transmission, then insert gauge pin through small elongated hole in gauge and hole in throttle lever Check position of protractor gauge pointer If pointer is at zero, the throttle mechanism is not distorted **If throttle lever distorted, replace it with a new one.**

Pressure Rise Point ("R" Reverse Range) 1954 Models: With throttle lever pin through the elongated hole in gauge and hole in throttle lever, advance the throttle fully (down) The lever should travel 28° to 33° Connect a tachometer and set engine idle speed at 600 RPM with selector lever in "R" (reverse) range Observe pressure at 0° throttle lever position The pressure should be 60-80 lbs (Ford), 76-96 lbs (Mercury) From underneath the car advance throttle lever slowly and observe the angular reading at the point where pressure starts to rise Pressure rise should begin between 3½-4½° throttle advance Continue to advance throttle lever slowly until maximum pressure is indicated, which should be 140-165 lbs (Ford), 154-186 (Mercury), and observe angular reading which should be 4½-7½° If above points not correct, adjust by changing throttle valve stop position (see Throttle Valve Stop Adjustment below)

Pressure Rise Point ("R" Reverse Rang) 1955 Models: With pin through the elongated hole in gauge and hole in throttle lever, advance the throttle lever fully (down) The lever should travel 28° to 33° Connect a tachometer and set engine idle speed at 600 RPM with selector lever in "R" (reverse) range. Observe pressure at 0° throttle lever position The pressure should be 50-63 lbs (All cars & trucks except 6 Cyl Pass Car), 47-60 lbs, (Ford 6 Cyl. Pass. Cars) From beneath car, advance throttle lever slowly and note angular reading at moment pressure begins to rise (3½° to 4½°) Continue to advance throttle lever slowly until maximum pressure is indicated on gauge. This pressure should be 175-190 lbs, (All cars & trucks except Ford 6 Cyl Pass Cars), 166-182 (6 Cyl. Pass Cars). Maximum pressure should occur at 9½° to 11½° throttle lever advance

Pressure Rise Point ("DR" Range) 1954 M d ls: Move selector lever to "DR" (drive) range and repeat the above procedure Maximum pressure should occur at 7° to 10½° throttle advance Maximum pressure should be 120-145 lbs

Pressure Rise Point ("DR" Drive Range) 1955 M dels: Move selector lever to "DR" (drive) range and repeat the above procedure Maximum pressure should be 130-150 lbs (All Cars & Trucks except 6 Cyl Pass Cars), 122-142 lbs

►*NOTE—If pressure regulation is not within above specifications, leave gauges attached (for a recheck after repairs) and adjust pressure as indicat d below.*

Throttle Valve Stop Adjustment: This adjustment requires draining transmission and removing oil pan Use bending tool No 77763 to bend the throttle valve stop within transmission case as follows

If pressure Rise Start is Over 4½° (in R v rs Rang)— Hold throttle outer lever against its stop, clamp protractor gauge on lever and set to read 0°, then advance lever to maximum travel Install bending tool over throttle valve stop, bend stop **toward** valve body to advance the stop position the number of degrees to bring the pressure rise to 4° in "R" range Check by returning the lever to stop position and reading protractor gauge (reading will indicate change in stop position)

►*CAUTION: Do not attempt to correct the stop setting if the pressure rise point is more than 4° ut of limits, since extreme bending of the stop can distort valve body plate and result in leakage. Replace stop plate (upper valve body front plate).*

If Pressure Rise Point is Und r 3½ ° (in R v rs Range)— Hold throttle lever against its stop and note protractor gauge reading Advance throttle lever to maximum travel and place throttle valve stop bending tool over stop Bend stop **away** from valve body far enough to bring pressure rise to 4° in "R" range (For example If pressure rise point was 2°, the required correction is 2° To make this correction, bend the stop an estimated amount, then remove tool and move

CONTINUED ON NEXT PAGE

FORDOMATIC, MERCOMATIC & TURBO-DRIVE (Cont.)

throttle lever against its stop. Subtract previously noted protractor gauge reading from present reading to determine amount of change). Repeat procedure as necessary to bring pressure rise to 4°. Install oil pan and fill transmission with Automatic Transmission Fluid type A.

AIR PRESSURE TESTS (WITH TRANSMISSION IN CAR): Raise car on hoist and remove transmission oil pan, and control valve assembly. Proceed as follows:

Front Clutch: Apply pressure to front clutch and governor input passage (see illustration). Listen for dull thud which indicates that clutch is operating. Keep air pressure in passage for several seconds to check for leaks in this part of system.

Governor Valve: Remove governor inspection cover. Apply air pressure to the same passage as for front clutch (above). Listen for a click and also watch valve snap inward.

Rear Clutch: Apply air pressure to rear clutch oil passage (see illustration). Listen for a dull thud to indicate clutch is operating Check for leaks in same manner as for front clutch (above).

Rear Band & Servo: Apply pressure to rear servo oil passage (see illustration), and observe band application.

Front Band & Servo: Apply pressure to front servo apply tube (rear tube), and observe band application.

▷*TESTING NOTE: If servos, bands, clutches, and governor operate with air pressure, then the no drive problems, erratic shift, or no upshift conditions indicate that the control valve assembly is the cause of the trouble. See "Control Valve" in OVERHAUL BELOW.*

TROUBLE SHOOTING & DIAGNOSIS

HIGH UPSHIFT (Intermediate-to-High): Throttle linkage is too short or throttle lever is bent. Valves sticking in governor or improper valve travel (check with air pressure). Governor oil delivery pipe leaking at connections (air pressure will indicate leak). Valve sticking in control valve assembly.

LOW UPSHIFT (Intermediate-to-High): Throttle linkage too long or throttle lever bent. Valves sticking in control valve assembly. Internal leak in control valve assembly (possible loose screws or mating surfaces require lapping).

ROUGH UPSHIFT (Intermediate-to-High): Throttle linkage not correct length or throttle lever bent. Bands require adjusting to factory specifications. Hydraulic operating pressures not correct. Valve sticking in control valve assembly. Internal leak in control valve assembly (possible loose screws or mating surfaces require lapping).

SLIPS (Light Throttle Upshifts): Throttle linkage too long, or bands out of adjustment.

SLIPS (Heavy Throttle Upshifts): Throttle linkage too long or throttle lever bent. Bands out of adjustment. Hydraulic operating pressure not correct. Valves sticking in control valve assembly. Internal leak in control

①–If manual shift made above speed indicated, transmission will shift from high to intermediate. If made below these speeds, transmission will shift from high to intermediate or low.

②–19 MPH or below.

FORDOMATIC, MERCOMATIC & TURBO-DRIVE (Cont.)

valve (possible loose screws or mating surfaces require lapping).

SLIPS (2-3 Upshift): Same possible conditions as for "SLIPS (Heavy Throttle Upshifts)" above.

ROUGH 3-2 DOWNSHIFT (Closed Throttle): Same possible conditions as for "SLIPS (Heavy Throttle Upshifts)" above.

NO FORCE DOWNSHIFT: Throttle linkage too long, or throttle lever bent. Accelerator pedal height not correct. Valves sticking in control assembly.

NO 2-1 KICKDOWN SHIFT (1955 MODELS): Throttle linkage too short. Throttle lever bent. Valves sticking in control valve assembly.

SLIPS 3-2 FORCED DOWNSHIFT: Bands out of adjustment.

NO 2-3 UPSHIFT: Valve sticking governor (check with air pressure). Governor oil delivery pipe leaking at connections (check with air pressure). Valves sticking in control valve assembly. Rear clutch inoperative (check with air pressure).

ROUGH REVERSE START: Engine idle incorrect. Throttle linkage not of correct length or throttle lever bent. Bands out of adjustment. Hydraulic operating pressures not correct. Valve sticking in control valve assembly. Internal leak in control assembly (possible loose screws or mating surfaces require lapping).

SLIPS IN INTERMEDIATE RATIO: Throttle linkage not adjusted properly. Bands out of adjustment. Hydraulic pressures not correct. Improper front servo travel (check with air pressure). Internal leak in control valve assembly (possible loose screws or mating surfaces require lapping).

SLIPS IN LOW OR REVERSE RATIO: Same as for "SLIPS IN INTERMEDIATE RATIO" above, except that rear servo travel should be checked with air pressure.

NO DRIVE IN "DR" RANGE: Bands out of adjustment. Front servo not releasing (check with air pressure). Front clutch not operating properly (check with air pressure).

NO DRIVE IN "LO" RANGE: Bands out of adjustment. Rear servo not operating correctly (check with air pressure). Front clutch not operating properly (check with air pressure). Valves sticking in control valve assembly.

NO DRIVE IN "R" RANGE: Same as for "NO DRIVE IN LO RANGE" above.

NO DRIVE IN ANY RANGE: Fluid level incorrect. Shift linkage not adjusted correctly. Hydraulic pressure not correct. A broken or improperly assembled front clutch will cause loss of drive in all positions except Reverse. Improperly assembled control valve assembly.

LOCKS UP IN REVERSE: Front clutch not releasing (check with air pressure). Shift linkage not adjusted correctly or not operating properly. Leak in rear servo apply passage (check with air pressure and make certain servo applies and releases freely without tendency to stick or chatter).

LOCKS UP IN "LO" OR "DR": Rear clutch is applied and not releasing (check with air pressure).

UNABLE TO START ENGINE BY PUSHING: Rear pump inoperative or a defective pressure regulator valve.

ROUGH 2-1 FORCED DOWNSHIFT (1955 MODELS): Rear servo sticking. Rear servo accumulator sticking.

ROUGH 1-2 UPSHIFT, THROUGH DETENT (1955 MODELS): Engine idle incorrect. Throttle linkage too short. Rear servo accumulator sticking or broken spring. Valves in valve body sticking.

MINOR REPAIRS (TRANSMISSION IN CAR)

The following transmission units can be removed for repair without removing transmission assembly from car. Raise car on hoist for these operations, then drain fluid from transmission and remove oil pan.

►*NOTE: For Disassembly & Overhaul of the following units, see OVERHAUL (TRANSMISSION UNITS) below.*

Governor Removal: Remove governor inspection cover from extension housing. Rotate the drive shaft to bring governor body in line with inspection hole. Remove the two screws that secure governor body to sleeve. Remove governor.

►*CAUTION: Use care not to drop bolts or governor valve into housing.*

Installation–Lubricate governor valve with transmission fluid and install valve in governor body (*CAUTION*–valve must move freely in body). Install governor body on counterweight with the **side plate forward** (*CAUTION*–fluid passages in governor body and counterweight must be aligned), install governor body attaching screws. Install inspection cover with NEW gasket, tighten cover screws to 4-6 ft. lbs. torque.

►**NOTE:** For the following operations, remove transmission fluid level indicator. Remove transmission filler tube and drain the fluid into clean container using a fine mesh wire screen for straining. (Fluid may be re-used). Then remove transmission oil pan and screen.

Front Servo Removal: Loosen lubrication tube from pressure regulator and rear pump and remove. (NOTE–If necessary, tap tube with soft hammer to remove. *CAUTION*–Do not bend or distort tube). Loosen control valve body attaching bolts. Remove servo attaching bolt and while holding servo strut with fingers, remove servo assembly.

Installation–Position servo band forward in case with band ends down. Position servo strut with large end indexing with servo actuating lever and small end indexing with band end. Rotate band, strut and servo into position, indexing tubes from valve body to servo, and anchor end of band with anchor in case. Install attaching bolt, tightening to 30-35 ft. lbs. Tighten control valve attaching bolts to 8-10 ft. lbs. Install lubrication tube and adjust servo band. See "Front Band Adjustment". Install screen, install oil pan using NEW gasket, tighten oil pan screws to 10-13 ft. lbs. Connect filler tube. Fill transmission to correct level (old fluid can be re-used), recheck fluid level with transmission at operating temperature.

Rear Servo Removal: Remove lubrication tube from rear pump and regulator. (*NOTE*–If necessary tap tube with soft hammer to remove). Remove rear pump intake tube. Remove front servo (see above). Take out rear servo attaching bolts, hold actuating and anchor struts with the fingers, remove rear servo assembly.

Installation–Position servo anchor strut and rotate servo band to engage strut. Hold in position with fingers. Position actuating lever strut and install servo, install servo attaching bolts (*CAUTION*–Longer attaching bolt must be installed in forward bolt hole), tighten attaching bolts to 40-45 ft. lbs. torque. Install front servo (see above). Install rear pump intake tube and lubrication tube. Adjust rear band (see BAND ADJUSTMENT). Install oil pan with NEW gasket, tighten oil pan screws to 10-13 ft. lbs. Connect filler tube. Fill transmission to correct level (old fluid can be re-used), recheck fluid level with transmission at operating temperature.

Control Valve Body Removal: Remove two "U" tubes from pressure regulator and control valve body. Loosen front servo attaching bolt three turns. Take out three valve body attaching bolts, lower the valve body and pull it off the servo tubes.

►*CAUTION–Use extreme care when removing valve body to prevent damage to body and attach d parts.*

Installation–Align servo tubes with holes in control valve body, position manual lever in neutral, position inner throttle lever between stop and downshift valve and at the same time push the throttle valve in to clear the transmission case **making c rtain that manual valve engages actuating pin manual detent l ver.** Install control valve body attaching bolts but do not tighten the bolts. Install two "U" tubes in pressure regulator and control valve body. Tighten control valve body attaching bolts to 8-10 ft. lbs. torque. Tighten front servo attaching bolt to 35-40 ft. lbs. torque. Adjust front and rear bands (see BAND ADJUSTMENT). Install oil screen, install oil pan using NEW gaskets, tighten oil pan screws to 10-13 ft. lbs. Connect filler tube. Fill transmission to correct level (old fluid may be re-used) recheck fluid level with transmission at normal operating temperature.

Pressure Regulator Removal: Remove lubrication tube. Remove control pressure tube and compensator tube from valve body and regulator. Remove pressure regulator spring retainer. (*CAUTION*–Maintain pressure on retainer to prevent springs flying out). Remove the control pressure and converter pressure valves. Take out pressure regulator attaching bolts and washers, remove regulator.

►*MAIN OIL PRESSURE REGULATOR VALVE INSTALLATION CAUTION:* If regulator removed to correct transmission "buzzing" noise, examine valve for undersize bleed flats and rotate valve 90° in bore from original position when re-installing it. This should correct the noise.

Installation–Install regulator body and attaching bolts and tighten to 17-22 ft. lbs. Install converter pressure and control pressure valves and make certain valves

CONTINUED ON NEXT PAGE

FORDOMATIC, MERCOMATIC & TURBO-DRIVE (Cont.)

operate freely in bore, then install valve springs and retainer Install large control pressure tube, small compensator tube, and lubrication tube Install oil screen, install oil pan using NEW gaskets, tighten pan screws to 10-13 ft lbs Connect filler tube Fill transmission to correct level (old fluid may be re-used), recheck fluid level with transmission at normal operating temperature

Manual & Throttle Lever Seal Replacement Remove control valve body (see above), disconnect manual and throttle linkage rods at transmission levers Remove nut on inner throttle lever shaft and remove inner throttle lever Remove outer throttle lever and shaft, remove throttle shaft seal from counterbore in manual lever shaft Take out cotter pin in each end of parking pawl torsion lever rod and remove the rod, rotate manual lever shaft until detent lever clears detent ball (*CAUTION*—do not allow detent ball to fly out), remove detent ball and spring Remove manual lever shaft nut, remove detent lever, remove outer manual lever and shaft assembly Remove manual shaft seal

►*1955 MERCOMATIC TRANSMISSION THROTTLE CONTROL INNER LEVER PRODUCTION CHANGE & SERVICE REPLACEMENT NOTE (To eliminate excessive ndplay)* Throttle Control Inner Lever Part No B5A-77283-A identified by the letter "0" stamped on lever is used in production and can be used for service replacement on 1954-55 transmissions When installing the later type lever the letter "0" must be installed toward inside of transmission

Installation—Coat outer diameter of new seal with Permatex No 3, install seal in case using tool No 77288 Install outer manual lever and shaft, rotate shaft until manual lever points downward, place detent lever on inner end of shaft, install attaching nut and tighten nut to 35-40 ft lbs torque Place detent spring and ball in hole in case (use piece of thin wall tubing to depress ball and spring), rotate detent lever until detent ball is held in place Install parking pawl torsion lever rod and cotter pins Install new throttle shaft seal, outer throttle lever and shaft, inner throttle lever and attaching nut, tighten nut to 25-28 ft lbs Connect manual and throttle rods to outer levers Check linkage for free movement Install control valve assembly and other parts *See Control Valve Assembly Installation (above)*

TRANSMISSION & CONVERTER REMOVAL

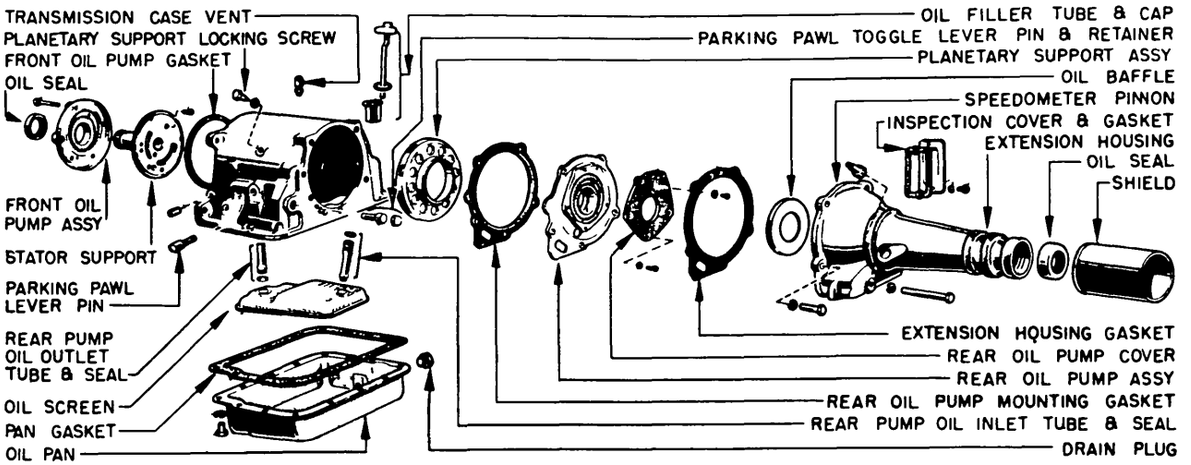
►*TRANSMISSION & CONVERTER REMOVAL NOTE Transmission and converter can be removed as an assembly, or transmission can be removed separately (on most models) without disturbing converter*

1954 FORD 6 & V8

1) Raise car on hoist or place on jack stands with wheels at least 10" off the floor Fold back floor mat then remove the two rubber plugs covering the floor access holes Remove the two top converter housing to-engine bolts On V8 models remove the starter On V8 models remove the starter On 6 cyl models remove the access plate Remove one of the converter drain plugs Rotate converter 180° and remove the other drain plug *(NOTE—Converter can be drained after removal from car if desired)*

2) On 6 cyl models remove all the lower converter housing-to-engine bolts except one located over the starter and the one located over the exhaust pipe Remove transmission linkage splash shield Remove converter air duct assembly then disconnect throttle and manual control rods from transmission Remove starter assembly drain transmission then remove drive shaft assembly

3) On V8 models disconnect the fluid filler tube at transmission oil pan and drain transmission Remove converter housing upper cover (V8) then remove the six converter-to-flywheel drive plate bolts *(CAUTION—Take precautions to prevent converter from slipping out of housing when transmission removed)*



4) Position engine support bar to permit lowering the V8 engine ¾" below normal position Disconnect throttle and manual linkage at transmission levers Disconnect accelerator pedal shaft at cross shaft Disconnect drive shaft at rear axle and remove drive shaft Remove speedometer cable then disconnect parking brake assembly at cross member and move equalizer to one side

5) Remove the two engine rear support-to-transmission bolts Position a transmission jack under transmission and raise transmission slightly to take weight off crossmember Remove crossmember Lower transmission until engine is supported firmly on support bar With the transmission resting on transmission jack remove remaining converter housing-to-engine attaching bolts

6) On 6 cyl models remove the oval cover on engine rear plate Remove six flywheel-to-converter cover bolts Install engine support bar and adjust tightly to oil pan flanges Remove the two remaining converter housing-to-engine attaching bolts

7) On V8 models move the jack supporting the transmission and converter assembly toward the rear sufficiently to clear the converter pilot Remove the six flywheel-to-engine crankshaft flange attaching bolts then remove flywheel assembly

8) On 6 cyl models tilt the converter and transmission assembly slightly and remove transmission assembly toward rear sufficiently to remove the six fly wheel-to-engine crankshaft attaching bolts Remove flywheel to provide sufficient clearance then lower converter and transmission assembly

TYPICAL TRANSMISSION CASE & EXTENSION HOUSING ASSEMBLY

1955 FORD PASS. CARS & TRUCKS (EXCEPT THUNDERBIRD)

1) Place car on hoist On truck models, drain radiator, fold front of floor mat back and remove covers from converter housing access bolt holes Loosen water inlet and outlet hose clamps at oil cooler and pull hoses off cooler On all cars and trucks, remove the two upper converter-to-engine bolts and lockwashers then raise vehicle with the hoist

2) Disconnect oil filler tube at oil pan and drain transmission Remove converter housing front plates (8 Cyl) or the access plate (6 Cyl) Remove one of the converter housing drain plugs Rotate converter 180°, then remove second drain plug Drain converter

►*NOTE Converter may be drained after it is removed from car.*

3) Disconnect drive shaft at rear axle and remove shaft. On F-250, F-350, or P-350 trucks, remove the four bolts attaching drive shaft coupling yoke at parking brake assembly

4) Remove the six flywheel-to-converter drive plate bolts Position the drive plate horizontally, and install the lower converter housing front plate (8 Cyl), or wedge the converter from sliding out of housing when transmission is removed

5) Disconnect starter cable at starter, then disconnect transmission-to-frame ground cable at transmission and remove starter On truck models, remove bolts attaching oil cooler to support brackets, dis-

CONTINUED ON NEXT PAGE

FORDOMATIC, MERCOMATIC & TURBO-DRIVE (Cont.)

connect oil cooler inlet and outlet hoses at transmission and remove oil cooler Remove converter air duct and linkage splash shield (cars) or the exhaust duct shield (trucks)

6) Disconnect manual and throttle linkages at transmission Disconnect speedometer cable at transmission On Pass. Cars, remove the two engine rear support-to-transmission bolts Position a transmission jack under transmission and raise it slightly to take weight off crossmember. On trucks, with the transmission jack in place remove the converter housing crossmember bolts. On all vehicles, then remove the two lower converter housing-to-engine bolts

7) Tilt rear of converter and transmission assembly upward slightly, then move assembly toward rear of vehicle sufficiently to remove the six engine crankshaft flange-to-flywheel attaching bolts Remove flywheel to provide sufficient clearance, then lower converter and transmission assembly

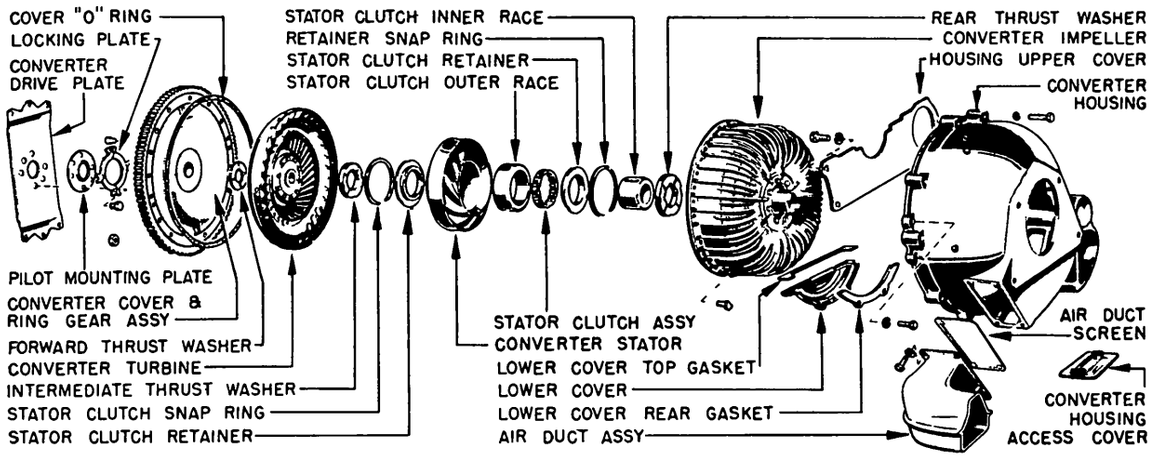
Torque Converter Removal (from Transmission): *See "Torque Converter Overhaul" below*

THUNDERBIRD

►*NOTE The converter and transmission assembly cannot be removed with engine in the car. Either the engine can be removed first, or transmission, converter and engine can be removed as an assembly*

1) Remove engine *(see "Engine Removal" in Ford Special Data)* If converter and transmission have been removed with the engine, they can be removed from the engine by removing the six converter-to-flywheel drive plate bolts, then removing the four converter housing to engine attaching bolts

2) To remove converter and transmission after the engine has been removed separately, remove the two transmission extension housing-to-rear engine support attaching bolts Remove speedometer cable at transmission Disconnect the manual shift control lever at transmission Move transmission forward and remove forward drive shaft, then remove converter and transmission from car



Torque Converter Removal (from Transmission): *See "Torque Converter Overhaul" below.*

1954-55 LINCOLN & MERCURY

1) Remove ground strap from battery Remove bolts and nuts securing throttle linkage bar bracket to engine and body Place car on support stands with all four wheels approximately 12' off ground On Mercury models with single exhaust pipe, remove nuts securing muffler inlet and cross over pipe to exhaust manifolds Remove manifold outlet pipe from mounting bracket at rear of manifold and move exhaust system away from working area.

2) Disconnect manual linkage and throttle linkage at transmission Disconnect speedometer cable at extension housing Disconnect drive shaft at rear universal joint and remove drive shaft from transmission output shaft Remove air duct from converter housing

3) Remove splash deflector, and converter housing lower plate Drain converter by removing one drain plug, then rotate engine 180° and remove second drain plug

1954 TORQUE CONVERTER ASSEMBLY

Drain fluid from transmission

4) Remove engine rear mount-to-frame crossmember bolts Position transmission lift under transmission and raise engine and transmission sufficiently to install support tool Remove rear engine mount from transmission On 1954 Mercury & 1955 Lincoln, remove the detachable frame crossmember (1955 Mercury models have a tubular crossmember with brackets welded to the crossmember) Lower lift under transmission to allow engine to rest on support tool Reposition transmission lift under transmission assembly and raise lift just enough to relieve weight of transmission on engine

5) Remove starter and upper converter housing plate with seal Remove six bolts securing converter to flexible drive plate. Remove the bolts securing converter housing to engine block

6) Remove transmission and converter assembly by sliding assembly toward rear of car sufficiently to disengage converter housing dowels and converter cover pilot Secure converter to converter housing to prevent damage to converter. Lower the assembly and remove from under car

Torque Converter Removal (from Transmission): *See "Torque Converter Overhaul" below.*

TRANSMISSION REMOVAL (WITHOUT CONVERTER)

►*NOTE: On most cars and trucks, the transmission can be removed without removing the converter assembly.*

1954 FORD 6 & V8

1) Place car on hoist or support car securely on jack stands with all wheels approximately 12" off the floor Drain transmission case by disconnecting filler tube at transmission oil pan connection Disconnect manual control rod and throttle control rod from levers on transmission case Disconnect speedometer cable Disconnect parking brake cable assembly at crossmember and move cable and equalizer to one side

2) Disconnect propeller shaft at rear universal joint flange remove shaft assembly by pulling it to rear to disconnect forward end from transmission Remove engine rear support-to-transmission bolts Install jack under transmission and raise engine and transmission just enough to install engine support bar under rear end of crankcase

3) With engine weight on support bar raise transmission just enough to remove weight from crossmember take out attaching bolt at each end and remove cross member

4) With transmission securely supported by jack remove four transmission-to-converter housing bolts and slide transmission straight back to disengage the turbine shaft then lower transmission and remove it from beneath car

1955 FORD PASS. CARS & TRUCKS (EXCEPT THUNDERBIRD & SUNLINER)

1) Raise vehicle with a hoist and drain fluid from transmission Disconnect drive shaft at rear axle and remove drive shaft

2) On trucks, disconnect oil cooler-to-transmission fluid inlet and outlet lines at transmission Remove bolts holding oil cooler on support brackets, then move cooler to one side

3) Remove converter air duct from pass cars, and remove exhaust duct splash shield from trucks

4) Disconnect manual control and throttle linkage at transmission Disconnect speedometer cable at extension housing. On pass. cars, remove the two rear support-to-transmission bolts Position a transmission jack under transmission and raise it slightly to take weight off crossmember Remove crossmember bolts and crossmember

5) On all vehicles, with transmission jack in place, remove the four transmission-to-converter housing attaching bolts On trucks, remove oil cooler from front support bracket Tilt rear of transmission slightly upward and move assembly toward rear, with a jack, until clear of turbine shaft Lower assembly and move it from under vehicle

1954-55 MERCURY 1955 LINCOLN

1) Place car on support stands with all four wheels

CONTINUED ON NEXT PAGE

FORDOMATIC, MERCOMATIC & TURBO-DRIVE (Cont.)

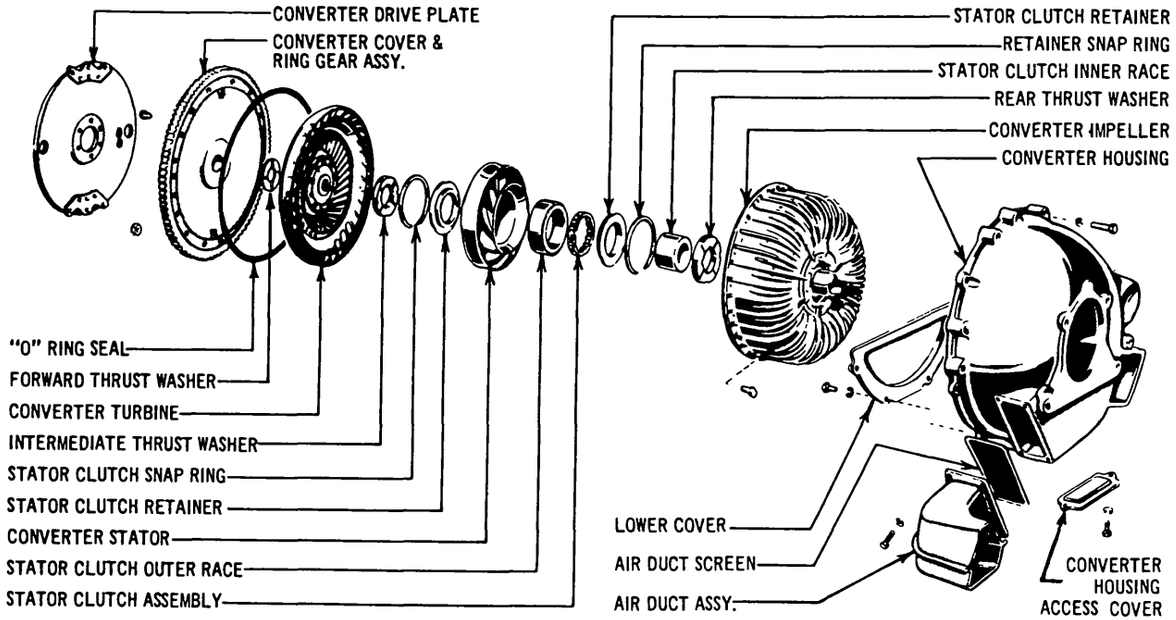
approximately 12" off floor. On Mercury models with single exhaust pipe, disconnect muffler pipes at exhaust manifold and the outlet pipe at support bracket, and move complete exhaust system away from work area.

2) Drain fluid from transmission and disconnect manual and throttle linkage at transmission. Disconnect speedometer cable at extension housing. Disconnect drive shaft at rear universal joint and remove drive drive shaft from transmission output shaft.

3) Remove rear engine mount to frame crossmember bolts. (Mercury models have a tubular crossmember with brackets welded to crossmember). Position lift under transmission and raise engine and transmission and raise engine and transmission sufficiently to install engine support tool. Remove rear engine mount from transmissions. On 1954 Mercury & 1955 Lincoln, remove the detachable crossmember from frame (1955 Mercury models have a tubular crossmember with brackets welded to the cross member).

4) Lower lift under transmission and allow engine to rest on support tool. Reposition transmission lift to relieve the weight of transmission. Remove four bolts securing transmission to converter housing.

5) Remove transmission by sliding assembly toward rear of car sufficiently to disengage the turbine shaft. Lower the assembly and remove from under car.



TORQUE CONVERTER OVERHAUL

►*DISASSEMBLY & REASSEMBLY CAUTION: CLEANLINESS IS EXTREMELY IMPORTANT WHEN OPENING UP TRANSMISSION. Thoroughly clean outside of case first, clean each part as removed.*

►*1955 FORDOMATIC CONVERTER BALANCE MARK IDENTIFICATION:* Balance marks are identified by a metal strap on the impeller cover and an inked stamp on the impeller casting. After car has been in service the inked mark may be difficult to see, therefore, it is recommended that before the cover is removed from the impeller, both parts should be marked with aligned dots of prussian blue *(CAUTION–Do not prick punch).*

TORQUE CONVERTER REMOVAL (From Transmission): Grasp converter cover with both hands and pull straight out. *(CAUTION–*To prevent damage to front seals, do not rock assembly from side to side). Remove converter housing attaching bolts and remove housing from transmission.

DISASSEMBLY: Remove converter cover attaching bolts and nuts. Remove cover and "O" ring seal. Remove bronze thrust washer from turbine and remove turbine. Remove stator from pump housing *(CAUTION–Check and locate the balancing marks on cover and stator so they may b replaced in the exact same position).* Remove thrust washer from pump hub and from turbine hub. Remove sprag clutch inner race and remove snap ring retaining outer hub to stator *(CAUTION–Do not burr snap ring groove).* Remove outer hub, sprag assembly, outer race and inner hub as an assembly. Separate hubs and sprag assembly from outer race. Remove snap ring retaining inner hub to stator.

1955 TORQUE CONVERTER ASSEMBLY

INSPECTION: Inspect converter blades for looseness, and check thrust surfaces for scores and splines for burrs and wear. Inspect seal surfaces and front pump driving lugs for wear. Inspect sprag assembly for worn or broken sprags or broken or distorted spring. Inspect bushings for wear or scoring (if bushings worn, polish bearing surface of journal with crocus cloth to eliminate possibility of wear having been caused by rough bearing surface).

REASSEMBLY: Install stator inner hub and snap ring. Turn assembly over, install outer race in stator. Install sprag assembly in outer race making sure that sprags are pointed in the right direction. Install outer hub and outer hub snap ring. Insert Tool No. 7946, tapered side first, into sprag assembly while rotating tool counter-clockwise to position sprags. Install inner race with spline section up. Guide tool No. 7946 with hand while pushing inner race into position. Check stator for clockwise rotation while holding the inner race. Install new seal in pump hub and install hub in pump. Tighten hub capscrews to 8-10 ft. lbs. Install thrust washer into hub of converter pump and install stator with the word "front" (stamped into face of stator) upward. Install thrust washer in hub of turbine and install turbine. Install bronze thrust washer on turbine hub. Position converter cover on pump housing with new "O" ring seal and properly align balance marks on cover and housing *(CAUTION–Cover and housing must be installed in the same position noted when these parts disassembled).* Install all converter bolts and tighten to 25-28 ft. lbs. in the sequence indicated below. Install converter housing on transmission case and tighten attaching bolts to 40-45 ft. lbs. Install converter assembly and press it firmly into position on turbine shaft. *(CAUTION–Do not "rock" converter assembly while installing it on shaft (will damage oil seals).*

►*COVER BOLT TIGHTENING SEQUENCE (To prevent leaks):* Tighten two nuts directly opposite each other just snug, tighten two nuts 90° from first two similarly, tighten two nuts 45° from first four nuts similarly, Continue this sequence until all nuts have been tightened **just snug,** then torque all nuts in same sequence to 25-28 ft. lbs. torque.

TRANSMISSION DISASSEMBLY

►*DISASSEMBLY & REASSEMBLY CAUTION: CLEANLINESS IS EXTREMELY IMPORTANT WHEN OPENING UP TRANSMISSION. Thoroughly clean outside of case first. CLEAN each part as removed with cleaning fluid or gasoline and dry with air–wiping cloths will leave lint on parts.*

DISASSEMBLY OF TRANSMISSION (Into Major Units): With transmission on bench fixture, (tool No. 7000-C-D recommended for holding transmission), remove all transmission units as follows:

1) Remove pan and gasket and take out fluid screen.

2) Remove pressure regulator spring retainer, regulator springs, control pressure and converter pressure regulator valves.

►*CAUTION: Maintain pressure on retainer to prevent valve springs from flying out.*

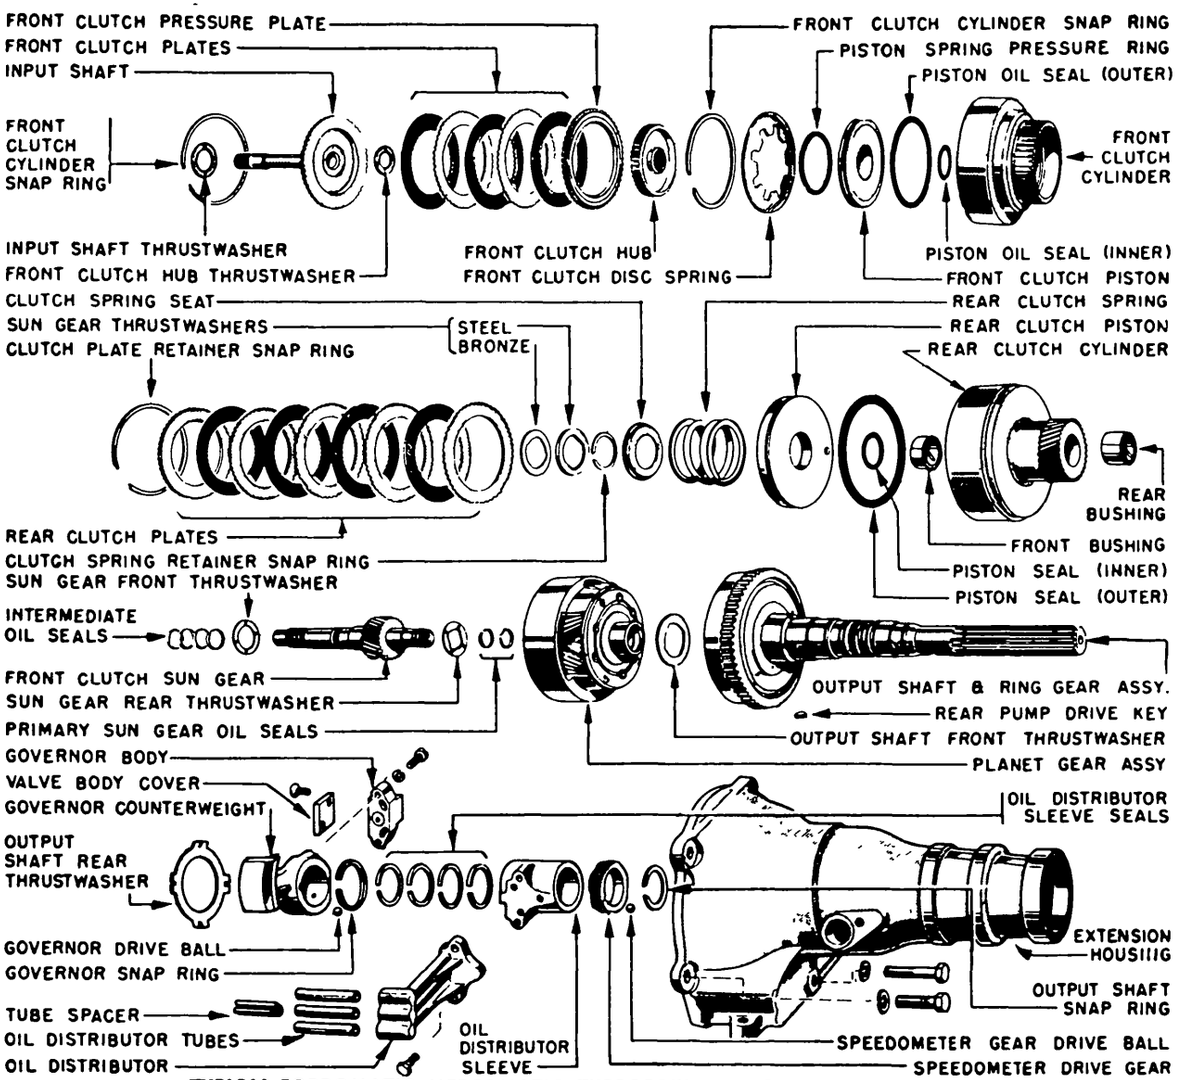
3) Loosen pressure regulator and valve body attaching bolts, and remove lubrication tube from pressure

CONTINUED ON NEXT PAGE

FORDOMATIC, MERCOMATIC & TURBO-DRIVE (Cont.)

regulator and rear pump. NOTE—If necessary tap tube with soft hammer. *CAUTION—do not bend or distort tube.*

4) Remove rear pump intake tube, being careful not to bend or distort it.



5) Remove compensator pressure tube (small) and control pressure tube (large) from pressure regulator and valve body. NOTE—If necessary, tap tube with a soft hammer. *CAUTION—do not bend or distort tube.*

6) Remove pressure regulator spring retainer, pressing it inward toward regulator to release. Remove pressure regulator springs, control pressure and converter pressure regulator valve. Remove regulator body attaching bolts and washers and remove body from case. NOTE—After removing regulator body from case, replace valve in body to protect them.

7) Loosen front and rear servo band adjusting screws five turns and loosen front servo attaching bolts three turns. Remove valve body attaching bolts and raise valve body to clear case and disengage valve body to clear case and disengage valve body to servo tubes and remove valve body.

8) Remove front servo apply and release tubes by twisting and pulling tubes. Take out front servo attaching bolt, hold front servo strut with fingers, lift servo out.

9) Remove rear servo attaching bolts and while holding actuating and anchor struts with fingers, lift servo from case (*CAUTION—Do not allow struts to drop into case*).

TYPICAL FORDOMATIC, MERCOMATIC, TURBODRIVE TRANSMISSION INTERNAL UNITS

10) *CHECK TRANSMISSION ENDPLAY before proceeding with disassembly, as follows:* Remove one front pump attaching bolt and mount dial indicator & support tool No. 77067 in this bolt hole so that contact button rests on end of turbine shaft. Install Extension Housing Seal Replacer 7657 (1954); 7657-D (1955) on output shaft to provide support for shaft. Pry front clutch cylinder toward rear of transmission using a large screwdriver, and set dial indicator to zero while maintaining a slight pressure on clutch cylinder. Remove screwdriver and pry units forward (toward front of transmission) by inserting screwdriver between large internal gear and case. Record indicator reading (endplay) for use in step 17 (below). This endplay should be .010-.029". Remove dial indicator and support and remove tool from output shaft.

11) Remove front pump attaching bolts and remove front pump assembly. (NOTE—If pump is tight in case, use soft hammer to loosen pump). Remove pump to case gasket. *CAUTION—Pull pump off shaft carefully to avoid damaging oil seal.*

12) Remove five extension housing-to-transmission bolts (these bolts also hold rear oil pump on case), withdraw extension housing carefully while holding rear pump in place. *CAUTION—Pull housing off output shaft carefully to avoid damaging rear oil seal.*

13) Remove speedometer drive gear snap ring from output shaft and take off the speedometer drive gear. (*CAUTION*—Do not lose drive ball).

14) Remove fluid distributor attaching bolts and slide distributor and tube from transmission. Remove distributor sleeve from output shaft. Carefully remove the four seal rings from the output shaft with the fingers (*CAUTION*—use care not to damage these rings).

15) Remove governor snap ring from shaft and slide governor assembly from output shaft. (*CAUTION*—Use care so as not to damage seal rings on output shaft. Do not lose governor drive ball).

16) Remove rear pump discharge tube using tool 77869 and remove pump from case. Remove extension housing and pump gaskets. Remove rear pump drive key from output shaft. Remove bronze thrust washer from output shaft. (NOTE—Washer may come off with pump). Hold rear drum forward and remove the output shaft.

17) Remove selective thrust washer from rear of pinion carrier. If endplay as recorded in step 10 (above) was not within limits of .010-.029", replace this washer with one of proper thickness to give desired endplay. This washer furnished in following sizes: .063-.061", .069-.067", .076-.074", .083-.081".

18) Remove two seal rings from primary sun gear shaft. *CAUTION—use care not to distort rings.*

19) Remove pinion carrier from case and remove bronze thrust washer.

20) Mark rear band position so that it can be assembled in the same position. Remove band by squeezing ends together and tilting band forward.

CONTINUED ON NEXT PAGE

FORDOMATIC, MERCOMATIC & TURBO-DRIVE (Cont.)

21) Remove two center support bolts (on outside of case-one on each side). Press on end of turbine shaft to force clutch units toward rear of transmission and remove center support from case.

22) Remove rear and front clutch assemblies from transmission case as a unit. Install clutch assembly into bench fixture, tool No. IP-77530 and remove thrust washer from front of turbine shaft. Remove the front band from case. Lift front clutch assembly from primary gear shaft. *(CAUTION–*Do not rock assembly while lifting to prevent damage to seal rings)

23) Remove bronze and steel thrust washers from primary sun gear shaft and then remove the front clutch seal rings from primary sun gear shaft. Lift rear clutch assembly from shaft. *(CAUTION–*Do not rock assembly while lifting to prevent damage to seal rings). Remove rear clutch seal rings and thrust washers from shaft.

TRANSMISSION OVERHAUL (TRANSMISSION UNITS)

►*DISASSEMBLY & CLEANING CAUTION:* Handle all parts with care to avoid nicking or burring bearing surfaces and mounting faces. Clean all parts with clean solvent and dry with air. DO NOT use wiping cloths which might deposit lint and interfere with proper operation of transmission. Minor scores or burrs may be removed with crocus cloth. *CAUTION–When polishing valves use extreme care not to round edges of valve lands.*

►*REASSEMBLY CAUTION. Use all new gaskets when assembling or installing units in transmission. Lubricate all internal parts with Automatic Transmission Fluid Type "A" (vaseline may be used to retain gaskets and thrust washers). Tighten all bolts, nuts, and screws to correct torque.*

PRIMARY SUN GEAR SHAFT (Disassembly): Remove rear clutch seal rings by applying pressure on one end and at back of ring forcing ring into groove at these two points. Other end will spring out and free the hook. Remove thrust washer from thrust face of primary gear.

Inspection: Inspect all thrust surfaces and journals for wear or scores. Inspect sun gear for broken, chipped, or worn teeth. Inspect shaft splines and ring grooves for wear or burrs. Check all fluid passages for evidence of leakage and make certain passages are clean and free from obstructions. Check seal rings for wear by installing rings in bore and measuring end gap which should be .002-.009", check rings for free fit in groove (must not bind) If front clutch lubrication valve not operating properly, repair it by installing a new kit.

Reassembly: Install bronze thrust washer against thrust face of primary sun gear, install seal rings in shaft grooves. Seals can be installed in the same manner in which they were removed (see Disassembly above)

REAR CLUTCH (Disassembly): Using arbor press and tool No. 77515, remove clutch release spring snap ring *(CAUTION–*Guide spring retainer while releasing press to prevent retainer interfering with snap ring groove. Remove retainer, release spring, pressure plate snap ring, and pressure plate. Remove the four bronze and four steel clutch plates (Ford & Mercury), Five bronze and Five steel plates (Lincoln), from the drum. Place splined end of primary sun gear shaft in clutch piston bore, entering it as far as it will go, apply air pressure to hole in end of shaft which will force clutch piston out of cylinder *(CAUTION–*Hold hand over piston to prevent it flying out and being damaged) Remove outer seal ring from groove in piston and inner seal ring from clutch drum. Discard these seals (do not re-use).

Inspection: Inspect drum band surface, the bushing, and thrust surfaces for scores. Remove minor scores with crocus cloth. Replace badly scored parts. Inspect needle bearings for worn or loose rollers. Inspect gear teeth for burrs or wear. Inspect clutch piston bore and piston inner and outer bearing surfaces for scores. Check fluid passages for obstructions, making sure that they are free and clear. Inspect clutch plates for scores, and check plates for fit on clutch hub serrations. Replace all plates that are worn or do not fit properly *(CAUTION–*Front clutch plates differ from rear clutch plates and are not interchangeable). Check coning of the steel plates. Position plates on a flat surface, then check coning with a feeler gauge. Plates are coned to .010" clearance and should be checked on the inside diameter. Inspect clutch pressure plate for scores on clutch plate bearing surface. Replace plate if deeply scored. Check clutch release spring for distortion and discard if badly bent.

Reassembly: Lubricate all parts with Automatic Transmission Fluid Type "A". Install clutch piston inner seal ring in groove in drum. Install a new outer seal ring on piston and install piston in clutch drum. Install four steel and four bronze clutch plates (Ford & Mercury), five steel and five bronze (Lincoln), alternately, starting with steel plate, convex side up (Ford & Early 1954 Mercury), concave side up (Late 1954 Mercury & 1955 Lincoln & Mercury) Install clutch pressure plate with bearing surface down, and install snap ring Make sure snap ring is fully seated in groove. Install clutch release spring, then position retainer on spring Position the clutch assembly in an arbor press using Tool No 77515 positioned on spring retainer and compress clutch spring. Install snap ring *CAUTION–While compressing the spring, guide retainer to avoid interference with snapring groove. Make sure snap ring is fully seated in groove*

FRONT CLUTCH: Disassembly–Remove clutch cover snap ring and remove turbine shaft (input shaft) from clutch drum Remove thrust washer and clutch hub Remove three bronze and two steel clutch plates (1954), four bronze and three steel (1955) and pressure plates Using arbor press and tool No 77565 depress clutch release spring and remove snap ring Release spring pressure, remove clutch release disc spring from drum Using air pressure and a piece of 3/16" tubing, (bend at end for entry into hole in clutch bore) force piston out of cylinder *(CAUTION–Hold hand over piston to prevent damage)* Remove piston inner seal from clutch cylinder and remove piston outer seal from groove in piston

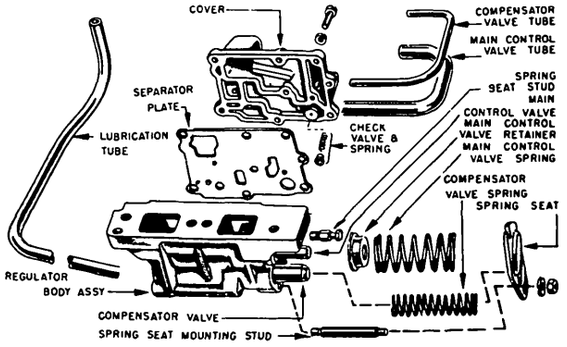
Inspection: See "Rear Clutch Inspection" above and follow the same procedure except that all front clutch plates are flat. *CAUTION–Front and rear clutch plates are not interchangeable.*

►*FRONT CLUTCH ASSEMBLY PRODUCTION CHANGE (ALL TRANSMISSION):* To prevent gear noise or clutch "roll over" during manual shift from "D" to "N", Front Clutch Plate (bronze). Part No. B5A-77519-A is used to replace two of the original four bronze plates. Install one later type plate identified by additional parallel grooves on both sides, next to clutch pressure plate, and the other installed on top of the balance of the plates. These later type plates can be used to correct the above condition in early 1955 transmissions

Reassembly: Install a new piston inner seal ring in clutch cylinder and a new outer seal ring in piston groove. Install piston in clutch housing. *(CAUTION–Make certain that steel bearing ring is in place on piston).* Position release spring in cylinder with **concave side up,** place spring compressor tool on spring and compress spring in an arbor press to enable installation of snap ring, make sure that snap ring is fully seated in groove. *NOTE–Complete reassembly of front clutch after rear clutch assembly has been installed on primary sun gear shaft as indicated below.*

PRIMARY SUN GEAR SHAFT & CLUTCH (Reassembly): After individual units assembled (Shaft and Front & Rear Clutches), place primary sun gear shaft assembly in bench fixture and install rear clutch assembly on sun gear shaft *(CAUTION–Center seal rings on shaft to prevent breakage as clutch assembly installed).* Install steel and bronze thrust washers on shaft in that order. Install two seal rings in shaft grooves. Install two seal rings in shaft grooves. Install front clutch housing on primary gear shaft while rotating clutch units to mesh rear clutch plates with serrations on clutch hub being careful not to damage seal rings as clutch assembly being installed. Install clutch hub in clutch cylinder with deep counterbore down. Install bronze thrust washer on clutch hub. Install pressure plate in clutch cylinder with bearing surface up then install three bronze and two steel (1954), four bronze and three steel (1955), clutch plates alternately, starting with a bronze plate *(CAUTION–Lubricate all plates with Automatic Transmission Fluid Type "A" as they are installed)* Install turbine shaft in clutch cylinder and install snap ring in groove, making sure that it is fully seated Install bronze thrust washer on turbine shaft Assembly is now ready for installation in transmission case *See "Transmission Reassembly" below*

FRONT PUMP (Disassembly): Remove pump cover attaching screws and remove cover with stator support. Mark the driven gear with Prussian Blue to assure correct assembly and remove drive and driven gears from pump body. To remove seal from pump body, mount the pump body on transmission case, use tool No. 1175-AB to remove seal



►*CAUTION: Extreme care must be taken not to scratch or mar pump gears or bearing surfaces*

CONTINUED ON NEXT PAGE

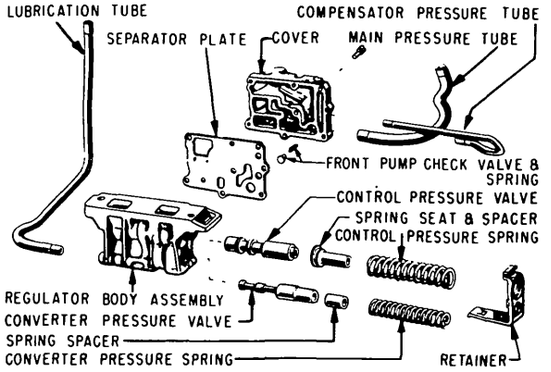
FORDOMATIC, MERCOMATIC & TURBO-DRIVE (Cont.)

Inspection: Inspect bushing, gear pockets and crescent for scores. Inspect front cover, pump body, gear teeth and stator support splines for burrs. Check pump for evidence of contact between outside diameter of drive gear and crescent. REPLACE PUMP if such contact noted. Check bushing for wear and scoring.

Reassembly: Use tool No. 77837 to install new seal in pump body *(CAUTION–*coat outside diameter of seal with Permatex No. 3 before installation to prevent fluid seepage). Install pump driven gear in pump body in accordance with marks made before disassembly, install drive gear. Install pump cover, attaching screws, lockwashers, and tighten cover screws evenly to 1-3 ft. lbs. Check pump for free movement.

1954 PRESSURE REGULATOR ASSEMBLY

REAR PUMP: (Disassembly): Remove screws and lockwashers securing pump cover to pump body and remove cover. Using Prussian Blue, mark pump drive and driven gears to assure correct assembly, and remove gears from body.



►*CAUTION–Handle pump parts with care to avoid scratching or marring.*

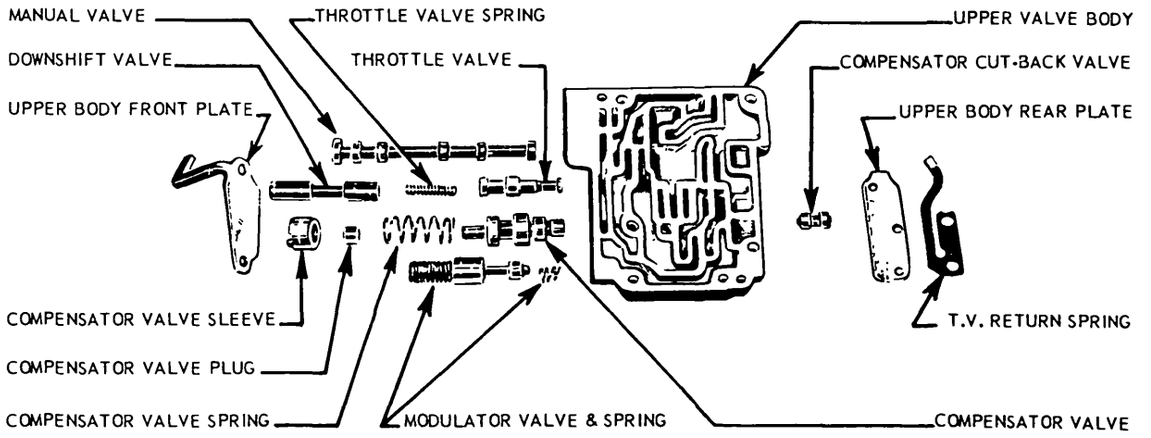
Inspection: Inspect all pump parts for excessive wear, score, or burrs. Check fluid passages for obstructions. Check pump for evidence of contact between outside diameter of drive gear and crescent. REPLACE PUMP if such contact noted. Check bushing for wear or scoring.

R assembly: Install pump driven gear into pump body, positioning gears as marked on disassembly. Install drive gear into position as marked. Install pump cover, install cover screws with lockwashers, tighten screws evenly to 50-60 inch lbs. (¼"), 20-30 inch lbs.,(10-24 screws). Check pump for free movement of gears.

PRESSURE REGULATOR BODY (Disassembly): Remove valves from body. Take out cover attaching screws, remove cover and separator plate.

Inspection: Inspect regulator body and cover mating surfaces. Check fluid passages in body and fluid passages in separator plate for obstructions. Inspect valves and valve bores for scoring and check freedom of valves in valve bores. Check regulator valve springs for distortion. Wash thoroughly in clean solvent and blow dry with air.

1955 PRESSURE REGULATOR ASSEMBLY



Reassembly: Install check valve spring in regulator cover and position valve on spring *(see "Pressure Valve Installation Caution" below).* Position separator plate on regulator cover. Hold regulator and cover together and check for free movement of valve. Place regulator body in position on separator plate and install attaching screws. *NOTE–Do not install valves at this time as they should be installed after regulator assembly is installed in transmission. See "Transmission Reassembly" below.*

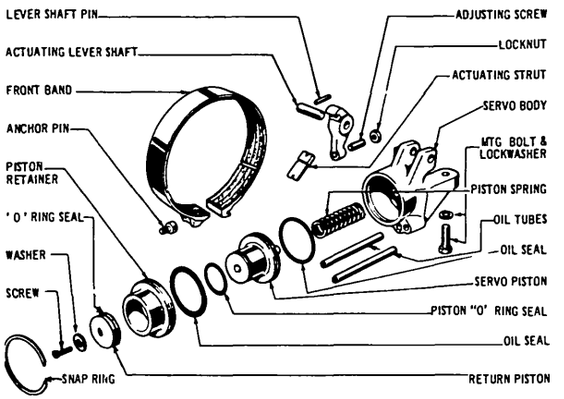
►*MERCOMATIC & TURBO-DRIVE PRESSURE REGULATOR VALVE SPRING & SPACER INSTALLATION CAUTION:* It is extremely important that the spring seat and spacer be installed so that the cupped end fits over the end of the control pressure valve, and the stem fits down through the control pressure spring. Two types of spacers are used in production, one having the small diameter end closed, and the other with the end open. Install either spacer as indicated above.

CONTROL VALVE (Disassembly): 1954 Models–Remove manual valve. Take out one screw attaching separator plate to valve body. Remove upper body front plate *(NOTE–Plate is spring loaded, apply pressure to plate while removing attaching screws).* Remove compensator sleeve, plug, compensator spring, compensator valve, modulator valve spring and valve, downshift valve and spring. Take out two screws attaching throttle valve return spring to upper body, remove the spring. Take out remaining screw attaching upper valve body rear plate and remove the plate *(CAUTION–Plate is spring loaded, apply pressure while removing screws).* Remove 3-2 control valve and spring, low inhibitor valve and spring and governor plug. Remove the end body *(CAUTION–End body is spring loaded, apply pressure while removing screws).* Remove low regulator plug and shift valve plug from end body, then remove end body plate. Remove shift valve inner and outer springs and shift valve, low regulator valve and transition valve. Remove attaching bolts and separate valve bodies. Remove cover end body. Remove front servo apply regulator valve from cover. Remove separator plate from upper body. Remove check valve seat.

CONTROL VALVE (Disassembly): 1955 Models–During disassembly of valve avoid damage to valve parts and keep valve parts clean. Place valve assembly on a clean cloth while performing the disassembly operation. *(NOTE–Do not separate the valve bodies until after valves have been removed).* Remove manual valve and remove one screw attaching separator plate to lower valve body. Remove upper body front plate *(NOTE–The plate is spring loaded. Apply pressure to plate while removing the attaching screws).* Remove compensator spring and plug, remove valve spring and valve. Remove modulator valve retainer, both large and small springs and valve. Remove downshift valve and spring. Remove two screws attaching throttle valve return spring to upper body, then remove spring. Remove the remaining screw attaching upper valve body rear plate to valve body, then remove plate. Remove throttle valve, then the compensator cut back valve. Remove lower body side plate *(apply pressure to plate while removing as it is spring loaded).* Remove the 2-1 shift valve spring and valve, low inhibitor valve and spring, then remove the 2-3 shift valve

CONTINUED ON NEXT PAGE

1955 CONTROL VALVE UPPER B DY ASSEMBLY

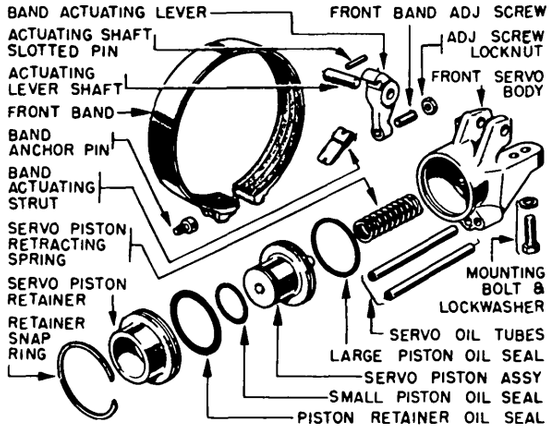


FORDOMATIC, MERCOMATIC & TURBO-DRIVE (Cont.)

and governor plug. Remove the end body *(End body is spring loaded. Apply pressure while removing attaching screws).* Remove orifice control valve plug and 2-3 shift valve plug from end body and remove end body plate. Remove 2-3 shift valve outer and inner springs, then remove shift valve. Remove orifice control valve and transition valve and spring. Remove attaching bolts and screws and separate bodies. Remove separator plate from upper body and remove check valve seat, valve and spring from lower body

Inspection: *(CAUTION–Handle all parts carefully to avoid scoring, burrs and distortion).* Clean all parts thoroughly in clean solvent and blow dry with air. DO NOT USE CLOTH FOR WIPING PARTS (lint left by a cloth may cause poor valve operation). Inspect all mating surfaces for burrs, scratches, and flatness. Check all passages for obstructions. Inspect all valves and valve bores for scoring and check valves for free movement in bores (valves should slide in bore of own weight). Valves can be polished with crocus cloth.

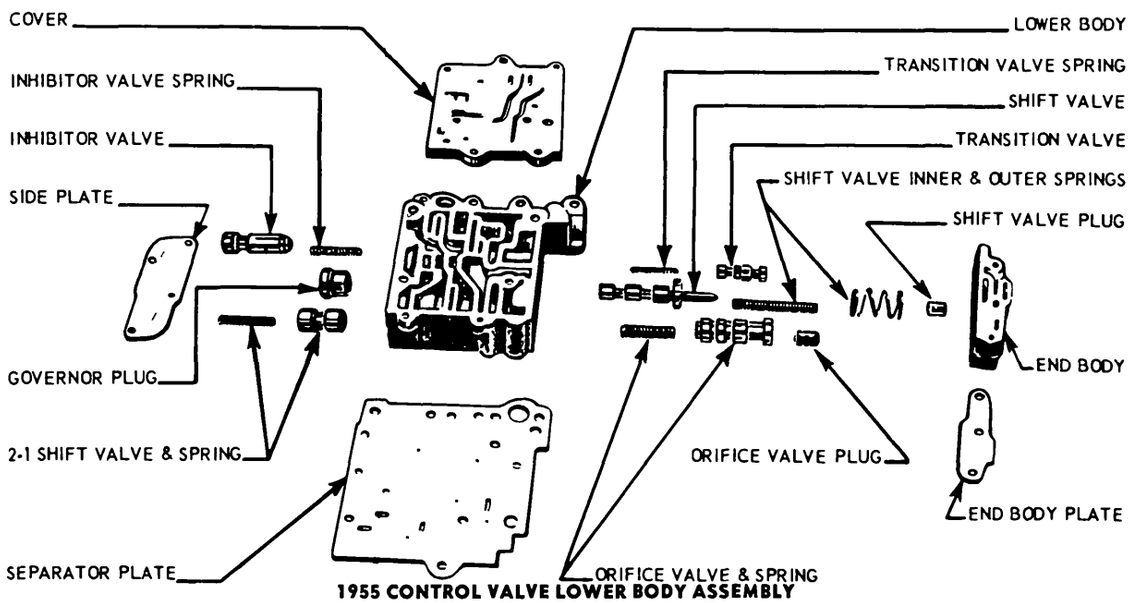
►*CAUTION–Do not round the sharp edges of valves and plugs.*



Reassembly (1954 Models): *(NOTE–Arrange parts in correct position. Rotate valves and plugs when inserting them in bores, to avoid shearing of soft body castings).* Install separator plate on upper valve body, install but **do not tighten** separator plate screws Install check valve seat in lower valve body, install front servo apply regulator valve in cover and plug in cover end body Install cover end body on cover but **do not tighten** attaching screws Position lower body on upper body install lower body cover and attaching bolts

TURBODRIVE FRONT SERVO & BAND ASSY.

Tighten the bolts evenly to 4-6 ft. lbs , tighten separator plate screws to 20-30 inch lbs *(CAUTION–Excessive tightening of these bolts may distort valve body and cause valves or plugs to stick)* Tighten cover and body screws to 20-30 inch lbs Check for free movement of front servo apply regulator valve by shaking valve body Install plate on lower end body and make certain that countersunk head screw installed in correct hole Install low regulator and shift valve plugs in end body Install transition valve, low regulator valve, and shift valve in lower body. Install shift valve inner and outer springs. Install end body on lower body, install governor plug in lower body. Install low inhibitor valve spring and valve, 3-2 control valve spring and valve, then install lower body side plate Install modulator plug in upper body, install throttle valve, position upper body rear plate on upper body with plate between end lands of throttle valve, install one screw in hole next to throttle valve, position throttle valve return spring on plate and install remaining plate-to-valve body screws. Install compensator valve and spring, downshift spring and valve, and modulator valve and spring. Install plug in compensator valve sleeve (castellated end out) and install assembly in body. Install upper body front plate, install separator plate-to-lower body screw, install manual valve.



Reassembly (1955 Models): *(NOTE–Arrange parts in correct position. Rotate valve and plugs when inserting them in bores, to avoid shearing of soft metal castings).* Install separator plate on upper body (do not tighten screws). Install check valve spring, valve, and seat in lower body Position lower body on upper body. Install lower body cover and tighten attaching bolts finger tight. Align the valve body attaching bolt

TYPICAL FORDOMATIC & MERCOMATIC FRONT SERVO & BAND ASSEMBLY

holes in the separator plate and lower body. Tighten the four valve body bolts to 4-6 ft. lbs. *(CAUTION–Excessive tightening of these bolts may distort valve bodies, causing valves or plugs to stick).* Install the three lower cover to lower body screws and tighten to 20-30 inch lbs.• Install the plate on lower end body and tighten attaching screws. Install orifice control and shift valve plugs in end body. Install transition valve and spring, the orifice control valve and spring, 2-3 shift valve in lower body. Install shift valve inner and outer springs, and install end body on lower body, *(CAUTION–Make sure that inner spring is piloted on shift valve regulator plug).* Install governor plug in lower body. Install low inhibitor valve spring in valve, and install spring and valve. Install 2-1 shift valve spring in valve, and install valve and spring. Install lower body side plate. Install compensator cut-back valve in upper body. Install throttle valve and position upper body rear plate on upper body with the plate between end lands of throttle valve. Install one plate to body screw in hole next to throttle valve. Position throttle valve return spring on plate, and secure plate in place with the remaining plate to valve body screws. Install compensator valve and spring and downshift

CONTINUED ON NEXT PAGE

1955 CONTROL VALVE LOWER BODY ASSEMBLY

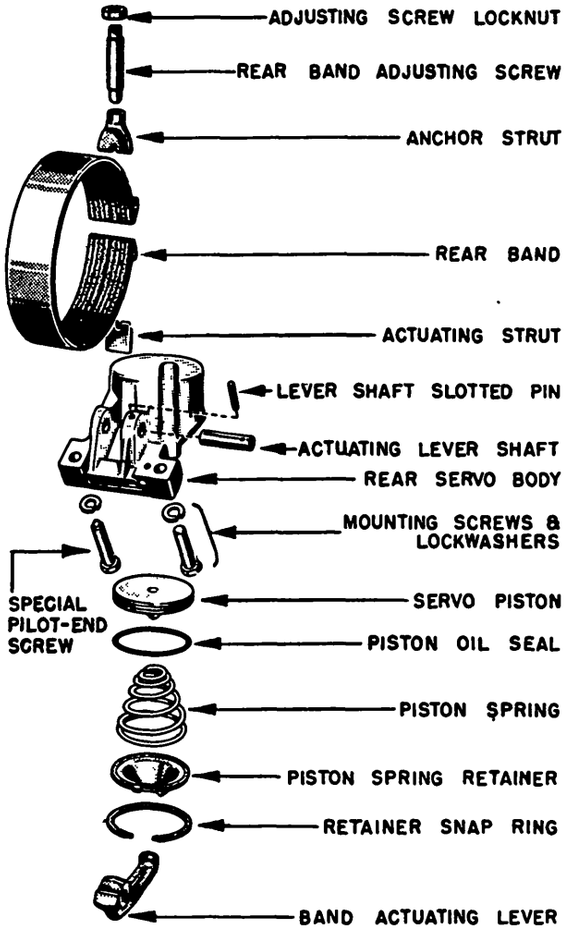
FORDOMATIC, MERCOMATIC & TURBO-DRIVE (C nt.)

spring and valve. Install modulator small spring, valve, spring, and retainer as an assembly. Install the plug in the compensator valve sleeve, castellated end out, and install assembly in body, with smooth end toward body. Install upper body front plate. Install separator plate to lower body screw and install manual valve.

GOVERNOR (Disassembly): Remove governor body side plate attaching screws, remove plate. Remove governor body attaching screws and remove body from counterweight. Remove governor valve from body.

Inspection: Inspect valve and valve bore for scores and check free movement of valve in bore. Inspect all fluid passages for obstructions. Inspect mating surfaces for burrs and distortion.

Reassembly: Install governor valve in bore of governor body and install body cover plate and attaching screws. Mount governor body on counterweight, making sure that fluid passages line up with passages in counterweight. Install body attaching screws. Tighten body-to-counterweight screws.



FRONT SERVO (Disassembly–Ford & Mercury): Remove piston retainer snap ring *(CAUTION–Servo piston is spring loaded. Apply pressure to piston when removing snap ring).* Remove servo piston and retainer from servo body (NOTE–If necessary, tap servo piston guide lightly with soft hammer to remove from servo body). Remove servo spring, and remove retainer from piston and seal from retainer.

Disassembly (Lincoln): Proceed as with Ford & Mercury (above), then loosen to one half its length the screw that secures servo piston release piston to servo piston stem. Tap screw head with soft hammer until stem is forced from release piston. Separate release piston, piston retainer and piston. Remove seal from release piston. Remove "O" ring seals from piston.

Inspection: Inspect servo body for cracks. Inspect piston and piston bore for scores. Check fluid passages for obstructions. Check actuating lever for free movement and inspect for wear. (NOTE–If necessary to replace actuating lever or shaft, remove retaining pin and push shaft out of bracket). Inspect threads in lever and on adjusting screw. Check servo spring and servo band for distortion. Inspect servo band lining for excessive wear and bond to metal band. (NOTE–Band should be replaced if worn to a point where grooves are not evident). Inspect bands for cracks and distortion.

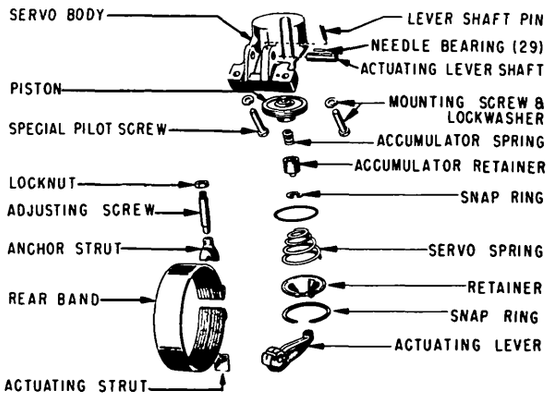
Reassembly (Ford & Mercury): Install new "O" ring seals on piston, and new oil seal on piston retainer. Lubricate seals and install retainer on piston. Position servo spring in servo body. Lubricate and install piston and retainer assembly in servo body. Press retainer into servo body and install snap ring. *(CAUTION–Make sure snap ring is fully seated in groove).* Install adjusting screw and locknut in actuating lever if previously removed. Check operation by applying air pressure to apply hole.

Reass mbly (Lincoln): Install new "O" ring seals on piston, and install new seal on piston retainer. Lubricate seals and install retainer on piston. Install new oil seal on release piston and retainer piston and

1954 REAR SERVO & BAND ASSEMBLY

piston retainer. Install new "O" ring seals on piston. Install piston in retainer and move piston to full release position in retainer. Place piston release piston in position, concave side toward stem and press into place. Install screw retaining release piston to piston stem. Complete reassembly in same manner as for Ford & Mercury (above).

REAR SERVO (Disassembly): *(NOTE–Ford & Mercury Rear Servo is smaller in diameter than that used on Lincoln).* With a 1/8" pin punch, remove servo actuating lever shaft retaining pin, and remove shaft and operating lever *(CAUTION–Use care when removing actuating lever to avoid losing needle bearings).* While pressing down on servo spring retainer, remove snap ring (release pressure on retainer slowly). Remove retainer and servo spring. Hold hand over piston to prevent damage and force piston from servo body with air pressure. Press down on accumulator piston and hold in this position while removing "cir-clip" type lock ring with lock ring pliers. With lock ring removed, gradually release accumulator piston until all tension has gone from spring. Remove piston seal ring from servo piston.



Insp cti n: Inspect servo body for cracks, and piston bore for scores. Inspect servo body-to-transmission case mating surface for burrs. Check fluid passages for obstruction and passage plugs for tightness in body. Inspect piston stem for scores. Inspect accumulator bore and piston for scores and wear, and accumulator spring for distortion. Inspect actuating lever, socket, and shaft for scores and wear. Check needle bearings for wear and distortion. Inspect servo spring for distortion. Inspect servo band lining for excessive wear and bond to metal band. (Band should be replaced if worn to point where grooves are not clearly evident). Inspect band and struts for distortion and band ends for wear.

Reassembly: Install new seal ring in servo piston. Install accumulator spring and piston in servo piston and retain with lock ring. Install piston in servo body (lubricate parts to facilitate assembly). Install servo spring with small end against servo piston and install retainer. Compress spring and install snap ring, making sure that snap ring is fully seated in groove. Place needle bearings in actuating lever shaft hole. With a pencil, position needle bearings around hole. Lock bearings in place by placing thumb over bearings and rotating clockwise. Install actuating lever with socket in lever bearing on piston stem. Needle bearing retainers at each side of actuating lever shaft hole must be installed with actuating lever. Install actuating lever, aligning the retaining pin holes and bearing retainers, and install pin. Check lever for free movement and then check operation of servo by applying air pressure to apply hole.

DISTRIBUTOR SLEEVE (Inspection): Inspect all passages for obstructions. Inspect sleeve bore for scores or excessive ring wear. Inspect mating surfaces for burrs and flatness. Check fit of fluid tubes. *NOTE–* Make sure spacer is on center tube.

PINION CARRIER (Inspection): Inspect servo band surfaces for scores. Inspect inner bushing for scores. Check free movement of pinions on pins and inspect

CONTINUED ON NEXT PAGE

1955 REAR SERVO & BAND ASSEMBLY

FORDOMATIC, MERCOMATIC & TURBO-DRIVE (Cont.)

for worn or broken teeth. Check pinion endplay (.010-.020"). Pinion pins must be a tight fit in carrier. Check all fluid passages. Check journal bushing for scores. *NOTE*–Planet carrier is serviced only as an assembly.

OUTPUT SHAFT (Inspection): Inspect thrust surfaces and journals for scores. Inspect internal gear for broken or worn teeth. Inspect aluminum sleeve for scores and check ring grooves for burrs. Inspect keyway and drive ball socket for wear. Inspect splines for burrs or wear. Inspect external parking gear teeth for damage and speedometer drive gear for burrs

EXTENSION HOUSING (Inspection): Inspect housing for cracks and drive shaft slip yoke bearing surface for scores. Inspect gasket surface for burrs. If inspection reveals it necessary to remove rear seal, use tool No. 1175-AB. (NOTE–Rear seal may be replaced without removing transmission from car). Use tool No. 7657 (1954), No 7657-D (1955) and install new seal in extension housing Remove inspection cover and gasket and check fluid baffle for tight fit in housing

TRANSMISSION CASE LINKAGE (Disassembly): Remove throttle lever nut and take off inner and outer throttle levers. Remove throttle lever shaft seal from counterbore in manual lever shaft. Remove parking mechanism actuating rod, detent ball and spring. Remove manual lever shaft nut, detent and outer manual lever and shaft. Remove torsion lever retainer clip and take off torsion lever assembly. Disassemble torsion lever assembly by rotating lever while holding spring. Disengage pawl return spring from toggle link pin and remove pin. Remove pawl pin by working pawl fore and aft until pin protrudes from case. Remove toggle pin retainer clip, toggle pin, pawl return spring, spring retainer and link. Remove toggle lever pin by tapping lever toward rear of case, then remove plug, toggle lever pin and lever (NOTE–toggle lever pin is held in place by the plug). Remove manual shaft seal and transmission vent from case.

Inspection: Inspect each part of parking mechanism for wear, distortion or other damage.

Reassembly: Assemble toggle lever, link, pawl return spring and pawl and install assembly in transmission case. Install toggle lever and pawl pins. Install torsion lever assembly. (NOTE–Use screwdriver to position spring on torsion lever). Install washer and retainer clip. Coat outer diameter of new manual shaft seal with Permatex No. 3 and use Tool 77288 to install seal in case. Install manual lever and shaft in case, mount detent lever and tighten attaching nut to 35-40 ft. lbs. torque. Install detent spring and ball *(NOTE–* use a piece of thin tubing to depress ball and spring while rotating detent). Position ends of parking pawl torsion lever rod in detent lever and torsion lever and secure with cotter pins. Install new seal on throttle lever shaft, install outer throttle lever and shaft in case, install lever on inner end of shaft and tighten attaching nut to 35-40 ft. lbs. Check linkage for free operation without binding.

TRANSMISSION CASE (Inspection): Inspect case for cracks and stripped threads. Inspect all gasket and mating surfaces for burrs. Inspect all bearing surfaces for wear, scores, and burrs.

TRANSMISSION REASSEMBLY

►*REASSEMBLY CAUTION: Use Automatic Transmission Fluid Type "A" only to lubricate parts for assembly. DO NOT use any other form of lubricant. Use all new gaskets and tighten all bolts and screws to correct torque specifications. DO NOT USE FORCE WHEN ASSEMBLING PARTS. If parts do not assemble freely, examine parts for cause of difficulty.*

CLUTCH ASSEMBLIES: Install front band in transmission case so that anchor end aligned with anchor in case. Install clutch assemblies into transmission case from the rear *(CAUTION–Do not allow clutches to separate)*, while positioning servo band on drum. Hold units together while making installation. Position center support in case, aligning hole in center support with hole in right hand side of case. Install right and left hand center support outer bolts and external tooth lockwashers *(CAUTION–Lockwashers must be installed with the rolled edge toward transmission case to insure tight seal).*

PINION CARRIER & OUTPUT SHAFT: Position rear servo band in transmission case, with the strut ends up. Place anchor end (identified by a depression in center of strut retainer), toward adjusting screw. Install a bronze thrust washer on thrust face inside pinion carrier. To install pinion carrier assembly, position rear band over drum while meshing the planet pinions. Install two seal rings on primary sun gear shaft, and check rings for free movement in grooves. Install selective thrust washer on rear of planet carrier, retaining it in place with the transmission fluid. *(NOTE–If endplay was not within specifications, when checked prior to disassembly, replace washer with one of proper thickness).* Install output shaft, carefully meshing internal gear with pinions.

REAR PUMP: Position rear pump drive key in keyway on output shaft. Position new front and rear gaskets on pump body, retaining gaskets with transmission fluid. Install thrust washer on pump body with the bronze side up. Align thrust washer tangs with bosses on pump body, then install the rear pump *(CAUTION–* Be sure drive key is aligned with keyway in pump drive gear).

GOVERNOR: Position governor drive ball in the pocket in output shaft. Retain ball with transmission fluid. Install governor assembly aligning groove with ball in output shaft. Install governor snap ring. *NOTE–Install governor with the governor body plate toward front of transmission.*

DISTRIBUTOR: Place the four seal rings in distributor sleeve, and check ring gap. Check fit of seal rings in grooves of output shaft. Install distributor sleeve on output shaft, chamfer forward (lubricate parts to aid assembly) Install distributor and tubes on sleeve, making sure passages in sleeve and distributor are aligned. Install attaching bolts and lockwashers. Tighten bolts finger tight. Insert distributor tubes in transmission case, until spacer on center tube is against case, then tighten distributor attaching bolts to 8-10 ft. lbs. Install a new seal on rear pump outlet tube and install tube in transmission case and rear pump body.

EXTENSION HOUSING: Position speedometer drive gear ball in pocket in output shaft, retaining it with fluid. Install speedometer drive gear, and gear snap ring. Insert extension housing oil seal replacer and pilot in housing, then install extension housing on transmission case. Install attaching bolts and external tooth washers. *(CAUTION–Washers must be installed with rolled edge toward transmission case to insure a tight seal).* Tighten extension housing attaching bolts to 28-30 ft. lbs. Install governor inspection cover and a new gasket on housing.

FRONT PUMP: Position a new front pump gasket in counterbore of transmission case. Install front pump, aligning pump bolt holes with holes in case. Install three of the pump attaching bolts and tighten them to 17-22 ft. lbs.

TRANSMISSION ENDPLAY (Checking): Mount a dial indicator support on front pump bolt hole. Mount dial indicator on support so that contact rests on end of turbine shaft. Use a large screw driver to pry front clutch drum toward rear of transmission. Set dial indicator to zero. Remove screw driver and pry units toward front of transmission case by inserting the screw driver between large internal gear and transmission case. Note indicator reading. Endplay should be .010-.029". Remove indicator and remove tool from extension housing. Install the one remaining front pump attaching bolt and tighten it to 17-22 ft. lbs

FRONT SERVO: Position front band forward in case with band ends up. Position servo strut with the slotted end aligned with servo actuating lever and the small end aligned with band end. Rotate band, strut, and servo into position engaging anchor end of band with anchor end in case. Locate servo on dowel in case, then install attaching bolt (or bolts), tightening them only two or three turns. Install servo tubes

REAR SERVO: Position servo anchor strut, then rotate rear band to engage the strut. Position servo actuating lever strut with a finger, then install servo and attaching bolts. Tighten bolts to 40-45 ft. lbs

PRESSURE REGULATOR BODY: Install pressure regulator body and attaching bolts and tighten bolts to 17-22 ft. lbs. Install control and converter valve guides and springs and install spring retainer. Install a new seal ring on rear pump intake tube, then install tube in case. *NOTE–On 1955 models when installing spring retainer be sure that both tangs attach at the same time.*

CONTROL VALVE BODY: Install control valve assembly, using care to align servo tubes with control valve. Align the inner throttle lever between throttle lever stop and downshift valve, and at the same time push the throttle valve in to clear transmission case. *(CAUTION–Align manual valve with actuating pin in the manual detent lever. Do not tighten attaching bolts).* Install the large control pressure tube in valve body and regulator. Install small control pressure compensator tube in valve body and regulator. Install lubrication tube in rear pump and regulator body.

CONTINUED ON NEXT PAGE

FORDOMATIC, MERCOMATIC & TURBO-DRIVE (C nt.)

Tighten control valve body attaching bolts to 8-10 ft. lbs. Tighten front servo attaching bolts or bolt to 30-35 ft. lbs.

ADJUSTMENT (Front Servo): Loosen front servo adjusting screw locknut, then back nut off three turns. Loosen adjusting screw five complete turns. Using the front band adjusting wrench, tool No. 7225, insert a ¼" spacer between lever and stem, then tighten the screw until ratchet overruns. **Back the adjusting screw ne complete turn,** then tighten locknut to 20-25 ft. lbs.

ADJUSTMENT (Rear Servo): Loosen adjusting screw locknut three turns with a ¾" socket of the rear band adjusting wrench. Back off the adjusting screw until free travel is obtained. Using tool No. 7195, tighten adjusting screw until ratchet overruns, then back off the adjusting screw 1½ turns. Hold rear servo adjusting screw stationary, and tighten the locknut to approximately 40 ft. lbs.

FLUID SCREEN & PAN: Position fluid screen over rear pump inlet tube then over front pump inlet tube. On 1955 models press screen down firmly and install screen retaining clip. In trucks, position the oil cooler (if so equipped) to sump discharge tube in case. Place a new gasket on transmission case, then install the pan Install attaching bolts and lockwashers and tighten to 10-13 ft. lbs

TRANSMISSION & CONVERTER INSTALLATION

1954 FORD 6 & V8

1) Position converter assembly in transmission housing *(CAUTION–Make sure that converter does not slip from housing during installation).* Raise assembly on a jack until transmission extension housing can slide back over frame crossmember (on 6 cyl models) Install flywheel assembly on engine crankshaft flange and tighten bolts to 75-85 ft lbs

2) Remove all dirt, grease and burrs from converter pilot bore in flywheel Apply a heavy film of white lubricant evenly on converter bearing surface *(NOTE–Excessive lubricant in pilot bore will prevent proper entry of converter pilot into bore, and will force converter rearward, scoring the front pump)*

3) Move the assembly forward and properly align converter pilot and housing dowel holes Install the four lower converter housing-to-engine attaching bolts **but do not tighten at this time.** Align both of the flywheel access holes with drain plugs in converter cover then tighten the converter housing-to-engine attaching bolts to 40-45 ft lbs *(CAUTION–If converter housing-to-engine bolts are tightened when converter cover and flywheel are not properly aligned, it will be necessary to check flywheel for distortion, and housing and impeller flange for cracks or damage Front pump will also have to be checked for damage).* Check converter assembly for binding by shifting the assembly back and forth by hand If no binding exists, install the six flywheel-to-converter bolts and tighten them to 25-28 ft lbs If a binding condition exists, converter and housing must be realigned

4) Raise engine and replace the crossmember, then install the crossmember bolts. Lower the assembly onto crossmember and install engine rear support bolts. Remove engine support bar. Apply a coating of Automatic Transmission Fluid to universal joint knuckle, and install drive shaft Install parking brake and speedometer cable.

5) Connect manual and throttle linkage to transmission levers. Install the converter housing cover (V8 models) or the access plate (6 cyl. models). Then install the starter Install the fluid filler tube to transmission oil pan and tighten securely Install remaining converter housing-to-engine attaching bolts Lower car to floor

6) Install the two top converter housing-to-engine bolts and tighten to 40-45 ft. lbs., and replace the two rubber access hole plugs. Fill transmission with Automatic Transmission Fluid Type "A" Check converter and transmission assembly for fluid leakage, then adjust the manual and throttle linkages.

1955 FORD PASS. CARS & TRUCKS (EXCEPT THUNDERBIRD & SUNLINER)

1) If converter has been removed from converter housing, position converter in housing, then install converter housing lower cover plate (8 Cyl.), or wedge converter in places (6 Cyl.) to prevent converter slipping out of housing. Rotate converter until drive plate bolt holes are in horizontal position (8 Cyl), or in the vertical position (6 Cyl.). Position flywheel on crankshaft flange, then install attaching bolts

2) Move converter and transmission assembly forward into position, using care not to damage converter drive plate and converter pilot. Install lower converter housing to engine bolts and tighten them to 40-45 ft. lbs. Install crossmember on pass. cars. Lower transmission until extension housing rests on crossmember and install extension housing to crossmember bolts.

3) On trucks, install converter housing to crossmember bolts. On all vehicles position flywheel drive plates, and install drive plate attaching bolts. Tighten drive plate bolts to 28 ft. lbs. Install converter drain plugs and access plates. On trucks, position the oil cooler on support brackets, then install cooler. Connect oil inlet and outlet lines to transmission.

4) Coat universal joint knuckle with transmission fluid, then install drive shaft. Connect speedometer cable at transmission. Connect manual linkage at transmission manual lever. Install converter air duct and the linkage splash shield (pass. cars), exhaust duct shield (trucks).

5) Install starter motor and connect transmission to frame ground strap at transmission. Connect fluid filler tube to oil pan. Lower hoist, then position water inlet and outlet lines on oil cooler. Tighten hose clamps securely. Install the upper two converter housing to engine bolts and tighten to 40-45 ft. lbs. Replace covers on converter housing access holes and floor mat. Fill radiator with water.

6) Fill transmission with Automatic Transmission Fluid Type "A" *(see "Lubrication" above).* Check transmission and converter assembly for fluid leaks, adjust manual and throttle linkages *(see "Linkage Adjustment" above)*

THUNDERBIRD

►*INSTALLATION NOTE: Converter and transmission assembly must be installed b fore engine installed in chassis. The converter and transmission assembly can be installed in the chassis separately before engine is installed, or converter, transmission, and engine may be installed together as a unit*

1) To attach converter and transmission to engine before assembly into chassis as a unit, first align converter pilot, housing dowel holes, and drive plate holes. Remove all foreign material from converter pilot bore in crankshaft. Apply a heavy film of lubricant evenly on converter pilot bearing surface. *(CAUTION–Excessive lubricant in pilot bore will prevent proper entry of converter pilot into bore, forcing converter rearward and scoring front pump)*

2) Install pilot studs in two of the converter housing to engine bolt holes. Remove converter housing lower front cover plate. Move converter and transmission forward into position using care not to damage converter drive plate and converter pilot. Install four converter housing to engine bolts, remove pilot studs, then tighten bolts to 40-45 ft. lbs

3) If engine has been removed separate from converter and transmission assembly, mount transmission on a transmission floor jack and position assembly in car. Connect drive shaft to transmission output shaft. Install the two extension housing to rear engine support bolts. Connect speedometer cable and manual linkage at transmission. Install engine lifting sling and lower engine carefully into engine compartment, starting converter pilot into crankshaft. Make sure studs on manifold are aligned with holes in muffler inlet pipe, and dowels in block engage holes in converter housing. Raise car and position jack stands. Install engine front insulator bolt, and right and left hand insulator support bolts. Connect exhaust pipe to manifold and lower car to floor

4) Install two lower converter housing to engine bolts and tighten them to 40-45 ft. lbs. (Tighten bolts slowly and evenly to avoid binding on dowel pins). Install converter housing to engine bolts, and tighten them to 40-45 ft lbs. Align flywheel and drive plate bolts with converter. Install the six bolts and tighten them to 25-28 ft. lbs. Complete engine installation.

1954-55 MERCURY 1955 LINCOLN

1) Position transmission and converter assembly under car, raise it into position and move it forward to engage converter pilot with hole in crankshaft *(CAUTION–Guide assembly carefully to avoid damage to flexible drive plate and converter pilot).*

2) Install converter housing attaching bolts and tighten to 40-45 ft. lbs. Install six bolts securing converter to flexible drive plate and tighten to 25-28 ft. lbs. (On 1954 Mercury & 1955 Lincoln, install detachable frame crossmember to "X" member) Install engine rear mount to transmission Remove engine support tool, lower engine and install rear engine mount to crossmember bolts and remove lift Connect speedometer cable at extension housing

CONTINUED ON NEXT PAGE

FORDOMATIC, MERCOMATIC & TURBO-DRIVE (Cont.)

3) Connect throttle and transmission manual linkage to transmission levers. Adjust linkage (see "Linkage Adjustment" above). Install converter housing upper plate with new seal. Install starter, converter drain plugs, and place fluid filler tube on pan and tighten filler hex nut to 40-50 ft. lbs.

4) Install converter housing lower plate. Install duct on converter housing and deflector between frame and housing. Install drive shaft, (lubricate front universal slip yoke to aid installation). (On 1955 Mercury with single exhaust, install exhaust system). Check operation of neutral switch. Install throttle linkage brackets to engine and body using original nuts and bolts. Install battery ground cable. Fill transmission with Automatic Transmission Fluid Type "A" (see "Lubrication" above).

TRANSMISSION INSTALLATION (WITHOUT CONVERTER)

1954 FORD 6 & V8

1) Install two special guide pins in the top transmission-to-converter housing attaching bolt holes. mount transmission jack and position it under car. Rotate the engine to position front pump drive lugs on converter pump assembly in a vertical position. Rotate front pump to position the slots in the pump assembly in a vertical position. Apply lubriplate to seal the surface on converter pump cover hub. Raise transmission and move it toward front of car.

2) *(CAUTION–Be sure to align turbine shaft splines with turbine hub splines and the converter pump lugs with slots in front pump drive gear).* Install the two lower transmission-to-converter housing attaching bolts. Remove the two guide pins and install the two upper attaching bolts. Tighten bolts to 40-45 ft. lbs.

3) Raise engine and install frame crossmember, then install crossmember bolts Lower engine onto crossmember and install engine rear support-to-transmission bolts. Remove engine support bar and install drive shaft Install parking brake assembly and speedometer cable. Connect manual & throttle linkage to transmission levers

4) Install transmission drain plug. Fill transmission with Automatic Transmission Fluid Type "A". Check transmission for indications of leakage.

1955 FORD PASS. CARS & TRUCKS (EXCEPT THUNDERBIRD & SUNLINER)

►*NOTE: On Thunderbird and Sunliner it is not possible to remove the transmission (without converter) due to limited clearance.*

1) Install guide pins in the two top transmission to converter housing bolt holes. Mount transmission on jack and position it under vehicle. Rotate engine to position the front pump drive lugs on converter impeller housing in a vertical position. Rotate front pump to position slots in front pump drive gear in a vertical position. Apply lubriplate to seal the surface on the converter impeller cover hub. (If a new transmission is being installed, position a new rubber extension housing duct shield over end of housing)

2) Raise transmission and move it toward front of vehicle *(CAUTION–*Be sure to align the turbine shaft splines with turbine hub splines and the converter impeller lugs with slots in front pump drive gear)

3) On trucks, position the oil cooler front support bracket on case. On all vehicles, install the lower transmission to converter housing attaching bolts. Remove the two guide pins and install the two upper attaching bolts. Tighten bolts to 40-45 ft. lbs.

4) On cars, install the frame crossmember and bolts. Lower transmission onto crossmember and then install engine rear support to transmission bolts. On trucks, position the oil cooler on the support bracket and install attaching bolts. Connect oil cooler to transmission oil lines at transmission. Tighten fittings securely. Install universal joint yoke onto transmission output shaft and connect drive shaft

5) On F-250, F-350 & P-350 trucks, coat universal joint knuckle with transmission fluid. Install the four bolts attaching drive shaft coupling yoke at the parking brake assembly, then connect drive shaft at rear axle. Connect speedometer cable at extension housing.

6) Connect manual linkage and throttle linkage to transmission levers and adjust the linkage (see "Linkage Adjustment" above). Connect fluid filler tube to oil pan and tighten fitting securely. Lower vehicle to floor and fill transmission with Automatic Transmission Fluid Type "A" (see "Lubrication" above).

1954-55 MERCURY

1955 LINCOLN

1) Install guide pins, tool No. ST-0711 into top transmission to converter housing attaching bolt holes. Mount transmission on lift and position under car. Rotate engine to position front pump drive lugs on converter pump housing in a vertical position. Rotate transmission front pump to position slots in pump drive gear in a vertical position. Apply lubriplate to seal surface on converter pump cover hub.

2) Raise transmission and move toward front of car *(CAUTION–*Use care to index turbine shaft splines with turbine hub, and lugs on converter pump with slots in front pump drive gear). Install two lower transmission to converter housing attaching bolts. Remove the two guide pins and install two upper attaching bolts and tighten to 40-45 ft. lbs.

3) On 1954 Mercury & 1955 Lincoln, install detachable crossmember to "X" member. Install rear engine mount to transmission.

4) Raise engine and transmission sufficiently to remove engine support fixture. Lower unit to crossmember and install rear engine mount to crossmember bolts. Install drive shaft. (Lubricate front universal joint yoke with transmission fluid to aid assembly).

5) Connect speedometer cable at extension housing. Connect manual and throttle linkage to transmission levers. Adjust linkage (see "Linkage Adjustment").

6) On 1955 Mercury with single exhaust system, install exhaust system. Place fluid filler tube in position on pan and tighten filler tube hex nut to 40-50 ft. lbs. Remove support stands and lower car to floor. Fill transmission with Automatic Transmission Fluid Type "A" (see "Lubrication" above). Road test car.

HYDRA-MATIC DRIVE DRAINING & REFILLING

ALL 1946-51 HYDRA-MATIC CARS

Lubrication Intervals: (All Cars)—**Check Fluid** every 2000 miles. **Drain & Refill** every 25,000 miles.

CAUTION—This 25000 mile interval supersedes earlier specified intervals.

►**Oil Level Indicator Air Cleaner**—Clean the mesh type air cleaner (in dipstick cap) every 10000 miles or twice each year.

Checking Fluid Level: Check only with engine warm and idling at hot or slow idle speed (choke valve open, fast idle inoperative).

1) With transmission oil hot, run engine for at least 2 minutes with selector lever in "N" (to insure fluid coupling being filled so that true oil level reading will be secured).

2) Turn back floor mat and remove cover over dipstick location (right front of transmission). Clean all dirt and lint from around opening and dipstick to prevent this dirt entering transmission when dipstick removed.

3) With engine idling, and selector lever in "N", check fluid level reading on dipstick.

4) Add fluid as required to bring level up to full "F" mark on dipstick. *NOTE*—Approximately 1½ pints required to raise level from "L" to "F".

►*CAUTION—Do not fill above "F" mark on dipstick (may cause foaming when oil is hot).*

Draining & Refilling: Drain oil only when transmission warm (immediately after operation).

1) Remove flywheel housing lower cover (or hand hole cover on Cadillac), turn fluid coupling until drain plug in torus cover points downward, remove plug and drain fluid coupling.

2) Remove drain plug at rear end of transmission oil pan and drain transmission case.

3) **Replace both drain plugs and tighten securely.**

4) Install 8 qts. new Hydra-Matic fluid (7 qts. on Frazer, Kaiser, Nash) through dipstick opening on top of case.

5) Start engine and run it at speed equivalent to 20 MPH. for at least 1½ minutes with selector in "N" (to fill fluid coupling). Return engine to slow idle speed.

6) Check fluid level (see above), add fluid to bring level up to "F" mark on dipstick (approximately 3-4 qts. required).

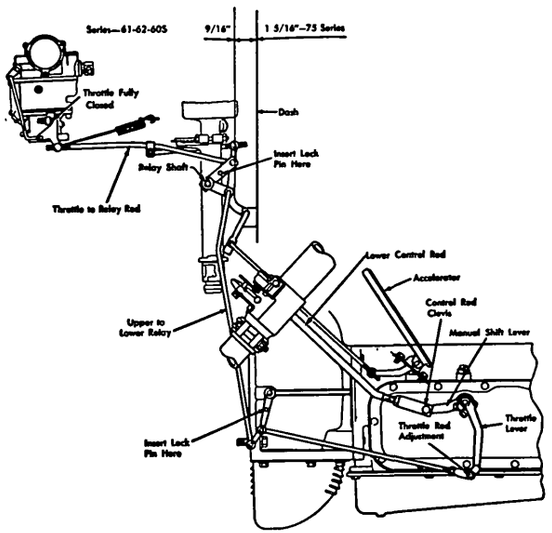
►*CAUTION—Correct level should be determined by dipstick reading rather than exact amount of fluid added* and level must always be checked.

Fluid Capacity: Approximately 11 qts. (refill), 12 qts. (after transmission disassembled).

Recommended Fluid: Hydra-Matic Fluid as furnished by car manufacturer or Automatic Transmission Fluid Type "A" as furnished in containers bearing "AQ-ATF" symbol.

►*FLUSHING CAUTION—Flushing of the unit is not required. Use only regular Hydra-Matic fluid for this purpose.*

LINKAGE ADJUSTMENT



ALL 1946-51 HYDRA-MATIC CARS

►*LINKAGE ADJUSTMENT CAUTION: Adjustments must be made in correct order and exactly as shown below for each car model.*

1946-48 CADILLAC

(1) Manual Control Linkage—Disconnect manual control rod from control lever on transmission case, move control lever to extreme rearward (reverse) position (lever will be held in this position by detent ball). Move Selector Lever on steering column to the Reverse "R" Position. Adjust the clevis on the lower end of control rod until clevis pin can just be inserted freely through clevis and control lever, tighten clevis locknut and install clevis pin.

(2) Throttle Control Rod—Set engine idling speed at 375 Engine RPM. with engine warm (fast idle inoperative). Disconnect throttle rod trunnion at carburetor by removing forward end of retracting spring, install gauge pin in holes in upper relay lever and distributor housing so that lever is locked in position, adjust trunnion on throttle connector rod so that it slides freely into throttle lever without disturbing slow idle position of throttle, install retracting spring and adjust position of spring clip so that center line of spring hole in clip is exactly 5 15/64" from throttle lever trunnion.

1946-48 CADILLAC CONTROL LINKAGE

(3) Throttle Control Lower Relay Lever—With upper relay lever locked by gauge pin inserted through lever into hole in distributor housing, disconnect clevis at throttle lever on transmission case and disconnect lower end of vertical rod connecting upper and lower relay levers. Install second gauge pin through hole in lower relay lever and hole in bell housing so that lever is locked in position, adjust vertical rod by bending rod forward or backward at original bend in rod (use Bending Tool J-2029) until it can be connected to lower relay lever freely (use care to maintain original alignment of rod). Connect vertical rod. With correct adjustment, gauge pin in lower relay lever should be free in lever and housing holes. NOTE—Do not remove gauge pins until following adjustments have been made.

(4) Throttle Lever Position—Install special Throttle Lever Checker (Tool J-2239) on rear face of transmission case. Insert clevis pin in end of throttle lever. Pin should enter hole in checking tool marked "46, 47, 48" freely. Bend lever (up to ½") using Tool J-2029 to secure correct position (replace lever if more than ½" bend required). Check center-to-center distance between upper and lower holes on lever. This must be 4¾".

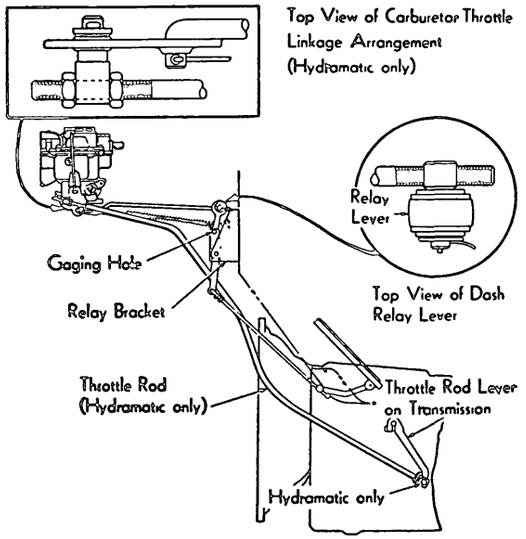
(5) Throttle Lever Linkage—With gauge pins installed in upper and lower relay levers and with throttle rod disconnected from throttle lever on transmission case, use Spring Scale, Tool J-544, to pull throttle lever against its stop in Reverse (extreme rear) position **using a load of ⅜-½ lb.** as measured by the spring scale. Hold throttle lever in this position, pull lower horizontal rod back to remove all play from lower relay lever, adjust clevis on rod so that pin freely enters holes in clevis and throttle lever, **then screw clevis three compl te turns forward on rod,** connect rod, remove gauge pin from lower relay lever.

(6) Upper Relay Lever Position—With upper relay lever locked by gauge pin, disconnect trunnion on horizontal rod connected to upper relay upper lever, adjust trunnion until it will slide freely into relay upper lever when center of hole in lever is exactly 9/16" (Series 60S, 61, 62), 1 5/16" (75, 76) from face of dash (measure from a straightedge placed across pocket in dash—do not measure to bottom of this pocket). Remove gauge pin from relay lever.

(7) Accelerator Pedal Rod—With upper relay lever free (gauge pin removed), disconnect accelerator pedal rod from lower lever of upper relay lever, hold carburetor throttle valve in wide open position and depress accelerator pedal to floor, adjust accelerator pedal rod by turning rod in trunnion until nd of rod slips freely into upper relay lower lever, connect rod. CAUTION—Recheck adjustment to mak certain that carburetor throttle lever is against its wide open stop when pedal depressed to floor.

Neutral Switch—Mounted on lower end of steering column. Adjust position of switch so that starter operative (switch closed) only when selector lever is in Neutral position. NOTE—When installing switch, make certain that operating pin engages slot in switch lever.

1949-51 CADILLAC



(1) Manual Control Linkage—Disconnect manual control rod from control lever on transmission case. Move control lever to drive position (move lever fully forward, then move lever toward rear until first detent position is reached). Place slecetor lever on steering column against stop in "DR" position. Adjust clevis on transmission end of control rod until clevis pin can just be inserted freely through clevis and lever. Connect control rod.

(2) Throttle Lever P sition—Disconnect throttle rod at throttle lever on transmission case. Check lever

C NTINUED N NEXT PAGE

HYDRA-MATIC LINKAGE ADJUSTMENT (Continued)

position by installing checking gauge, Tool J-3065, (see Tool Revision Note below) on rear face of transmission case with long leg of tool extending forward along left side of transmission case. Move throttle lever to extreme rear position. Insert clevis pin through hole in lever and correct hole in checking gauge (holes in gauge marked for use with individual model transmissions). If pin does not enter hole in gauge freely, bend lever as required, using tool J-2029. Remove gauge and reconnect throttle rod to throttle lever.

1949-51 CADILLAC CONTROL LINKAGE

▷*TOOL J-3065 (THROTTLE LEVER GAUGE) REVISION FOR USE WITH LATE 1950-51 CARS:* Two modifications required to adapt tool for use on later model transmissions. (1) Drill a 9/32" hole in long leg of tool at a point 9/16" from lower edge (tool in correct position on transmission), and 4.271" from contacting face of short leg of tool. Mark this hole "L50-51". The other hole in gauge nearest short leg, should be marked "49E50", and should be used for 1949 & Early 1951 transmissions. (2)—Cut off narrow end of short leg so that total overall length is 4 5/16" to provide clearance on transmission case.

(3) Throttle Control Linkage—Disconnect carburetor throttle rod at dash relay lever by removing spring clip and freeing trunnion from lever. Install ¼" drill rod through hole in relay lever and hole in bracket to position lever. See that carburetor throttle lever in correct hot or slow idle position (stopscrew against stop and set for correct 375 RPM. idling speed), adjust trunnion on rear end of throttle rod until trunnion enters relay lever freely, connect trunnion and install spring clip. Back off both nuts on throttle rod at carburetor throttle lever, push on end of rod so that transmission throttle lever and valve is against its stop, turn rear nut on throttle rod up against the carburetor throttle lever trunnion, then back the nut off 3 complete turns (1946-48), 4 turns (1950), 3½ turns (1951), finally tighten front nut on rod securely against trunnion. Check to see that linkage moves freely. Remove drill rod from relay lever. Check and adjust accelerator pedal position.

(4) Accelerator Pedal Position—Depress pedal fully and see that it touches floor mat with slight pressure when carburetor throttle valve wide open (NOTE—if floor mat removed, allow ½" clearance between pedal and floor in wide open position). Adjust pedal position, as required, by changing length of pedal to relay lever rod (adjusting trunnion located at pedal end of rod).

(5) Neutral Switch—Adjust position of switch so that starter operative (switch closed) only when selector lever in "N" position.

▷*CAUTION*—Do not move switch so far in neutral position that travel of lower lever is limited by switch arm in the reverse position.

1951 FRAZER & KAISER

Throttle Control Linkage:

1) Disconnect rear throttle rod from throttle lever (longer lever) on left side of transmission.

2) Carburetor Rod—Loosen carburetor extension shaft lock bolt in slot in upper bellcrank on left side of cylinder head, install Linkage Adjustment Pin KF-91 through holes in bellcrank and bracket. With engine temperature at 150-160° (choke valve wide open, fast idle inoperative) and transmission warm, set engine idle speed at 425-450 RPM. with selector lever in N. Tighten carburetor extension shaft lock bolt so that shaft is locked to bellcrank. Do not remove adjustment pin at this time.

3) Front Throttle Rod—Check alignment of holes in lower bellcrank and bracket on left side of crankcase below starter. If Linkage Adjustment Pin KF-91 can not be inserted freely through both holes, disconnect front throttle rod from lower bellcrank and adjust length of rod so that pin can be inserted after rod connected. Connect rod and install pin. Do not remove adjustment pins until all adjustments completed.

4) Transmission Throttle Lever—Tighten clamp bolt on throttle lever on transmission case to 12-15 ft. lbs. torque. Check lever position by installing Throttle Lever Checking Gauge KF-78 flat against machined surface on back of case with gauging leg extending forward along transmission side cover (CAUTION—clean transmission case surface before installing gauge). Move throttle lever to rear position against stop and install clevis pin in hole in lever as gauging point, move gauge upward toward lever. Notch in gauge should align with pin in lever and inner face of lever should just touch outer face of gauge. Bend lever with Bending Tool KF-79 to secure this position. Remove gauge.

5) Rear Throttle Rod—Connect rear rod to throttle lever on transmission (loosen trunnion nuts to align rod and lever) with anti-rattle spring between rod and lever. Adjust trunnion on rod to rear (turn front nut against trunnion) until throttle lever seats lightly against stop in rear position, then shorten rod by backing off trunnion front nut two full turns, lock adjustment by turning rear nut up securely against trunnion. Remove Linkage Adjustment Pins from the upper and lower bellcranks.

6) Accelerator Pedal Rod—Hold carburetor throttle valve in wide open position. Adjust accelerator pedal rod (turn adjusting sleeve on rod to rear of upper bellcrank on cylinder head) so that clearance between pedal and floor mat is approximately ¼".

Selector Lever (Manual Control) Linkage:

1) On Kaiser cars, hold selector lever firmly down in "Lo" position and tighten control shaft upper bracket clampscrew securely.

NOTE—Not required on Frazer cars.

2) Back off both locknuts at control rod trunnion (at control shaft lever on steering column on Kaiser, at idler bellcrank lever below starter on Frazer). Tighten shift lever clamp bolt on left side of transmission case to 10-13 ft. lbs. torque.

3) Place selector lever in "Lo" position, move shift lever on transmission to extreme rear position and then move lever forward to first detent position (this is Lo). Turn forward locknut finger tight against trunnion, then lengthen rod by turning locknut one additional full turn, tighten both locknuts against trunnion securely (CAUTION—do not change trunnion position on rod).

Neutral Safety Switch (Kaiser only):

NOTE—Switch on Frazer is non-adjustable).

1) Place selector lever in "Dr" position. Loosen lockscrew on neutral safety switch bracket (screw hole slotted to permit adjustment), adjust switch position so that starter will not operate when starting button pressed.

2) Place selector lever in "N" position. Check clearance between neutral safety switch arm and stop on switch bracket. Clearance should be 1/16" and starter should operate when starting button is pressed.

3) Tighten lockscrew securely.

1950-51 HUDSON

Throttle Control Linkage:

1) Check engine idle speed and set at 480-520 RPM. with engine at normal operating temperature (fast idle inoperative), transmission warm, and selector lever in neutral "N" position.

2) Carburetor Throttle Rod—Make certain carburetor throttle closed with stopscrew against stop in hot or slow idle position. Adjust length of accelerator cross shaft operating rod (connecting carburetor extension shaft lever on left side of cylinder head to bellcrank on left rear side of engine) by backing off one trunnion nut and tightening opposite nut on forward end of rod until gauge pin J-2544 can be entered freely through hole in bellcrank and hole in cylinder block boss (6 Cyl.) or hole in throttle support assembly (8 Cyl.) at rear end of rod. Tighten both trunnion nuts securely and recheck setting. Remove gauge pin.

3) Transmission Throttle Lever—Disconnect throttle rod at throttle lever (outer longer lever) on side of transmission case. Tighten lever clamp bolt to 10-15 ft. lbs. torque. Check lever position by installing Throttle Lever Checking Fixture J-2195 on back of case with gauging leg extending forward along transmission side cover (CAUTION—clean transmission case surface before installing gauge). Move throttle lever to extreme rear position against its stop. Gauge pin should enter hole in throttle lever freely and inner face of lever should be against larger diameter of gauge rod. Bend lever, as required, to secure this position using bending tool J-3310. Remove gauge and connect rod to lever.

4) Transmission Throttle Rod—Disconnect rod by removing trunnion cotter pin and washer from accelerator pedal link bellcrank on left rear side of cylinder block. Position bellcrank by inserting gauge pin J-2544 through hole in accelerator bellcrank

CONTINUED ON NEXT PAGE

HYDRA-MATIC LINKAGE ADJUSTMENT (C ntinu d)

and hole in cylinder block boss (6 Cyl.) or hole in throttle support assembly (8 Cyl.). Move transmission throttle lever to rear position against stop by pressing back on rod. Adjust trunnion position on rod (back off one nut, tighten opposite nut) until trunnion pin freely enters hole in bellcrank. Connect trunnion to bellcrank, then **shorten rod by backing off rear nut exactly 1½ turns,** tighten front nut securely. Remove gauge pin from bellcrank.

5) Accelerator Pedal Rod—Back off trunnion nuts on accelerator pedal rod at accelerator pedal link bellcrank on left side of cylinder block. Hold carburetor throttle valve in wide open position, depress accelerator pedal fully against its stop, turn rear nut up against trunnion, **then lengthen rod by turning nut up ¼" further,** tighten front nut against trunnion. This will provide approximately 1/16" clearance between accelerator pedal and its stop.

Manual Control Linkage:

1) Tighten upper and lower control tube brackets on steering column securely. Disconnect transmission shift rod at lower lever on steering column.

2) Position transmission shift lever in "Lo" by pressing backward on shift rod until lever is in extreme rear position against stop and then pulling rod forward until lever reaches **first detent position** (this is "Lo").

3) Place selector lever on steering column in "Lo" position by pulling lever toward reverse as far as possible without lifting the lever.

4) Adjust length of shift rod by turning clevis on forward end of rod until clevis pin hole aligned with hole in steering column lever without disturbing position of either lever, then **increase length of rod by turning clevis one complete turn** off rod, connect rod to lever and tighten clevis locknut. Check all positions of selector lever to make certain that each position indexes properly on dial.

Neutral Safety Switch:

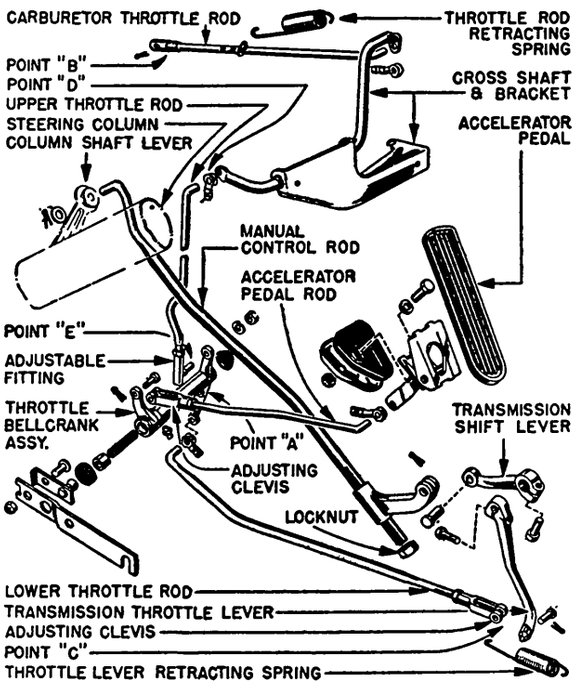
1) Place selector lever in neutral "N" position.

2) Loosen safety switch mounting bracket screw, shift safety switch and bracket (screw hole is slotted to permit this adjustment) until clearance between switch lever and stop on bracket is 1/16", tighten mounting screw.

3) Check operation of switch. Starter should operate when ignition switch turned on and starter button depressed. **Starter should not operate** with selector lever in any other position (check in the "Dr" position).

1949-51 LINCOLN

Throttle Control Linkage:



1) Check and adjust engine idle speed to 375-400 RPM. with engine at normal operating temperature (fast idle inoperative), transmission warm, and selector lever in neutral "N" position. Shut engine off.

2) Disconnect retracting spring hooked to carburetor throttle rod, disconnect rod at carburetor throttle lever. Disconnect upper throttle rod at bellcrank lever (lower end). Disconnect lower throttle rod at throttle lever on left side of transmission case.

3) Transmission Throttle Lever—Check lever position by installing Gauge J-3298 on back of case with gauging leg extending forward along transmission side cover. Move lever to extreme rear position against its stop. Clevis pin in lever hole should align with notch in gauge and inner face of lever should just touch outer face of gauge. Bend lever with tool J-3310 to secure this position.

4) Install Gauge Pin J-2544 through hole in bellcrank lever and bracket (see illustration) to align lever. Leave pin in place while making following adjustments.

5) Carburetor Throttle Rod—Connect rod to carburetor throttle lever (adjust ball socket by turning screw in until snug on carburetor lever ball, then back off 1-2 cotter pin holes and install cotter pin). Connect retracting spring from dash to nearest nib on carburetor rod.

LINCOLN HYDRA-MATIC CONTROL LINKAGE

6) Upper Throttle Rod—With gauge pin inserted in bellcrank lever on left side of engine, hold carburetor throttle lever in closed position with stopscrew on low point of fast idle cam (hot or slow idle position), adjust fitting on lower end of upper throttle rod so that rod can be connected to bellcrank lever without disturbing throttle position. Connect rod.

7) Lower Throttle Rod—With gauge pin inserted in bellcrank lever on left side of engine, connect retracting spring at transmission throttle lever and frame cross-member (spring will hold lever in rear position while making adjustment). Adjust clevis on rear end of lower throttle rod until clevis pin will just enter clevis and hole in throttle lever freely, **then shorten rod by turning clevis 6 turns on the rod.** Connect rod and tighten clevis locknut.

8) Accel rator Pedal Rod—With gauge pin inserted in bellcrank lever on left side of engine, adjust clevis on forward end of pedal rod so that tip of accelerator pedal pad is exactly 3⅞" *from top of the floor carpet,* connect rod and tighten clevis locknut. Remove gauge pin from bellcrank lever.

9) Check entire throttle linkage for free operation without binding. Make certain that carburetor throttle rod returns throttle valves to hot or slow idle position against stop with engine at normal operating temperature.

10) 3-4 Shift Point—Check shift point by operating car on level road with minimum throttle. **This 3-4 shift must occur at 25 MPH on cars having transmissions before Serial No. L50-4549, and 23 MPH on cars having transmissions after this Serial Number.** Adjust by making slight readjustment of lower throttle rod clevis at transmission throttle lever. Increase length of rod to lower the 3-4 shift point, decrease length to raise shift point.

►***CAUTION—Throttle rod clevis must not be turned more than 7 turns (one turn more than standard setting of 6 turns) from point where throttle lever is against its stop.***

Manual Control Linkage:

1) Disconnect manual control rod from shift lever (short lever) on side of transmission case, place shift lever in "Lo" position (move lever to extreme rear position, then move lever forward to **first** detent position which is Lo).

2) Place selector lever in "Lo" against the low range stop.

3) Loosen locknut and adjust clevis on rear end of manual control rod until clevis pin can just be inserted freely through clevis and hole in lever without disturbing the rod or lever positions, **th n lengthen rod by turning clevis on complete turn,** connect rod and tighten clevis locknut.

Neutral Safety Switch:

1) Loosen switch bracket mounting screws (on steering column directly below column shaft lever).

2) Place selector lever in "Dr" position. Rotate switch and bracket assembly (mounting screw holes are slotted) so that starter circuit is open. Then move selector lever to "N" position and make certain that starter circuit is closed. Tighten switch mounting screws.

►***CAUTION—Starter circuit must be open in all selector positions except neutral "N".***

1950-51 NASH

►***1951 ADJUSTMENT CAUTION:*** **A single Throttle Control Rod is used (instead of Upper & Lower rods with connecting bellcrank on left side of crankcase) and step (4) is not required when adjusting throttle control linkage on 1951 cars.**

Throttle Control Linkage:

1) Disconnect throttle rod (rear rod on 1950 cars) from throttle lever on left side of transmission.

2) Check engine idle speed and set to 375 RPM. with engine warm (fast idle inoperative), transmission warm, and selector lever in neutral "N" position.

3) Carburetor Throttle Link Rod—Disconnect link rod at upper bellcrank on left side of cylinder head. Install adjusting pin J-4158 through holes in the upper bellcrank and the mounting bracket. Adjust clevis on bellcrank end of carburetor throttle lever link so that clevis pin enters clevis and bellcrank

CONTINUED N NEXT PAGE

HYDRA-MATIC LINKAGE ADJUSTMENT (Continued)

without moving throttle lever stopscrew away from its stop, tighten locknut and connect rod. Do not remove adjusting pin from bellcrank.

▷1951 Note—Disregard step (4) on these cars (single throttle rod is adjusted in same manner as Rear Throttle Rod in step (6) below.

4) Front Throttle Rod—With the upper bellcrank locked by adjusting pin, check position of lower bellcrank on left side of crankcase below starter by inserting a second J-4158 adjusting pin through holes in bellcrank and support bracket. If pin does not enter holes freely, disconnect throttle rod at upper bellcrank, install adjusting pin in lower bellcrank, adjust rod length by loosening locknut and turning trunnion end on upper end of rod. Tighten locknut and connect rod. Do not remove adjusting pins until following adjustments have been completed.

5) Transmission Throttle Lever Position—See that clamp bolt on throttle lever on transmission case is tight, place Throttle Lever Checking Gauge J-2545 flat against machined surface on back of case with gauging leg extending forward along transmission side cover. Install clevis pin in hole at outer end of throttle lever, hold lever against stop in extreme rear position. Move gauge upward. Notch on gauge should pass over pin in lever and inner face of lever should just touch outer face of gauge. Bend lever as required using Bending Tool J-3310.

▷*CAUTION—Do not twist lever or spring shaft when adjusting.*

6) Rear Throttle Rod—With bellcranks locked by the adjusting pins, hold throttle lever on transmission case in extreme rear position against the stop, adjust trunnion on transmission end of rear throttle rod by backing off one trunnion nut and tightening opposite nut until trunnion pin enters hole in throttle lever freely, then back off forward trunnion nut two complete turns, tighten rear nut securely (this will "shorten" rod), connect rod to throttle lever, remove adjusting pins from upper and lower bellcranks.

Starter Switch:

1) Place selector lever in Neutral "N" position. Check alignment of operating plunger (spring-loaded pin) on side of operating lever on steering column and starting switch plunger (must be in line so that switch plunger depressed by operating plunger when selector lever lifted upward in "N" position).

2) Adjust switch to align plunger by loosening switch bracket mounting screws and shifting switch bracket on steering column (holes are slotted to permit this adjustment).

Manual Control (Selector Lever) Linkage:

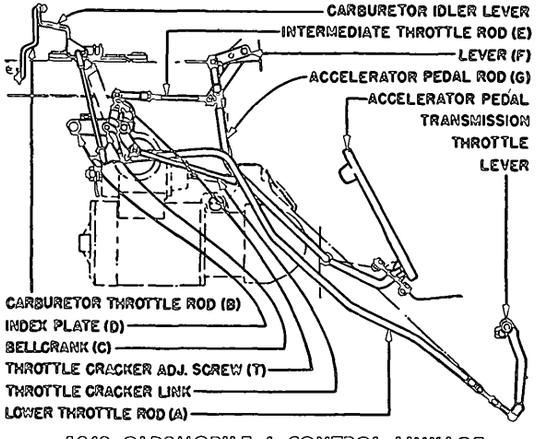
1) Place steering wheel selector lever in "Lo" position and see that operating lever on steering column is against low range stop (right side) of notch in starter switch bracket.

2) Disconnect control rod at shift lever on left side of transmission case.

3) Move transmission shift lever to "L" position (place lever in extreme rear "R" position, then move lever forward until next detent position is reached), adjust clevis on transmission end of control rod until clevis pin enters hole in lever freely, then lengthen rod by turning clevis off one complete turn, tighten locknut and connect rod.

1946-48 OLDSMOBILE 6 & 8

Manual Control—Disconnect lower control relay rod at lever on side of transmission case and lower control rod at intermediate lever on cross-member bracket (remove clevis pins and spring washers, loosen clevis locknuts). Move manual control lever on transmission to reverse position (all the way back against stop—rotate propeller shaft by hand until anchor engages and lever is against stop). Position intermediate lever so that gaging hole lines up with hole in bracket, insert locking pin (Tool J-1469) through both holes to lock lever in position. Adjust clevis on lower control relay rod so that rod can be connected without disturbing position of transmission lever, connect rod (CAUTION—use spring washer on clevis end to prevent rattles), remove locking pin from intermediate lever. Move manual lever on transmission to "LO RANGE" position (move lever all the way forward to "Neutral", then move lever back to second detent position). Place Selector lever against stop which prevents shifting into reverse (without raising lever) by pulling down on lower control rod until stop is felt. Adjust clevis on lower end of control rod so that clevis pin can be inserted without disturbing position of selector lever or intermediate lever, then lengthen rod by turning clevis one full turn, connect rod to intermediate lever (CAUTION—use spring washer on clevis end to prevent rattles).



Throttle Control (1946 & Early 1947)—Adjust with engine idling speed properly set at 375 RPM (slow idle speed) and with transmission in Neutral. Remove small spring lock from trunnion on idler lever (on cylinder head above oil filler cap), adjust length of carburetor rod by turning trunnion adjusting nut until locking pin (Tool J-1469) slips freely through holes in bell-crank (on side of engine block below trunnion) and indexing plate with carburetor throttle lever in slow-idle position, tighten trunnion locknut and position adjusting nut so that trunnion spring lock can be replaced. CAUTION—If tightening trunnion locknut changes alignment of gaging holes (recheck alignment with Tool J-1469), loosen locknut and lengthen rod one-half turn, tighten locknut and recheck alignment. Make sure carburetor rod moves freely in idle and full-throttle positions. Install trunnion spring lock.

Throttle Control (Late 1947 & 1948)—Adjust with idling speed properly set at 375 RPM. (slow idle speed with engine warm and selector lever in Neutral). Disconnect throttle control rod at auxiliary bellcrank on cylinder head (6 cyl. cars), at cross-shaft (8 cyl. cars), adjust rod by bending the rod until locking pin (Tool J-1469) slips freely through holes in bellcrank and indexing plate (on side of engine) with rod connected and carburettor throttle closed. Check to see that carburetor rod moves freely throughout travel from idle to full throttle position.

Throttle Lever Position—Position of hole in end of throttle lever on transmission case may change (if valve body, inner throttle lever and shaft assembly, or outer lever replaced) and should be checked. Install Gauge J-2195 (against machined surface on back of case with gauging rod extending forward to throttle lever), disconnect rod at throttle lever on transmission case. Tip of gauge rod should enter hole in end of throttle lever freely. If lever position incorrect, remove lever and bend, as required, for correct position.

Throttle Lever Control Linkage—Disconnect the rod at throttle lever on side of transmission case, move throttle lever all the way back against stop, make certain that carburetor throttle in slow-idle position and adjust clevis on rod so that it can be connected to throttle lever on transmission without disturbing position of lever and linkage, then shorten rod by turning clevis one full turn, connect rod to lever. Adjust accelerator pedal rod so that idler lever under toeboard (to which pedal rod connected) will have 3/32-5/32" clearance between lever and rib in body toe pan. CAUTION—This clearance necessary to allow carburetor to return to slow idle position.

Throttle Cracker Adjustment (6 Cyl.)—Must be correctly set for starting. .0325" to .0351" (1/16") clearance between throttle stopscrew and highest step of fast idle cam with starting pedal fully depressed (starter pinion fully meshed). Adjust by loosening locknut and turning adjusting screw on accelerator bellcrank (screw contacts lug on lever linked to starter pinion shift lever).

1949 OLDSMOBILE 6 CONTROL LINKAGE

Throttle Cracker Adjustment (8 Cyl.)—Set for correct throttle opening for starting. To adjust, disconnect starter cable at starter switch (for foot operated starters), disconnect coil lead to distributor (for solenoid operated starters), depress starter pedal or pushbutton to full down position (engine will be turning over on solenoid starter cars) to fully mesh starter pinion, loosen locknut and turn adjusting screw on accelerator bell-crank (screw contacts lug on lever linked to starter pinion shift lever) so that clearance between throttle stopscrew and highest step of fast idle cam is .105-.125" (⅛").

CONTINUED ON NEXT PAGE

HYDRA-MATIC LINKAGE ADJUSTMENT (C ntinu d)

Fourth-to-Third Throttle Downshift—Should be checked whenever linkage adjusted to insure proper operation and prevent damage to linkage. To adjust with engine stopped, pull transmission throttle rod all the way forward until throttle lever on transmission is against stop, hold in this position and bend stop lip on indexing plate (at bell-crank on side of engine) for clearance of 1/16-3/32" between lip and stop on bell-crank.

Safety Switch Adjustment—Clearance between switch and stop should be 1/16-3/32" between lever and stop with selector lever in "Neutral" position. To adjust, loosen switch bracket locking screw, adjust switch (bracket is slotted). NOTE—With correct adjustment starter operative only when selector lever placed in Neutral "N" position.

1949-50 OLDSMOBILE 6

(1) Manual Control Linkage—Same as for 8 Cyl. models (following).

(2) Throttle Control Linkage—See that carburetor set for correct hot or slow idle speed of exactly 350 RPM. with selector lever in "DR" position. Use safety lock tool J-4396 installed on accelerator pedal to prevent accidentally racing engine when warming up engine and transmission prior to setting idle speed. Then adjust linkage in following order:

Transmission Throttle Lever—Disconnect lower throttle rod from lever on side of transmission case. Install checking tool J-2195 on machined surface on rear face of transmission case with gauging rod extending forward toward lever. Hold throttle lever back against stop. If small end of tool does not enter hole in lever freely in this position, bend lever as required using tool J-2029. Do not connect throttle rod to lever at this point.

Carburetor Throttle Rod (B)—Disconnect rod (B) at carburetor throttle valve lever. Align bellcrank (C) with index plate (D) by inserting Gauge BT-25 through holes in lever and plate. Hold carburetor throttle lever in slow idle position, bend rod (B) using tool GA-38 so that it can be connected without disturbing lever positions. Connect rod. Gauge BT-25 should now slip in and out of holes in lever and index plate freely. Remove gauge.

Lower Throttle Rod (A)—See that carburetor in slow idle position (throttle lever against stop), hold transmission throttle lever fully back against its stop, adjust length of rod (A) by loosening locknut and turning clevis until clevis pin enters hole in lever freely, then **shorten rod by one full turn of the clevis**, tighten locknut and connect rod.

1949 Intermediate Throttle Rod (E)—Disconnect accelerator spring, disconnect rod (E) by removing clevis pin at forward end. Insert Gauge BT-25 through hole in lever (F) and hole in bracket. Adjust clevis on forward end of rod (E) so that gauge BT-25 will enter holes in lever and bracket freely with rod connected. Connect rod and remove gauge.

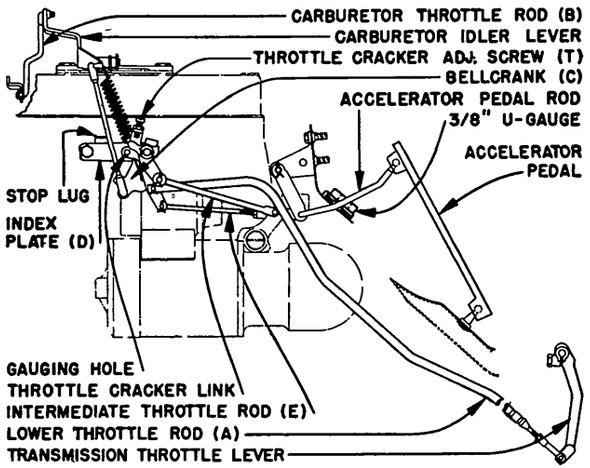
1950 Intermediate Throttle Rod (E)—Disconnect rod (E) from bellcrank lever by taking out cotter pin at forward end, install special "U" gauge on accelerator pedal rod to prevent pedal bottoming on grommet retainer on floor (make gauge up from piece of 3/8" flat stock). Pull rod (E) forward until accelerator pedal pad rests firmly on gauge (floor mat must be away from pedal), hold carburetor throttle wide open, adjust rod by turning it in or out of clevis on rear end until it can be just entered in bellcrank, connect rod, tighten clevis locknut, remove gauge.

1949 Accelerator Pedal Rod (G)—***This rod not adjustable on 1950 cars.*** First disconnect accelerator pedal rod (G) by removing clevis pin at lever (F). Hold carburetor throttle lever in wide open throttle position, push down lightly on rod (G) so that pedal stop touches floor mat (CAUTION—floor mat must be flat against floor cover). Adjust clevis on end of rod (G) so that clevis pin enters hole in lever (F) freely, then **shorten clevis by six full turns**, connect rod. This will provide approximately 1/4" clearance between pedal stop and floor mat when carburetor throttle in wide open position.

(3) Throttle Cracker Linkage—Disconnect coil to distributor lead (to prevent starting engine), press starter button to fully engage starter drive (solenoid pinion shift). With starter fully engaged, loosen locknut and turn adjusting screw (T) on lever on side of engine for clearance of .062-.085" between carburetor throttle stopscrew and high step of fast idle cam (cam turned to cold or fast idle position).

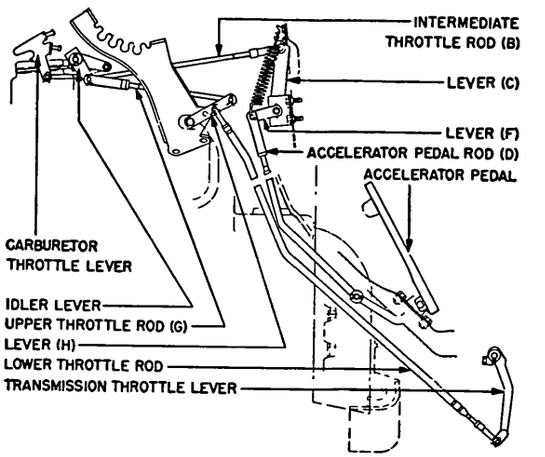
(4) Bellcrank & Index Plate Clearance—Bend stop lug on index plate (D) so that clearance between lug and lip on bellcrank (C) is 1/32-1/16" with bellcrank in full open position as limited by transmission throttle lever.

(5) Starter Safety Switch Adjustment—Same as for 8 cyl. models (following).



1949-51 ODSMOBILE 8

(1) Manual Control Linkage—Loosen clevis locknut at rear end of lower control rod (from steering column to intermediate lever on frame cross-member). On 1949 cars, loosen clevis locknut at rear end of lower control relay rod (from intermediate lever to transmission control lever) and disconnect rods at intermediate lever and transmission. Adjust Lower Control Relay Rod on 1949 cars only ***(CAUTION—this rod not adjustable on 1950-51 cars).***



Lower Control Relay Rod (1949 Cars). ***This rod not adjustable on 1950-51 cars.*** Move the transmission control lever all the way back into Reverse position (rotate propeller shaft by hand until reverse anchor engages and lever is against stop). Position intermediate lever on cross-member so that gauging hole in lever lines up with hole in bracket, insert Gauge BT-25 through both holes to maintain lever position. Adjust clevis on rear end of relay rod so that rod can be connected without disturbing position of levers. Connect rod and remove gauge from intermediate lever.

Lower Control Rod—Place transmission control lever in "LO" position (move lever all the way forward to Neutral, then move lever back to the second detent "LO" position). Place steering column selector lever at end of Lo range against stop which prevents movement into Reverse without raising lever (pull down on lower control rod until stop is felt). Adjust clevis on lower end of lower control rod until pin can just be slipped freely through clevis and intermediate lever without disturbing lever positions, **then lengthen rod by turning clevis one full turn (1949-50), two full turns (1951)**, tighten locknut and connect rod.

(2) Throttle Control Linkage—See that carburetor set for correct hot or slow idle speed of exactly 350 RPM. with selector lever in "DR" position. Use safety lock tool J-4396 installed on accelerator pedal to prevent accidentally racing engine when warming up engine and transmission prior to setting idle speed. Then adjust linkage in following order:

1950 OLDSMOBILE 6 CONTR L LINKA E

1949-51 OLDSMOBILE 8 CONTROL LINKAGE

Transmission Throttle Lever—Disconnect lower throttle rod from lever on side of transmission case. Install checking tool J-2195 on machined surface on rear face of transmission case with gauging rod extending forward toward lever. Hold throttle lever back against stop. If small end of tool does not enter hole in lever freely in this position, bend lever as required using tool J-2029. Do not connect rod to lever at this point.

Upper Throttle Rod (G)—Disconnect rod (G) from lever (H). Insert gauge BT-25 through three holes in cross shaft assembly. Adjust rod (G) in

CONTINUED ON NEXT PAGE

HYDRA-MATIC LINKAGE ADJUSTMENT (Continued)

or out of clevis at forward end until rod can be connected without moving carburetor throttle lever from its hot or slow idle position. Tighten clevis locknut, connect rod, remove gauge from lever.

▷*CAUTION—If clevis at forward end of rod (C) disconnected, this clevis must be installed with open side facing away from engine.*

Lower Throttle Rod—See that carburetor is in slow idle position (throttle lever against stop), hold transmission lever fully back against its stop, adjust length of the rod by loosening locknut and turning clevis until clevis pin enters hole in lever freely, then shorten rod by one full turn of the clevis, tighten locknut and connect rod.

Intermediate Throttle Rod (B)—Disconnect rod at lever (C) on dash. See that carburetor throttle lever in hot or slow idle position (throttle lever against stop), adjust clevis on rod so that distance from rear face of lever (C) to bottom of depression in dash is 5/16-3/8" (88), 7/32-9/32" (98), tighten clevis locknut and connect rod.

1949 Accelerator Pedal Rod (E)—Unhook accelerator spring, disconnect rod (E) at lever (F) by sliding clevis off lever pin. Hold accelerator pedal down lightly against floor mat but do not push down on rod (CAUTION—floor mat must be flat on floor). Adjust clevis on upper end of rod (E) until it just slides freely on lever pin, then shorten clevis by six full turns, connect rod, install spring. This will provide approximately ¼" clearance between pedal stop and floor mat when carburetor throttle in wide open position.

▷*CAUTION—Clevis on upper end of rod (E) must be installed with open side facing toward engine.*

1950 88 Accelerator Pedal Rod (E)—This model has idler lever on dash and additional short adjustable rod between this lever and lever (C). Install special "U" gauge on accelerator pedal rod to prevent pedal bottoming on grommet retainer on floor (make gauge up from piece of ⅜" flat stock). Disconnect this short rod from lever (C), depress accelerator pedal until it bottoms on gauge (floor mat must be away from pedal), hold carburetor throttle wide open, adjust clevis on upper end of rod until it can just be connected to pin on lever (C), tighten clevis locknut, connect rod, remove gauge.

▷*CAUTION—Clevis on upper end of rod must be installed with open face toward engine.*

1951 88 Accelerator Pedal Rod (E)—Same design as 1950 88 but adjusted differently: Disconnect short rod from lever (C), depress accelerator pedal until clearance between face of rod boss on underside of pedal and floor mat is ¼" (CAUTION—floor mat must be in place), hold carburetor throttle valve in wide open position, adjust clevis on upper end of short rod so that it just slides over pin on bracket, tighten clevis locknut and connect rod.

▷*CAUTION—Clevis on upper end of rod must be installed with open face AWAY from engine.*

1950-51 98 Accelerator Pedal Rod (E)—See illustration. Disconnect accelerator pedal rod (D) from lever on dash. Depress accelerator pedal until clearance between tip of pedal and floor mat is ¼" (CAUTION—floor mat must be in place), hold carburetor throttle valve in wide open position, adjust clevis on upper end of rod (D) until it slides over pin in bracket, tighten clevis locknut and connect rod.

▷*CAUTION—Clevis on upper end of rod must be installed with open face AWAY from engine.*

▷Throttle Cracker Note—No throttle cracker (as used on 6 cyl. cars) is used. When starting cold engine, first opening of throttle allows fast idle cam to rotate so that special starting step of cam holds throttle open for starting. When starting hot engine, open throttle approximately 1/3 by depressing accelerator pedal.

(3) Starter Safety Switch Adjustment—Loosen switch bracket locking screw just enough so that slotted bracket can be moved. Place selector lever on steering wheel in "N" neutral position. Adjust switch by moving bracket so that clearance between lever and stop is 1/16-1/32", tighten bracket screw.

1948 PONTIAC

1. Carburetor Throttle Rod—Disconnect control rod at throttle lever (outer lever) on side of transmission case. Check to make certain that engine idle speed correctly set at 365-385 RPM. hot or slow idle (with engine at 150-160°F., transmission warm, selector lever in Neutral). Disconnect carburetor throttle rod from throttle control intermediate lever (6 cyl.) or from lever on cross-shaft (8 cyl.) on cylinder head. Install Adjusting Pin J-2544 through holes in lever and bracket to position lever. Adjust trunnion on carburetor rod so that trunnion pin will just enter hole in lever without moving carburetor throttle lever stopscrew from against its stop. Tighten trunnion locknut, connect rod. Do not remove Adjusting Pin until following adjustments made:

▷*CAUTION—On 6 Cyl. cars, position carburetor throttle rod upward away from ignition wires before tightening locknut.*

2. Throttle Control Rear Rod (Acelerator Pedal Intermediate Rod)—With adjusting pin J-2544 installed in lever on cylinder head (1. above), check position of accelerator pedal lever on dash. If second Adjusting Pin J-2544 cannot be inserted freely through holes in levers and bracket, disconnect rod at throttle control idler lever (on side of engine), adjust trunnion on rod until adjusting pin can be inserted freely with rod connected, tighten locknut and connect rod. Leave this adjusting pin in the ped al lever while following adjustments made:

3. Transmission Throttle Lever Front Rod—With Adjusting Pins in place in lever on cylinder head and in accelerator pedal lever on dash (1. & 2. above), check position of transmission throttle idler lever on lower edge of crankcase under starter. If third Adjusting Pin J-2544 cannot be inserted freely through holes in lever and bracket, disconnect rod at cylinder head lever, adjust rod length by turning upper end fitting until adjusting pin can be inserted freely with rod connected, tighten end fitting locknut. Remove all three adjusting pins.

4. Transmission Throttle Lever Position—See that clamp bolt in transmission lever (outer lever on side of case) is securely tightened. Check position of lever by installing Throttle Lever Checking Gauge J-2545 flat against rear surface of transmission case with edge of gauge against side cover. With clevis pin installed in lever, hold lever in rear position against stop, move gauge upward. Notch in gauge should pass over pin in lever and inside face of lever should just touch outer face of gauge. Bend lever, as required, using tool J-2807, to secure this position. Recheck lever position.

▷*CAUTION—Use extreme care not to twist lever or spring shaft when bending lever for correct position. Check rod alignment with lever for free action without binding.*

5. Transmission Throttle Lever Rod—Hold transmission throttle lever in extreme rear position against stop (see 4. above), adjust clevis on rear end of throttle rod so that clevis pin can just be inserted freely through clevis and hole in lever, then shorten rod by turning clevis up one full turn, tighten clevis locknut and connect rod.

6. Manual (Shift Control) Linkage—Hold selector lever down firmly in "Lo" position, tighten control shaft upper bracket clampscrew securely. Move selector lever to Reverse "R" position. Loosen locknuts on trunnion at forward end of forward control rod (at lower end of selector lever shaft), tighten control shaft lower bracket securely. Disconnect rear rod at shift lever (inner lever) on transmission case, tighten shift lever clampscrew securely. Install Adjusting Pin J-2544 through holes in lower control relay lever (to which lower end of forward rod connected) and bracket to lock lever. Move transmission shift lever to extreme rear (Reverse) position (NOTE—rotate propeller shaft by hand to insure reverse engagement). Adjust clevis at lever end of rear rod so that rod can be connected to shift lever without disturbing lever position, connect rod. Remove adjusting pin from relay lever. Move transmission shift lever to "Lo" position (move lever forward until next (Lo) detent is felt to engage). Move selector lever to "Lo" position against stop which prevents further lever movement into reverse (without raising lever). Turn lower locknut on forward control rod (under control shaft lever trunnion) up until it contacts trunnion, then turn locknut up one additional turn. Tighten upper locknut securely against trunnion.

7. Throttle Cracker Adjustment—Important for satisfactory starting operation. *See "Accelerator Linkage Adjustment" under CARBURETOR on each car model page for complete instructions.*

8. Starter Interlock Adjustment—Must be adjusted so that depressing starter pedal to start engine (with Hydra-Matic selector lever in any other position than Neutral), will move selector lever to Neutral "N" position. To adjust, disconnect battery cable at starter (to prevent starter operating while adjusting), tighten neutralizer lever attaching bolts on starter shift lever. Depress starter pedal fully. Adjust length of interlock rod by turning locknuts at trunnion on lower end of neutralizer lever so that selector lever indicator is in exact neutral "N" position, then lengthen rod by turning trunnion nuts one additional full turn. Lock trunnion nuts securely. Check operation by placing selector lever in various positions and noting action when starter pedal depressed fully.

CONTINUED ON NEXT PAGE

HYDRA-MATIC LINKAGE ADJUSTMENT (C ntinued)

1949 PONTIAC

(1) Carburetor Throttle Rod—Disconnect control rod at throttle lever (outer lever) on side of transmission case. Check engine idle speed and set for 365-385 RPM. hot or slow idle speed with engine temperature at 150-165°F., transmission warm and selector lever in neutral "N". Loosen checknuts at trunnion on carburetor throttle rod at throttle control intermediate lever (6 cyl.), cross-shaft lever (8 cyl.) on cylinder head, install adjusting pin J-2544 through holes in lever and bracket on left side of cylinder head. Tighten trunnion checknuts being careful not to move carburetor throttle stopscrew away from its stop. Do not remove adjusting pin.

►*CAUTION—On 6 cyl. cars, position carburetor throttle rod upward and away from ignition cables.*

(2) Transmission Throttle Front Rod—Check adjustment by inserting second adjusting pin J-2544 through holes in transmission throttle idler lever and bracket (on left side of crankcase below starter). If pin does not enter both holes freely, adjust rod length by disconnecting rod at upper (cylinder head lever) end of rod and screwing end fitting in or out Connect rod but do not remove adjusting pins.

(3) Throttle Control (Accelerator Pedal) Rear Rod—Loosen front checknut at trunnion on forward end of rod (at idler lever on left side of crankcase above starter), tighten rear checknut until accelerator pedal rocker lever lug just contacts lever bracket on dash, then back off rear checknut three full turns, tighten front checknut so that trunnion is locked on rod. Remove adjusting pins from intermediate lever on cylinder head and idler lever on left side.

(4) Transmission Throttle Lever Position—See that clamp bolt on transmission throttle lever securely tightened, check position of lever by installing Checking Gauge J-2545 flat on machined rear face of transmission case with edge of gauge against side cover. Install trunnion pin in lever, hold lever in extreme rear position. Move gauge upward. Notch in gauge should pass over pin in lever and inside face of lever should just touch outer face of gauge. If not, bend lever with tool J-2807, and recheck lever

(5) Transmission Throttle Rear Rod—Hold transmission throttle lever in rear position against stop, adjust trunnion position on rod by backing off one checknut and tightening opposite nut until trunnion pin enters hole in lever freely, then shorten rod one full turn (back off front nut, tighten rear nut one turn), connect rod.

(6) Manual Control Linkage—Hold selector lever under steering wheel down in "LO" position firmly, tighten control shaft upper bracket clampscrew securely. Back off both trunnion checknuts at forward end of manual control rod (at steering column control shaft lever), place manual control lever on transmission case in "LO" (move lever forward from extreme rear to second position where detent is felt to engage). With both levers held in "LO" position, tighten rear (lower) nut against trunnion finger tight, then lengthen rod by turning nut up one additional turn, tighten forward checknut against trunnion securely.

(7) Starter Neutralizer Switch—Place selector lever in "DR" position. Loosen switch bracket clampscrew (on steering column at lower end of selector shaft), shift switch and bracket (screw hole is slotted) until starter does not operate when starter button depressed. Move selector lever to "N" position. Check to see that switch arm does not touch stop on switch bracket, and that starter operates when starter button depressed. Tighten bracket clampscrew.

►**Neutralizer Switch Replacement (first cars)**—On cars before Serial No. P6RH-1063 (6 Cyl.), P8RH-1384 (8 Cyl.), if backing light terminal posts pushed into switch case and interfering with operation of switch arm, install new No. 1997846 switch which has posts staked to prevent this occurrence.

1950-51 PONTIAC

(1) Carburetor Throttle Rod—Disconnect throttle rod at throttle lever (outer lever) on left side of transmission case. Check and adjust engine idle speed to 365-385 RPM. hot or slow idle with engine at 150-160°F., transmission warm, and selector lever in Neutral "N". Install adjusting pin through holes in carburetor intermediate lever on left side of cylinder head and lever bracket. Adjust nuts at trunnion on carburetor throttle rod (back off one nut, tighten opposite nut) until adjusting pin is free with carburetor throttle lever stopscrew against its stop. Tighten trunnion nuts but do not remove adjusting pin.

(2) Transmission Throttle Front Rod—Check adjustment by inserting second J-2544 adjusting pin through holes in idler lever (left side of crankcase below starter) and lever bracket. If pin does not enter both holes freely, adjust length of transmission throttle front rod at trunnion on upper end of this rod (back off one nut, tighten opposite nut), then tighten both nuts securely, remove both adjusting pins (intermediate lever and idler lever).

(3) Accelerator Pedal Rod—Loosen front locknut on pedal rod at throttle control idler lever on left side of engine, depress accelerator pedal until carburetor throttle is just wide open, check clearance between lower face of accelerator pedal and floor mat. If clearance not ¼" at closest point, adjust pedal by turning rear nut at trunnion on forward end of rod in or out as required, then tighten front nut securely.

(4) Transmission Throttle Lever Position—With rear rod disconnected at transmission case throttle lever, check tightness of lever clamp bolt (12-15 ft. lbs. torque), check lever position by installing Checking Gauge J-2545 flat against machined rear face of transmission case with edge of gauge against side cover flange. Install trunnion pin in lever, hold lever in extreme rear position, move gauge upward, align gauge with trunnion pin. Inside face of throttle control lever should just touch outer side face of gauge and pin in lever should enter slot in gauge freely. Adjust by bending lever with tool J-2807.

(5) Transmission Throttle Rear Rod—After checking and adjusting transmission throttle lever, connect rear rod trunnion at lever, loosen rear locknut on trunnion, adjust rod length by turning front locknut toward trunnion until throttle lever is just back against its stop, then shorten rod by backing off front nut one turn, tighten rear nut securely.

(6) Manual Control Linkage—Hold selector lever under steering wheel down in "LO" position firmly, tighten control shaft upper bracket clampscrew securely. Back off both trunnion checknuts at forward end of manual control rod (at steering column control shaft lever), place manual control lever on transmission case in "LO" (move lever forward from extreme rear to second position where detent is felt to engage). With both levers held in "LO" position, tighten rear (lower) nut against trunnion finger tight, then lengthen rod by turning nut up ne additional turn, tighten forward checknut against trunnion securely.

(7) Starter Neutralizer Switch—Place selector lever in "DR" position. Loosen switch bracket clampscrew (on steering column at lower end of selector shaft), shift switch and bracket (screw hole is slotted) until starter does not operate when starter button depressed. Move selector lever to "N" position. Check to see that switch arm does not touch stop on switch bracket, and that starter operates when starter button depressed. Tighten bracket clampscrew.

HYDRA-MATIC BAND ADJUSTMENT

ALL 1946-51 HYDRA-MATIC CARS

►*EXTERNAL BAND ADJUSTMENT PRODUCTION CHANGE (EXC. OLDSMOBILE):* Front band adjustment specifications have been changed to 7.7 turns tight (except Oldsmobile). This supersedes previous instructions. Rear band adjustment remains the same.

►***BAND ADJUSTMENT CAUTION: Do not attempt to adjust bands EXTERNALLY (without removing oil pan) unless Adjusting Tool J-2681 (or Kaiser-Frazer No. KF-96) and accurate Tachometer are used. Otherwise remove oil pan and use special servo gauges.***

ADJUSTMENT—EXTERNALLY using Adjusting Tool J-2681 (or Kaiser-Frazer KF-96) and Tachometer:

1) Block front wheels securely and set hand brake firmly to prevent car moving while adjusting.

2) Remove front floor mat and adjusting hole cover over adjusting screws on left side of transmission.

3) Run engine until temperature is normal and engine idles at hot or slow idle speed of 375-400 RPM.

4) Connect and adjust tachometer for accurate recording of engine speed.

5) Place selector lever in "DR" position ("LO" position on Oldsmobile Whirlaway).

6) Adjust carburetor throttle stopscrew so that engine idles at exactly 700 RPM. Then adjust bands:

Front Band (After steps 1 through 6):

7F Install the adjusting tool on front band adjusting screw, loosen adjusting screw locknut (turn long handle while holding short handle stationary).

8F) Loosen band adjusting screw (turn sh rt handle) until engine speed increases to 900-1000 RPM. (800-900 RPM. on Hudson—this will make it unnecessary to back adjusting screw all the way out).

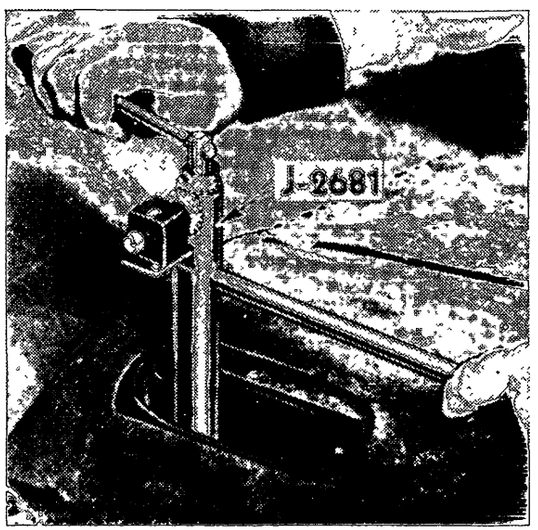
►*NOTE*—If no increase in engine speed noted when adjusting screw loosened, band has probably been slipping in service. Remove oil pan and inspect band and drum. With pan off, adjust bands as directed in ADJUSTMENT—WITH PAN OFF below and disregard following steps.

9F) Tighten band adjusting screw slowly until engine speed drops to 700 RPM., loosen adjusting screw

CONTINUED ON NEXT PAGE

HYDRA-MATIC BAND ADJUSTMENT (Continued)

until engine speed increases, then tighten adjusting screw until engine speed again drops to exactly 700 RPM., watch tachometer for 30 seconds to note any increase in engine speed. If increase noted, tighten adjusting screw 1/10 turn. Repeat this procedure until engine speed remains at 700 RPM. for at least 30 seconds,



10F) Set counter on adjusting tool to 00. Hold locknut stationary, tighten adjusting screw exactly 7.7 turns (supersedes previous settings) so that counter reads 7.7 on all models except Oldsmobile (See Oldsmobile Note below). Hold adjusting screw from turning, tighten locknut.

OLDSMOBILE NOTE—On "Whirlaway" cars where transmission has been modified to start in 1st gear, band should be adjusted to 6½ turns tight rather than 5½ turns previously specified for all transmissions.

Rear Band (After steps 1 through 6):

7R) Install the adjusting tool on rear band adjusting screw, loosen adjusting screw locknut (turn long handle while holding short handle stationary).

8R) Loosen band adjusting screw (turn short handle) until engine speed increases to 900-1000 RPM. (800-900 RPM. on Hudson—this will make it unnecessary to back adjusting screw all the way out).

HYDRA-MATIC BAND ADJUSTING TOOL J-2681

NOTE—If no increase in engine speed noted when adjusting screw loosened, band has probably been slipping in service. Remove oil pan and inspect band and drum. With pan off, adjust bands as directed in ADJUSTMENT—WITH PAN OFF below and disregard following steps.

9R) Tighten band adjusting screw slowly until engine speed drops to 700 RPM., loosen adjusting screw until engine speed increases, then tighten adjusting screw until engine speed again drops to exactly 700 RPM., watch tachometer for 30 seconds to note any increase in engine speed. If increase noted, tighten adjusting screw 1/10 turn. Repeat this procedure until engine speed remains at 700 RPM. for at least 30 seconds.

10R) Place selector lever in "N" position.

11R) Set counter on adjusting tool to 00. Hold locknut stationary, tighten band adjusting screw exactly 2 turns until tool counter reads 2.0.

12R) Place selector lever in "DR" position. Hold band adjusting screw from turning, tighten locknut securely.

After Front & Rear Bands Adjusted.

Reset engine idle speed as follows:

Car Model	Idle Speed	Selector Lever
Cadillac	375 RPM.	"Dr"
Frazer & Kaiser	425-450 RPM.	"N"
Hudson	480-520 RPM.	"N"
Lincoln, Nash	375 RPM.	"N"
Oldsmobile (exc. Whirlaway)	375 RPM.	"Dr"
Oldsmobile (Whirlaway)①	350 RPM.	"Dr"
Pontiac	365-385 RPM.	"N"

①—When Whirlaway transmissions modified to start in 1st gear, set idle speed at 375 RPM. in "Dr".

ADJUSTMENT—WITH OIL PAN OFF Using Servo Gauges J-1693 & J-5071 (Kaiser-Frazer KF-92 & KF-77): Drain transmission case by removing plug at rear of oil pan, remove pan, remove front compartment floor mat and floor hole cover over band adjusting screws. Adjust each band:

Front Band (Gauge J-1693 or Kaiser-Frazer KF-92):

1) Loosen locknut and back off front band adjusting screw approximately 5 turns. Make certain that band is centered on drum.

2) Remove pipe plug from bottom of front servo.

3) Loosen hexagonal headed adjusting screw on gauge by hand until approximately ⅛" of adjusting screw threads are exposed above gauge body. Screw gauge into pipe plug hole in front servo by hand

4) Tighten hexagonal adjusting screw on gauge by hand until gauge stem is felt to just touch piston in servo, then continue to tighten adjusting screw with a wrench exactly 6 full turns (see Oldsmobile Note below) from point where stem first contacted piston.

OLDSMOBILE WHIRLAWAY NOTE—On cars where transmission has been modified to start in 1st gear, band should be adjusted to 5 turns tight rather than 6 turns as above.

5) Tighten front band adjusting screw until knurled washer on gauge (at upper end of hexagonal adjusting screw) is just free to turn. Hold band adjusting screw from turning and securely tighten adjusting screw locknut.

6) Loosen gauge adjusting screw at least six turns, remove gauge from servo. Install pipe plug in servo and tighten securely.

Rear Band (Gauge J-5071 or Kaiser-Frazer KF-77):

1) Place the gauge on the finished surface of the Accumulator body with leg of gauge resting on rear servo stem.

2) Loosen locknut and back off rear band adjusting screw until face of actuating lever (which contacts servo stem) is well away from the face of the gauge.

3) Tighten band adjusting screw until face of band actuating lever just contacts gauge.

▷*CAUTION—If adjusting screw turned too far when making this adjustment, back screw off SEVERAL TURNS and repeat adjustment.*

4) Hold band adjusting screw from turning and tighten adjusting screw locknut securely. Remove gauge.

HYDRA-MATIC TESTING
ALL 1946-51 HYDRA-MATIC CARS

For test and repair purposes, the first basic types of Hydramatic Transmissions are identified below.

Hydra-Matic Types

1—Not Modulated Pressure. Mechanical Reverse.
2—Modulated Pressure. Mechanical Reverse.
3—Not Modulated Pressure. Hydraulic Reverse.
4—Modulated Pressure. Hydraulic Reverse.
5—"WHIRLAWAY" Either Type 2 or Type 4).

WHIRLAWAY TRANSMISSION NOTE—This transmission is basically the same as other Hydra-Matic Transmissions except for arrangement of shifts in "Dr" Range ("Lo" Range—1 & 2, "Dr" Range—1, 2, 3). *CAUTION*—Some Whirlaway Transmissions may be found which have been modified to start in 1st gear in "Dr" Range.

MODULATED PRESSURE: Main line or throttle pressure is regulated by the pressure regulator valve, depending on throttle pressure. This throttle pressure acts upon a throttle valve pressure plug house within pressure regulator. Inner end of plug bears against pressure regulator which controls main line pressure, adding force to the pressure regulator spring thus adding to main line pressure. (See illustrations).

HYDRAULIC REVERSE: Consists of a cone clutch arrangement within the reverse unit and allows for "Rocking" the car without danger of clashing gears. Transmisisons with hydraulic reverse can be identified by trying to shift into reverse with the car moving forward. Gears will clash and resistance will be apparent on cars without hydraulic reverse.

▷*CAUTION—Before performing any Hydramatic tests check fluid level in transmission and bring up to "FULL" mark on indicator, using recommended fluid only. Check engine idle and set at recommended speed.*

ROAD TEST: If possible, choose a route that includes a hilly section to test for open throttle upshift, slippage and throttle downshift points, and a level section for upshift point tests. Refer to Hydramatic Shift Point table for correct shift speeds.

STALL TEST: This test can be made to determine engine performance, transmission band slippage or damaged torus member. Engine speed must remain between test limits for normal engine and transmission operation (See Table below.) Bring engine to normal operating temperature and connect electric tachometer. Place selector lever in "Dr" position, set hand and foot brakes securely and depress accelerator pedal to floor. *(CAUTION—Extreme care must be used in making this test. NEVER HOLD THROTTLE OPEN MORE THAN ONE MINUTE. If engine speed EXCEEDS maximum limit by more than 200 RPM, close throttle immediately).*

STALL TEST LIMITS

Car	Minimum RPM	Maximum RPM
Cadillac	1500	1700
Hudson	1450	1650
Kaiser-Frazer	1450	1650
Lincoln	1350	1600
Nash	1450	1650
Oldsmobile "6"	1500	1600
Oldsmobile "8"	1700	1800
Pontiac	1400	1600

Engines operating within test limits indicate transmission and engine are normal.

CONTINUED ON NEXT PAGE

HYDRA-MATIC TESTING (Cont.)

If engine speed is BELOW MINIMUM limit, engine needs tune-up. (NOTE—Low engine RPM will result if torus members are damaged and are locked together). If engine speed goes ABOVE MAXIMUM limit, bands are slipping, fluid level low, or torus check valve or front pump relief valve sticking or missing. Before adjusting bands make valve check (below).

Checking Valves—Set hand brake and run engine for 1½ minutes, then with engine idling check fluid level (Selector lever in "N" position), see that fluid is at "FULL" mark on indicator. Shut off engine and wait ten minutes. Re-check fluid level with engine off. If the fluid level has not raised more than ½", torus check valve and front pump relief valve are operating satisfactorily. Test shift points (See Hydramatic Shift Points).

MAIN OIL PRESSURE (Cars WITHOUT Modulated Pressure): Remove front floor mat and hole cover plate over band adjusting screw. Remove plug from transmission case (between band adjusting screws), using 7/16" six point socket. Install Pressure Gauge (Kent-Moore No. J-2540). With transmission oil warm, start engine and run at 1000 R.P.M. Oil pressure should be 75 to 90 lbs. Apply both hand and foot brakes and move selector lever from "N" to "Dr", "Lo" and "R". Oil pressure should remain equal at all positions.

►*NOTE*—Rear Oil Pump may be checked separately by driving the car at 30 to 40 M.P.H. in Third speed in "Dr" range. Move selector lever to "N" and turn the ignition key off. Pressure on gauge should not be less than 55 lbs.

MAIN OIL PRESSURE (Cars WITH Modulated Pressure, except Oldsmobile "Whirlaway" Tranmission).

Zero Throttle Pressure—At 30 M.P.H. in fourth speed, with Zero Throttle, oil line pressure should be 55 to 72 lbs. (Cadillac 60-72 lbs..)

Full Throttle Pressure—Full throttle pressure in fourth speed at 30 M.P.H. (full throttle without going thru detent) should be between 75 and 105 lbs. (Cadillac 20 to 35 lbs. higher than zero throttle pressure test reading). Use brake to hold car at 30 M.P.H.

►*NOTE*—Rear oil Pump may be checked in the same manner as cars without Modulated Pressure.

Oldsmobile "Whirlaway" Transmission Cars: Place selector lever in "Dr" and set engine idle speed at exactly 350 RPM (375 RPM if Whirlaway transmission modified to start in 1st gear). Pressure should not be less than 35 lbs.

Line Pressure Modulation Test (Oldsmobile)—With selector lever in "Dr" and car traveling at 30 M.P.H. in third gear, pressure on gauge should not be less than 60 lbs., and should increase at least 20 lbs., as throttle position is changed from zero to full throttle.

REVERSE PRESSURE (Cars WITH Hydraulic Reverse): Install pressure gauge (see Main Oil Pressure above). Make sure Pressure Regulation is normal in forward speeds, then note pressure in "Dr" and "Lo" with engine idling at normal speed. Move lever to "R". Pressure should be as high or higher than in "Dr" or "Lo". Apply brakes and accelerate engine to half throttle. The pressure should gradually increase to 125 lbs., minimum. If the pressure does not check satisfactorily, a leak in the reverse oil system or a poorly operated pressure regulator is indicated.

HYDRA-MATIC SHIFT POINTS IN M.P.H.
(Selector Lever as Indicated)

CADILLAC 60S, 61, 62

UPSHIFTS:		1-2	2-3	3-4
Minimum Throttle	("Dr")	5-7	11-14	16-20
Full Throttle	("Dr")	9-15	26-35	59-67

HYDRA-MATIC TROUBLE SHOOTING & DIAGNOSIS

ALL 1946-51 HYDRA-MATIC CARS

▷*NOTE—75% of all troubles can be corrected by external adjustments and oil level. Over 80% of the remainder of troubles can be corrected with transmission in the car. See "HYDRA-MATIC OVERHAUL" following.*

LIGHT THROTTLE SHIFT POINTS HIGH: (With Full Throttle Shift points normal)—Throttle linkage adjusted incorrectly. Adjust throttle linkage and check for worn or loose control rods.

FULL THROTTLE SHIFT POINTS: (Either too high or too low or do not occur)—Governor valves not operating properly, leakage at governor assembly, broken oil rings or missing governor balancing plug. Governor ring lands might be worn. Correct by freeing valves, check for warped surfaces. Replace parts as necessary.

NO THROTTLE DOWNSHIFT IN "Dr" RANGE: (From 4 th to 3rd (3rd to 2nd Oldsmobile) above 20 M.P.H.)—Insufficient accelerator travel due to interference of throttle linkage or at floor carpet. Throttle controls improperly adjusted or lever bent or loose on shaft. Spring lock in downshift valve may be missing.

TRANSMISSION DOES NOT RESPOND TO SHIFT LEVER POSITION: Pin which picks up manual valve in valve body is not operating in groove in manual valve. To check, shift selector lever into reverse. If severe clashing results or if lever goes into reverse but car locks up and fails to move backwards, pickup pin is not operating manual valve. Remove side cover and engage pin.

TRANSMISSION FAILS TO DRIVE CAR: Usually caused by failure of one or both bands to be applied. Check for low oil pressure. Front or rear band adjustment incorrect. Manual valve mispositioned, or sticking torus check valve. See Oil Pressure Tests.

ERRATIC RESPONSE TO SHIFT LEVER: Inner manual control valve lever loose on shaft. Replace lever assembly.

ERRATIC TRANSMISSION OPERATION (Slipping and jerking during Light Throttle acceleration): May be caused by improper governor operation due to ring land on governor having been worn off by ring. To check for this condition, first make certain Linkage Adjustment and Band Adjustment are correct, warm up transmission thoroughly, check performance on light to medium acceleration for following conditions: (1) First shift point occurs at approximately 5 MPH. and there is considerable slippage above this point, (2) Shift into high occurs at higher than normal speed, (3) Car jerks when starting after stopping in reverse. If above conditions noted, remove and inspect the governor for worn ring land. *See Hydra-Matic Overhaul data.*

SHIFT LEVER STICKS IN REVERSE OR PARK POSITION (When parked on steep hill): Caused by rough surface on face of tooth on parking pawl engaging reverse internal gear. Replace parking pawl with new part having smooth surface (no tool marks). Pawl cannot be reworked (special shape and case-hardened).

HUNTING: Adjust throttle linkage, check valve assembly and clean thoroughly and reface.

HAS SECOND AND FOURTH SPEED ONLY: (1st & 3rd speed Oldsmobile)—Clean and reface valve assembly. Check front unit for possible locking.

ALL SHIFTS ROUGH: Adjust throttle linkage and servo bands. Clean and reface valve assembly. Check transmission passages for leaks. Check oil pressure.

TWO-THREE SHIFT ROUGH: *(1-2 shift Oldsmobile Whirlaway)*—Follow instructions under ALL SHIFTS ROUGH and also check front and rear servos.

NO FOUR-THREE DOWNSHIFT: *(3-2 Oldsmobile Whirlaway)*—Adjust throttle linkage. Inspect, clean and reface control valve assembly.

SLIPS AFTER FOUR-THREE DOWNSHIFT: *(3-2 Oldsmobile Whirlaway)*—Check front servo.

WILL NOT SHIFT, STAYS IN SAME GEAR: Check valve assembly and governor. Front or rear units not operating properly. Check for possible locking.

SHIFTS ABOVE SECOND SPEED (IN LOW RANGE): Adjust manual linkage. Check control valve assembly and governor.

SLIPS IN VARIOUS SPEEDS: Check fluid level and oil pressure. Adjust servo bands, clean control valve

SLIPS OUT OF REVERSE: (Except cars with hydraulic type reverse). Overhaul reverse anchor.

LOCKS UP ON REVERSE COAST: Check oil pressure. Clean and reface control valve assembly. Rear servo not operating properly.

CREEPS FORWARD WHEN IN "R" POSITION: Rear unit not operating correctly. Excessive drag in rear clutch.

CLASHES WHEN PROPERLY SHIFTED TO "R": Engine idle speed too fast. Control valve plugged or dirty. Reverse anchor not operating correctly.

NO DRIVE WHEN ENGINE IS FIRST STARTED: Check fluid coupling and front pump. Test oil pressure.

CREEPS EXCESSIVELY IN "Dr": Engine idle speed too high.

CAR WILL NOT BACK UP: (Unless throttle is opened excessively)—Rear band not released due to low oil pressure caused by leakage or compensator valve auxiliary plug pin missing.

BANDS APPLIED VIOLENTLY, ENGINE SPEEDS UP: Low oil pressure or level. Pressure regulating valve sticking. Front pump may not be operating properly or there is a bad oil leak in the system. Check oil pressure and oil level. Free up pressure regulator valve or install new valve.

SEVERE "CLUNK" ON 3-2 DOWNSHIFT AT HIGH SPEED WITH CLOSED THROTTLE: *(2-1 downshift Oldsmobile Whirlaway)*—Rear check valve is not operating properly. Check valve may be broken. Stuck or broken ring in accumulator piston. Rear clutch piston may also be binding on its pilot.

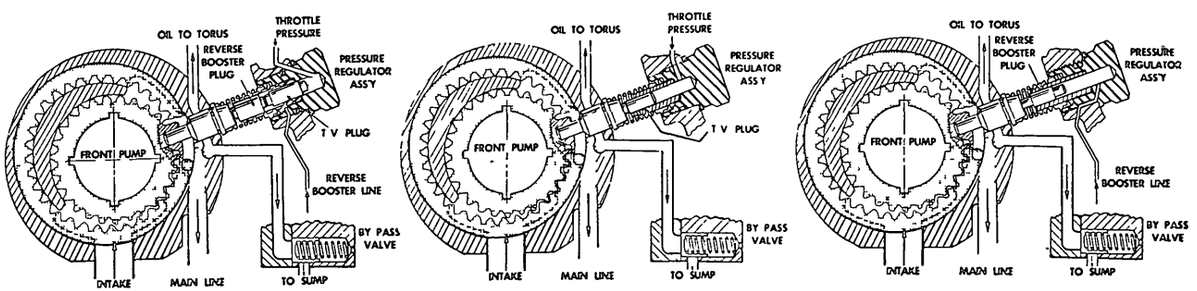
SELECTOR LEVER RATTLES (Caused by loosening of lever or breaking of Retainer Spring): To correct, check retainer nut and tighten if found loose. If nut tight and lever is loose and rattles, check for broken retainer spring or missing anti-rattle spring and spring stop. Install special retaining spring which has ⅛" slot to allow installation on lever and make certain that spring does not hang up on threads during installation of lever.

TRANSMISSION RATTLES (Oldsmobile Whirlaway Transmissions): "Tip In" Rattles (noted when car idling with selector lever in "Dr" or just as accelerator pedal is depressed) or "Float" Rattles (noted when car creeping at 2-3 MPH. on level road with selector lever in "Dr"—noise will be accentuated by rough engine). If tuning up engine does not eliminate this complaint, transmission can be modified to start in first gear in Drive Range. *See "Oil Control Valve Assembly" Note under Assembly of Units in Hydra-Matic Overhaul data in this section.*

CAUTION—See Linkage Adjustment and Band Adjustment data for special settings when above modification made.

CARS WITH HYDRAULIC REVERSE

CLICKING OR RATCHETING NOISE: (With selector lever in Reverse and car moving forward 2 to 4 M.P.H.).—This condition is due to parking pawl trying to engage reverse internal gear. This condition is usually the result of a sharp drop in line pressure. Check as follows:



1) Check line pressure in reverse (see Testing). If pressure too low, check reverse clutch apply oil pipe and reverse booster apply oil pipe for leaks, inner and outer cone clutch piston seals for leakage, valve body sealing surfaces for flatness (check on surface plate), and leakage between extension housing and transmission case.

2) Check engine idle speed and tune engine (rough engine may cause this condition).

3) Reverse check valve located in detent plunger housing should be firmly attached to retainer by rivet, opposite end should extend ¼" above face of retainer in free position, .062" hole should line up with hole in detent plunger spacer. Valve face should be flat against spacer when installed. Replace assembly if necessary.

4) Parking block piston return spring stop seat should be ½" to 17/32" from face of bracket. The parking blocker spring should never be altered. If distorted, it should be replaced.

CONTINUED ON NEXT PAGE

MODULATED PRESSURE & HYDRAULIC REVERSE

MODULATED PRESSURE & MECHANICAL REVERSE

NOT MODULATED PRESSURE & HYDRAULIC REVERSE

HYDRA-MATIC PRESSURE REGULATOR VALVE ASSEMBLY

HYDRA-MATIC TROUBLE SHOOTING & DIAGNOSIS (C nt.)

►*NOTE*—A second type spring stop and a new spring are now being used. The stop has a fixed setting and is mounted under both bracket bolts. The new spring has a free length of 1".

NO DRIVE IN REVERSE: This condition will occur if front servo exhaust body spacer is installed in reverse. Under this condition oil pressure does not increase when selector lever is placed in Reverse position. Pressure will increase to 150-170 lbs. when transmission shifts from 1 to 2.

SLIPPING IN REVERSE ONLY: Check for Low Oil Pressure in Reverse, Inoperative Front Servo Exhaust Valve, Key missing or defective in stationary cone, Stationary Cone or Cone Clutch Piston worn excessively, Front Servo & Band operation not operating properly, Valve Body Assembly dirty (sticking valves or oil leaks), Stationary cone distorted by handling when disassembled.

SELECTOR LEVER WILL NOT GO INTO REVERSE: Check for: Governor G-1 weight stuck wide open or broken governor ring (separating main line pressure from G-1 pressure to reverse blocker piston), Governor ring groove or gap clearances incorrect, Governor sleeve defective, Parking Pawl Crank bent, Detent Plunger in inner control lever stuck, Reverse Blocker Piston sticking or piston spring weak or broken.

EXCESSIVE SQUAWK IN REVERSE (May occur when selector lever out of Reverse if reverse unit not fully disengaged): Check for low oil pressure and galling of stationary cone and cone clutch piston. If reverse not fully disengaged also check for: Check Valve in detent plunger retainer in valve body plugged, Reverse Clutch Spring inoperative or weak, High spot or galling of stationary cone and cone clutch piston, cone clutch piston release springs defective or weak, Rear Bearing Dowels too high.

LOW OIL PRESSURE, SLIPPAGE, DELAYED AND ERRATIC UPSHIFTS: These conditions will exist when one or the other of the two ¼" cup shaped plugs are missing from the parking bracket. (CAUTION—These plugs are not service parts and should never be removed). If plugs are loose or missing, replace assembly.

REVERSE CONE ENGAGES WHEN IN DRIVE: This condition can occur when there is excessive leakage into the reverse apply circuit. Check for leakage as follows:

1) Check front servo exhaust valve for proper fit in exhaust body. Clearance should be .002".
2) Inspect detent retainer spacer and valve body surfaces that contact spacer. Replace control valve if necessary.
3) Check Throttle Valve plug in Pressure Regulator for excessive clearance. If greater than .002" replace Regulator plug assembly.
4) Neoprene seal on Pressure Regulator Plug defective. Use extreme caution when installing plug not to damage seal (remove all sharp corners or burrs in transmission case with round hone, place small amount of grease on seal before installing assembly, DO NOT use wrench to start pressure regulator plug in housing).

HYDRA-MATIC REMOVAL & INSTALLATION

ALL 1946-51 HYDRA-MATIC CARS

1946-51 CADILLAC

Removal: Support car with all wheels approximately 12" above floor. Remove floor carpet & pads, front seat cushion, and center floor pan. Disconnect propeller shaft at rear universal joint, remove shaft and front universal joint and yoke, remove flywheel housing pan. Drain transmission and fluid flywheel by taking out both drain plugs. Support rear end of engine with jack under oil pan (use block of wood on jack or use special Engine Support Stand Tool. Install Transmission Hoist, Tool J-1636B, in front compartment over floor pan opening, screw eyebolt securely into top of transmission, attach hoist cable hook to eyebolt, lift transmission just enough to take strain off rear support. Disconnect rear support at transmission extension housing, remove the bracket cross-member carrying the support. Remove throttle rod and manual shift rod from levers on the transmission case, remove both levers and the lower relay lever from flywheel housing. Disconnect speedometer cable at rear of transmission. Remove spark plugs and starter from engine. Remove 30 capscrews holding fluid coupling cover to flywheel, push cover toward rear of car to disengage flywheel dowels (CAUTION—Do not pry cover away from flywheel). Lower the jack under the engine until top of bell housing is flush with top of opening in floor pan. Remove the bolts holding bell housing to engine crankcase. Remove transmission and bell housing as a unit by moving it to the rear and lowering it to the floor.

Installation: Make certain that face of flywheel and torus cover are clean and free from all nicks or burrs, install NEW gasket on face of flywheel (use grease to retain gasket—do not use shellac or sealing compounds). Raise transmission in place carefully, make certain that mainshaft enters pilot bearing and that dowels in crankcase enter holes in housing squarely, align flywheel and torus cover so that large dowel pin and large dowel hole (marked by yellow paint) are at top and small dowel pin and small hole at the bottom. Install four flywheel housing-to-crankcase screws and tighten evenly to 45-50 ft. lbs. Install one torus cover screw adjacent to each dowel pin and tighten these screws just snug, install two more cover screws (90° from first two screws) and tighten these just snug (CAUTION—this procedure necessary to insure evenly applied pressure which will prevent leaks). Install all remaining torus cover screws, tighten all screws evenly to 20-25 ft. lbs. torque. Check torus cover drain plug tightness before installing flywheel lower cover. Raise engine approximately 1" (use jack and wooden block under oil pan), install engine rear support bracket, lower engine, connect support. Install and connect propeller shaft, speedometer cable, starter, spark plugs, transmission throttle lever and manual control lever. Fill transmission with Hydra-Matic fluid and adjust linkage. *See separate instructions.*

1951 FRAZER & KAISER

Removal: Raise car and support it on stands. Drain transmission case (remove oil pan drain plug). Disconnect speedometer cable and housing at rear bearing retainer, rear throttle rod and manual control rods at levers on transmission case. Disconnect propeller shaft at center bearing (Frazer), rear universal joint yoke (Kaiser), remove shaft by sliding front universal yoke out of transmission case. Install Support Fixture KF-104 under rear of engine and turn up support studs to remove engine weight from cross-member (CAUTION—do not raise engine more than enough to take weight off cross-member). Disconnect hand brake cable from bracket on cross-member, free engine from support cushions, remove cross-member with engine support cushions attached. Take off flywheel lower cover, drain fluid coupling by removing drain plug in torus cover. Remove throttle lever (Long lever) from transmission case. Mark torus cover and flywheel to insure reassembly in same position (CAUTION—necessary to maintain balance), remove all torus cover-to-flywheel attaching bolts. Lower engine slightly so that upper housing attaching bolts are accessible. Use transmission support jack (KF-106) under transmission to support transmission weight and remove strain from mounting bolts, remove all housing mounting bolts. Thread one 9/16"-12 bolt into housing bolt hole directly above dowel pin on each side of housing, turn up bolts evenly until dowel pins are freed from front housing, then remove these bolts. Move transmission straight back until it is free, then lower it carefully (CAUTION—turn flywheel so that end of mainshaft passes between two bolts), remove transmission from beneath car.

Installation: See that face of flywheel and torus cover mounting flange are clean and free from nicks or burrs, install NEW gasket on face of flywheel (use grease to retain gasket—do not use shellac or sealing compounds). Turn flywheel so that one dowel pin approximately 4" below edge of front flywheel housing. Carefully raise transmission in place and guide mainshaft pilot into pilot bearing in crankshaft. Align torus cover and flywheel marks (made at removal), push transmission forward until dowels in flywheel rear housing enter holes in front housing. Install attaching bolts and lockwashers in rear flywheel housing and tighten securely. Install all (30) torus cover-to-flywheel bolts and tighten finger tight (CAUTION—these are special alloy steel bolts), tighten these bolts in following order to insure even pressure and prevent leaks:

(1) Tighten one bolt adjacent to each dowel to 12-15 ft. lbs. torque.
(2) Tighten two bolts located 90° from dowels (evenly spaced between first two bolts) to 12-15 ft. lbs. torque.
(3) Tighten all bolts in rotation to 20-25 ft. lbs.
(4) Retighten all bolts in rotation to 30-35 ft. lbs.

Check tightness of torus cover and transmission oil pan drain plugs, install flywheel housing lower cover. Install engine support cross-member and connect engine support cushions. Install and connect transmission throttle lever, connect manual control rod. Connect speedometer cable and hand brake cable. Fill transmission with Hydra-Matic fluid and adjust linkage. *See separate instructions.*

1950-51 HUDSON

R moval: Disconnect battery ground cable first.

1) Disconnect starter cable and remove starter.
2) Take out bolt attaching breather pipe to valve

C NTINUED ON NEXT PAGE

HYDRA-MATIC REMOVAL & INSTALLATION (Cont.)

chamber cover and bracket-to-flywheel housing bolt, remove breather pipe.
3) Turn back floor mat to expose two upper floor opening covers and remove covers for access to top flywheel housing-to-engine bolts, remove these two bolts.
4) Raise car and support securely on jack stands.
5) Disconnect propeller shaft at rear universal joint and at front universal joint (CAUTION—tape journal bearing cups to universal journal to avoid losing bearings). Take out center bolt attaching center bearing support and slide propeller shaft to rear to provide clearance at transmission.
6) Disconnect speedometer cable at transmission rear bearing retainer. Disconnect rear throttle rod and manual control rod from levers on side of transmission case.
7) Remove left hand engine side rear stone guard by taking out 4 self-tapping screws.
8) Disconnect return spring at hand brake cable lever and cable clevis at pull rod slide link, remove cable retainer clip at engine support cross-member, pull cable forward and through the cross-member.
9) Take out two bolts attaching each engine rear support insulator to cross-member. Install transmission support jack under transmission case (hydraulic hoist with transmission cradle), raise transmission just enough to remove weight from cross-member. Disconnect and remove cross-member (4 screws on bottom and 3 on top at each end).
10) Install Engine Holding Fixture J-4651 to support engine weight (holes provided in frame side rail just below steering housing support and in same location on opposite side for engagement of support hooks), adjust support hooks so that front end of engine clears center tie rod by approximately ½" and weight of engine is supported by fixture.
11) Remove flywheel housing lower dust cover, drain fluid coupling by removing drain plug in torus cover.
12) With engine supported by fixture and transmission supported by jack, remove all torus cover attaching screws, remove flywheel housing lower right hand bolt (use ⅝" universal socket and 14" extension) leaving the bolt in the hole, remove lower left hand bolt (use 9/16" universal socket and 14" extension).
13) Pull transmission straight back until transmission shaft pilot clears pilot bushing in flywheel, then lower transmission carefully (CAUTION—use care that shaft does not strike flywheel bolts).

Installation: Reverse the removal procedure above and note the following important points:
Torus Cover & Flywheel Gasket—Make certain face of flywheel and torus cover mounting flange are clean and free from nicks and burrs. Use petrolatum to hold NEW gasket on face of flywheel (DO NOT use shellac or sealing compounds).
Flywheel Housing Bolts—Tighten all four bolts evenly to 40-50 ft. lbs. torque.
Torus Cover Bolts—After all bolts have been installed, tighten bolts in following order to insure even pressure and to prevent leaks:
(1) Tighten one bolt adjacent to each dowel pin to 12-15 ft. lbs. torque.
(2) Tighten two bolts located 90° from dowel pins (equally spaced between first two bolts) to 12-15 ft. lbs. torque.
(3) Tighten all bolts in rotation to 20-25 ft. lbs.
(4) Retighten all bolts in rotation to 26-31 ft. lbs.
Engine Support Cross-member—Install and tighten bolts in engine rear support insulators first, then install screws mounting cross-member on frame.
Filling Transmission with Fluid—*See REFILLING.*
Transmission Linkage—Connect throttle and manual control rods and adjust linkage. *See separate instructions.*

1949-51 LINCOLN

Removal: Support car securely with all four wheels approximately 8" off floor.
2) Remove front seat and front floor carpet, disconnect throttle rod at accelerator pedal, remove front floor pan cover.
3) Disconnect propeller shaft at rear universal joint, remove propeller shaft and universal joint from transmission spline shaft.
4) Remove flywheel housing pan and engine plate. Drain transmission case (drain plug at rear of pan) and fluid coupling (drain plug in torus cover).
5) Disconnect rear motor mount from frame cross-member and remove the bottom half of the rubber mount.
6) Place jack under rear end of engine oil pan with wooden block on jack to prevent damage to pan, raise engine sufficiently to install engine support.
7) Remove detachable cross-member from frame X-member. Lower jack under engine until engine rests on support.
8) Install transmission lifting hoist over floor pan opening in front compartment (adjust legs of hoist to fit car and attach cables to floor pan to prevent tipping of hoist). Screw eyebolt securely in tapped hole in top of transmission case, attach cable hook, take up slack in cable so that weight of transmission and fluid coupling taken off engine support.
9) Disconnect manual control rod and lower throttle rod at levers on side of transmission case, remove throttle lever (longer lever) to prevent damaging lever during removal of transmission. Disconnect speedometer cable at rear of transmission.
10) Remove spark plugs from engine. Disconnect and remove starter motor.
11) Take out 30 5/16" capscrews mounting torus cover on flywheel, push cover toward rear of car to disengage locating dowel pins.
▷*CAUTION—Do not pry cover away from flywheel (will damage gasket surface on cover and flywheel).*
12) Take out 6 bolts mounting flywheel housing on engine.
13) Remove transmission and flywheel housing as an assembly by moving unit toward rear of car until flywheel housing dowels and main shaft are disengaged, then lower assembly (tilt front end down and move it forward to free transmission bearing extension from frame cross-member) and remove from beneath car.

Installation: Make certain that face of flywheel and torus cover mounting flange are clean and free of all nicks and burrs.
1) Install NEW gasket on face of flywheel using grease to retain gasket (DO NOT use shellac or sealing compounds).
2) Raise transmission in place carefully, make certain that mainshaft enters pilot bearing and that dowels in engine enter holes in housing squarely, align flywheel and torus cover so that large dowel pin and large dowel hole are at the top.
3) Install six flywheel housing-to-engine bolts and tighten evenly to 45-50 ft. lbs. torque.
4) Install one torus cover screw adjacent to each dowel pin in flywheel and tighten these screws just snug, then install two more screws (at 90° from first two) and tighten these just snug (CAUTION—this procedure necessary to insure evenly applied pressure which will prevent leaks). Install remaining torus cover screws, tighten all screws evenly to 20-25 ft. lbs. torque.
5) Check torus cover drain plug tightness, install flywheel housing pan and engine plate.
6) Raise engine approximately 1" (use jack and wooden block under oil pan), install frame cross-member, lower engine into place, install engine mount.
7) Install and connect propeller shaft, speedometer cable, starter, spark plugs, transmission throttle lever. Connect manual control lever rod.
8) Fill transmission with Hydra-Matic fluid and adjust linkage. *See separate instructions.*

1950-51 NASH

Removal: Raise car and support securely on stands (support rear of car at body side sills and place hydraulic jack under rear axle assembly).
2) Drain transmission case and fluid coupling (remove flywheel lower cover for access to drain plug.
3) Remove accelerator pedal and front compartment floor mat, take out screws in floor hole cover and remove cover.
4) Disconnect hand brake cable at adjusting yoke, disconnect speedometer cable and housing at transmission adapter, disconnect rear throttle rod and manual control rod at levers on left side of transmission case, remove rear brake hydraulic hose bracket from floor pan to prevent damage to lines.
5) Disconnect torque tube from rear bearing retainer by taking out flange mounting bolts, disconnect propeller shaft by sliding universal joint yoke to rear and free of transmission driveshaft, move torque tube out of the way.
6) Place jack under rear end of engine oil pan (use block of wood on jack to prevent damage to pan), or use special Engine Support Fixture J-4179 installed under engine to support engine so that all weight removed from rear engine support cross-member.
▷*CAUTION—Do not raise engine more than necessary to remove engine support cross-member.*
7) Remove rear engine support cross-member (take out bolts in rear bearing retainer so that rubber cushion removed as unit with cross-member).
8) Loosen clamp bolt and remove throttle control lever (longer lever) from left side of transmission
9) Remove 30 capscrews and lockwashers mounting torus cover on rear face of flywheel.
10) Lower engine slightly so that upper housing attaching bolts accessible through floor pan opening. Install special transmission holding tool J-2803 on hydraulic jack (CAUTION—tool must be securely fastened to jack pad), place jack under transmission with tool securely engaging transmission case oil pan, lift transmission just enough to remove weight from mounting bolts in flywheel housing.

CONTINUED ON NEXT PAGE

HYDRA-MATIC REMOVAL & INSTALLATION (Cont.)

11) Remove attaching bolts, nuts, and lockwashers holding rear flywheel housing on front housing, take out upper rear stud on each side, use two 9/16" USS bolts to disengage dowels (screw one bolt evenly into each of above stud holes until dowels are free of front housing, then remove bolts).

12) Move transmission to rear until it is free, then lower assembly (CAUTION—turn flywheel so that end of mainshaft passes between two of the flywheel-to-crankshaft bolts), remove transmission from beneath car.

Installation: Reverse the removal procedure above and note the following important points:

Torus Cover & Flywheel Gasket—Make certain that face of flywheel and mounting flange on torus cover are clean and free from all nicks and burrs. Install NEW gasket on face of flywheel (use petrolatum to hold gasket—DO NOT use Shellac or sealers).

Transmission Alignment—Turn flywheel so that one dowel pin is approximately 4" below lower edge of front housing (so that mainshaft will pass between two crankshaft bolts) and turn torus cover so that dowel pin hole is in corresponding position. Lift transmission into place carefully, guide mainshaft pilot into pilot bushing and push transmission forward so that dowels in rear flywheel housing enter holes in front housing squarely.

Flywheel Housing Bolts—Install all rear flywheel housing-to-front housing bolts and stud nuts and tighten evenly and securely (NOTE—Rear engine mountings must be installed on lower studs before nuts are tightened).

Torus Cover Bolts—Install all bolts and tighten finger tight, then tighten these bolts in following order to insure even pressure and avoid leaks:

(1) Tighten one bolt adjacent to each dowel pin to 12-15 ft. lbs. torque.

(2) Tighten two bolts located 90° from dowel pins (equally spaced between first two) to 12-15 ft. lbs.

(3) Tighten all bolts in rotation to 20-25 ft. lbs.

(4) Retighten all bolts in rotation to 30-35 ft. lbs.

Filling Transmission with Fluid—*See REFILLING.*

Transmission Linkage—Connect manual control rod. Install throttle lever and connect rear throttle rod. Adjust linkage. *See separate instructions.*

1946-48 OLDSMOBILE

Removal: Support car with all four wheels approximately 8" above floor. Remove foot accelerator pad, floor mat, center floor pan. Disconnect speedometer cable. Disconnect propeller shaft at rear universal joint, remove by sliding shaft out at splined joint. Remove flywheel housing pan. Drain transmission and flywheel by taking out both drain plugs. Remove outer throttle lever from transmission case, disconnect control rod from manual shift lever. Remove two upper rear engine mounting bolts, remove master cylinder to brake shaft bracket, disassemble strut from shaft, remove clevis pin from lower control relay rod. Raise engine approximately ½" off mountings with jack just forward of crankcase drain plug (use block of wood on jack). Remove 3 bolts from each side of cross-member at frame side rail, remove cross-member by tipping top toward front of car and moving cross-member forward. Install transmission lifting tool J-1502 in front compartment over floor pan opening. Thread special eye-bolt, Tool No. J-1636SA-5, in tapped hole in top of transmisssion case and attach cable hook to eye-bolt. Lift transmission just enough to take strain off mounting bolts, remove 30 bolts holding fluid flywheel cover on flywheel, remove five bolts holding rear half of bell housing to front half. Lower engine slightly until top of bell housing is flush with top of opening in floor pan, thread two standard transmission bolts into bell housing (on each side just above dowel pins) to force bell housing from dowel pins, then remove these bolts. Remove transmission and rear bell housing by moving it to rear and downward.

CAUTION—Do not allow end of mainshaft to strike crankshaft bolts (turn flywheel so that shaft passes down between two bolts).

Installation: Reverse the removal procedure above and note the following important points:

Torus Cover & Flywheel Gasket—Make certain face of flywheel and torus cover mounting flange are clean and free from nicks and burrs. Use vaseline to hold NEW gasket in place on face of flywheel (DO NOT use shellac or sealing compounds).

Torus Cover Alignment & Tightening—Align torus cover over dowel pins in flywheel(just start the flywheel capscrews by hand to align torus cover (CAUTION—these capscrews are special type). AFTER rear bell housing mounting bolts have been tightened, tighten all torus cover screws evenly to 30 ft.lbs. torque.

Filling Transmission with Fluid—*See REFILLING.*

Transmission Linkage—Install throttle lever and rod, connect manual control rod., Adjust linkage. *See Linkage Adjustment.*

1949 OLDSMOBILE

Removal: *CAUTION—Rocket engine requires different removal procedure as follows:* Disconnect accelerator pedal rod at bellcrank, remove floor mat and center floor pan. Remove upper transmission to bell housing capscrews. Raise car approximately 8" off floor and securely support all four wheels. Drain fluid coupling and transmission case. On 8 cyl. cars, remove engine side pans, disconnect starter wiring, remove starter, remove lower flywheel housing (necessary to remove exhaust pipe bracket and crankcase ventilator bracket from housing first). Install Rear Engine Support, Tool No. BT-28, to support rear end of engine. Remove engine mount to cross-member bolts (left side), capscrews (right side), and two capscrews attaching engine mount to flywheel housing (right side only). Remove bolts attaching intermediate lever bracket to cross-member, and bolts attaching cross-member to frame (3 bolts on each side). Lift engine approximately ½" and remove cross-member (CAUTION—do not lift engine more than necessary to remove cross-member). Then remove transmission in same manner as on previous Oldsmobile models.

Installation: Reverse the removal procedure above and note the following important points:

Torus Cover & Flywheel Gasket—Make certain face of flywheel and torus cover mounting flange are clean and free from nicks and burrs. Use vaseline to hold NEW gasket in place on face of flywheel (DO NOT use shellac or sealing compounds).

Torus Cover Alignment & Tightening—When installing transmission align torus cover over dowel pins in flywheel *(CAUTION*—On 8 Cyl. cars, one dowel is larger than standard and torus cover must be turned to align the larger dowel with the larger dowel pin hole). After transmission rear bell housing attaching bolts tightened, install torus cover capscrews and tighten snugly, then tighten all screws to 30 ft.lbs. torque.

Filling Transmission with Fluid—*See REFILLING.*

Transmission Linkage—Install throttle lever and rod, connect manual control rod., Adjust linkage. *See Linkage Adjustment.*

1950-51 OLDSMOBILE

Removal: Use twin-post hoist to raise car, or support car securely on jack stands.

1) Remove transmission oil pan plug and drain transmission case.

2) On 8 Cyl. cars only, disconnect engine side pans at rear and drop these down for access to starter, disconnect starter wiring and remove starter.

3) On 8 Cyl. cars only, free exhaust pipe bracket and crankcase ventilator bracket from lower flywheel housing and remove housing. Remove flywheel housing pan.

4) Drain fluid coupling by removing drain plug from torus cover.

5) Disconnect propeller shaft at rear universal joint, pull shaft to rear to disengage forward end from transmission.

6) Disconnect speedometer cable at transmission case. Free intermediate lever bracket from frame cross-member by taking out two bolts.

7) Install special transmission lift (hydraulic jack and transmission cradle) under transmission and raise transmission and engine just enough to remove weight from engine support cross-member.

8) Free engine mounts from cross-member by taking out two bolts (left side), two capscrews (right side). Take out three cross-member to frame bolts at each side. Lift engine approximately ½" and remove cross-member (CAUTION—do not lift engine more than necessary to remove cross-member). Then lower engine just enough (approx. 1½") for access to upper rear bellhousing-to-front bellhousingcapscrews (CAUTION—do not lower engine more than 1½" unless upper radiator hose and exhaust pipe-to-manifold connections are loosened).

9) Disconnect manual control rod and throttle rod from levers on side of transmission case, remove throttle lever to prevent damaging lever during transmission removal.

10) Remove all torus cover-to-flywheel capscrews

11) Install Rear Engine Support BT-28 to support engine when transmission taken out. Remove rear bell housing-to-front bellhousing capscrews.

12) Move transmission to rear and lower it to the floor. CAUTION—Turn flywheel so that end of mainshaft passes between two flywheel bolts.

Installation: Reverse the removal procedure above and note the following important points:

Torus Cover & Flywheel Gasket—Make certain face of flywheel and torus cover mounting flange are clean and free from nicks and burrs. Use vaseline to hold NEW gasket in place on face of flywheel (DO NOT use shellac or sealing compounds).

Torus Cover Alignment & Tightening—On 6 Cyl. cars, engage paint-marked dowel pin in flywheel with dowel pin hole in cover which is also paint-

C NTINUED ON NEXT PAGE

HYDRA-MATIC REMOVAL & INSTALLATION (Cont.)

marked (both dowel pins are same size but original paint-marked position must be maintained for correct run-out and balance). On 8 Cyl. cars, one dowel pin is larger than the other and this larger dowel must engage the larger dowel pin hole. Install all torus cover screws and tighten snugly, then tighten all screws evenly to 30 ft. lbs. torque.

Filling Transmission with Fluid—*See REFILLING.*

Transmission Linkage—Connect manual control rod. Install throttle lever and connect rear throttle rod. Adjust linkage. ***See separate instructions.***

1948-51 PONTIAC

Removal: Support car on stands with all wheels 8" above floor. Drain transmission oil pan. Remove accelerator pedal, front floor mat, and transmission hole cover in floor. Disconnect speedometer cable and housing at transmission. Disconnect propeller shaft at rear universal and remove by sliding it to rear and free of transmission output shaft. Remove flywheel housing bottom cover (remove crankcase ventilator outlet pipe and loosen exhaust pipe bracket to aid cover removal). Drain fluid coupling by removing plug in cover. Disconnect hand brake cables at idler lever and remove lever (not required on Convertibles). Disconnect shift lever control rod from inner lever on transmission case, remove throttle control (outer) lever. Remove all (30) torus cover-to-flywheel bolts and lockwashers (work through pan opening in housing). Disconnect two rear engine mountings and reinforcing plates from cross-member, disconnect shift control lever bracket from cross-member. Use a jack under the rear end of the engine oil pan (place 4x4x10" wood block on jack to prevent damage to pan), raise rear end of engine until rear mountings ½" above cross-member (CAUTION—do not raise engine more than necessary for cross-member removal). Take out three cross-member mounting bolts on each side of car, remove reinforcing plates from inside frame side rails, remove cross-member (tap down at both ends until right end rests on exhaust pipe, tap left end down clear of side rail, lift right end over exhaust pipe). Lower rear end of engine until rear flywheel housing attaching bolts accessible through hole in floor. Use hydraulic jack and tool J-2808 (special transmission mounting fixture —fixture must be securely fastened on jack pad) and lift transmission slightly to remove stress on mounting bolts. Take out six rear housing-to-front flywheel housing bolts (two lower bolts on each side also retain engine rear mountings). Thread a 9/16"-12 bolt in center hole in each side of housing (directly above dowel pins) to remove dowel pins from rear housing (remove bolts when dowels are free). On all models except Convertibles (see Convertible Note below), remove transmission by moving it toward the rear and lowering it to the floor (CAUTION—to prevent mainshaft striking flywheel mounting bolts when lowering transmission, turn flywheel so that shaft passes down between two bolts).

Convertible Transmission Removal Note—Use a rope looped around rear end of transmission and extending through floor pan hole to inside of car to guide transmission. Remove speedometer driven gear, shaft, and sleeve assembly. With transmission moved to rear to clear engine, raise rear end of engine as high as possible (CAUTION—do not allow end of transmission main shaft to scrape on face of flywheel). Tilt transmission down at front (lift rear end with guide rope), and remove from beneath car.

Installation: Reverse the removal procedure given above and note the following important points:

Torus Cover & Flywheel Gasket—Make certain face of flywheel and torus cover mounting flange are clean and free from nicks or burrs. Install NEW gasket on face of flywheel (use petrolatum to hold gasket—DO NOT use Shellac or sealers).

Transmission Alignment—Turn flywheel so that one dowel pin is approximately 4" below left side of front flywheel housing (so that mainshaft will pass between two crankshaft bolts), turn torus cover so that dowel pin hole is in corresponding position. Lift transmission into place carefully guiding mainshaft into pilot bearing (CAUTION—see that pilot bearing spacer in place on end of mainshaft).

Flywheel Housing Bolts—Install and tighten all six bolts securely **with rear engine mountings installed on lower bolt on each side.**

Torus Cover Bolts—Install all bolts and tighten finger-tight, then tighten these bolts in following order to insure even pressure and avoid leaks:

(1) Tighten one bolt adjacent to each dowel pin to 12-15 ft. lbs. torque.

(2) Tighten two bolts located 90° from dowel pins (equally spaced between first two) to 12-15 ft. lbs.

(3) Tighten all bolts in rotation to 20-25 ft. lbs.

(4) Retighten all bolts in rotation to 30-35 ft. lbs.

Filling Transmission with Fluid—*See REFILLING.*

Transmission Linkage—Connect manual control rod. Install throttle lever and connect rear throttle rod. Adjust linkage. ***See separate instructions.***

HYDRA-MATIC OVERHAUL

►CHANGES, CAUTIONS, CORRECTIONS

►*1946-50 GEAR TYPE FRONT PUMP REPLACEMENT (Cars with Mechanical Type Reverse):* A variable delivery (rotor type) front pump as used in 1952 and later production is available for service replacement on earlier cars with Gear Type Front Pumps and Mechanical Type Reverse. Replacement pumps are furnished in complete kits consisting of Pump Assembly, Gasket, Intake Pipe, and Oil Screen Assembly. *CAUTION—When Rotor Type Pump is installed a new Pressure Regulator MUST ALSO BE INSTALLED.*

►*1951 PRESSURE REGULATOR VALVE SERVICE REPLACEMENT: (To eliminate "Clicking" noise when operating and surge noted when engine started).* New type valve with rubber cushions on contact areas. Used in later production and may be installed on early transmissions to correct above complaints. See disassembly data for valve removal and installation. New and old type valves are interchangeable.

►*1946-52 REAR CLUTCH HUB SERVICE REPLACEMENT (CADILLAC & PONTIAC):* New clutch hub is relieved approximately .030" in front face of hub to allow space for thrust washer. New design eliminates wear between hub face and snap ring. Cadillac Service Kit Part No. 8615418, and Pontiac Part No. 8615451, is available for service replacement.

►**ELIMINATION OF DOWEL PIN IN REAR PLANETARY UNIT DRUM (1951 Production Change):** Late 1951 transmissions do not have dowel pin between rear unit internal gear and rear unit drum (pin and pin hole discontinued). Early and new type parts furnished for service and **both parts must be of same type.**

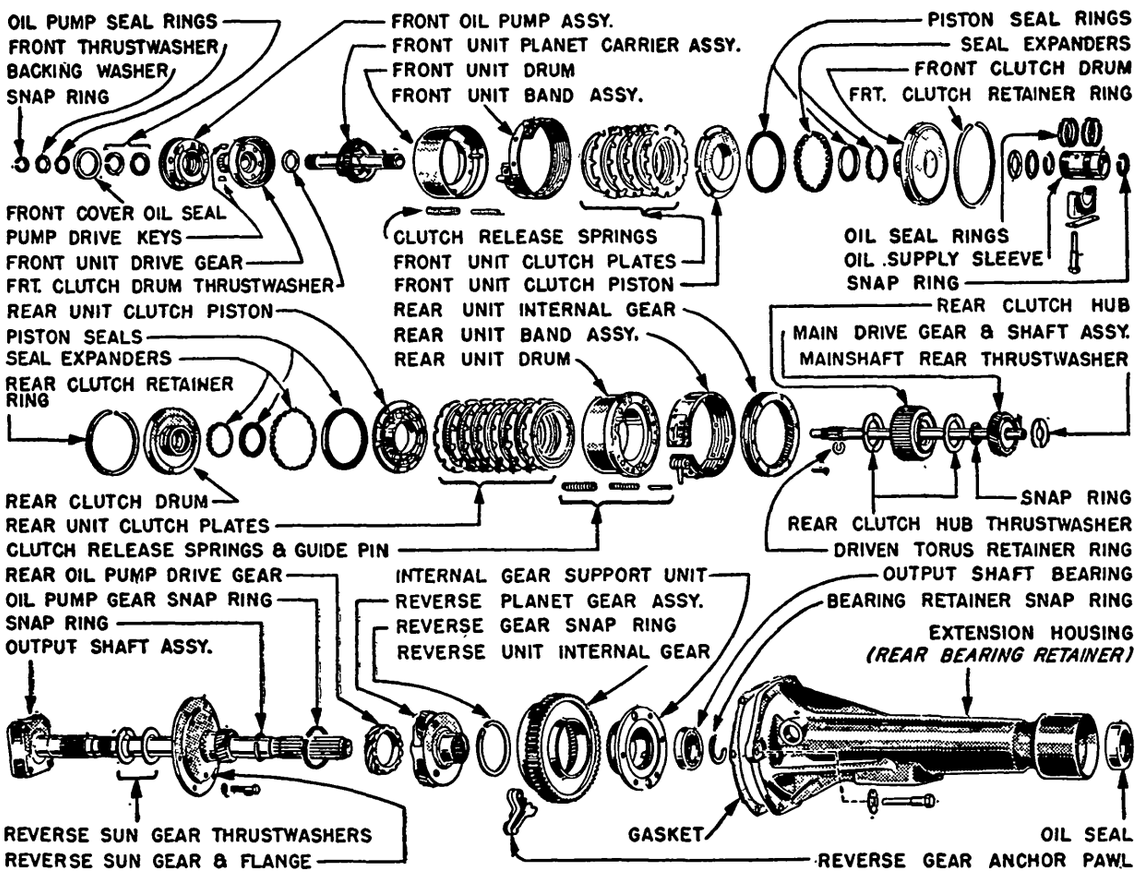
►**1951 FRONT SERVO EXHAUST VALVE ASSEMBLY CHANGE (to eliminate buzzing noise when shifting into Reverse):** This new assembly used in production on late 1951 cars and can be installed on earlier cars (assemblies are interchangeable).

DISASSEMBLY OF TRANSMISSION

Torus, Torus Cover, Bell Housing. Move manual control lever on side of transmission toward rear to reverse position and remove oil level indicator from case. Straighten main shaft nut lock plate (using a chisel and light hammer) and remove the main shaft nut. Slide driven torus member off transmission shaft *(CAUTION:—If torus member sticks, tap end of mainshaft with rawhide hammer while pulling torus on hub).* Remove driving torus snap ring and driving torus assembly. Torus cover member plate can then be removed.

►*CAUTION:* Do not attempt to remove torus cover and driving torus by pulling and pushing on torus cover in a rough manner as this will possibly result in a broken oil seal ring. Instead, work hub of torus cover back thru oil seals gently, and then pull torus cover forward with a quick jerk.

Take out the four capscrews and lock washers holding the flywheel housing to front of transmission case. Remove flywheel housing. On Oldsmobile take out ⅛" oil pressure line plug from transmission case, and place transmission case in holding fixture.



Manual Lever, Oil Pan and Side Cover. Loosen lock screw holding manual lever to shaft and remove lever. Drive out open type driven torus retainer ring from main shaft using Tool J-1458, being careful main shaft is not damaged. Remove all capscrews from oil pan and side cover and remove oil pan and side cover from transmission. Lift oil pump screen from rear pump intake pipe. Straighten two front intake pipe bolt locks and loosen the two capscrews while lifting slightly on the pipe to avoid dropping capscrews into transmission case. Remove intake pipe from case.

Parking Brake Bracket and Control Valve (Cars with Hydraulic Type Reverse): Back off front and rear band adjusting screws at least 5 turns and remove parking brake pawl support bolt from rear of case and position anchor down in case as far as possible (Pawl can not be removed at this time). Remove pressure regulator reverse oil pipe (Do not bend pipe). Loosen two bolts holding parking brake bracket assembly to transmission case and place detent control lever in "L" position. Unhook parking brake release spring from pin assembly and inside oil pipe. Remove four bolts holding control valve assembly to transmission case and work control valve assembly toward front of case to remove governor pipes and reverse clutch pipe. Remove bolts from brake bracket assembly and remove piston release spring and stop. Carefully remove sleeve from governor to avoid damage to oil rings. Remove parking pawls from case.

Servos and Rear Oil Pump (Cars with Hydraulic Type Reverse). Remove front and rear servo attaching bolts and rear oil pump attaching bolts. Separate front and rear servo at oil transfer pipe by moving rear servo toward rear of transmission, then remove servo and rear pump discharge pipe. Remove front pump delivery pipe by pulling straight up from front pump. Position governor so that large round end is toward front of transmission and position one reverse drive flange attaching bolt up. Remove rear pump and governor by moving toward control valve assembly side of transmission base.

Servos and Control Units. Hold rear pump discharge pipe brass fitting in front serv and loosen pipe nut. (Do not remove pipe from coupling). Loosen front and rear band adjusting lock nuts, then loosen adjusting screws approximately five turns each. Re-

CONTINUED ON NEXT PAGE

HYDRA-MATIC FRONT UNIT, REAR UNIT, & REVERSE DRIVE ASSY. (WITH UT HYDRAULIC REVERSE)

HYDRA-MATIC OVERHAUL (Cont.)

move front and rear servo attaching screws and take both servos out as a unit. NOTE:—As servos are lifted from the case, the rear pump discharge pipe will rotate in the coupling and fall free without bending the pipe. (The pipe is connected in the same manner when installing the servos to the transmission case). Remove the rear pump discharge pipe from the pump, then remove the front delivery pipe.

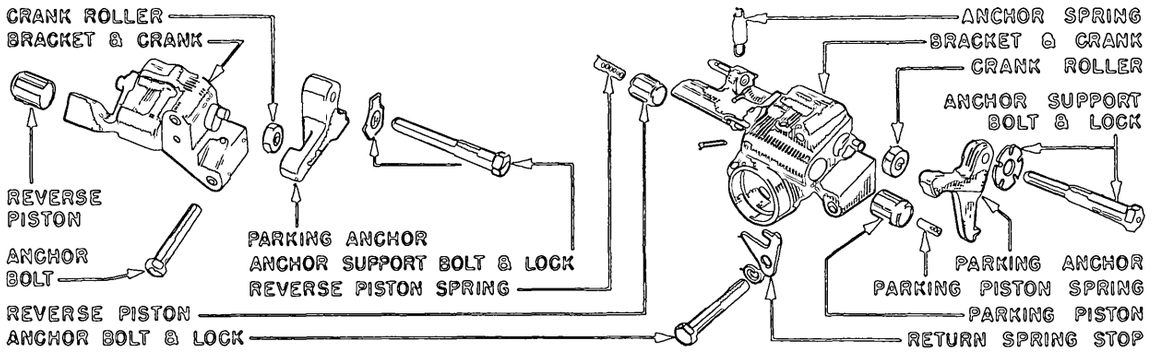
Main Oil, Control Valve Body. *NOTE:*—Governor runout may be checked at this point before removal of oil control body. (See "Governor Runout Check" instructions). Position manual control detent lever so steel ball is in the "LO" range detent position, then remove four valve body mounting screws. Remove control body by sliding forward along transmission case. Oil delivery pipes from valve body to governor sleeve may come off with valve body. If they do not come off with valve body, they should be pulled out of governor sleeve at this time.

Reverse Shifter Bracket Assembly. Remove mounting bolts and take off the reverse shifter bracket, being careful not to lose the shims, spring or roller.

Rear Oil Pump and Governor Assembly. Remove the two screws holding the rear oil pump and governor to transmission case. Rear oil pump and governor can be removed as an assembly by positioning one reverse drive flange attaching screw up. Governor must be rotated so that the large round governor weight is toward the front of the transmission while removing the assembly. Take the assembly from the case by moving it toward control valve assembly side of the case and raising rear of pump to clear case.

Pressure Regulator Assembly. Remove pressure regulator plug, spring and valve from side of transmission case, holding it under pressure during removal as it is under spring tension.

Front Oil Pump and Front Unit Drive Gear. Remove snap ring holding front unit drive gear on front end of intermediate shaft and remove steel and bronze thrustwashers from shaft. (NOTE:—These washers have a smaller diameter than similar washers used in the transmission and should be kept separate). Remove front pump retaining screws and copper washers from its counterbore. Snap ring pliers can be used for this. Front pump, gasket and front unit drive gear will now come off as an assembly. Remove bronze thrustwasher in front of planet carrier.



Check End Clearance of Main Shaft. Install main shaft End Play Guide J-2587 over main shaft and front planet carrier and set up dial indicator on transmission case using Tool J-1465. Insert screwdriver between front clutch drum and center bearing cap, holding front planet unit forward. The screwdriver should be placed at an angle to prevent damage to oil delivery sleeve. Move shaft back and forth. End Clearance should be .004" to .005". Be sure to get just the float in the shaft. Do not force hard enough to compress clutch release springs. (NOTE:—Record amount of end clearance so the proper size washer can be installed when transmission is reassembled). Remove indicator and special tools.

Reverse Gear Assembly and Main Shaft (Cars without Hydraulic Type Reverse): Loosen rear bearing retainer to reverse internal gear support attaching bolts. This aids in the disassembly after removal of rear bearing retainer from transmission case. Remove reverse drive flange attaching bolts and straighten reverse anchor support bolt lock. Then remove the reverse anchor support bolt and reverse anchor. Remove rear bearing attaching bolts and remove reverse assembly from transmission case. If assembly sticks, tap front end of main shaft with soft hammer.

▷*CAUTION:* The selective washer may stick to the main shaft or it may remain in the counterbore of the output shaft. Be sure to remove this washer when reverse assembly is removed.

Reverse Assembly and Main Shaft (Cars with Hydraulic Type Reverse): Remove rear bearing retainer oil seal and take out six center gear and drive flange attaching bolts. (Drive flange can be held from turning by bracing screw driver under drive flange bolt head). Install Tool J-2173 between center bearing cap and rear clutch drum to prevent drum from moving forward. Remove five bolts attaching rear bearing retainer to transmission case and carefully remove reverse assembly from transmission case. (If shaft sticks, tap on front end of drive shaft with rawhide hammer. *CAUTION*—The selective washer may stick to the main shaft or it may remain in the counter bore of the output shaft. Be sure to remove this washer when reverse assembly is removed. Remove stationary cone lock key).

Front and Rear Units. Install rear hub holding Tool J-2174 to rear unit drum, using a reverse drive flange attaching screw. Bend back edges of lock plate under two center bearing cap mounting screws, remove screws and bearing cap. Lift both front and rear planetary assemblies, with bands, from transmission case.

MECHANICAL REVERSE TYPE — HYDRAULIC REVERSE TYPE

REVERSE BLOCKER ASSEMBLY

OVERHAUL OF UNITS

OVERHAUL: Transmission Units.

Front Servo Unit, Disassembly. Separate front and rear servos from oil delivery pipes, then remove two capscrews holding front band release band to servo body, and remove front band release cylinder. Booster spring, retracting spring retainer and retracting spring can now be removed. Take front band release piston from cylinder and remove servo piston from servo body.

Remove pipe plug and lock wire holding 4 to 3 valve in place, and take valve from servo body.

Rear Servo Unit, Disassembly. Place rear servo in press and bring ram down to rest on spring retainer. Remove two retainer screws and lockwashers holding spring retainer to servo body. Release press slowly until servo springs are released, then remove servo from press. Take out servo spring retainer, accumulator spring, compensator piston and two compensator springs. Remove accumulator body and piston assembly from servo body. Rest the accumulator body on a vise with copper jaws and tap accumulator piston thru spring and accumulator body. Booster spring and booster piston can be taken from body.

▷*NOTE:* To replace a broken or leaking check valve in the accumulator, drive out the rivet holding check valve in place and remove check valve and plunger. Clean body and passages and install plunger. Install check valve, inserting the notch in the valve under the shoulder at the small end of the plunger. Insert new rivet thru valve and into body. Peen the rivet.

▷*NOTE:* Small bleed hole in valve must be over hole in body.

Oil Control Valve Body, Disassembly. (*CAUTION:*—Manual lever detent ball is under tension and may become lost unless care is taken to remove detent spring and steel ball). Move manual control lever slowly past reverse position while holding fingers around casting to catch spring and ball. Remove seal and two springs from manual control shaft. Remove the two screws holding inner and outer valve body castings together. Separate castings and remove separator plate. Remove three screws holding governor pipe end casting to valve body and take off the pipe end casting and separator. Remove cover plate from regulator plug casting. Take out the three screws holding regulator plug end casting to inner casting and remove end casting. Hold regulator casting and inner valve body together while removing screws to avoid springs jumping out of place. Remove 1st and 2nd regulator plug spring, 2nd to 3rd shifter valve spring and 3rd to 4th shifter valve spring. Remove the three shifter valves. Valves should be free to move from body by pushing on opposite ends against governor plugs with fingers. Remove three governor plugs. Take off detent ball and spring retainer and remove steel plate over compensator valve and throttle detent

CONTINUED ON NEXT PAGE

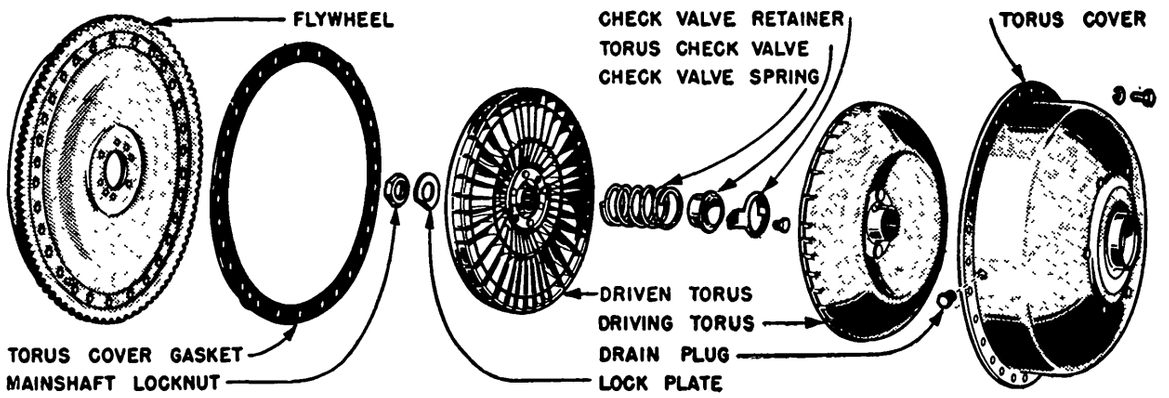
HYDRA-MATIC OVERHAUL (C nt.)

plug in outer body. Remove compensator valve, spring, and detent plug from outer valve body. Double transition valve will now slide out. Remove "T" valve, throttle valve spring and throttle valve. Remove the spring holding compensator valve auxiliary plug in place. Compensator valve can now be removed by inserting a 1/8" punch into hole in plug and using another punch to push valve from body.

Rear Oil Pump and Governor Assembly, Disassembly. Remove plug from governor oil delivery sleeve and pull sleeve off governor body. Mark edge of governor body and edge of governor drive flange so they may be reinstalled in the same position. Remove governor body from drive flange and remove oil seal rings from governor body, being very careful not to damage rings while they are being removed.

►*CAUTION:* Do not attempt to remove the governor weights.

Remove two screws retaining small governor plunger and bushing, and take out small governor plunger stop. Pull governor plunger and bushing assembly from body. Remove the four bolts holding rear pump cover to pump body and take off cover, internal tooth oil pump can then be removed.



Front Oil Pump Unit Drive Gear, Disassembly. Remove front pump from front unit drive gear; tap gear with composition hammer if necessary. Hold front pump assembly with Tool J-2184-1. (*CAUTION:*—No attempt should ever be made to hold pump body by inserting bar into the intake bore or pressure regulator piston bore.) Remove two 1" long and one 5/8" long screws and copper washers from front pump cover, using an offset screwdriver. Remove one 1 3/8" screw and copper washer from rear of pump. Take front pump cover from body. (*CAUTION:*—Tap lightly with a soft hammer at dowel area but *DO NOT PRY WITH A SCREWDRIVER AS THIS WILL DAMAGE THE LAPPED SURFACE.)* Use care not to drop gears out of gear pocket when cover is removed. Remove by-pass valve and spring from pump body and take out both internal and external pump gears. Remove oil seal from pump cover and take two oil seal rings from front cover.

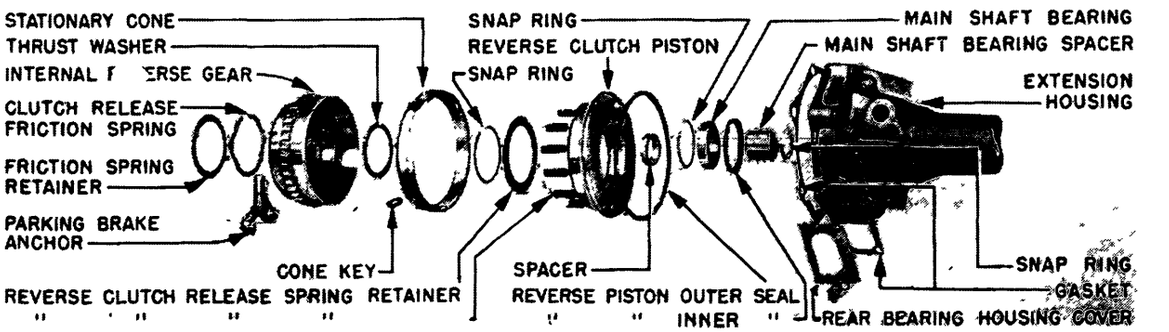
Reverse Gear and Main Shaft Disassembly (Cars without Hydraulic Type Reverse): Remove the speedometer driven gear and sleeve assembly from rear bearing retainer. Take out the five internal gear-support bolts and copper washers. Lift up rear bearing and remove by tapping end of output shaft with soft hammer. Remove open type snap ring from back of output shaft ball bearing. Lift gear, support and output shaft as an assembly and bump end of output shaft on block of wood. This will allow weight of internal gear and support to bump speedometer drive gear off end of output shaft. Remove reverse internal gear support snap ring and internal gear. With a soft hammer tap the ball bearing from internal gear support.

►*CAUTION:*—Do not disassemble the reverse center gear and drive flange assembly as this is serviced as a complete unit.

Remove steel and bronze thrustwashers from output shaft and remove bearing retainer seal.

Revers Gear and Main Shaft Disassembly (Cars with Hydraulic Reverse): Remove stationary cone lock key and speedometer driven gear and sleeve assembly from rear bearing retainer. Remove snap ring on output shaft inside of rear bearing retainer at

HYDRA-MATIC TORUS ASSEMBLY



ball bearing. (This snap ring is smaller than other snap rings used in transmission). With output shaft standing on carrier end, remove bearing retainer from output shaft (It may be necessary to tap output shaft with soft hammer while holding rear bearing retainer to separate units). Remove reverse internal gear and stationary cone from rear bearing retainer by compressing stationary cone by hand. Remove snap ring locating ball bearing in rear bearing retainer. (Install new snap ring when assembling). Remove ball bearing from retainer and with Tool J-4670, compress reverse cone clutch release coil springs and remove large snap ring. Take out spring retainer and coil springs (6). Pull reverse piston straight out (do not attempt to turn piston as it is located by four dowel pins). Remove outer oil seal from reverse piston and inner oil seal from hub of rear bearing retainer and take large thrust washer from reverse intenal gear. By using large snap ring pliers, expand stationary cone and remove from internal gear, then remove clutch release flat spring and retainer. Remove snap ring holding planet carrier to output shaft and remove carrier, now remove the remaining snap ring and remove sun gear and drive flange assembly from output shaft.

Rear Unit and Front Unit from Intermediate Shaft. Remove both bands and place intermediate shaft with front and rear planet assemblies into holding fixture J-2190. Remove rear clutch hub snap ring lift rear unit and rear clutch hub as an assembly from intermediate shaft. Remove rear clutch hub front snap ring from intermediate shaft and take off oil delivery sleeve. Remove snap ring back of front unit center gear. (*CAUTION:*—Hold snap ring open to avoid damaging bearing surface on shaft.) Front unit can now be taken from shaft. Remove steel and bronze thrustwashers from drum back of front unit center gear. (NOTE: These washers are similar to those used ahead of the front unit and should not become mixed.)

Front Unit, Disassembly. Place front unit in press and apply enough pressure to allow the snap ring to be removed. Take assembly from press and separate the drums by tapping front face of center gear with soft hammer. (*CAUTION:* Use care not to lose springs.) Remove annular piston from clutch drum by bumping front face of center gear on soft wood block. Take out the inner and outer clutch release springs and remove composition and steel clutch plates. (NOTE—The number of clutch plates vary with transmission models). With a blunt edge screw driver, remove rubber seal and brass liner from annular piston and clutch drum piston.

Rear Unit, Disassembly. Remove rear clutch hub Tool J-2174, and take clutch hub and front thrustwasher from drum. Place rear unit in press and remove drum retainer snap ring. Remove the assembly from press and separate the drums by tapping lightly on rear thrust face of drum with block of wood and light hammer. Tap clutch drum on block of wood and remove annular piston. Remove inner and outer clutch release spring and guide pins. (NOTE—Front

CONTINUED ON NEXT PAGE

HYDRAULIC TYPE REVERSE ASSEMBLY

HYDRA-MATIC OVERHAUL (Cont.)

and rear clutch release springs are interchangeable but guide pins are used only in rear unit). Remove composition and steel clutch plates. (NOTE—The number of clutch plates vary with transmission models). Remove two filister head cap screws that retain rear unit internal gear to drum and remove internal gear by tapping lightly with a soft hammer. Remove seals and brass liner from piston.

ASSEMBLY OF UNITS

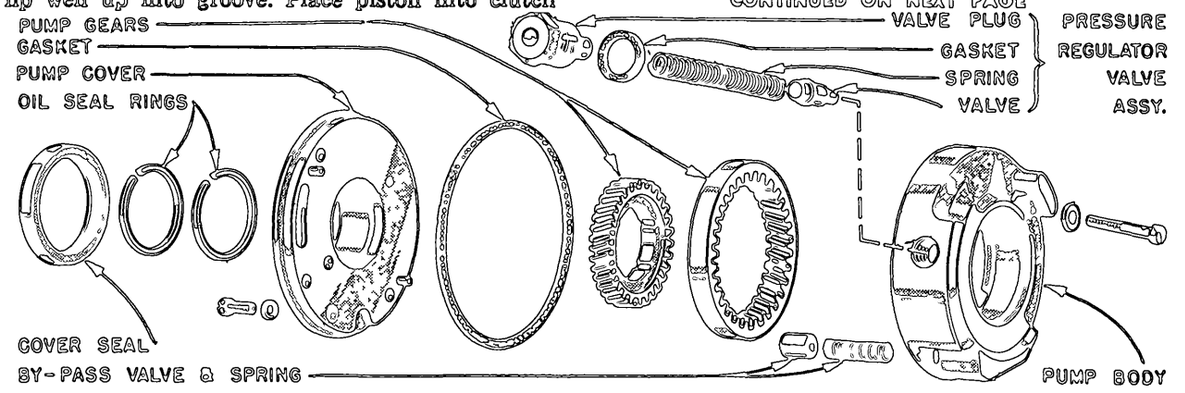
ASSEMBLY: Before assembly of transmission and the component units is attempted, a thorough inspection should be made of each part. It is very important to distinguish between parts that are simply "worn in" and those worn to the extent they effect the operation of the unit. Only worn, broken or damaged parts should be replaced.

Pressure Regulator Valve. Inspect pressure regulator valve, spring and gasket for damage. Valve must have free fit in front pump body and end coils of spring must fit freely over valve.

▷Modulated Pressure Regulator Assembly. Overhaul of this unit is the same as for previous models. A modulated oil line valve has been added to this assembly, fitting into the plug, which is now sealed with a neoprene gasket. Do not use this type regulator valve on earlier models.

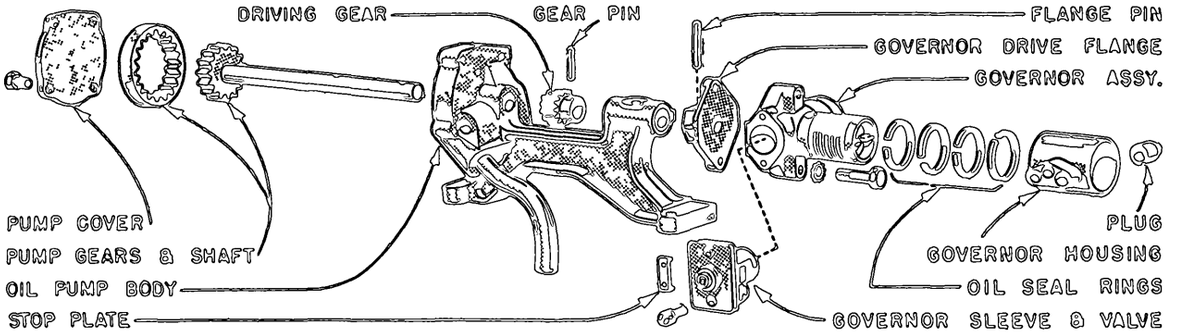
Front Unit Assembly: Inspect both bands for burned or worn lining and check steel bands for distortion or cracks, inspect strut on rear band for alignment and free pivoting. The rear band is furnished with strut attached. Inspect anchor ends of front band for broken welds or worn sockets.

CAUTION: Do not pry either band open or distort band in any manner as they are surface ground at the factory for drum fit.



Place intermediate shaft assembly in holding fixture J-2187 with clutch hub up. Place front unit drum over hub to rest on pinion gears with drive pin up. Install clutch into front drum, alternating plates, beginning with a composition (drive) plate and finish with a steel (driven) plate. Assemble the driven plates with square notches over the drive pins. (*NOTE:* Apply Hydra-Matic oil to face of each plate surface as assembled.) Install inner and outer clutch release springs thru plates into holes in drum unit. Now take the clutch drum and install new inner brass expander into ring groove in clutch drum, with expanding ring down. While holding brass expander in position, work new inner piston rubber seal into ring groove with lip down, over brass expander. (*CAUTION:* Work expander well back into position under seal so brass edges are not exposed.) Place new large rubber seal over front piston beyond seal groove. Install new large brass expander in piston, work seal well into groove. Install piston into clutch drum resting on large outer seal. Align square notches in piston with holes in drum. While applying pressure slightly to piston, guide seal into bore with flat side of blunt screwdriver. Install front clutch drum and piston assembly over intermediate shaft into front drum assembly. (*CAUTION:* Be sure clutch release springs enter into recesses of clutch piston.) Lift front unit assembly off intermediate shaft, place in press and press clutch drum below snap ring groove. Install clutch drum snap ring, positioning gap of snap ring between two snap ring holes. (*CAUTION:* Snap ring must be well seated into groove to prevent interferance with ledge on drum.) Release assembly from press and tap face of sun gear with a soft hammer so the clutch drum will seat against the snap ring. Remove intermediate shaft from holding fixture and insert hub into drive plates and drum by rolling drum on bench while pressing firmly into position. Place assembly into holding fixture and install bronze, then steel thrustwasher over intermediate shaft. NOTE: Locating lug on steel washer must fit over flat portion of shaft. Install snap ring.

▷*CAUTION:* If flakes of facing material can be removed by scratching the surface with thumbnail, the plate should be replaced. Discoloration is not an indication of failure.

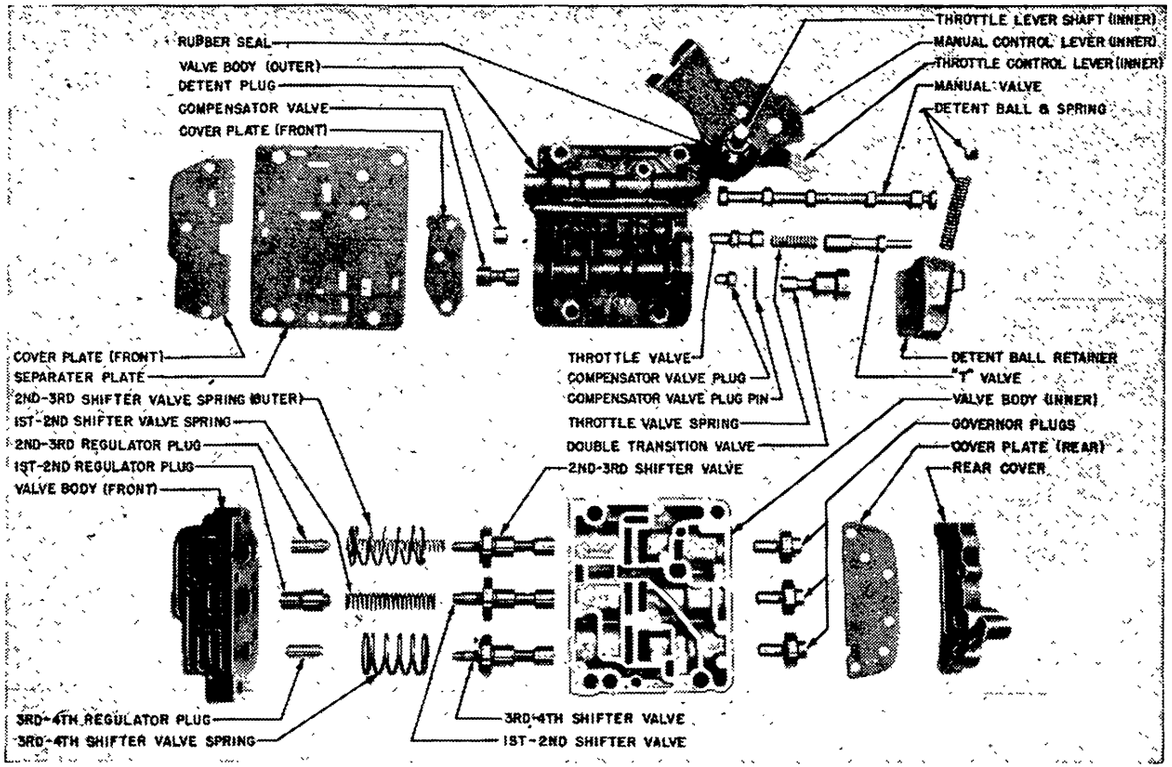


Rear Unit, Assembly. Place rear unit drum, less internal gear, on the bench with drive pin up and install the drive and driven plates into drum beginning with a composition (drive) and finish with a steel (driven) plate. Assemble driven plate with square notches over drive pins. (NOTE: Apply Hydra-Matic oil to face of each plate as assembled.) Position new inner rubber seal on clutch drum above groove. Install new small brass expander into ring groove of clutch drum with expander ring down. While holding the brass expander in position, work the rubber seal into ring groove with lip down over brass expander. (*CAUTION:*—Work brass expander well back into position under seal so brass edges are not exposed.) Place new large rubber seal over rear piston beyond ring groove and install new large brass expander in piston with lips up. While holding expander in position, work rubber seal with lip well up into groove. Place piston into clutch drum resting on outer rubber seal. Align square notches in piston with holes in drum. While applying alight hand pressure to piston, guide seal into bore with a blunt screwdriver. Install rear clutch drum and piston assembly over drive pins into drum unit. Install clutch drum snap ring, positioning gap of ring between two drive pin holes. (NOTE: With a wooden block and hammer, tap clutch drum until clutch seats against snap ring.) Install inner and outer clutch release springs and guide pins. Assemble rear unit inernal gear to rear drum, locating on dowel, and install and tighten two filister head screws. Install front bronze thrustwasher into deep counterbore in rear clutch hub and retain with grease. Install rear hub and thrustwasher into clutch drive plates. Rotate hub and drum on bench to mesh splines with teeth of plates. Install rear clutch hub holding Tool J-2174 on rear drum to hold hub in place. Install oil delivery sleeve over intermediate shaft with long bearing up. Compress exposed oil delivery sleeve rings with ring compressor J-1537 and tap oil delivery sleeve into bore of front clutch drum with soft hammer. Install rear clutch hub front snap ring into second groove on intermediate shaft, and install snap ring.

Reverse Unit Reassembly (Cars without Hydraulic Reverse): Install the steel then the bronze thrust washer into thrust washer retainer on reverse sun gear and flange assembly. Retain in place with grease. Install output shaft into reverse sun gear and drive flange assembly, seating shaft firmly against washers, then holding shaft firmly against washers, stand

CONTINUED ON NEXT PAGE

HYDRA-MATIC FRONT OIL PUMP & PRESSURE REGULATOR VALVE



HYDRA-MATIC REAR OIL PUMP & GOVERNOR

HYDRA-MATIC OVERHAUL (C nt.)

shaft on pinion end. Install sun gear snap ring. Place reverse planet carrier over output shaft with bronze oil pump gear down, meshing pinion with sun gear. Assemble reverse internal gear on gear support and install large snap ring. Place internal gear and support over output shaft meshing internal teeth with pinions. Place ball bearing over output shaft and tap into counterbore of internal gear support. Install open type snap ring in groove of output shaft behind inner race of ball bearing. Install a new bearing retainer seal. Slide rear bearing over output shaft and line up attaching bolt holes in retainer with bolt holes in internal gear support. Tap housing in place with a soft hammer. Dip threads of five attaching bolts, and copper washers in Permatex No. 3. Install bolts and tighten finger tight. Final tightening is done with retainer in case.

Reverse Unit Reassembly (Cars with Hydraulic Type Reverse): Hold reverse center gear in left hand with drive flange up; install the steel thrust washer, and then the bronze thrust washer in drive flange recess. Still holding reverse center gear in left hand, insert output shaft end through drive flange and center gear until carrier bottoms on the two thrust washers. Hold drive flange and center gear tightly against the carrier to keep thrust washers from moving and set assembly on the bench with carrier end down. (*CAUTION*—Do not pick up this assembly until completely assembled to prevent washers from slipping out of place). Install reverse planet carrier over output shaft with bronze drive gear down, meshing pinions with the sun gear. (Be certain unit is bottomed against reverse planet carrier snap ring). Install snap ring on output shaft to position planet carrier. Install reverse clutch release flat spring and spring retainer on internal gear side of reverse internal gear. Make certain spring is in recess. If retainer tips are misaligned, preventing centering, use new retainer. Install reverse stationary cone on reverse internal gear cone, using large snap ring pliers to spread stationary cone. (*CAUTION*—Do not spread cone more than necessary.) Install large bronze thrust washer over collar of internal gear. Install outer seal on cone piston with seal lip toward flat side of piston, and work well into groove. Install inner seal with lip down and work well into groove. Install reverse cone piston in rear bearing retainer (using Tool J-4752) so it rests on the four dowel pins. Turn the reverse cone piston until the four dowel pins are aligned with holes in piston and carefully push piston into retainer. (*CAUTION*—Use extreme care when installing, to prevent damage to seal). To make certain piston is fully seated, lay a straight edge across face of piston and measure from straight edge to face of rear bearing retainer. The measurement should be 3/8" to 13/32". Install the six clutch coil springs and spring retainer. Compress springs with Tool J-4670 and install large snap ring, holding retainer in place, and remove tool. Install ball type bearing in rear bearing retainer, making sure bearing is fully and squarely seated. Install new large special type snap ring in rear bearing retainer, locating ball bearing. Install internal gear and stationary cone into rear bearing retainer, compressing cone by hand (Position keyway of stationary cone so it will line up with keyway in case when installed.) With output shaft standing on carrier end, place rear bearing retainer over ouptput shaft and mesh carrier gears with internal gear. (*CAUTION*—Use care to prevent damage to bushing and ball bearing in rear bearing retainer. Install snap ring on output shaft, locking rear bearing retainer to output shaft (This snap ring is smaller than other snap rings used in transmission). Install speedometer gear in rear bearing retainer and install retainer gasket. Install stationary cone to case lock key, holding in place with petrolatum until installing in case.

HYDRA-MATIC DRIVE CONTROL VALVE ASSY. (FIRST TYPE)

Front Pump Assembly. Inspect pump drive and driven gears for damaged teeth or scored end surfaces. Inspect pump body for scored gear pockets and check all passages for obstruction. Be sure small drilled hole at end of pressure regulator valve bore is open. Inspect bushing in body for wear or scores. Slight wear of the bushing in the front pump body is permissable as long as the wear is not sufficient to effect the operation of the transmission. If excessive wear is present on one side of the pump bushing, a careful check should be made of the torus cover runout at the hub which must not exceed .005" total dial indicator reading. Inspect pump cover for scored surfaces, loose dowels, or obstructed passages. Check oil seals for damage and freedom in grooves, and inspect front drive gear for scored surfaces, worn bushings, or damaged teeth. Relief valve must be free in bore and free length of spring must be 1-25/64".

If necessary, install new oil seal rings in pump cover. *CAUTION:* Check new ring gap in torus cover before installing rings in pump cover. (Gap .001" to .007".) New seal in pump cover must be installed with step side up. Drive seal into place with Tool J-2170. Apply sealing compound around edge of cover and seal. Using Permatex No. 3. Lubricate both pump gears with Hydra-Matic fluid and install both gears in gear pockets of body. (Be sure Prussian Blue side of driven gear is up.) Install the relief valve spring, and relief valve into pump body. Press down on valve and insert feeler stock in slot to hold valve down. Install pump body, locating over dowels. Apply sealing compound under heads of screws. Install screws and new copper washers. Hold pump with Tool J-2184-1 and tighten screws to 12-15 lbs. ft. torque. Remove feeler stock from relief valve. Turn pump assembly over and install screw using a new copper washer. Torque to 12-15 lbs. ft. Assemble the front pump over front drive gear, aligning keys to keyway.

Governor and Rear Pump, Assembly. Inspect pump gears for damaged teeth and check cover and gear pockets in body for scores. Inspect ring lands and rings for freedom in grooves. If lands are damaged or worn thin replace the complete governor assembly. Inspect both G-1 (round shaped) and G-2 (square shaped) governor valves for free movement. Both plungers should have a free movement of from .118" to .148". Inspect oil delivery sleeve for ring scores and governor plug for freedom in its bore. In-

CONTINUED N NEXT PAGE

HYDRA-MATIC OVERHAUL (C nt.)

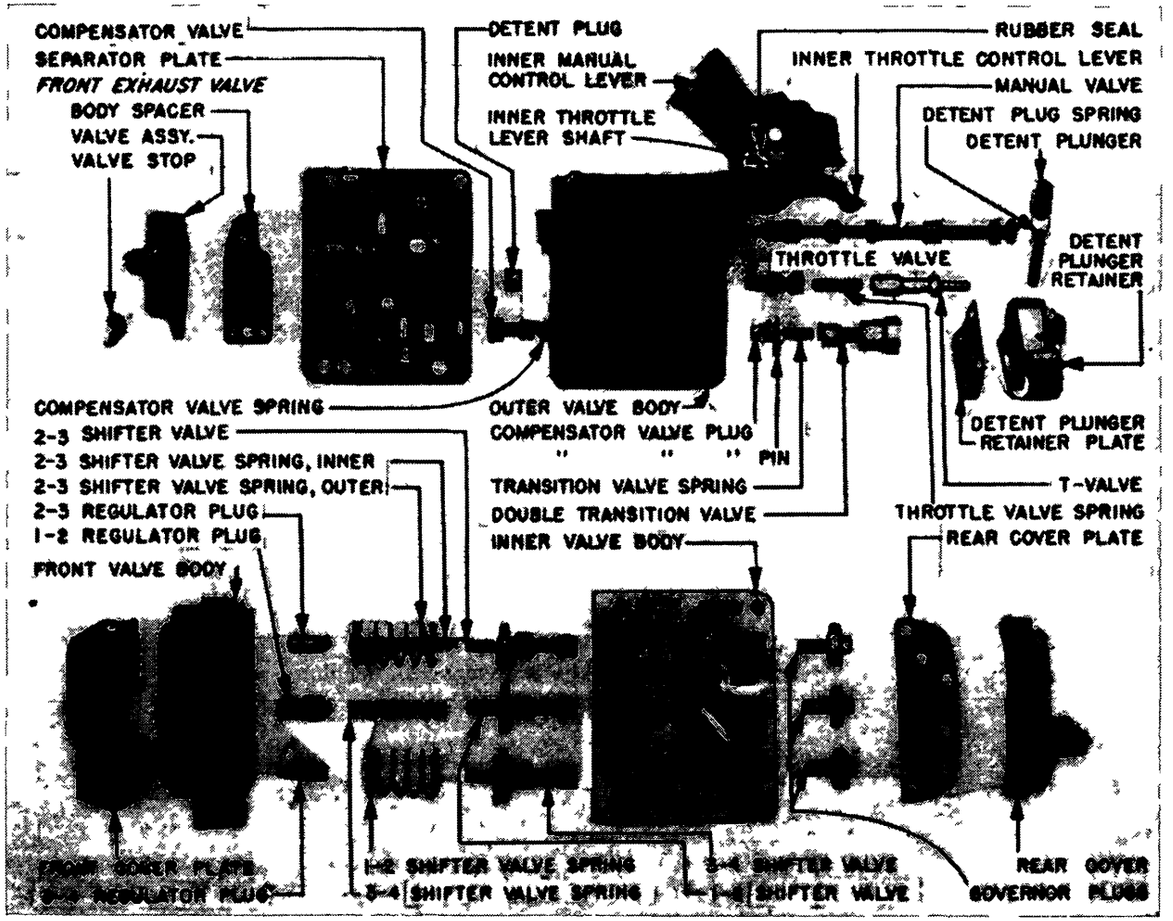
stall pump driven gear (inner) and shaft with (inner) drive gear in pump body, sliding (outer) driven gear on shaft. Install pump cover. Install governor drive flange on pump shaft. Line up holes in gear and drive flange within pump shaft and install new pins. Peen ends of pins using Tool J-2183-1 and S-2183-2. (*CAUTION:* Height of peened end of pins must not exceed .070".) Install G-2 governor plunger and bushing assembly in governor body, with slot in bushing for governor plunger stop, up. Install and tighten G-2 governor plunger and bushing assembly attaching screws and lock washers. While holding G-2 plunger in, install the plunger stop with the two small holes up. (*CAUTION:* Be sure stop does not extend above surface of governor body.) If needed, install governor oil seal rings on governor body. Check ring gap in oil delivery sleeve (Gap .001" to .007"). Install oil delivery sleeve with chamfer next to governor body; use care not to damage rings while compressing them into oil delivery sleeve. Position governor assembly on drive flange, lining up locating marks. Install governor body to flange bolts and lockwashers. Tighten to 6 to 8 lbs. ft. torque. Install governor sleeve plug.

Front Servo, Assembly. Inspect all parts for scores, broken rings, freedom of ring in grooves and dirt in passages. Inspect servo springs for distortion of collapsed coils Booster Spring length 61/64", Retracting Spring length 1 33/64", Release Spring length 1 29/32" Install and tighten brass fitting into servo body Install 4 to 3 valve into bore of body and align slot with hole for valve retainer and install retainer Install screw plug over 4 to 3 valve and install dowel pin if removed from servo body Install servo piston into body and align slot in sleeve over dowel pin Install front band release piston into cylinder, using care when compressing spring Place booster spring over front band release piston and place retracting spring retainer over piston stem on booster spring Place retracting spring over piston stem Place band release cylinder assembly on servo body Cylinder should seat squarely on body before bolts are installed Insert and tighten attaching bolts and lockwashers

►**Modulated Front Servo Assembly.** Apply piston increased in size, and ball check replaced with a flat valve. **Do not use on earlier models.**

Rear Servo, Assembly. Inspect actuating lever for free operation and worn socket. Check servo body, pistons, and accumulator body for scores. Clean all passages. Be sure check valve is not broken and the check valve plunger is free. Inspect all servo springs for damage or collapsed coils. Free length of springs in the rear servo are Rear Servo Main Spring 4 11/32", Accumulator Apply Spring 1 15/64", Booster Spring 1 17/32", Compensator Outer Spring (To Early 1951) 3 15/32", (Late 1951) 3 59/64", Compensator Inner Spring (To Early 1951) 3 25/32', (Late 1951) 3 15/32" Install accumulator piston in accumulator body, using care not to damage piston ring Install accumulator apply spring over stem with small tapered end seated against shoulder Install boooster spring in booster piston Make sure spring fits snugly in recess in bottom of booster piston Install booster piston in accumulator body Install accumulator assembly in servo body, using care not to break the booster piston ring Place two compensator springs in bore of accumulator piston and install compensator piston over springs Place servo spring and retainer with attaching bolts and lockwashers in position and place complete assembly into press Slowly compress springs while tightening mounting screws (CAUTION—Use extreme care to avoid breaking oil seal rings on compensator piston) Test operation by applying air to rear band release passage

►**Modulated Rear Servo Assembly.** New "Quick Dump" feature eliminates long pause shifting to reverse **Do not use on earlier models.**



Driven Torus Check Valve, Assembly. Position torus check valve spring over hub of driven torus member and place check valve over hub. Place check valve retainer over valve and press assembly against torus hub and tighten in place with attaching bolts. Bend ends of retainer against flats of bolts. Press down on valve to check for free movement.

Oil Control Valve: ***CAUTION—See Oldsmobile Whirlaway Transmission Note (at end) for modtifications which may have been made in control valve to permit the transmission to start in first gear with selector lever in "Dr".***

Assembly—Clean valves and bodies thoroughly with gasoline and inspect carefully to see they are not damaged and are free from burrs. Burrs can be removed by using fine crocus cloth. (*CAUTION:*—This type of valve has sharp edges to prevent dirt from wedging between valve and body. Therefore, when removing burrs, do not round off corners and edges.) Check all moving parts of valve for free movement in their bores and operating positions.

►*NOTE:*—The manual control valve is the only valve furnished separately. If it becomes necessary to replace one of the other valves or one of the bodys, a complete front or rear valve body assembly may be replaced. The spacer plate between the inner and outer body assemblies is also furnished separately. Check the fit of the throttle valve inside lever and shaft in hub of the inside manual control lever on the outer valve body. If the shaft binds in the hub or is excessively worn, or if the oil seal is missing or damaged, repairs are necessary. Proceed as follows: Drive out throttle valve shaft pin. Replace the throttle valve inside lever and shaft and oil seal. To assemble control valve, carefully assemble compensator auxiliary plug into the outer valve body, using a punch to hold plug. Install plug pin. Install throt-

CONTINUED ON NEXT PAGE

HYDRA-MATIC DRIVE C NTR L VALVE ASSY. (LATER TYPE)

HYDRA-MATIC OVERHAUL (C nt.)

tle valve, throttle valve spring, "T" valve and detent plug. Install compensator valve and spring and double transition valve. Check for freeness. Install outer valve body front plate on outer valve body being sure the inner throttle lever is inside of stop, and install screws holding retainer to valve body. Install the manual control lever. To do this: Rotate inside manual control lever counterclockwise past the reverse position. Insert manual valve detent spring in bore of detent ball retainer. Insert detent ball over spring. Push ball and spring into bore with fingers while rotating manual control lever clockwise into "LO" position. Install manual shaft seal inner washer with small inside diameter over manual control shaft, dish up. Install manual shaft seal outer washer with large inside diameter over manual control shaft, dish down. Install the rubber manual shaft seal over the shaft with lip extending into the inside diameter of outer washer. *(See Control Valve Assembly Illustration.)* Install regulator plugs 1-2, 2-3, and 3-4 in front valve body and check for freeness. Install the three governor plugs in inner valve body. Install shifter valves 1-2, 2-3 and 3-4 in inner valve body and check for freeness. Install inner valve body plate and valve body rear cover on body. Install 1-2 regulator plug spring in valve body. 2-3 valve spring, 2-3 regulator plug spring and 3-4 valve spring can be installed. Lay front valve body and inner valve body on clean surface, line up regulator springs in inner body with regulator plugs in front body. Compress springs with front body and install attaching screws. Position front body plate on front body and install screws. Be sure plate does not extend over face of inner body. Position the valve body spacer plate on the inner body, position outer body on spacer plate and insert the four valve body to transmission case attaching bolts through valve bodies and spacer plate to hold spacer plate in position while tightening the inner and outer valve body attaching screws.

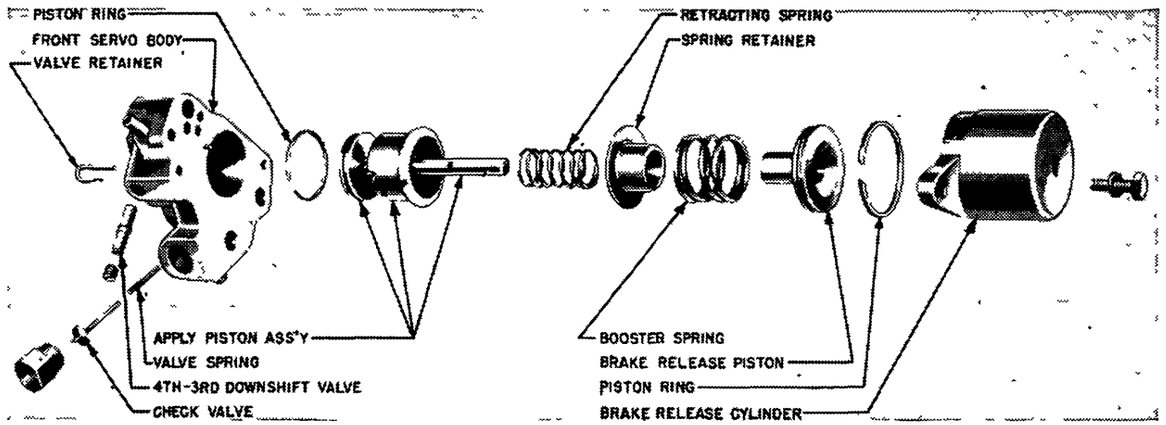
►**Modulated Oil Control Valve Assembly.** Identified by three attaching bolts instead of two.

CAUTION—Previous type oil control valve assemblies must not be used on modulated pressure transmissions.

►*OLDSMOBILE WHIRLAWAY TRANSMISSION NOTE*—Some transmissions have been modified to permit car starting in first gear with selector lever in "Dr" position: (1) 1-2 Governor Plug Spring removed and discarded (accessible by removing governor plug end casting from valve body). (2) Special Bushing No. 562189 inserted in oil orifice behind 1-2 shifter valve to reduce diameter of orifice to .078" (bushing should be driven into hole with punch and light hammer so that top is flush with casting). See Linkage Adjustment and Band Adjustment for special settings used when these modifications made.

REASSEMBLY OF TRANSMISSION (INSTALLATION OF UNITS)

INSTALLATION OF UNITS IN TRANSMISSION CASE.



Front and Rear Units. Remove front and rear units from holding stand and position front band over front unit drum so short anchor end will be positioned to fit over adjusting screw when units are placed in case. Install suitable spring or wire to hold front band on front drum. Install front and rear units in case by lowering front end of intermediate shaft into case first. Remove spring and position anchor end of band over adjusting screw. Position center bearing cap over oil delivery sleeve. Lightly tap bearing cap in place. Install a new center bearing cap lock plate under attaching bolts and tighten to 40-50 lbs. ft. torque. Bend lock plate up around bolts, using large pliers. (*CAUTION:* Do not use screwdriver to pry corners of lockplate up, as this may damage lapped edge of transmission case.) Install screwdriver between center bearing cap and rear clutch drum to keep drum from moving forward. Remove rear clutch hub holding tool from drum. Position rear clutch hub rear thrustwasher in the counterbore of rear hub and retain with grease. Install correct size washer in counterbore of output shaft and retain in place with grease. (NOTE: If main shaft did not have correct end clearance prior to disassembly, select proper washer to bring end clearance within limits of .004-.015".) Selective washers are furnished in the following six sizes:

Mark	Size	Mark	Size
1	.055-.059	4	.079-.083
2	.063-.067	5	.087-.091
3	.071-.075	6	.095-.099

Install a new rear bearing retainer to transmission case gasket on retainer, align holes and retain in place with grease. Install main shaft in output shaft and position reverse assembly into rear end of transmission case so mounting bolt holes aligned.

►*NOTE:* Revolve output shaft to facilitate meshing planet gears with rear unit internal gears.

Position reverse anchor in transmission case and install reverse anchor support bolt and lock. Do not tighten bolt. Start rear bearing retainer to case attaching bolts and lockwashers. Align holes in reverse flange and rear durm and install reverse drive flange bolts and lockwashers. After two bolts are entered finger tight, remove screwdriver. Tighten bolts to 10-13 lbs. ft. torque. (*CAUTION:* Tighten the six bolts evenly without distorting flange.) Push rear bearing retainer against case, then tighten mounting bolts and rear anchor support bolts evenly to 28-33 lbs. ft. torque. Turn up anchor support bolt locks. Tighten rear bearing retainer to reverse internal gear support bolts to 28-33 lbs. ft. torque. Test for freeness by turning mainshaft, output shaft and front and rear drum units.

HYDRA-MATIC DRIVE FRONT SERVO

Front Pump and Front Drive Gear. Position bronze thrustwasher over intermediate shaft and place pump cover gasket over front pump cover. Install front pump and front drive gear assembly over intermediate shaft. Align locating counterbore in pump cover with counterbore in case. Install pump locating washer in counterbore and install pump attaching bolts (with flat copper washer) finger tight. (NOTE: These bolts will be tightened after front servo is installed.) Install the bronze, then the steel thrustwasher over intermediate shaft against front end of front drive gear. Install snap ring holding thrustwashers in place. Install open type snap ring in groove on main shaft.

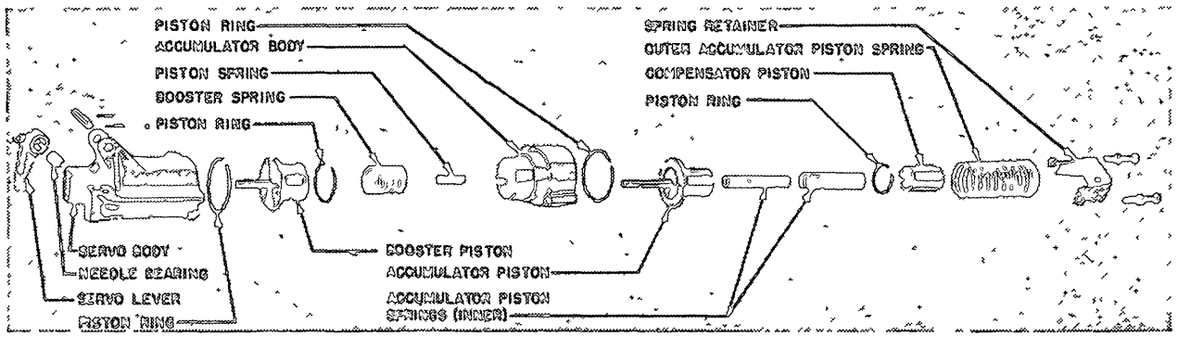
Governor and Rear Pump Assembly (Cars with Hydraulic Type Reverse): Before installing the rear pump, make certain the pump to case mating surface is free of nicks and burrs, and that attaching bolt holes in the case have a good chamfer. Position large round governor weight to front of transmission and locate one reverse drive flange attaching bolt up, to provide clearance for pump and governor assembly to slide into case.

Governor and Rear Pump. Position the large round governor weight to the front of transmission and locate one reverse flange attaching bolt up, to provide clearance for pump and governor assembly to slide into transmission case. Slide the pump and governor assembly into position in case and install and tighten attaching bolts and lockwashers to 15-18 lbs. ft. torque.

Oil Control Valve. Install three oil delivery pipes into holes in governor oil delivery sleeve and pull oil delivery sleeve out ⅛". With inside manual lever in "LO" position, push control valve assembly onto oil delivery pipes. Lower control valve assembly into position and push delivery sleeve in to bring control valve assembly against case. Install attaching bolts and lockwashers and tighten to 6-8 lbs. ft. torque. (NOTE:—Be sure governor oil delivery sleeve plug is in place.)

Check Governor Runout. Mount dial indicator on side of transmission case so that point of indicator rests against governor oil delivery sleeve. Rotate main shaft several revolutions and note runout of sleeve as measured on indicator. Total runout should not exceed .005". If within this limit, check no further.

CONTINUED ON NEXT PAGE



HYDRA-MATIC OVERHAUL (Cont.)

If runout exceeds .005", mark position of governor body on drive flange. Remove control valve assembly and remove bolts holding governor body to drive flange. Rotate main shaft and note runout of drive flange as measured on dial indicator. This should not exceed .002". If runout exceeds this limit, replace governor drive flange, gear set, or complete rear pump assembly. If runout of flange is less than .002", rotate governor body 180° from original position and reinstall governor body on flange. Recheck for runout, and if limit is still exceeded, replace governor and sleeve.

Reverse Shifter Bracket Installation (Cars without Hydraulic Reverse): Position retracting spring & roller on bracket assembly and assemble bracket and shims to transmission case. Tighten bolts to 15-18 lbs. ft. torque. Check backlash between reverse internal gear and anchor as follows: Install reverse gear backlash gauge J-2650 and dial indicator. Place inside manual lever in reverse position and hold reverse anchor against bolt with screwdriver to remove float. Rock reverse gear with Gauge and take reading on dial indicator. Remove or install shims between reverse bracket and transmission case to obtain correct backlash of .016" to .049". To increase backlash add shims.

Front & Rear Servo Installation (Cars without Hydraulic Reverse): Install front pump discharge pipe in front pump body and insert plain end of rear pump discharge pipe into hole in rear pump. Position front servo with piston stem in socket on end of front band, place servo on front pump discharge pipe, enter rear pump discharge pipe into brass fitting in servo. Lower servo on case. Enter front servo attaching bolts and lockwashers. Do not enter more than 2 or 3 turns. Place rear servo in position engaging rear band strut with actuating lever while entering oil transfer pipe from front servo. Enter rear servo attaching bolts, then tighten all four servo bolts to 23-28 lbs. ft. torque. Tighten coupling end of rear pump discharge pipe in front servo. Install front pump intake pipe to front pump, using a new gasket and attaching bolt locks. Tighten bolts to 10-12 lbs. ft. torque and bend locks up against flat of bolts. Tighten front pump attaching bolts, with copper washers to 10-13 lbs. ft. torque. (NOTE:—Cover should protrude .003" to .015" out of case. If cover protrudes less than .003" add a pump cover gasket to allow cover to protrude within limits.

Front and Rear Servos (Cars with Hydraulic Reverse): Install front pump delivery pipe in front pump body and position front servo with piston stem in slot on end of front band; place serve on front pump delivery pipe and push servo into position against case. Enter front servo attaching bolts and lock washers about three threads. Enter rear pump discharge pipe into passage in front servo and rear pump. Place rear servo in position, engaging rear band strut with actuating lever while entering oil transfer pipe from front servo. Enter rear servo attaching bolts and tighten. Install rear pump bolts and tighten. Check governor runout (see below). Install front pump intake pipe to front pump, using a new gasket and attaching bolt locks. Tighten attaching front pump intake pipe bolts and secure [illegible] by bending against bolt heads. Tighten the front pump attaching bolts. NOTE—Cover should protrude .003" to .015" out of case. If less than .003", add a pump cover gasket.

HYDRA-MATIC DRIVE REAR SERVO

Parking Brake Bracket and Control Valve (Cars with Hydraulic Type Reverse): Remove parking brake pawl support bolt from case (this bolt was previously installed to insure alignment of threads). Install pawl into position in case, but let pawl slide down as far as possible. DO NOT INSTALL PARKING BRAKE PAWL SUPPORT BOLT. Install three oil delivery pipes into parking brake bracket assembly, then place chamfered side of oil delivery sleeve over end of the governor and press gently on, guiding rings into the oil delivery sleeve. Install blocker piston spring, piston release spring stop and start bracket to case bolts into case. Install roller on pawl crank, raise pawl to position and install support bolt and lock plate. Tighten bolt and bend lock plate over flat of bolt. Install pawl return spring over inside oil delivery pipe and hook other end over parking brake lever pin. Install reverse clutch pipe with "L" end in rear of transmission case, then install control valve assembly over three oil delivery pipes and reverse clutch pipe and start bolts. Press valve body and bracket assembly against case and tighten the bolts evenly. Torque to 6-8 ft.lbs. With the rear pump bolts and parking bracket bolts loose, install governor to sleeve aligning tool J-4731 over governor. Turn rear pump to several positions and rotate the tool in each position to be certain no bind exists. Shift the rear pump or parking bracket slightly if necessary to relieve bind. Tighten the rear pump and parking bracket bolts to 15-18 ft. lbs. Install pressure regulator reverse oil pipe.

Adjust Front Band. Remove the pipe plug from front servo. Loosen adjusting screw of Gauge J-1693, until ⅛" of threads are exposed above gauge body. Install gauge, tightening by hand only. Tighten the gauge adjusting screw with fingers until the stem of the gauge is felt to just touch piston in front servo. (NOTE:—While tightening screw, be sure band is lined up over drum.) Tighten adjusting screw on gauge, six complete turns from the point where it was felt by hand that stem just touched piston. Tighten front band adjusting screw until knurled washer on top of adjusting gauge is just free to turn. Hold band adjusting screw and tighten band adjusting screw lock nut securely to 40-50 lbs. ft. torque. Loosen gauge adjusting screw at least six full turns, remove gauge, install pipe plug.

Adjust Rear Band. With rear band centered on drum, tighten band adjusting screw until actuating lever contacts face of Gauge J-5071. (*CAUTION:* Do not go beyond adjustment. If adjusting screw is accidentally turned beyond adjustment, loosen two or three turns and repeat adjustment.) Hold band adjusting screw and tighten lock nut to 40-50 lbs. ft. torque.

Pressure Regulator and Pressure Line Plug. Place a new gasket over pressure regulator plug. With regulator valve and guide assembled into spring, locate valve on seat in front pump. Apply pressure on regulator plug and tighten in transmission case to 40-50 lbs. ft. torque. Apply sealing compound (Permatex No. 3) to threads of oil pressure line pipe plug and install plug between band adjusting screws.

Transmission Oil Screen and Pan. Slide oil screen over front pump intake pipe and position over rear pump intake pipe. Install oil pan on transmission case, using a new gasket, and tighten attaching bolts to 10-13 lbs. ft. torque. Install new drain plug screw gasket and tighten plug to 35-45 lbs. ft. torque.

Flywheel housing, Torus Cover and Members. Position housing on front of transmission and install attaching bolts and lockwashers. Tighten to 80-90 lbs. ft. torque. Apply light film of Lubriplate to seal surface on torus cover and install torus on splines of front drive gear. Push on cover evenly, without rocking, to prevent damage to oil seal rings. Install drive torus on intermediate shaft and install snap ring. Install driven torus on main shaft against open snap ring. Move manual lever into reverse position and install new main shaft lockplate with ear over flat on torus hub. Install main shaft nut and tighten to 15-20 lbs. ft. torque. Bend lockplate up against nut. Install oil level indicator.

INSTALLATION IN CAR

See REMOVAL & INSTALLATION data

DUAL-RANGE HYDRA-MATIC DRAINING & REFILLING

Lubrication Intervals: Check fluid level every 1000 miles (Hudson, Lincoln, Nash, Oldsmobile); 2000 miles (Cadillac, Kaiser, Pontiac); every day (Chev. Truck). Drain and Refill every 25,000 miles.

►**Oil Level Indicator or Vent Air Cleaner**—Clean the mesh type air cleaner (in cap on right top side of transmission case) every 10000 miles or twice each year.

Checking Fluid Level: Check only with engine warm and idling at hot or slow idle speed (choke valve open, fast idle inoperative).

1) With transmission oil hot, run engine for at least 2 minutes with selector lever in "N" (to insure fluid coupling being filled so that true oil level reading will be secured).

2A) On cars with dipstick in filler cap on transmission case (see Note below), turn back floor mat and remove cover over dipstick location (right front of transmission case). Clean all dirt and lint from around opening and filler cap to prevent dirt entering transmission when cap and dipstick removed.

2B) On cars with dipstick in filler tube in engine compartment (at right rear corner of engine), raise hood for access to filler cap and dipstick.

►*OIL FILLER & DIPSTICK LOCATION:* Located in transmission case on 1954-55 Chev. Truck; 1952-54 Hudson, Nash, & Pontiac; 1952-55 Kaiser & Willys. Located in engine compartment on right side 1952-55 Cadillac,. Lincoln & Oldsmobile. 1955 Hudson, Nash, & Pontiac.

3) With engine idling and selector lever in "N" (Neutral) 1952-55 Cadillac, Hudson, Kaiser, Nash, Pontiac, & Willys; 1953-55 Oldsmobile; 1954-55 Chev. Truck. "LO" (Low) 1952 Oldsmobile; "DR" (Drive) 1952-54 Lincoln, check fluid level as indicated on dipstick.

4) Add fluid as required to bring level up to full "F" mark on dipstick. *NOTE*—Approximately 1½-2 pints required to raise level from "L" to "F".

►***CAUTION—Do not fill above "F" mark on dipstick (may cause foaming when oil is hot.)***

Draining & Refilling: Drain oil only when transmission warm (immediately after operation).

►***OLDSMOBILE DRAINING NOTE: Oil drain hole in Hydra-Matic oil pan discontinued during 1953 and is not used on later models. Drain the oil by placing a pan as close under the point where filler tube enters oil pan. Loosen and remove retaining collar and rotate tube out of the way. Fluid coupling will continue to be drained in the usual manner.***

►***NASH STATESMAN & RAMBLER HYDRAMATIC OIL DRAIN HOLE PRODUCTION CHANGE***—A ¾" hole has been drilled in rear cross member directly under torus cover drain plug. To position torus drain hole for draining, line up timing mark on crankshaft dampener in a horizontal position, either right or left. See following for drilling hole in early production cars.

►**Drilling Drain Hole in Crossmember (Nash Statesman & Rambler)**—Drill a ¾" hole in rear cross member (center of hole to be 1" forward of edge of large center hole stamped in cross member). ***CAUTION—Extreme are must be taken so that drill does not damage torus cover.***

1) Remove flywheel housing lower cover (or hand hole cover), turn fluid coupling until drain plug in torus cover points downward, remove plug and drain fluid coupling.

2) Remove drain plug at rear end of transmission oil pan and drain transmission case.

3) Replace both drain plugs and tighten securely.

4) Install 8 qts. 1952-55 Cadillac, Kaiser, Lincoln, & Nash Ambassador; 1952-54 Hudson (Exc. Jet), Oldsmobile, & Pontiac. 5 qts. 1952-55 Nash Rambler, Nash Statesman, & Willys; 1953-55 Hudson Jet; 1954-55 Chev. Truck; 1955 Hudson Hornet, Hudson Wasp, Oldsmobile, & Pontiac.

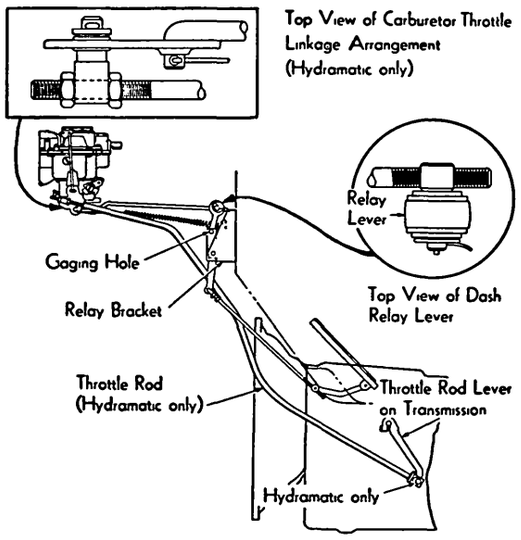
5) Start engine and run it at speed equivalent to 20 MPH. for at least 1½ minutes with selector in "N" (to fill fluid coupling). Return engine to slow idle speed.

6) Check fluid level (see above), add fluid to bring level up to "F" mark on dipstick (approximately 3-4 qts. required).

►***CAUTION—Correct level should be determined by dipstick reading rather than exact amount of fluid added.***

Recommended Fluid: Hydra-Matic Fluid as furnished by car manufacturer or Automatic Transmission Fluid Type "A" as furnished in containers bearing "AQ-ATF" symbol.

►***FLUSHING CAUTION—Flushing of the unit is not required. Use only regular Hydra-Matic fluid for this purpose.***



DUAL-RANGE HYDRA-MATIC LINKAGE ADJUSTMENT

1952-54 CADILLAC

LINKAGE ADJUSTMENT: ***CAUTION—Make adjustments in correct order and exactly as follows:***

(1) Manual Control Linkage—Disconnect manual control rod from control lever on transmission case. Move control lever to drive position (move lever fully forward, then move lever toward rear until first detent position is reached). Place selector lever on steering column against stop in "DR-4" position. Adjust clevis on transmission end of control rod until clevis pin can just be inserted freely through clevis and lever. Connect control rod.

(2) Throttle Lever Position—Disconnect throttle rod at throttle lever on transmission case. Check lever position by installing checking gauge, Tool J-3065-A on rear face of transmission case with long leg of tool extending forward along left side of case. Move throttle lever to extreme rear position. Insert clevis pin through hole in lever and hole in checking gauge. If pin does not enter hole in gauge freely, bend lever as required using bending tool J-2029. Remove gauge, connect throttle rod to lever.

1952-55 CADILLAC HYDRA-MATIC LINKAGE

(3) Throttle Control Linkage—Disconnect carburetor throttle rod at dash relay lever by removing spring clip and freeing trunnion from lever. Install ¼" drill rod through hole in relay lever and hole in bracket to position lever. See that carburetor throttle lever in correct hot or slow idle position and set for correct idle speed of 375 RPM. (1952), 400 RPM (1953-54). Adjust trunnion at rear of throttle rod until trunnion enters relay lever freely, connect trunnion and install spring clip. Back off both nuts on throttle rod at carburetor throttle lever, push on end of rod so that transmission throttle lever and valve is against its stop, turn rear nut on throttle rod up against the carburetor throttle lever trunnion, **then back the nut off 3 complete turns,** finally tighten the front nut on the rod securely against trunnion. Check to see that linkage moves freely. Remove drill rod from relay lever. Check and adjust accelerator pedal position.

(4) Accelerator Pedal Position—Depress pedal fully and see that it touches floor mat with slight pressure when carburetor throttle valve wide open. (NOTE—If floor mat removed, allow ½" clearance between pedal and floor in wide open position). Adjust pedal position as required, by changing length of pedal to relay lever rod (adjusting trunnion located at pedal end of rod).

(5) Neutral Switch—Adjust position of switch so that starter operative (switch closed) only when selector lever in "N" position.

►***CAUTION***—Do not move switch so far in neutral position that travel of lower lever is limited by switch arm in the reverse position.

1955 CADILLAC

Manual Control Linkage: Disconnect manual control rod from control lever on transmission case Move control lever to drive position (move lever fully forward, then toward rear until first detent position is reached). Place selector lever on steering column against stop in "DR-4" position Adjust clevis on transmission end of rod until clevis can just be inserted freely through clevis and lever Connect control rod.

Neutral Safety Switch Adjustment: Adjust position of switch on steering column so that switch is "off" when manual valve is in a position to move the car. ***CAUTION—Do not move the switch so far in the neutral direction that the travel of the lower lever in the reverse direction is limited by the switch arm.***

►*THROTTLE LEVER POSITION PRODUCTION*

CONTINUED ON NEXT PAGE

LINKAGE ADJUSTMENT

1955 CADILLAC (Continued)

CHANGE: On cars after Serial No. 67273 *(Last 5 digits of complete serial Number—See "Model Identification" on Car Model page)*, a new throttle lever is used which requires that a measurement of 4½" from rear machined surface of transmission case to hole in lever be used for setting lever position instead of using Gauge J-3065-C as on earlier transmissions.

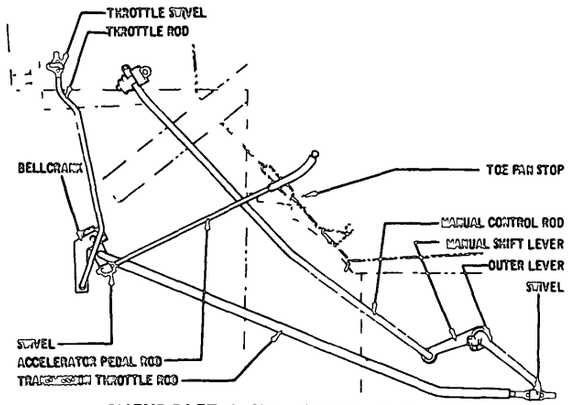
Throttle Linkage Adjustment: *CAUTION—On cars with Rochester Carburetors and Air-Conditioning, the engine must be running when throttle linkage is adjusted.* 1) Remove throttle control lever clevis pin at transmission and check lever position with Tool J-3065-C *(See "Throttle Lever Production Change" above for checking lever position on later cars)*. Fit tool on rear face of transmission case and insert clevis pin through lever and hole in gauge marked "49E 50," while lever is in its rearward position If throttle lever is misaligned, correct by bending lever with Tool J-2029. Assemble linkage to transmission throttle lever and install cotter pin

2) Disconnect spring between carburetor and relay rod at trunnion and remove trunnion from dash relay lever. Place a ¼" drill shank through gauging hole in dash relay lever and into dash relay bracket. Set carburetor throttle in fast idle position with transmission in "DR" range (400 RPM—Std. Engine. 480 RPM—Eldorado Engine).

3) Adjust carburetor-to-dash relay rod trunnion to allow free entry into dash relay lever. Connect spring in trunnion.

4) On Cars With Single Carburetor—Back off both jam nuts on throttle valve rod at carburetor to allow free movement of rod in trunnion. Push end of throttle valve rod to position transmission throttle valve against its stop. Bring rear jam nut up against trunnion and back off 9 flats (1½ turns). *(NOTE—This adjustment may be changed to improve shift characteristics after road test).* Tighten front jam nut, check to be sure there is no bind in linkage

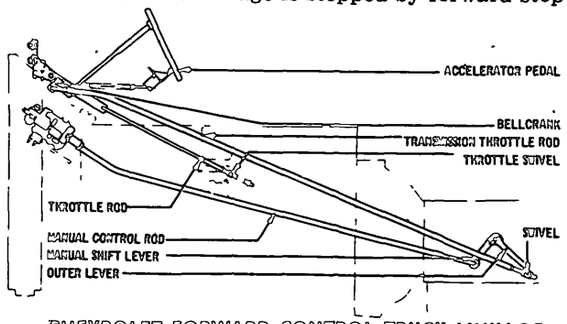
5) On Cars With Two Carburetors—Remove locknut, adjusting nut and spring from forward end of throttle valve control rod. Back off rear locknut and adjusting nut on throttle valve rod to permit free movement of rod in trunnion. Push on end of throttle valve rod to position throttle valve in transmission against its stop. Bring rear adjusting nut up against trunnion and back off 3 turns (18 flats), then tighten locknut. Install spring and adjusting nut on front end of throttle valve rod. Adjust nut until the distance between the front face of the trunnion and the rear face of the adjusting nut is 1 13/32". Hold adjusting nut in this position and install locknut. Recheck above dimension.



6) Remove ¼" drill rod from dash relay and check position of accelerator pedal with wide open throttle. Pedal should touch floor mat with light pressure (allow ½" clearance if floor mat has been removed) when throttle is wide open. Adjust accelerator pedal position at pedal end of dash relay-to-accelerator pedal rod. Road test car to insure proper shifting characteristics.

1954 CHEVROLET TRUCKS

Manual Control Linkage: (All Models)—Move shift control lever from "N" position to first detent that is felt. In this position indicator should line up with symbol "1-4." Check control lever in each of the other positions for indicator alignment. If adjustment is not satisfactory, proceed as follows: If gearshift control shaft upper support bracket is loose, tighten the clamp screw while holding control lever firmly against stop between "1-3" position and "1-2." While holding lever in "1-3" against the stop which prevents accidental shift into "1-2," loosen gearshift control rod swivel. Make sure transmission outer lever is in the three speed drive position "1-3" (third position from front or rear). With control lever in "1-3" position and held against stop, and with transmission outer lever in the three speed drive position, tighten gearshift control rod swivel.



Neutral Safety Switch Adjustment: Place control lever in "1-4" position. With ignition off, operate starter control. Starter should not operate. If it does, check the other positions in the same manner. If starter operates in any position except "N," adjust as follows: Loosen two switch assembly mounting screws. Place selector lever in "N," and with clip over flats on end of shifter shaft, insert pin into mounting bracket of switch and locating plate. Tighten screws to secure switch in this position and remove locating screws.

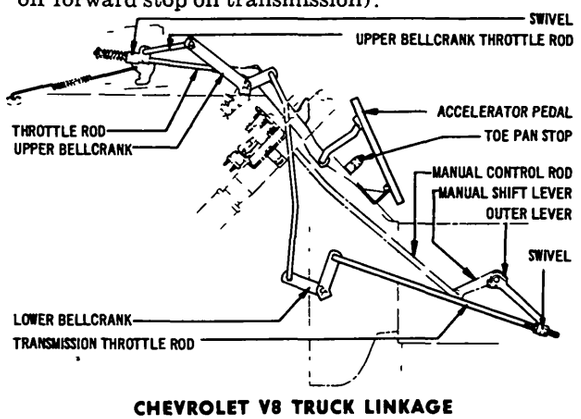
Throttle Linkage Adjustment: (6 Cyl. Hydra-Matic Drive Trucks, except Forward Control)—With engine at normal operating temperature and idle speed set at 400-450 RPM, remove lower end of carburetor throttle lever-to-bell crank rod from lever on bell crank. Install Lever positioning Gauge J-5609 in hole in lever and gauge hole in pan rail of engine block (hole is located toward rear of bell crank position), and leave gauge in this position. Remove swivel from bell crank-to-transmission outer lever at transmission and move transmission outer lever back against stop. Check distance from hole in outer lever to back of transmission with Gauge J-2545-C. Bend lever as necessary for free entry of gauge in lever hole using tool J-5260 *(CAUTION—Do not apply force to stops at either end of lever travel).* Hold outer lever back against stop and adjust swivel position on bell crank-to-transmission rod so it just enters hole in transmission lever. Remove Positioning Gauge from bell crank and reinstall throttle rod Recheck engine idle speed with idle screw against stop on carburetor, and adjust carburetor throttle-to-bell crank rod so swivel at upper end freely enters hole in throttle lever. At this point, shorten bell crank-to-transmission outer lever by turning swivel lock nuts two full turns. Remove bell crank-to-carburetor throttle rod upper swivel from lever and pull rod upward until linkage is stopped by forward stop in transmission. Hold in this position and adjust accelerator-to-bell crank rod swivel until accelerator pedal is against floor stop, then shorten rod one full turn. Replace upper end of throttle-to-bell crank rod in throttle lever.

CHEVROLET 6 CYL. TRUCK LINKAGE
(EXCEPT FORWARD CONTROL)

Throttle Linkage Adjustment: (Hydra-Matic Drive Forward Control Models)—With engine at normal operating temperature and idle speed set at 400-450 RPM, remove accelerator pedal-to-bellcrank rod and install Carburetor Control Lever Adjusting Gauge J-5629 with slotted end resting on inside shoulder of hex head brass fitting on intake manifold and pin end in rod hole in lever on bell crank. Leave gauge in this position. Remove swivel from bell crank-to-transmission outer lever rod at transmission and move lever back against stop. Check distance from hole in outer lever to back of transmission with Gauge J-2545-C. Bend lever as necessary for free entry of gauge in lever hole using tool J-5260 *(CAUTION—Do not apply force to stops at either end of lever travel).* Hold outer lever back against stop and adjust swivel position on bell crank-to-transmission rod so it just enters hole in transmission lever, then shorten bell crank-to-transmission outer lever rod two full turns. Recheck engine idle speed with idle screw against stop on carburetor. Adjust carburetor throttle-to-bell crank rod so swivel at lower end freely enters hole in throttle lever. Remove Positioning Gauge from bell crank lever. Remove carburetor throttle-to-bell crank rod from throttle lever and pull bell crank-to-transmission outer lever rod up toward floorboard until linkage is stopped by forward stop

CHEVROLET FORWARD CONTROL TRUCK LINKAGE

in transmission. Hold rod in this position and install accelerator pedal-to-bell crank rod in bell crank lever, and adjust swivel so accelerator pedal is against toe board stop. Install carburetor throttle-to-bell crank rod, then shorten accelerator pedal-to-bell crank rod one full turn.



Throttle Linkage Adjustment: (V8 Hydra-Matic Drive Trucks)—Back out throttle valve adjusting screw so throttle valve is in the tightly closed position and swivel on end of throttle rod is against lug on upper bellcrank throttle rod. Remove swivel from

CONTINUED ON NEXT PAGE

LINKAGE ADJUSTMENT

1.54 CHEVROLET TRUCKS (Con..)

transmission throttle lever and move lever back against its internal stop. Check distance from hole in lever to rear face of transmission case with Throttle Lever Checking Gauge J-2545-C. Bend transmission lever with Tool J-5260, if necessary, to allow entry of gauge into hole *(CAUTION—Do not apply force against stop at either end of lever travel)*. Adjust length of transmission throttle rod so swivel just enters hole in transmission throttle lever. Adjust engine idle speed to 425 RPM with selector lever in "N" position. This adjustment will move transmission throttle lever off its internal stop. Depress accelerator pedal to obtain 5/8" distance between toe pan stop and bottom of pedal, then adjust length of throttle rod to give full open throttle. Depress pedal until transmission throttle lever is tight against forward stop on transmission and turn screw on toe pan stop up against accelerator pedal. Release pedal and turn screw upward **two full turns** and secure screw with jam nut (transmission throttle lever will be moved slightly off forward stop on transmission).

CHEVROLET V8 TRUCK LINKAGE

1952 HUDSON

LINKAGE ADJUSTMENT: *Adjust exactly as follows:*
►*1952 HYDRA-MATIC THROTTLE LEVER CONNECTION CAUTION:* New No. 307556 lever with **two** holes at outer end for throttle rod connection used on later cars. Connect rod as follows:

Inner Hole—5B & 6B with Twin Carburetors.

Outer Hole—All other models (including 5B & 6B with single carburetor).

LEVER CHECKING CAUTION—When using Gauge J-2195 to check lever position, apply gauge rod to lower (outer) hole in lever.

Throttle Control Linkage: Make certain that throttle return spring hooked in lower hole of cross-shaft lever. Then proceed as follows:

1) On all models, set carburetor idle speed at 490-510 RPM. with engine at normal operating temperature (choke wide open, fast idle not operating), transmission warm, selector lever in Neutral "N."

2) On Model 4C only, with throttle lever stopscrew against its stop, adjust throttle control bellcrank-to-carburetor rod so that gauge pin J-2544 freely enters two holes in bellcrank and slotted hole in bellcrank support bracket, then remove pin.

3) On all models, with carburetor throttle lever stopscrew against its stop, adjust throttle bellcrank shaft operating rod (by backing off one trunnion nut and tightening opposite nut) until gauge pin J-2544 freely enters notch or hole in accelerator pedal link bellcrank lever and hole in cylinder block. Tighten trunnion nuts securely, recheck bellcrank position, remove adjusting pin.

4) On all models, check position of outer throttle lever on transmission case as follows: Install Checking Gauge J-2195 flat against back surface of transmission case (CAUTION—clean machined surface to insure correct seating of gauge) with leg of gauge extending forward along side cover. Hold transmission throttle lever back against its stop in rear position. Hole in outer end of lever should center on small diameter of gauge pin and inner face of lever should just touch larger diameter of gauge rod. **Do not** force lever against its stop. Bend lever as required **using Bending Tool J-3310.** Reconnect throttle rod to lever.

5) On all models, disconnect transmission throttle rod from accelerator pedal link bellcrank lever by taking out trunnion pin, position bellcrank by inserting gauge pin J-2544 through notch or hole in bellcrank and into hole in cylinder block. Push transmission throttle lever to rear and against its stop lightly, adjust rod by backing off one trunnion nut and tightening opposite nut until trunnion pin enters hole in bellcrank lever freely, connect rod to bellcrank lever, then back off rear trunnion nut approximately 1¾ turns (or clearance between nut and trunnion is 1/16"—check with 1/16" shim), tighten front locknut securely to bring trunnion up against rear nut. **This will shorten the rod by this 1¾ turns of the nut.** Adjust accelerator pedal trunnion by loosening one trunnion nut and tightening opposite nut until clearance between accelerator pedal and the pedal stop is 1/64-1/16" with carburetor throttle valves wide open.

Manual Control Linkage: Disconnect transmission shift rod at manual control lower lever on steering column. Position transmission shift lever on side of transmission case in "DR-3" by moving lever to rear as far as it will go (Reverse position) and then moving lever forward **two** detents (to third or middle position). Move selector lever on steering column to "DR-3" position (move lever toward reverse as far as possible without lifting selector lever). Adjust shift rod by turning clevis on forward end of rod until clevis pin holes line up with hole in manual control lower lever, then **lengthen rod by turning clevis one full turn on rod,** connect rod and tighten clevis locknut. Operate selector lever in all positions to make certain that lever indexes properly with indicator dial.

Neutral Safety Switch: Place selector lever in Neutral "N" position, loosen mounting screw in safety switch mounting bracket, adjust switch to close approximately midway between "N" and "DR" on indicator dial, tighten mounting screw securely. Check to make certain that starter operates only when selector lever in "N" position.

1953-54 HUDSON

LINKAGE ADJUSTMENT: *Adjust exactly as follows:*

Transmission Throttle Lever Adjustment—On all models, check position of outer throttle lever on transmission as follows: Install Checking Gauge J-2195 flat against back surface of transmission case (CAUTION—clean back surface of transmission case and machined surface to insure correct seating of gauge) with leg of gauge extending forward along side cover. Hold transmission throttle lever back against its stop in rear position. Hole in outer end of lever should center on small diameter of gauge pin and inner face of lever should just touch large diameter of gauge rod. **Do not force** lever against its stop. **Bend lever as required using Bending Tool J-3310.** Reconnect throttle rod to lever.

Throttle Control Linkage: *NOTE—Adjustment of Transmission Throttle Lever should be made BEFORE transmission throttle control levers are adjusted. See Transmission Throttle Lever Adjustment above.*

Engine Idle Adjustment—On all models, adjust engine idle speed to 490-510 RPM with engine at normal operating temperature, transmission warm and selector lever in "N" (Neutral) position.

1) **Models 1C, 1D, 2C, 2D With Single Carbs.**—Install throttle gauge pin J-2544 in lower bell crank, and adjust throttle bell crank operating rod (rod from lower bell crank to upper bell crank) to 2 9/32", measured from centerline of throttle control bell crank-to-carburetor rod clevis pin, and the top of the machined surface of cylinder head. Tighten jam nut securely. With throttle return spring attached and idle adjusting screw against its stop, and the gauge pin J-2544 still in place in lower bell crank, adjust throttle control bell crank-to-carburetor rod until clevis pin slides freely into holes in clevis and hole in bell crank. Tighten jam nut. With gauge pin in place in lower bell crank, and transmission throttle lever (on transmission case) back against its rear stop, adjust length of transmission throttle rdo (rod from transmission lever to lower bell crank) so that it is 3/32" **shorter** than the actual distance between the holes. Tighten jam nut. Remove gauge pin from lower bell crank and adjust length of accelerator pedal-to-bell crank rod to give full throttle, with 1/64" to 1/16" clearance between accelerator pedal and pedal stop.

2) **Models 1C, 1D, 2C, 2D With Twin Carbs.**—Install gauge pin J-2544 in lower bell crank and in upper bell crank holes, then adjust length of throttle bell crank operating rod (rod from lower bell crank to upper bell crank) so that operating rod trunnion pin enters bell crank. Tighten jam nut. With gauge pins still in place, and both carburetors off fast idle (choke open) and with throttle return spring attached, adjust both bell crank-to-carburetor rods so clevis pin slides freely through clevis and lever. Tighten jam nuts. *Complete adjustment as indicated for models with Single carburetor (above).*

3) **Models 4C, 4D, 5C, 5D With Single Carbs.**—With Carburetor throttle idle screw against its stop and carburetor off fast idle, adjust throttle bell crank-to-carburetor rod so that gauge pin J-2544 will freely enter gauge pin holes in throttle bell crank and the slotted hole in throttle control bell crank support bracket. After making adjustment, remove gauge pin. Adjust throttle bell crank operating rod (rod between upper and lower bell cranks) until gauge pin will freely enter seat in accelerator pedal link bell crank lever and gauge hole in cylinder block, (located at end of starter motor). Tighten jam nut. With gauge pin remaining in place in lower bell crank, disconnect transmission throttle rod

C NTINUED ON NEXT PA E

LINKAGE ADJUSTMENT

1953-54 HUDSON (Cont.)

at accelerator bell crank lever. Lightly push transmission throttle valve lever rearward against its stop, and adjust the throttle rod so that the trunnion pin will slide freely into accelerator pedal bell crank lever. Install trunnion pin, flat washer and cotter pin. With trunnion pin in position, loosen rear adjusting nut approximately 1¾ turns or until a 1/16" shim can be installed between rear lock nut and trunnion; remove shim and tighten locknut (front) without turning rear lock nut. This will pull throttle lever forward off stop. Remove gauge pin.

4) Models 4C, 4D, 5C, 5D With Twin Carbs.—Insert gauge pin J-2544 through lower bell crank lever and into hole in cylinder block. Adjust length of throttle shaft operating rod (rod between lower and upper bell crank) so distance between center of clevis pin hole in throttle shaft lever (this lever connects with rod actuating throttle valve on carburetor) and top of cylinder block (machined surface) is 1.789". With gauge pins still in position, and with throttle return springs attached, adjust length of each throttle rod (rod between operating shaft and carburetor) so clevis pin slides freely through clevis and bell crank lever. Tighten jam nut securely. With gauge pin still in position, move transmission lever to rear stop, then adjust transmission throttle rod (rod between transmission throttle lever and lower bell crank) so that it is 1/16" shorter than the actual distance between trunnion (on lower bell crank) and clevis pin hole in transmission lever. Lock trunnion jam nuts. Remove gauge pin and adjust length of accelerator-to-bell crank rod assembly, to give a full throttle, with 1/64" to 1/16" clearance between accelerator pedal and pedal stop.

5) Model 7C & 7D With Single Carb.—With carburetor throttle idle screw against its stop and carburetor off fast idle, adjust accelerator cross-shaft, operating rod trunnion nuts (located adjacent to bracket on left side of cylinder head) until gauge pin J-2544 can be installed freely into accelerator pedal bell crank lever (ahead of starter on left side of engine crankcase), and the hole in cylinder block boss. Tighten trunnion nuts securely. Disconnect transmission throttle rod trunnion from accelerator pedal link bell crank lever. With gauge pin still in position in bell crank, hold transmission throttle lever back against its stop, then adjust transmission throttle rod so trunnion pin will slide freely into accelerator pedal link bell crank lever. Install trunnion pin, flat washer and cotter pin, and with trunnion pin in position, loosen rear adjusting nut (nearest transmission) approximately 1¾ turns or until a 1/16" shim can be installed between rear lock nut and trunnion. Remove shim and tighten front lock nut without turning rear lock nut. Remove gauge pin. Hold throttle wide open, and with accelerator pedal against its stop, adjust lower lock nut on accelerator pedal-to-bell crank rod until it touches trunnion, then increase adjustment ¼" further. This will give approximately 1/16" clearance between accelerator and stop.

6) Model 7C & 7D With Twin Carbs.—Throttle linkage adjusted in same manner as for models with Single Carburetor, except that both carburetor rods (from operating shaft to carburetor) must be adjusted alike.

Manual Control Linkage: Disconnect transmission shift rod at manual control lower lever on steering column. Position transmission shift lever on side of transmission case in "DR-3" by moving lever to rear as far as it will go (Reverse position) and then moving lever forward two detents (to third or middle position). Move selector lever on steering column to "DR-3" position (move lever toward reverse as far as possible without lifting selector lever). Adjust shift rod by turning clevis on forward end of rod until clevis pin holes line up with hole in manual control lower lever, then lengthen rod by turning clevis one full turn on rod, connect rod and tighten clevis locknut. Operate selector lever in all positions to make certain that lever indexes properly with indicator dial.

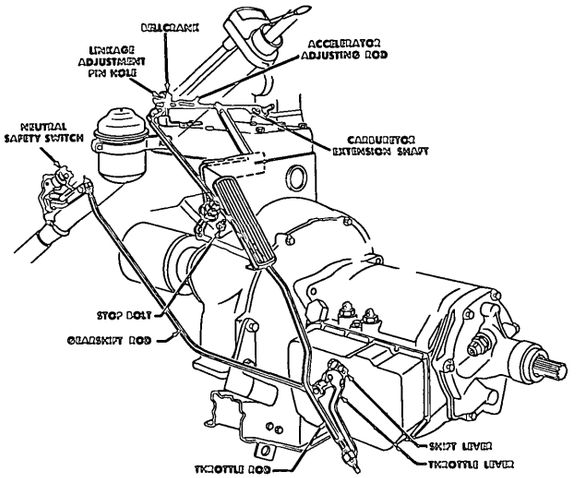
Neutral Safety Switch: Place selector lever in Neutral "N" position, loosen mounting screw in safety switch mounting bracket, adjust switch to close approximately midway between "N" and "DR" on indicator dial, tighten mounting screw securely. Check to make certain that starter operates only when selector lever in "N" position.

1955 HUDSON

(EXCEPT RAMBLER)

Manual Control Linkage: (All Models)—Place selector lever in "D-3" position and set operating lever against the stop on housing bracket. Remove clevis pin from gear shift control rod at side of transmission case and remove clevis from shift lever. Place transmission lever in "D-3" position and adjust clevis so pin passes freely through hole in clevis and in lever *(NOTE*—Be sure that operating lever is against stop on housing bracket). After adjustment has been completed, lengthen the control rod two full turns and replace clevis and cotter pin.

Throttle Linkage Adjustment: Adjust idle speed to 490-510 RPM (on cars with air conditioning, compressor must be running), engine at normal operating temperature, transmission warm and selector lever in "N" position.



Wasp—Adjust carburetor rods and install aligning pins J-2544 so that both pins index at rear upper throttle lever and lower bellcrank and hole in boss on cylinder block.

Hornet—Aligning pin J-2544 should fit freely in bellcrank lever and hole in boss on cylinder block. If alignment pin does not index, remove carburetor-to-throttle rod lever clevis pins and readjust rods.

All Models—After aligning pins installed, recheck and adjust carburetor idle adjusting screws. Disconnect throttle rod at left side of transmission case, clean machined surface of case and check lever position using Tool J-2915. Place gauge flush against machined end surface of case, with edge of gauge against transmission side cover. Gauge should fit freely in hole of throttle valve lever. If gauge does not fit through lever hole freely, use Bending Tool J-3310 and bend lever to proper location. Adjust trunnion on transmission throttle rod so rod fits freely in hole in lever. Then shorten rod 1/16" (two full turns) and connect rod to lever.

1952-55 KAISER

▷*FULL-THROTTLE SETTING NOTE*—If wide open throttle at carburetor can not be secured AFTER Throttle Linkage adjusted, bend lower end of bellcrank on left side of cylinder head (to which transmission rod attached) away from engine just enough to permit full throttle opening (CAUTION —do not bend offset portion of bellcrank further

TYPICAL KAISER HYDRA-MATIC LINKAGE

than parallel with upper portion of bellcrank and prevent throttle control extension shaft from bending by wedging screwdriver under shaft).

LINKAGE ADJUSTMENT: *Adjust exactly as follows:*

Selector Linkage (1952-53): Place selector lever in right hand drive position (DR-3), back off both nuts on control rod trunnion at control shaft lever on steering column. Make certain that outer shift lever on transmission case is in 3rd. speed position (third position from front or rear), turn lower trunnion nut up against trunnion finger tight to remove all play from linkage, then lengthen rod by turning the nut one full turn, tighten upper trunnion nut.

Selector Linkage (1954-55): Check clamp bolt on the shift lever at transmission and tighten if necessary. Proceed as follows: Place shift lever at transmission in intermediate position (intermediate is the center position or second detent from either end of shift lever travel). Back off both control rod trunnion lock nuts. Make sure the bolts securing gearshift shaft bearing to steering column are tight. Move lower gearshift lever to a position of 1/16" clearance between lower gearshift lever and intermediate stop on the gearshift shaft bearing support bracket. Tighten trunnion lock nuts. Operate linkage with upper gearshift lever a number of times, then shift transmission into intermediate position at transmission, and recheck allowable clearance between lower lever and intermediate stop. Check position on indicator at steering wheel and bend indicator as necessary to line it up with correct mark on quadrant.

Neutral Safety Switch: Place transmission in drive position. Loosen bolts holding neutral safety switch to gearshift shaft bearing support bracket. Rotate switch to a position where starting motor will not operate when key is turned to starting position. Hold switch in selected position, shift transmission

CONTINUED ON NEXT PAGE

LINKAGE ADJUSTMENT

1952-55 KAISER (C nt.)

to neutral and starter should then operate when key is turned on. If so, tighten bracket bolts. If necessary, the elongated adjustment bolt holes in the switch bracket can be enlarged.

Throttle Control Linkage: Disconnect rod at throttle control lever (long lever) on transmission case. Loosen carburetor extension shaft lock bolt, install Linkage Adjustment Pin (KF-91) through alignment holes in bellcrank and bracket on cylinder head. Make certain that carburetor idle speed correctly set at 425-450 RPM. *(CAUTION*—make this setting with engine at operating temperature of 150-160°F, choke valve wide open and fast idle not operating, transmission warm and selector lever in N), then tighten carburetor extension shaft lock bolt but **do not remove adjustment pin.** Check tightness of transmission throttle control lever clamp bolt (12-15 ft. lbs. torque). Check lever position by placing Throttle Lever Checking Gauge KF-146 on back of transmission case (CAUTION—clean machined surface on case to insure correct gauge positioning) with gauge leg extending forward on side of case. Clevis pin in lever should fit into forward slot in gauge. Bend lever as required for this position using Bending Tool KF-79. Connect throttle rod to lever (CAUTION—anti-rattle washer must be installed between trunnion and lever). Adjust throttle rod trunnion (back off one nut and tighten opposite nut) until control lever seats lightly against stop in transmission, then **shorten rod by backing off forward nut at trunnion 3 full turns,** tighten rear trunnion nut securely. NOTE—If shifts do not occur at correct speeds with minimum throttle with above setting, this control rod setting can be changed slightly. Remove Adjusting Pin from bellcrank on cylinder head, move carburetor throttle to wide open position, adjust turnbuckle on accelerator pedal rod (at bellcrank on cylinder head) so that accelerator pedal just touches the stop bolt.

1952-54 LINCOLN

►*1953 DIFFICULT FORCED DOWNSHIFT NOTE*—If difficulty encountered in obtaining a forced downshift, check length of accelerator-to-transmission rod. Rod assembly No. LA-9784-D, is a 1952 rod, and is shorter than 1953 rod, No. LA-9784-E. 1952 rod is 5.27" overall length, and 1953 rod is 5.44" overall length. If replacement of rod does not correct difficulty, see following correction.

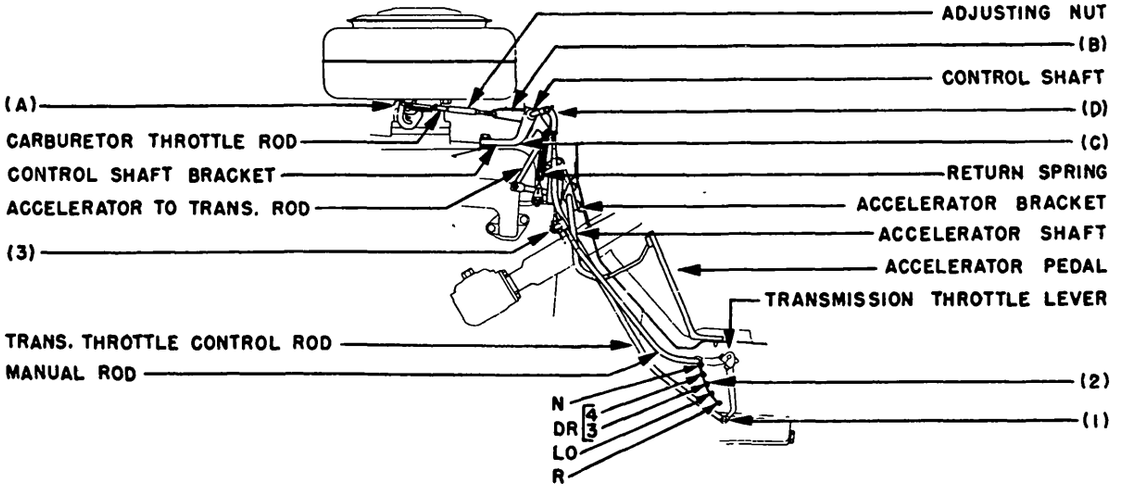
►*1953 FORCED DOWNSHIFT (Early Cars)*—Some early cars prior to Serial No. 53WA-12789-H (Wayne Plant), 53LA-7013-H (Los Angeles Plant) had transmission control shaft assembly Part No. LA-77230 shimmed up to eliminate toe-board interference with accelerator shaft, Part No. 9725-F. If difficulty is encountered in obtaining a forced downshift on these cars, replace Part No. 9725-F with accelerator shaft assembly Part No. 9725-G. When new part is installed, remove shims from underside of transmission control shaft assembly.

LINKAGE ADJUSTMENT: ***Adjust exactly as follows:*** **First check and adjust engine idle speed to 375-400 RPM. with engine at normal operating temperature (choke valve wide open and fast idle inoperative), transmission warm, and selector lever in "N".**

Throttl Linkage: Disconnect transmission throttle rod at forward end by taking out clevis pin "D".

1) Adjust carburetor throttle rod (between "A" and "B") by loosening locknuts and turning adjusting clevis on rod so that carburetor throttle lever stop-screw is against stop (Point "A") and control shaft assembly is against its stop (Point "C"). Tighten locknuts against adjusting clevis.

CAUTION—Throttle rod ends must be in alignment to prevent binding.



2) Hold throttle lever in slow idle position (stop-screw against stop at point "A"), push down firmly on transmission throttle rod so that lever is in its stop position, adjust clevis on forward end of rod (point "D") so that clevis pin can be entered freely, then remove pin and **shorten the rod by three full turns of the clevis.** Connect rod and tighten clevis locknut. Check shift points by road-testing car.

Manual Control Linkage: Disconnect manual control rod from lever on steering column (point "1").

1) Position selector lever under steering wheel in "Dr" position against its stop.

2) Position manual lever on transmission case in second position from top ("Dr" position—point "2").

3) Adjust manual control rod by turning adjusting trunnion on forward end until sleeve enters grommet hole freely, **then lengthen rod by turning trunnion one full turn,** connect rod. Check position of selector lever in all positions.

1952-54 LINCOLN HYDRA-MATIC LINKAGE

1952-54 NASH & RAMBLER

LINKAGE ADJUSTMENT: ***Adjust exactly as follows:***

Throttle Control Linkage: Check and adjust engine idle speed to 375 RPM (Except "Dual Jetfire"), 500 RPM ("Dual Jetfire"), with engine temperature at 150-160°, transmission warm, selector lever in neutral. Disconnect transmission throttle rod, at throttle lever on side of transmission. Clean machined surface at back of transmission case and place throttle lever checking gauge J-2545-A flush against surfaces with edge of gauge against transmission side cover. The throttle lever stud should fit freely in notch in gauge. Bend to proper location with tool J-3310 if gauge does not pass over throttle lever stud freely. Adjust transmission throttle rod (which is threaded into upper throttle rod yoke) to fit freely on throttle lever stud; **then shorten the rod approximately 2 turns (Except "Dual Jetfire"), 3 turns ("Dual Jetfire").** Install rod on stud and replace wave washer, flat washer and cotter pin.

Selector Lever Linkage: Place selector lever under steering wheel in the "D-3" position and set the operating lever against the stop on the starter switch bracket. Remove the clevis pin from the gear shift control rod at side of transmission case and remove clevis from shift lever. Place the transmission outer shift lever in the "D-3" range position. Adjust the clevis so the pin passes through hole in lever. (NOTE—Be sure the operating lever is against the stop on the starter switch bracket). After the adjustment has been completed, lengthen the control rod **two full turns** and replace the clevis pin and cotter key.

Starter Switch: ***Adjustment required only if control disassembled and switch location disturbed.***

1) Place selector lever in Neutral "N" position and check alignment of operating plunger on control lever on steering column with switch plunger (must be aligned so that switch plunger depressed by operating plunger when selector lever lifted upward in "N").

2) Adjust switch to align plunger by loosening switch bracket mounting screws and shifting switch and bracket on steering column (holes are slotted to permit this adjustment).

1955 NASH & RAMBLER

Manual Control Linkage: (All Models)—Place selector lever in "D-3" position and set lever against stop on starting switch bracket. Remove clevis pin from gear shift control rod at side of transmission case and remove clevis from shift lever. Place transmission shift lever in the "D-3" position and adjust clevis so pin passes freely through hole in clevis and in lever. *(NOTE*—Be sure that operating lever is against stop on housing bracket). After ad-

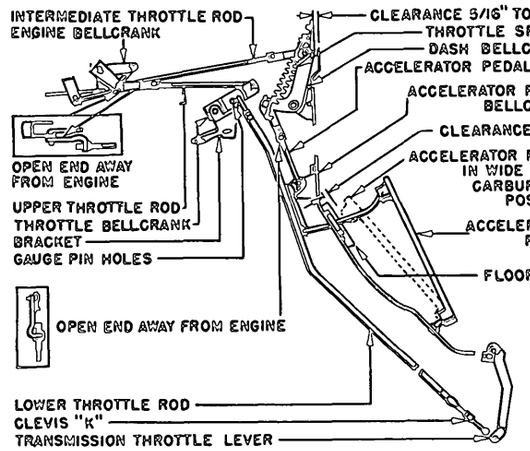
CONTINUED N NEXT PAGE

LINKAGE ADJUSTMENT

1955 NASH & RAMBLER (Cont.)

justment has been completed, lengthen the control rod two full turns and replace clevis and cotter pin.

Throttle Linkage Adjustment: Adjust engine idle speed at 450 RPM (500 RPM air conditioned cars, with compressor running), with engine and transmission at normal operating temperature and selector lever in "N" position. Disconnect throttle rod at throttle lever at side of transmission. Clean machined surface at rear of transmission case and place throttle lever checking gauge J-2545-C flush with case surface with edge of gauge against transmission side cover. The throttle lever stud should fit freely in notch in gauge. If gauge does not pass over throttle lever stud freely, use Bending Tool J-3310 and bend lever to proper position. Gauge notch must slide freely on stud pin. Adjust transmission throttle (which is threaded into upper throttle rod yoke) to fit freely on throttle lever stud; then shorten rod approximately two turns. Install rod on stud and replace wave washer, flat washer and cotter pin.



1952-53 OLDSMOBILE

LINKAGE ADJUSTMENT: *CAUTION—Series with 4-barrel carburetors have different throttle linkage. Make adjustments in following order.*

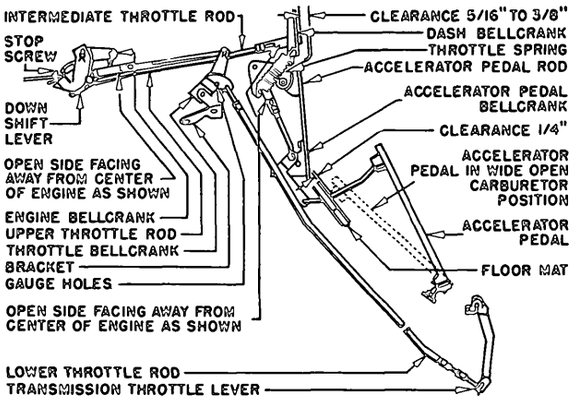
Adjustment Note—Poor engine performance affects Hydra-Matic Transmission operation; be sure engine is functioning properly before adjustments are made.

Manual Control Linkage (1952)—Loosen clevis locknut at rear end of lower control rod (from steering column to intermediate lever on frame cross-member) and disconnect this rod at the intermediate lever (relay rod from intermediate lever to transmission is non-adjustable). Adjust as follows:

Lower Control Rod—Place transmission control lever in "S" position (move lever all the way forward to neutral, then move lever back to the second detent "S" position). Place steering column selector lever at end of "S" range against stop which prevents movement into reverse without raising lever

OLDSMOBILE LINKAGE (2-BARREL CARB.)

(pull down on lower control rod until stop is felt). Adjust clevis on lower end of lower control rod until pin can just be slipped freely through clevis and intermediate lever without disturbing lever positions, then tighten rod by turning clevis one full turn, tighten locknut and connect rod.



Manual Control Linkage (1953): Loosen jam nut on shift rod clevis and neutral safety switch. Remove clevis pin from shift rod. Move manual control lever at side of transmission all the way forward into "N" position. Then raise and hold shift lever beyond "N" position against side of opening in jacket. Adjust shift rod clevis so that end of clevis contacts outside diameter of bushing in lower shift lever. Return lower shift lever to "N" position, insert clevis pin through clevis and bushing, assemble cotter pin to clevis pin. NOTE—Adjustment properly positions selector lever in relation to manual valve in valve body and assures correct pointer positioning in all selector lever positions. Adjust neutral safety switch as follows:

Neutral Safety Switch Adjustment (1952-53): Set Transmission in "N" detent. With switch assembled to steering gear and link connected to shift lever, insert .090" pin through switch lever and bracket. Tighten mounting bolt and withdraw .090" pin. Check setting by applying handbrake firmly, placing shift lever in "Dr" range, and turning ignition switch to "Start." While holding switch on "Start," slowly move shift lever toward "Neutral" until engine cranks and starts. Without moving shift lever after engine starts, accelerate to determine whether transmission is in gear. If switch properly adjusted transmission will not be in gear and car will not move.

Throttle Control Linkage (Series 88—2-barrel Carburetors): Apply hand brake firmly, warm up engine so that it idles at hot or slow idle speed.

1) With engine warm, disconnect upper throttle rod from bellcrank on engine (*CAUTION*—do not disconnect intermediate throttle rod to which upper throttle rod is connected at the bellcrank). Adjust engine idle speed to 400 RPM. with selector lever in "Dr" range, then turn off engine.

2) After setting idle speed, adjust length of intermediate throttle rod (free clevis from bellcrank on engine, turn rod in or out of clevis) until clearance between rear face of lever to which rod is connected

OLDSMOBILE LINKAGE (4-BARREL CARB.)

and depression in dash is 5/16-3/8", tighten clevis locknut and connect the rod.

3) Disconnect throttle return spring from bellcrank on dash, open carburetor throttle valves to wide open position, adjust clevis at bellcrank end of accelerator pedal linkage so that clearance between lower face of boss on underside of pedal and top of floor mat is ¼", tighten clevis locknut and connect rod (*CAUTION*—open side of clevis must be facing AWAY from engine).

4) Disconnect lower throttle rod from lever on left side of transmission case. Hold carburetor throttle lever in slow idle position against its stop, adjust length of upper throttle rod so that Pin Gauge BT-25 freely enters holes in bellcrank and hole in bracket on engine. Tighten clevis locknut and connect rod at bellcrank). *CAUTION*—open side of clevis must be AWAY from engine.

5) With lower throttle rod disconnected from transmission lever, check position of lever as follows: Install checking tool J-2195 on machined surface on rear face of transmission case with gauging rod extending forward toward lever. Hold throttle lever back against stop. If small end of tool does not enter hole in lever freely in this position, bend lever as required using tool J-2029. Do not connect rod to lever at this point.

6) After adjusting lever position, see that carburetor is in slow idle position (throttle lever against stop), hold transmission lever fully back against its stop, adjust length of the rod by loosening locknut and turning clevis until clevis pin enters hole in lever freely, then shorten rod by one full turn of the clevis, tighten locknut and connect rod.

Throttle Control Linkage (Super 88 & 98—4-barrel Carburetors): Disconnect accelerator pedal from accelerator rod (in front compartment), disconnect lower throttle rod (between bellcrank on engine and transmission case lever) at bellcrank, disconnect intermediate throttle rod at bellcrank on dash. Then proceed as follows:

1) Hold carburetor throttle valves in slow idle position, adjust intermediate throttle rod (turn clevis on rear end of rod) until clearance between rear face of bellcrank and depression in dash is 5/16-3/8" when rod connected. Tighten clevis locknut and connect rod (*CAUTION*—open side of clevis must face AWAY from center of engine).

2) Start engine and allow it to warm up (*CAUTION*—apply hand brake firmly to hold car). Adjust engine idle speed to 400 RPM. with selector lever in "Dr" range, then turn off engine.

3) Hold carburetor throttle valves in slow idle position, check alignment of two holes in bellcrank at rear of engine with hole in bellcrank bracket. If Gauge Pin BT-25 does not enter all three holes freely, adjust as follows: Disconnect upper throttle rod from bellcrank, adjust rod length (turn rod in or out of clevis at forward end) as necessary to line up bellcrank and bracket holes, tighten clevis locknut and connect rod.

4) Connect lower throttle rod to this bellcrank at rear of engine, disconnect lower end of rod from lever on left side of transmission.

5) Check and adjust transmission lever (see step 5 in Series 88 2-barrel carburetor adjustment above).

6) After adjusting lever position, see that carburetor is in slow idle position (throttle lever against

CONTINUED ON NEXT PAGE

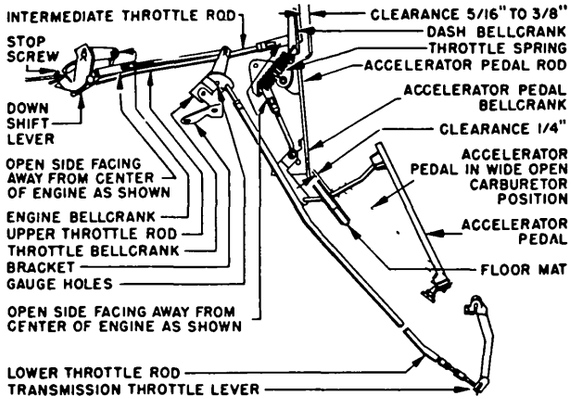
LINKAGE ADJUSTMENT

1952-53 OLDSMOBILE (Cont.)

stop), hold transmission lever fully back against the stop, adjust length of lower throttle rod by loosening locknut and turning clevis on rear end of rod until clevis pin enters hole in lever freely, then **shorten rod by three full turns of the clevis,** tighten locknut and connect rod.

7) Hold carburetor choke valve completely open, move intermediate throttle rod (from bellcrank on dash to bellcrank on engine to rear of carburetor) forward until carburetor throttle valves are in wide open position and throttle linkage has moved transmission lever fully forward and against its stop (through detent positions). Hold linkage in this position and turn stopscrew (on bellcrank just to rear of carburetor) down until it just contacts the downshift lever assembly (to which transmission throttle rod connected). Release linkage, then **back stopscrew off one complete turn** and tighten locknut. This will provide 1/32" clearance between stopscrew and downshift lever with transmission lever against its forward stop.

8) Connect accelerator pedal to accelerator rod inside car. Adjust clevis at upper end of accelerator pedal linkage (at bellcrank on dash) so that clearance between boss on underside of pedal and floor mat is ¼" with carburetor throttle valves in wide open position. *CAUTION*—Open side of clevis at bellcrank end of accelerator pedal linkage must face AWAY from center of engine.



1954-55 OLDSMOBILE

►*1955 TRANSMISSION MANUAL & THROTTLE LEVER PRODUCTION CHANGE:* Beginning with Car Serial No R55-76159 stamped on levers replace the former forged type The later throttle lever is not interchangeable with the forged type on earlier cars. The later stamped manual lever can be used for service replacement on 1954-55 models. Throttle Lever Bending Tool must be reworked for use with the stamped levers. See below.

►*THROTTLE LEVER BENDING TOOL J-2029 REWORK (For use with early & late type levers):* Grind a flat surface (⅛" deep) on left hand pivot pin adjacent to opposite pin (left hand pin is directly above movable lever of tool) The flat surface should be parallel to tool handle

Manual Control Linkage (All Models): Loosen jam nut on shift rod clevis and neutral safety switch Remove clevis pin from shift rod Move manual control lever at side of transmission all the way forward into "N" position Then raise and hold shift lever beyond "N" position against side of opening in jacket Adjust shift rod clevis so that end of clevis contacts outside diameter of bushing in lower shift lever Return lower shift lever to "N" position, insert clevis pin through clevis and bushing, assemble cotter pin to clevis pin

Neutral Safety Switch Adjustment: Set transmission in "N" detent With switch assembled to steering column and link connected to shift lever, insert .090" pin through switch lever and bracket Tighten mounting bolt and withdraw .090" pin Check setting by applying hand brake firmly, placing shift lever in "DR" position, and turning ignition switch to "Start" While holding switch on "Start," slowly move shift lever toward "N" until engine cranks

OLDSMOBILE LINKAGE (TYPICAL)

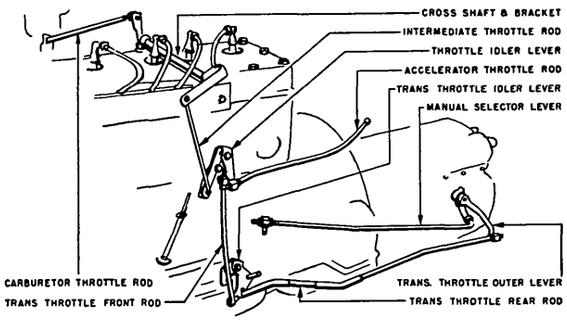
and starts Without moving shift lever after engine starts, accelerate to determine whether transmission is in gear If switch properly adjusted transmission will not be in gear and car will not move

Throttle Control Linkage (All Series with 2-Barrel & 4-Barrel Carburetors): 1) Remove throttle rod from transmission throttle lever and move throttle lever to the rear against its stop, and with Throttle Lever Gauge J-5605 placed flat against rear face of transmission case, rod on gauge should just enter hole in throttle lever The distance from rear face of transmission case to hole in throttle lever should be 6¾". Adjust by bending lever with tool J-2029 Attach throttle rod to transmission lever

2) Apply hand brake and allow engine to warm up. Place throttle lever in "Dr" position and adjust engine idle speed to 400 RPM Turn off engine Disconnect upper throttle rod from engine bellcrank Check clearance between end of intermediate throttle rod assembly and dash This distance should be 5/16" to 3/8" with carburetor on slow idle Adjust intermediate throttle rod assembly as necessary to obtain the specified clearance (NOTE—On 4-Barrel carburetors, open side of rod end should face away from center of engine, and toward center of engine on 2-Barrel carburetors)

3) Loosen jam nut and remove pin from lower throttle rod at throttle bellcrank, and with bellcrank against stop and intermediate throttle rod against its stop, the clevis pin should enter holes in clevis of lower throttle rod and hole in throttle bellcrank freely Adjust clevis on end of lower throttle rod so pin enters hole freely *CAUTION—Do not shorten or lengthen rod after this setting is obtained.*

4) With upper throttle rod assembly held rearward with light pressure to remove lash, the clevis pin should just touch gauge point on throttle bellcrank (gauge point is a curved projection above clevis pin hole in bellcrank) Adjust by rotating clevis so clevis pin just touches, or is within ½ turn short of gauge point Replace clevis pin and tighten jam nut



5) Hold choke completely open and move upper throttle rod assembly forward until throttle is wide open Continue pushing upper throttle rod until transmission throttle lever just stops at its forward position (Repeat this procedure several times until the exact forward position is distinctly felt) Do not force linkage beyond this point With linkage in this position there should be zero clearance between throttle bellcrank stopscrew and downshift lever With linkage held forward as outlined, loosen locknut on setscrew and adjust setscrew until it just contacts the downshift lever Release lever and tighten jam nut

6) Place a wood block 3⅞" long on top center of floor mat retainer and bring bottom of accelerator pedal down to rest on block With carburetor in slow idle position (choke completely off) pedal should just touch gauge block If necessary adjust accelerator position by disconnecting accelerator pedal rod from accelerator bellcrank on dash, and adjust accelerator pedal rod so that clevis just slides over pin with wood block in position and carburetor on slow idle Reassemble rod, making sure open side of rod end is facing away from center of engine Remove wood gauge block

1952-54 PONTIAC

LINKAGE ADJUSTMENT: ***Adjust exactly as follows:***
Throttle Control Linkage:

(1) Carburetor Throttle Rod—Disconnect throttle rod at throttle lever (outer lever) on left side of transmission case. Check and adjust engine idle speed to 365-385 RPM hot or slow idle with engine at 150-160°F., transmission warm, and selector lever in Neutral "N". Install adjusting pin through holes in carburetor intermediate lever on left side of cylinder head and lever bracket. Adjust nuts at trunnion on carburetor throttle rod (back off one nut, tighten opposite nut) until adjusting pin is free with carburetor throttle lever stopscrew against its stop. Tighten trunnion nuts but **do not remove adjusting pin.**

1952-54 TYPICAL PONTIAC HYDRA-MATIC LINKAGE

(2) Transmission Throttle Front Rod—Check adjustment by inserting second J-2544 adjusting pin through holes in idler lever (left side of crankcase **below** starter) and lever bracket. If pin does not enter both holes freely, adjust length of transmission throttle front rod at trunnion on upper end of this rod (back off one nut, tighten opposite nut), then tighten both nuts securely, remove both adjusting pins (intermediate lever and idler lever).

(3) Accelerator Pedal Rod—Loosen front locknut on pedal rod at throttle control idler lever on left side of engine, depress accelerator pedal until carburetor throttle is just wide open, check clearance between lower face of accelerator pedal and floor mat. If clearance not ¼" at closest point, adjust pedal by

CONTINUED N NEXT PAGE

LINKAGE ADJUSTMENT

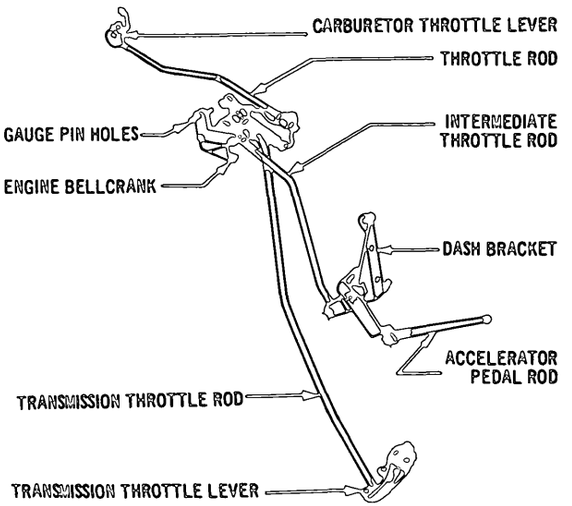
1952-54 PONTIAC (Cont.)

turning rear nut at trunnion on forward end of rod in or out as required, then tighten front nut securely.

(4) Transmission Throttle Lever Position—With rear rod disconnected at transmission case throttle lever, check tightness of lever clamp bolt (12-15 ft. lbs. torque), check lever position by installing Checking Gauge J-2545 flat against machined rear face of transmission case with edge of gauge against side cover flange. Install trunnion pin in lever, hold lever in extreme rear position, move gauge upward, align gauge with trunnion pin. Inside face of throttle control lever should just touch outer side face of gauge and pin in lever should enter slot in gauge freely. Adjust by bending lever with tool J-2807.

Manual Control Linkage: *CAUTION.* If gearshift control shaft upper bracket is found to be loose, tighten the clampscrew while holding selector lever firmly against the stop between the right hand "Dr" position and "Lo".

Manual Control Linkage Adjustment—Place the selector lever in right hand "Dr" position against the stop which prevents accidental shift to "Lo". Back off both control rod trunnion lock nuts at lever on steering column. See that the transmission outer shift lever is in the three-speed drive position (third position from front or rear). Turn lower trunnion nut against trunnion (finger tight) to remove clearance in linkage. Then lengthen rod by turning rear trunnion one full turn. Tighten upper locknut securely.



Neutralizer Switch Adjustment: Place selector lever in four speed range (left arrow) position. Loosen switch bracket clampscrew (on steering column at lower end of selector shaft), shift switch and bracket (screw hole is slotted) until starter does not operate when starter button depressed. Move selector lever to (N) neutral position. Check to see that switch does not touch stop on switch bracket, and that starter operates when starter button depressed. Tighten bracket clampscrew.

1955 PONTIAC

Manual Control Linkage: Place selector lever in "D" (right) position against stop which prevents accidental shift into low range. Loosen both front and rear trunnion locknuts and remove trunnion from transmission outer shift lever. Make sure that transmission outer shift lever is in "D" (right), which is second detent from front. Install trunnion (with locknuts loose) in outer shift lever, tighten front locknut against trunnion finger tight to remove clearance in linkage, tighten front locknut one complete turn to lengthen rod. Tighten rear locknut.

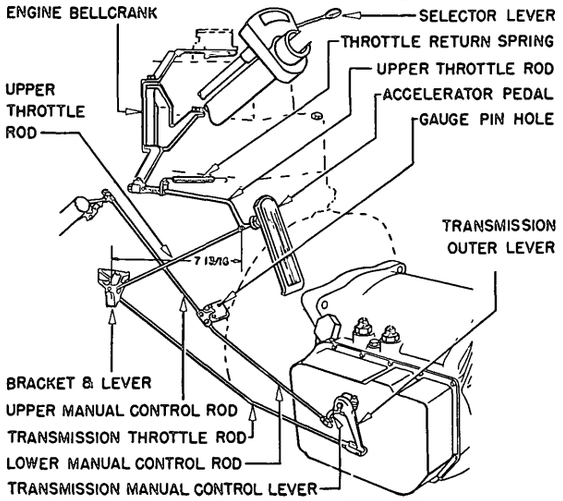
Neutral Safety Switch Adjustment: Place selector lever in "D" (left) position. Loosen switch mounting screw and adjust switch bracket to a position where starter will not operate when ignition key is turned to the start position. Place manual control lever in "N" position. Make certain that switch arm does not touch stop on switch bracket. Tighten mounting screw.

▷*PONTIAC THROTTLE LINKAGE PRODUCTION CHANGE:* The transmission throttle rod is now installed in lower hole of transmission throttle lever. When installing rod in lower hole on early cars it

1955 PONTIAC V8 HYDRA-MATIC LINKAGE

is very important that rod not touch left rear engine mount during any part of its travel.

Throttle Linkage Adjustment: With engine at normal operating temperature idle speed set at 390-410 RPM, and with selector lever in "N" position, install linkage adjustment pin J-2544 through holes in lever and bracket at rear of engine left block. Pin should fit free in holes without lever movement. If free fit not obtained, adjust trunnion nuts on carburetor throttle rod until pin is free, then lock nuts securely. Leave gauge pin in hole. Loosen trunnion nuts on transmission throttle control rod and push rod downward until control outer lever is felt to touch end of its travel (top nut must not be touching trunnion). Shorten throttle control rod two full turns by loosening lower nut two turns and tightening upper nut two full turns. Remove gauge pin. With carburetor throttle at full open position accelerator pedal should be at least ¼" from floor mat. If not, adjust as necessary at intermediate control rod trunnion.



1953-55 WILLYS

LINKAGE ADJUSTMENT: Before making adjustments, block rear wheels and set hand brake. Adjust idle speed to 575 RPM with engine and transmission at normal operating temperature, and with selector lever in "N" (Neutral).

Throttle Linkage: 1) Adjust upper throttle rod (rod from accelerator pedal to engine bell crank) so that when accelerator pedal fully depressed, carburetor throttle valve is in wide open position, and when accelerator is fully released, throttle valve is fully closed and engine is idling at 575 RPM. Adjustment is made at trunnion adjusting block at engine bell crank.

2) Adjust lower throttle rod (rod from accelerator pedal to bracket and lever on lower side of engine) at the trunnion so that the distance from hole in upper throttle rod (where lower throttle rod connects) to center of trunnion on lower throttle rod measures 7 13/16".

3) Disconnect transmission throttle rod (rod connecting throttle lever on transmission to bracket and lever on lower side of engine) clevis at transmission throttle lever. Insert clevis pin in hole in transmission lever and then place lever against rear stop. Place Tool No. 146 against machined surface on rear of transmission case. Clevis should fit freely in second notch of tool. If necessary use Bending Tool No. 1194 to bend lever to fit freely in this notch. (NOTE—If Tool No. 146 is not available, distance from center of clevis pin to machined surface on rear of case, with lever against rear stop, should be 3 9/16" to 3-⅝"). Adjust clevis on transmission throttle rod so clevis pin freely enters hole in transmission lever and holes in clevis, then shorten rod by two full turns of clevis, and attach clevis to lever. Check shift points by road testing

1953-55 WILLYS HYDRA-MATIC LINKAGE

Manual Control Linkage: 1) Place selector lever in "Dr. 3" position. Place a .184" diameter (min.) pin, or use a No. 14 drill, through hole in idler bell crank lever and bracket mounted on toe board panel (if hole is too small or constricted for the pin or drill, grind a pin to size making sure it is a snug fit). Adjust upper control rod (rod connected between bell crank and steering column lever), so that arrow on selector indicator is exactly under the "Dr. 3" mark on indicator quadrant. Make sure all play is eliminated, then tighten nut.

2) Loosen trunnion nuts on lower transmission control rod (rod between bell crank and transmission lever). Place transmission lever in "Dr. 3" position (this is the second detent forward from the rear stop, or the second detent backward from the front stop). Adjust lower rod so that all free play is eliminated, then shorten rod by one complete turn of the front trunnion nut. Lock trunnion by tightening both trunnion nuts, and remove aligning pin from idler bracket.

Neutral Safety Switch Adjustment: Place selector lever in "Dr. 4" position. Turn on starter switch, and if starter operates, loosen switch attaching screws on steering column and turn switch clockwise (facing toward rear of car) until starter no longer operates in "Dr. 4" position. Retighten switch on steering column.

Back-up Light Switch: Part of neutral safety switch, and no additional adjustment required.

DUAL-RANGE HYDRA-MATIC TROUBLE SHOOTING

►*NOTE—Most Hydra-Matic troubles can be corrected by external adjustments and correct oil level. See following table for trouble and possibe causes. See also "HYDRA-MATIC OVERHAUL."*

LIGHT THROTTLE SHIFT POINTS HIGH: (With Full Throttle Shift point normal)—Throttle linkage adjusted incorrectly. Adjust throttle linkage and check for worn or loose control rods.

FULL THROTTLE SHIFT POINTS: (Either too high or too low or do not occur)—Governor valves not operating properly, leakage at governor assembly, broken oil rings. Governor ring lands might be worn. Correct by freeing valves, check for warped surfaces. Replace parts as necessary.

NO THROTTLE DOWNSHIFT IN "Dr" RANGE: (From 4th to 3rd above 20 M.P.H.)—Insufficient accelerator travel due to interference of throttle linkage or at floor carpet. Throttle controls improperly adjusted or lever bent or loose on shaft. Spring lock in downshift valve may be missing.

TRANSMISSION DOES NOT RESPOND TO SHIFT LEVER POSITION: Pin which picks up manual valve in valve body is not operating in groove in manual valve. To check, shift selector lever into reverse. If severe clashing results or if lever goes into reverse but car locks up and fails to move backwards, pickup pin is not operating manual valve. Remove side cover and engage pin.

TRANSMISSION FAILS TO DRIVE CAR: Usually caused by failure of one or both bands to be applied. Check for low oil pressure. Front or rear band adjustment incorrect. Manual valve mispositioned, or torus check valve sticking. Front oil pump inoperative. See Oil Pressure Tests.

NO 3RD. OR 4TH. SPEED DRIVE (Drive normally in 1st. & 2nd. Speed): Rear clutch not applying due to: Leakage in line to clutch or in valve body, hole in transmission case to oil delivery sleeve or sleeve passage clogged, oil delivery sleeve incorrectly installed or oil rings broken, clutch oil seal leaking or clutch piston sticking.

SLIPS IN 1ST. 3RD, & REVERSE (Operation normal in 2nd. & 4th. Speed): Front band slipping due to: Leakage in valve body, passages in case, or in servo. Servo pistons sticking. Band incorrectly adjusted. Valves in valve body sticking. Throttle linkage incorrectly adjusted or not operating correctly.

SLIPS IN 1ST. OR 2ND. SPEED (Operation normal in 3rd. 4th., & Reverse): Rear band slipping due to: Leakage in valve body, passages in case, or in servo. Servo piston sticking. Band incorrectly adjusted. Valves in valve body sticking. Throttle linkage incorrectly adjusted or not operating correctly.

SLIPS IN "LO" RANGE (Operation normal in Reverse): Rear band slipping or not operating (see causes in 1st. & 2nd. Speed Slip above).

SLIPS OR CHATTERS ON 3-2 DOWNSHIFT: Rear band slipping or not operating (see causes in 1st. & 2nd. Speed Slip above). Rear servo operation incorrect due to: weak or broken servo springs or accumulator check valve stuck closed. Insufficient compensator pressure due to: Throttle linkage operating incorrectly or compensator valve stuck.

THROTTLE DOWNSHIFT FROM 3RD. SPEED DELAYED OR REQUIRES EXCESSIVE THROTTLE OPENING (May not occur until car stopped, usually occurs when transmission cold): Governor or valves in valve body sticking.

CLOSED THROTTLE 3-2 DOWNSHIFT OCCURS AT EXCESSIVELY HIGH SPEED (with severe "clunk"): Rear servo check valve not operatng correctly, accumulator piston rings stuck or broken, valves in valve body sticking, rear clutch piston binding on its pilot, governor operation incorrect, governor oil seal rings broken, or oil leak at governor assembly.

LIGHT THROTTLE DOWNSHIFT TO 3RD. SPEED OCCURS ABOVE 20 MPH. IN DRIVE RANGE (Or transmission "hunts" between 4th. & 3rd. Speeds): Throttle linkage adjustment incorrect or valves in valve body sticking.

UPSHIFTS ERRATIC OR MISSING (Starts in 3rd. or 4th. Speed in "Dr" Range, Starts in 2nd. Speed in "Lo" Range, May shift to 3rd. Speed in "Lo" Range or miss 3rd. Speed in "Dr" Range, May operate only in 2nd. Speed or only in 3rd. & 4th. Speeds in "Dr" Range): Governor valves sticking or valves in valve body sticking.

NO 4TH. SPEED UPSHIFT (2nd. & 3rd. Speed Upshifts normal): Governor valves sticking or valves in valve body sticking.

LIGHT THROTTLE UPSHIFT SPEEDS EXCESSIVELY HIGH (with violent band application when shifting from "N" to "Dr" when car standing): Governor valves sticking or valves in valve body sticking.

TRANSMISSION JUMPS OUT OF REVERSE: Manual control linkage rod adjusted too short.

SHIFT OUT OF REVERSE DIFFICULT: Inside manual cam lever surface rough or detent plunger rough.

ERRATIC RESPONSE TO SHIFT LEVER: Inner manual control valve lever loose on shaft. Replace lever assembly.

HUNTING: Adjust throttle linkage, check valve assembly and clean thoroughly and reface.

ALL SHIFTS ROUGH: Adjust throttle linkage and servo bands. Clean and reface valve assembly. Check transmission passages for leaks. Check oil pressure.

CREEPS FORWARD WHEN IN "R" POSITION: Rear unit not operating correctly. Excessive drag in rear clutch.

NO DRIVE WHEN ENGINE IS FIRST STARTED: Check fluid coupling and front pump. Test oil pressure.

CREEPS EXCESSIVELY IN "Dr": Engine idle speed too high.

CAR WILL NOT BACK UP: (Unless throttle is opened excessively)—Rear band not released due to low oil pressure caused by leakage or compensator valve auxiliary plug pin missing.

BANDS APPLIED VIOLENTLY, ENGINE SPEEDS UP: Low oil pressure or level. Pressure regulating valve sticking. Front pump may not be operating properly or there is a bad oil leak in the system. Check oil pressure and oil level. Free up pressure regulator valve or install new valve.

NO DRIVE IN REVERSE: This condition will occur if front servo exhaust body spacer is installed in reverse. Under this condition oil pressure does not increase when selector lever is placed in Reverse position. Pressure will increase to 150-170 lbs. when transmission shifts from 1 to 2.

SLIPPING IN REVERSE ONLY: Check for Low Oil Pressure in Reverse, Inoperative Front Servo Exhaust Valve, Key missing or defective in stationary cone, Stationary Cone or Cone Clutch Piston worn excessively, Front Servo & Band operation not operating properly, Valve Body Assembly dirty (sticking valves or oil leaks), Stationary cone distorted by handling when disassembled.

SELECTOR LEVER WILL NOT GO INTO REVERSE: Check for: Governor G-1 weight stuck wide open or broken governor ring (separating main line pressure from G-1 pressure to reverse blocker piston), Governor ring groove or gap clearances incorrect, Governor sleeve defective, Parking Pawl Crank bent, Detent Plunger in inner control lever stuck, Reverse Blocker Piston sticking or piston spring weak or broken.

EXCESSIVE SQUAWK IN REVERSE (May occur when selector lever out of Reverse if reverse unit not fully disengaged): Check for low oil pressure and galling of stationary cone and cone clutch piston. If reverse not fully disengaged also check for: Check Valve in detent plunger retainer in valve body plugged, Reverse Clutch Spring inoperative or weak, High spot or galling of stationary cone and cone clutch piston, cone clutch piston release springs defective or weak, Rear Bearing Dowels too high.

LOW OIL PRESSURE, SLIPPAGE, DELAYED AND ERRATIC UPSHIFTS: These conditions will exist when one or the other of the two ¼" cup shaped plugs are missing from the parking bracket. (CAUTION—These plugs are not service parts and should never be removed). If plugs are loose or missing, replace assembly.

REVERSE CONE ENGAGES WHEN IN DRIVE: This condition can occur when there is excessive leakage into the reverse apply circuit. Check for leakage as follows:

1) Check front servo exhaust valve for proper fit in exhaust body. Clearance should be .002".

2) Inspect detent retainer spacer and valve body surfaces that contact spacer. Replace control valve if necessary.

3) Check Throttle Valve plug in Pressure Regulator for excessive clearance. If greater than .002" replace Regulator plug assembly.

4) Neoprene seal on Pressure Regulator Plug defective. Use extreme caution when installing plug not to damage seal (remove all sharp corners or burrs in transmission case with round hone, place small amount of grease on seal before installing assembly, DO NOT use wrench to start pressure regulator plug in housing).

①—Based on 3.07-1 Axle Ratio.
②—Occurs at very high car speeds only (75 MPH.).
③—Dependent on Throttle position.
④—5-22 MPH. with throttle in Detent Position.
⑤—Downshifts 4-2, 20-15 MPH. 3-1, 11-8 MPH.
⑥—3-1 Downshift, 11-8 MPH.
⑦—Downshifts 4-2, 20-10 MPH. 3-1, 10-7 MPH.
⑧—3-1 Downshift, 10-7 MPH.
⑩—In "Dr. 4" position only.
⑪—Downshifts 4-2, 18-12 MPH. 3-1, 9-7 MPH.
⑫—3-1 Downshift, 9-7 MPH.
⑬—Correct for 15x6.70 Tires & 3.31-1 Axle Ratio.
⑭—For cars with 3.07-1 Axle Ratio.
⑮—Starts in Second Speed. Possible to start in First Speed by depressing throttle fully to floor.
⑯—2-4 Upshift (42 MPH).
⑰—4-2 Downshift (42 MPH).
⑱—31-36 (J-53 Trans.).
⑲—79-85 (J-53 Trans.).
⑳—21-18 (J-53 Trans.).
㉑—10-7 (J-53 Trans.).
㉒—12-18 (J-53 Trans.).

㉔—Upshifts 2-4 (34 MPH).
㉕—Downshifts 4-2 (33 MPH).
㉖—Upshifts 2-4 (30 MPH).
㉗—Downshifts 4-2 (29 MPH).

DUAL-RANGE HYDRA-MATIC BAND ADJUSTMENT

►*1953 CADILLAC REAR BAND SLIPPAGE CORRECTION: See "Overhaul" following.*

►*BAND ADJUSTMENT NOTE:* Internal Band Adjustments must be made on the following models: 1954-55 Cadillac; 1953-55 Oldsmobile; 1955 Pontiac. External Adjustments may be made on all other models.

►*1953 BAND ADJUSTMENT SPECIFICATION PRODUCTION CHANGE:* Front band adjustment specifications have been changed from 6.5 tight to 7.7 turns tight. *This change applies to all previous models except Oldsmobile.*

EXTERNAL ADJUSTMENT

►*ADJUSTING TOOL NOTE: DO NOT make an external adjustment if Adjusting Tool J-2681, J-2861-A or Kaiser-Frazer Tool No. KF-96, and an accurate tachometer are not available.*

1) Block front wheels securely and set hand brake firmly to prevent car moving while adjusting.

2) Remove front floor mat and adjusting hole cover over adjusting screws on left side of transmission.

3) Run engine until temperature is normal and engine idles at hot or slow idle speed of 375-400 RPM.

4) Connect and adjust tachometer for accurate recording of engine speed.

5) Place selector lever in "Dr" position ("Dr. 4"). except 1952 Oldsmobile (lever in "Lo" position).

6) Adjust carburetor throttle stopscrew so that engine idles at exactly 700 RPM. Then adjust bands:

Front Band (After steps 1 through 6):

7F) Install the adjusting tool on front band adjusting screw, loosen adjusting screw locknut (turn long handle while holding short handle stationary).

8F) Loosen band adjusting screw (turn short handle) until engine speed increases to 900-1000 RPM., (800-900 Hudson. This makes it unnecessary to back adjusting screw all the way out).

►*NOTE*—If no increase in engine speed noted when adjusting screw loosened, band has probably been slipping in service. Remove oil pan and inspect band and drum. With pan off, adjust bands as directed in ADJUSTMENT—WITH PAN OFF below and disregard following steps.

9F) Tighten band adjusting screw slowly until engine speed drops to 700 RPM., loosen adjusting screw until engine speed increases, then tighten adjusting screw until engine speed again drops to exactly 700 RPM., watch tachometer for 30 seconds to note any increase in engine speed. If increase noted, tighten adjusting screw 1/10 turn. Repeat this procedure until engine speed remains at 700 RPM. for at least 30 seconds.

10F) Set counter on adjusting tool to "OO". Hold locknut stationary and tighten adjusting screw exactly 7.7 turns (6.5 turns Chev. Truck). Hold adjusting screw from turning and tighten locknut.

Rear Band (After steps 1 through 6):

7R) Install the adjusting tool on rear band adjusting screw, loosen adjusting screw locknut (turn long handle while holding short handle stationary).

8R) Loosen band adjusting screw (turn short handle) until engine speed increases to 900-1000 RPM., (800-900 Hudson. This makes it unnecessary to back adjusting screw all the way out).

NOTE—If no increase in engine speed noted when adjusting screw loosened, band has probably been slipping in service. Remove oil pan and inspect band and drum. With pan off, adjust bands as directed in ADJUSTMENT—WITH PAN OFF below and disregard following steps.

9R) Tighten band adjusting screw slowly until engine speed drops to 700 RPM., loosen adjusting screw until engine speed increases, then tighten adjusting screw until engine speed again drops to exactly 700 RPM., watch tachometer for 30 seconds to note any increase in engine speed. If increase noted, tighten adjusting screw 1/10 turn. Repeat this procedure until engine speed remains at 700 RPM. for at least 30 seconds.

10R) Place selector lever in "N" position.

11R) Set counter on adjusting tool to 00.Hold locknut stationary, tighten band adjusting screw exactly 2 turns until tool counter reads 2.0

12R) Return selector lever to "Dr" position. Hold band adjusting screw from turning, tighten locknut securely.

Idle Speed Adjustment (After Bands Adjusted): *See Car Model pages for settings and procedure.*

INTERNAL ADJUSTMENT

►*ADJUSTING TOOL NOTE:* DO NOT make an internal adjustment if Front Servo Adjusting Gauges J-1693, J-1693A or Kaiser-Frazer Tool KF-92; Rear Band Adjusting Tool J-1460-A, J-5071 or Kaiser-Frazer Tool KF-77 is not available.

Front Band Adjustment (With Gauge J-1693, J-1693-A or KF-92):

1) Loosen locknut and back off front band adjusting screw approximately 5 turns. Make certain that band is centered on drum.

2) Remove pipe plug from bottom of front servo.

3) Loosen hexagonal headed adjusting screw on gauge by hand until approximately ⅛" of adjusting screw threads are exposed above gauge body. Screw gauge into pipe plug hole in front servo by hand.

4) Tighten hexagonal adjusting screw on gauge by hand until gauge stem is felt to just touch piston in servo, then continue to tighten adjusting screw with a wrench exactly five full turns from point where stem first contacted piston.

5) Tighten front band adjusting screw until knurled washer on gauge (at upper end of hexagonal adjusting screw) is just free to turn. Hold band adjusting screw from turning and securely tighten adjusting screw locknut.

6) Loosen gauge adjusting screw at least six turns, remove gauge from servo. Install pipe plug in servo and tighten securely.

Rear Band Adjustment (With Gauge J-5071, J-1470-A or KF-77):

1) Place the gauge on the finished surface of the Accumulator body with leg of gauge resting on rear servo stem.

2) Loosen locknut and back off rear band adjusting screw until face of actuating lever (which contacts servo stem) is well away from the face of the gauge.

3) Tighten band adjusting screw until face of band actuating lever just contacts gauge.

►*CAUTION—If adjusting screw turned too far when making this adjustment, back screw off SEVERAL TURNS and repeat adjustment.*

4) Hold band adjusting screw from turning and tighten adjusting screw locknut securely. Remove gauge.

DUAL-RANGE HYDRA-MATIC TESTING

►*"DUAL-RANGE" HYDRA-MATIC TESTING NOTE:* These transmissions have MODULATED PRESSURE and HYDRAULIC REVERSE and following test procedure will apply to all transmissions:

ROAD TEST: Operate the car over a test route and note performance and shift speeds. Select a test route that will provide for all types of operation: Hilly section to check full-throttle upshifts, slippage, and throttle downshifts; a level section to check closed throttle upshifts; and a quiet section to check for noise. *See Hydra-Matic Shift Point table for correct shift speeds.*

STALL TEST: Can be used to check engine and transmission performance. Connect accurate electric tachometer to check engine speed. Start engine and warm up engine and transmission to operating temperature. Apply foot brake firmly and set hand brake tight. Set selector lever in "Dr. 4" position. Depress accelerator pedal to the floor and NOTE ENGINE RPM. If engine speed not within limits shown in table, make further tests as indicated below.

►*CAUTION—Use extreme care in making this test and NEVER HOLD THROTTLE OPEN MORE THAN ONE MINUTE (15-20 seconds preferably). If engine speed exceeds maximum figure shown in table, CLOSE THROTTLE IMMEDIATELY to avoid possible damage to transmission.*

STALL TEST LIMITS

Model	Min. RPM	Max. RPM
1952-55 Cadillac	1700	1900
1954-55 Chevrolet Truck	1400	1600

①—232" Engine. ②—262" Engine.
③—308" Engine.

If engine speed below minimum—Engine requires tune-up, or front unit is locked up.

CONTINUED ON NEXT PAGE

TESTING (Cont.)

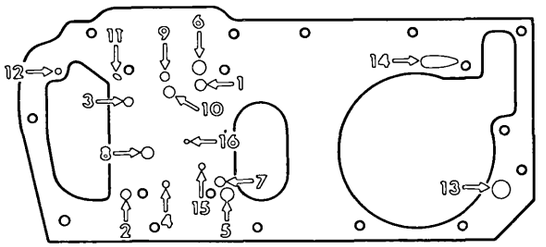
If engine speed above maximum—Bands are slipping, Torus check valve leaking or missing, or torus members damaged. Localize the trouble by making the following tests before adjusting the bands:

Check to determine which band slipping—Repeat the stall test (above) with selector lever in Revere "R" position. If engine speed still excessive, Front Band or Front and Rear Bands are slipping. If engine speed within limits, Rear Band only is slipping. Adjust bands.

Check for Missing or Leaking Torus Check Valve: Set hand brake lever securely, start engine and run at speed of 20 MPH. for approximately 1½ minutes. Reduce engine speed to normal idle speed, check fluid level and make certain that it is at "Full" mark on dipstick. Shut off engine and allow car to stand for 10 minutes. Recheck fluid level without starting engine. If level has not raised more than ½", torus check valve is operating satisfactorily and slipping bands or damaged torus members are indicated.

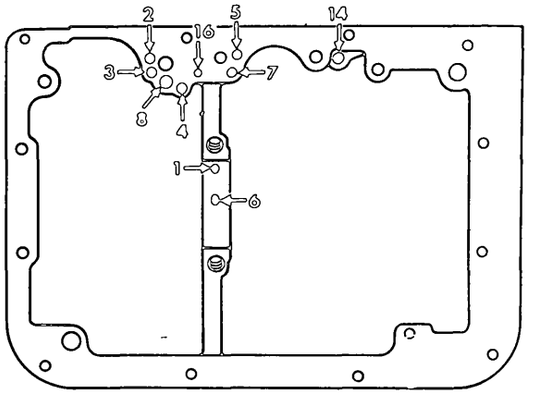
MAIN LINE OIL PRESSURE: *CAUGE CAUTION*—It is recommended that new 300 lb. gauge (J-2540-A) be used for making these pressure checks. Gauge used on previous Hydra-Matic transmissions (J-2540—160 lb. gauge) will not handle oil pressures under all conditions on these transmissions.

Checking Main Line Oil Pressure—Connect gauge at main oil line plug hole on top of case between band adjusting screws (accessible by lifting floor mat and removing metal plate over band adjusting screw hole). Make the following tests on the road (or with car up on jacks so that engine can be run to simulate road performance) after engine has been run sufficiently so that engine and transmission at operating temperature:



Idling Oil Pressure—With engine running at normal idling speed, note gauge pressure with selector lever in each position. In general, pressure should be equal in N, Dr. 4, Dr. 3, and Lo (10 lbs. maximum variation), and higher in R (reverse). *See table for specified pressures.*

Zero Throttle Pressure—With selector lever in "Dr. 4" position operate car at speed higher than 30 MPH *(See Chevrolet Truck Note below)*, close throttle and note gauge reading just as car speed drops to 30 MPH. *See Pressure Table.*



Full Throttle Pressure—With selector lever in "Dr. 4" position operate car at approximately 25 MPH (17 MPH on Chev. Truck), depress accelerator pedal to point where resistance of detent is felt but DO NOT go through detent (4-3 forced downshift), note gauge reading just as car speed reaches 30 MPH (19-22 MPH on Chev. Truck). *See Pressure Table for Specified pressures.*

SHOP TEST NOTE—If above test being made in the shop (with car on stands), this full throttle position of the control valve can be secured by disconnecting throttle control rod at lever on side of transmission case and moving the lever to the full throttle position (DO NOT move lever through detent), then note gauge reading.

Reverse Pressure—With car standing, place selector lever in Reverse "R", apply foot brake firmly to hold car stationary, accelerate engine to half-throttle position, note gauge reading. *See table for specified pressures.*

PRESSURE TEST POINTS
(SIDE OF TRANSMISSION CASE)

PRESSURE TEST POINTS
(BOTTOM OF TRANSMISSION CASE)

1952-54 Main Line Oil Pressures
(Pounds Per Square Inch)

Car	Idl'g	Zero Thtl.	Full Thtl.	Rev.
Cadillac		64-72	84-105	145-210
Hudson	40-68	60-68	85-93	125 Min.
Kaiser	55 Min.	55-72	80-95	125 Min.
Lincoln	50 Min.	64-72①	90-98③	145-185④
Nash	45-72②	45-72	75-105	125 Min.
Oldsmobile	50 min.	60 Min.	80 Min.	
Pontiac	50 Min.	65-72	90-98	145-210

①—AT 1200 RPM. ②—At 375 RPM.
③—At 1200 RPM. (below 80 lbs. indicates slipping).
④—At 2000 RPM.

1955 Main Line Oil Pressures
(Pounds Per Square Inch)

Car Model	Idling	Zero Thtl.	Full Thtl.	Rev.
Cadillac		64-72	104-112	145-210
Chev. Truck	50 Min.	60-68	85-93	135 Min.
Hudson	50 Min.①	60 Min.	80 Min.	125 Min.
Kaiser	55 Min.	55-72	80-95	125 Min.
Nash	50 Min.①	60 Min.	80 Min.	125 Min.
Oldsmobile	50 Min.②	60 Min.	85 Min.	150 Min.③
Pontiac	50 Min.	64-72	101-109	145-185
Rambler	50 Min.①	60 Min.	80 Min.	125 Min.

①—60 lbs. maximum in all ranges.
②—Idling at 400 RPM.
③—Idling at 600 RPM.

▷*CHECKING REAR OIL PUMP*—Operation of rear pump alone can be checked by following procedure (Idling test above will check operation of front pump alone, road tests involve front and rear pumps together): Operate car on the road in 4th speed (selector lever in Dr.4) at speed shown in table below, move selector lever to Neutral, turn ignition OFF (this will stop front pump operating so that all pressure will be supplied by rear pump), note gauge reading (see table below). *CAUTION—IF REAR PUMP NOT WORKING (NO PRESSURE) DISCONTINUE TEST IMMEDIATELY.* If low oil pressure indicated when testing both pumps, oil leak in system is indicated. If one pump alone has low oil pressure, trouble in this pump is indicated.

Rear Oil Pump

Car	Operating Speed	Pressure
Cadillac	40-45 MPH	75 lbs. Min.
Hudson	45 MPH	60 lbs. Min.
Kaiser	45 MPH	60 lbs. Min.
Oldsmobile①	30 MPH. Min.	55 lbs. Min.

①—Selector lever in "Dr 3" position.

TESTING HYDRA-MATIC OPERATION WITH AIR PRESSURE: *Following procedure can be used to check operation before disassembling transmission and can also be used after overhaul to insure proper operation before transmission installed in car.* Drain transmission, remove oil pan and screen. Remove side cover, control valve assembly, and reverse oil pipe. Use air line fitted with special air nozzle (Tool J-4353-1 etc.) so that air can be applied to oil passage holes on side of transmission case. Use approximately 80 lbs. air pressure and make tests listed below.

▷*See illustration for location of oil passage holes in transmission case.*

1) Front Clutch. Pressure at this point should actuate front clutch (piston movement will be audible if air applied intermittently, or can be felt if front drum held firmly by hand). *NOTE*—If large amount of air escapes around oil delivery sleeve area, recheck after servos removed to note point of leakage. If oil fog and large amount of air emitted from inside front end of front drum, faulty front clutch seal is indicated. Leakage from any other drilled passages inside case is indication of defective case or oil delivery sleeve.

2) Front Band Apply. Pressure at this point should actuate servo and apply front band. No appreciable air escape should be noted at servo mounting face on case (small amount of leakage at 4-3 valve exhaust hole and also front band release hole is permissible) (front band release hole leakage should only be leakage past ring gap, not blow-by).

3) Front Band Release. Pressure at this point will not actuate servo (piston held in released position by retracting spring) but air escape between servo body and case, or around band release cylinder should only be normal leakage past piston ring gap.

4) Governor Pressure (G1 to 4-3 Valve). Pressure at this point will leak around 4-3 valve retainer wire. No air should be noted between servo body and transmission case or from any other passage (small amount of air from Front Band Apply and Compensator passages).

5) Rear Band Release. Pressure at this point will release rear servo and band with no large escape

CONTINUED ON NEXT PAGE

TESTING (C nt.)

of air (small amount will escape through piston ring gaps but should not impede normal servo operation) and no appreciable amount of air should escape between servo mounting face and transmission case. No air escape should be noted from any other passage hole (except slight amount at Compensator hole—see item 7).

6) Rear Clutch. Pressure at this point should actuate rear clutch (piston movement will be audible if air applied intermittently, or can be felt if rear drum held firmly by hand). *NOTE*—If large amount of air escapes around oil delivery sleeve area, recheck after servos removed to note point of leakage. If oil fog and large amount of air emitted from inside rear drum assembly, faulty rear clutch seal or oil delivery sleeve rear ring is indicated. Leakage of air from any other passage hole on side of case indicates interconnected passages (defective case) or damaged oil delivery sleeve.

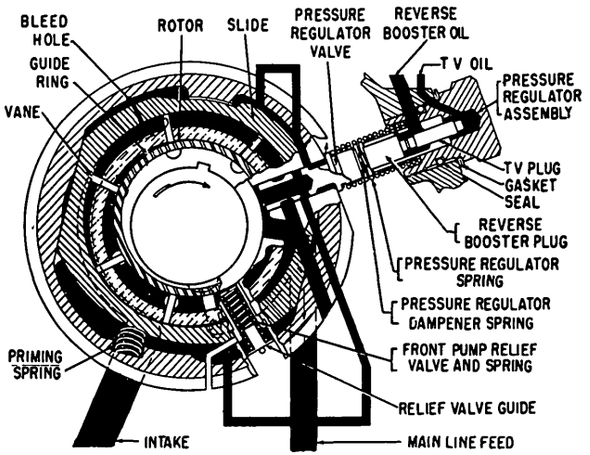
7) Compensator (to Front & Rear Servos). Pressure at this point should actuate rear servo to tighten rear band (band applied by spring) and to actuate front servo to apply band. No appreciable air escape should be noted (other than normal leakage through piston ring gaps) and no air should be noted at any other passage hole on side of case.

8) Main Line (Pump Feed): Pressure at this point should be an open blow-by due to fact that main line exhaust valve is in exhaust position.

9) Pressure Gauge Hole to Top of Case. Pressure at this point should produce NO evidence of air escape if pressure line plug (on top of case between band adjusting screw) is tight.

10) Exhaust (Port for Valve Body). Pressure at this point should blow freely through to inside of case. Make visual inspection of this hole to see that it is completely open for entire length (*CAUTION*—any obstruction of this hole will cause poor shifting).

11) T.V. Pressure to Regulator. Not necessary to check this passage (this is modulating pressure line to T.V. pressure plug in pressure regulator).



12) Reverse Booster to Pressure Regulator. Not necessary to check this passage (this is booster pressure line to reverse booster plug in regulator).

13) Reverse Pressure. Pressure at this point should actuate reverse cone clutch piston (piston movement should be audible if air applied intermittently, or can be felt if reverse internal gear grasped with the hand). If large amount of air escapes around cone clutch piston, outer and inner oil seal leakage in reverse cone assembly is indicated.

14) Governor Feed. Not necessary to check this passage (directs main line pressure to governor).

15) Line Exhaust. Not necessary to check this passage (passage exhausts main line pressure when engine is turned off and car is standing).

16) Low Rang (Manual Low Oil). Not necessary to check this passage (passage directs main line pressure oil to fast dump valve in rear servo).

1952-55 DUAL-RANGE HYDRA-MATIC, FRONT PUMP & PRESSURE REGULATOR

DUAL-RANGE HYDRA-MATIC REMOVAL & INSTALLATION

►***REMOVAL & INSTALLATION NOTE—Procedure on all cars is generally the same, however special points to be observed on each car model are listed under each step***

REMOVAL: Support car or truck securely on four jack stands so wheels are at least 12" off the floor or use a twin-post hoist). On all Nash Models and 1955 Hudson Models, place rear jack stands under rear of car at body sills and support rear axle with a jack.

1) Perform following operations noting special points to be observed on each car model as listed.

1952-55 Cadillac—Disconnect battery and remove starter. Remove slush deflector from lower flywheel housing. On 1952-53 models, remove spark plugs. On models with oil cooler, hoses at cooler must first be disconnected and hose ends plugged. When removing the oil pan, exercise caution when disconnecting the oil pump feed line from cooler valve in the oil pan.

1952-54 Hudson—Disconnect battery, remove starter, remove breather pipe, and remove two upper floor opening covers for access to upper flywheel housing bolts and remove these bolts. From underneath car, remove rear stone guard assembly on left side of engine. Disconnect hand brake cable lever return spring and disconnect cable at pull rod slide link, free cable clip at No. 3 crossmember and pull cable through crossmember toward front of car.

1955 Hudson (Except Rambler)—Disconnect hand brake cable at bellcrank and brake cable housing at bellcrank bracket.

1952-55 Kaiser—Disconnect hand brake cable from bracket on No. 2 crossmember (when removing this crossmember, leave engine support cushions attached to crossmember).

1952-54 Nash (Statesman with 12" Torus, and Ambassador)—Disconnect hand brake cable at bellcrank bracket, remove brake hose bracket from floor pan.

1952-54 Nash (Statesman & Rambler with 11" Torus)—Disconnect throttle rod at bellcrank. Disconnect hand brake from bracket below voltage regulator. Turn bracket toward front of car and position hand brake cable below steering gear housing. Remove distributor cap and oil filler dipstick.

1955 Nash (Except Rambler)—Disconnect hand brake cable at bellcrank and brake cable housing at bellcrank bracket.

1952-53 Oldsmobile—Disconnect side pan at rear and drop pan down (for access to starter), disconnect starter wiring and remove starter. Remove exhaust pipe bracket and crankcase ventilator bracket from flywheel housing.

1954-55 Oldsmobile—Disconnect starter cable assembly from junction block, then disconnect purple lead from safety switch, and black lead from main wiring harness. Free starter cable assembly from clip on fender.

1952-54 Pontiac—Remove accelerator pedal and front compartment mat, remove two upper hole covers in floor for access to upper flywheel housing bolts. Remove crankcase ventilator outlet pipe and loosen exhaust pipe bracket to aid removal of flywheel housing bottom cover. Disconnect hand brake cables at cross lever and remove cross lever. On cars with underseat heater, drain radiator and block, then remove clamp in X-member holding heater-to-radiator rear tube and defroster-to-heater tube, remove heater-to-radiator tube.

1955 Rambler—Support rear of body at side sills. Disconnect rear shock absorbers at rear axle tube and hand brake at yoke.

2) Drain transmission case by removing drain plug at rear end of transmission oil pan.

3) Remove flywheel housing lower cover or pan, drain torus by removing pipe plug from torus cover.

4) Disconnect speedometer cable at transmission.

5) On all transmissions with under-hood transmission filler tubes, disconnect tube at oil pan and remove tube.

6) Disconnect propeller shaft at rear universal and free shaft from transmission. Note following:

1952-54 Hudson—Disconnect propeller shaft at rear universal companion flange and at front universal, take out center bolt attaching center bearing housing to center bearing support. Slide propeller shaft to rear to allow clearance for transmission removal.

1955 Hudson (Except Rambler)—Disconnect torque tube from rear bearing retainer, then move rear axle and torque tube assembly to rear and separate by sliding the universal joint to rear off transmission output shaft.

1952-54 Nash (Statesman with 12" Torus, and Ambassador—Disconnect torque tube from rear bearing retainer on transmission, slide universal joint to rear off splines of transmission output shaft.

1952-54 Nash (Statesman & Rambler with 11"

CONTINUED N NEXT PA E

DUAL-RANGE HYDRA-MATIC REMOVAL & INSTALLATION (Continued)

Torus)—Disconnect torque tube at rear of transmission; then remove rear spring clamps from rear axle. Lower rear axle far enough to withdraw front universal joint from transmission output shaft.

1955 Nash (Except Rambler)—Disconnect torque tube from rear bearing retainer, then move rear axle and torque tube assembly to the rear and separate by sliding the universal joint to rear off transmission output shaft.

1955 Pontiac—Loosen exhaust pipe at cross over pipe flange.

1955 Rambler—Remove rear spring from front bracket attaching nuts and lower rear axle assembly, thus lowering the rear spring front brackets from floor pan. Slide rear axle and propeller shaft assembly to the rear, sliding universal joint from output shaft.

7) Disconnect throttle rod and manual control rods from levers on side of transmission case, remove throttle control lever (outer) from shaft to avoid damaging lever during transmission removal.

8) Install special engine Rear Support Bar (see note below) or support the engine with a hydraulic jack placed under the rear end of the oil pan.

▷*CAUTION—Use wooden block on jack to avoid damage to oil pan.*

Rear Support Bar Note—This tool consists of some type of cross-bar with end fittings that engage the frame side rails so that the rear end of the engine is supported by the frame. Tool is furnished under following part numbers: J-3068 (Cadillac), J-4651 (Hudson), KF-104 (Kaiser), BT-28 with Adaptors BT-42 (Oldsmobile).

9) Use transmission lift (Tool J-2808 and hydraulic jack, etc.) to lift transmission just enough to remove engine weight from rear supports.

10) Remove rear engine support cross-member:

1952-55 Cadillac—Disconnect engine rear support at extension housing, remove crossmember bracket on which support is mounted.

1952-54 Hudson—Remove engine rear support bolts attaching rear insulators to No. 3 crossmember, remove mounting screws at each end of crossmember.

1955 Hudson (Except Rambler)—Remove rear engine support crossmember, cushion, and bracket.

1952-55 Kaiser—Remove the No. 2 (engine support) crossmember leaving engine support cushions attached to crossmember.

1952-55 Nash & Rambler—Remove the rear engine support crossmember, cushion, and bracket.

1952-55 Oldsmobile—Disconnect engine mounts from crossmember and remove crossmember.

1952-55 Pontiac—Disconnect both rear engine mountings and reinforcing plates from crossmember, take out all crossmember-to-frame side rail bolts, tap both ends down until right end rests on exhaust pipe, then tap left end down until it clears frame side rail, slide crossmember out.

10) Make certain that torus cover and flywheel marked to insure re-installation in same position (NOTE—Some models have one large and one small dowel pin so that cover can only be installed in one position), remove all (30) torus cover-to-flywheel capscrews (accessible from below by turning flywheel), push cover back to clear flywheel dowels.

11) Lower engine and transmission just enough to provide access to flywheel housing upper bolts (*NOTE*—On Hudson, these bolts removed previously; on Oldsmobile, do not lower engine more than 1½" without removing upper radiator hose and loosening exhaust pipe to manifold connection).

12) Take out four flywheel housing bolts (*NOTE*—On 1952-54 Hudson, lower right hand bolt cannot be removed and should be left in bolt hole), move transmission and flywheel housing to the rear as a unit (see Dowel Disengaging Note below), until transmission shaft clears pilot bushing in flywheel, lower transmission to floor.

▷*CAUTION—To prevent end of mainshaft striking flywheel mounting bolts when lowering transmission, turn flywheel so end of mainshaft passes between 2 bolts.*

FLYWHEEL HOUSING DOWEL DISENGAGING NOTE—Housing can be freed from dowel pins in front housing by threading two 9/16"—12 bolts in center holes on each side of rear housing (directly above dowel pins), and turning these bolts in evenly until housing is free, then remove the bolts.

INSTALLATION: Before installing transmission, make certain that flywheel attaching bolts are tight and that pilot bearing is in good condition, clean face of flywheel thoroughly around entire bolt circle, make certain that grooves are clean and that mating faces of flywheel and torus cover are free from nicks or burrs (might prevent an oil-tight seal).

1) Install a NEW gasket on the face of the flywheel (use vaseline to hold gasket in place). Make certain that gasket is in good condition, free from tears and creases, and that it fits properly.

2) Raise transmission into position from beneath car making certain that flywheel turned to align marks on flywheel and torus cover (or that large dowel aligned with large dowel pin hole) and that transmission mainshaft enters pilot bearing squarely, push transmission forward into place so that flywheel housing engages dowels squarely.

3) Install flywheel housing attaching bolts (if engine lowered to permit access to upper bolts, it must be raised after bolts installed for cross-member installation). Tighten bolts evenly to 40-50 ft. lbs.

4) Install all flywheel-to-torus cover bolts and tighten finger-tight (CAUTION—these are special alloy-steel bolts and other types must not be substituted), tighten bolts exactly as follows:

Cadillac—Install one screw adjacent to each dowel pin and tighten until just snug, then install screws 90° from these screws and tighten just snug, install remaining torus cover screws and tighten all screws evenly to 40 ft.lbs. AFTER transmission installation completed, run engine up to 3500 RPM. and retighten all cover screws.

Hudson, Kaiser, Nash, Pontiac—Tighten two bolts adjacent to dowel pins to 12-15 ft.lbs. torque, tighten two bolts 90° from dowels to 12-15 ft.lbs. torque, then tighten all bolts in rotation to 20-25 ft.lbs. torque, finally tighten all bolts in rotation to 30-35 ft.lbs. torque (except Hudson—26-31 ft.lbs.).

▷Pontiac Torus Cover-To-Flywheel Lockwasher Production Change—Lockwashers have been eliminated at this point (not required in service).

Lincoln—Install cover screw adjacent to each dowel pin and tighten just snug, install screw 90° from each of these screws and tighten just snug, install remaining torus cover screws and tighten all screws evenly to 20-25 ft.lbs. torque.

Oldsmobile—Tighten all screws evenly, then torque screws evenly to 30 ft.lbs.

5) Install engine rear support cross-member, install and connect all parts disconnected or removed during transmission removal (see Removal data).

6) Make certain that torus cover and transmission oil pan drain plugs tight, fill transmission with fluid (see Draining & Refilling data), adjust linkage (see Linkage Adjustment).

DUAL-RANGE HYDRA-MATIC OVERHAUL

▷CHANGES, CAUTIONS, CORRECTIONS

▷*MAINSHAFT ENDPLAY TOLERANCE SPECIFICATION CHANGE: Mainshaft endplay tolerance has been increased from .004-.015" to .004-.018".*

▷*1952 PRESSURE REGULATOR VALVE CHANGE* (To eliminate "Clicking" noise when operating and surge noted when engine started). New type valve with rubber cushions on contact areas. Used in later production and may be installed in early transmissions to correct above complaints. See disassembly data for valve removal and installation. *New and Old type valves are interchangeable.*

▷*1952 FRONT PUMP CHANGE TO PREVENT BREAKAGE*—New pump assembly with improved rotor used in later transmissions (see Identification Note below for car markings when this pump installed).

Only NEW TYPE PUMPS SHOULD BE USED FOR SERVICE REPLACEMENT and transmission should be disassembled and thoroughly cleaned whenever a broken pump is found in service (CAUTION—Oil screen should be replaced and rear pump, parking brake bracket, and governor should be checked for possible damage caused by metal particles).

Pump Identification—New type pumps marked by letter "S" on face of pump opposite dowel pin.

Transmission Identification (with New Type Pump)—Transmission serial number plate will be marked by "X" stamped directly after serial number (Cadillac transmissions marked by daub of white paint—paint mark will be found above body identification plate on cowl). *NOTE*—Transmissions and cars should be marked in this manner when new type pump installed.

▷*1952 FRONT SERVO PISTON ASSEMBLY CHANGE* (to provide better oil seal within release cylinder): Two distinct production changes made: 1) Gasket used between release cylinder and servo body on later transmissions and this gasket should be installed in first transmission whenever servo disassembled. 2) Improved piston assembly with longer shoulder diameter to provide better oil seal within release cylinder used on later transmissions. This later type assembly interchangeable with first type but DIFFERENT SERVO SPRING USED WITH EACH TYPE CYLINDER. *See Front Servo Overhaul Data for gasket installation and spring identification.*

▷*1952 OVERRUN CONTROL VALVE CHANGE* (to cor-

CONTINUED ON NEXT PAGE

HYDRA-MATIC OVERHAUL
►CHANGES, CAUTIONS, CORRECTIONS (Continued)

rect slippage in "Dr. 3" when using engine as a brake): New type valve used in later transmissions to prevent possibiilty of valve sticking under above conditions due to force of front band apply pressure against side of valve. New type valve has groove on side near domed end and is furnished for service under same part number as previous type. *See Front Servo OVERHAUL data for Overrun Valve installation. Car can be checked for slippage as follows:*

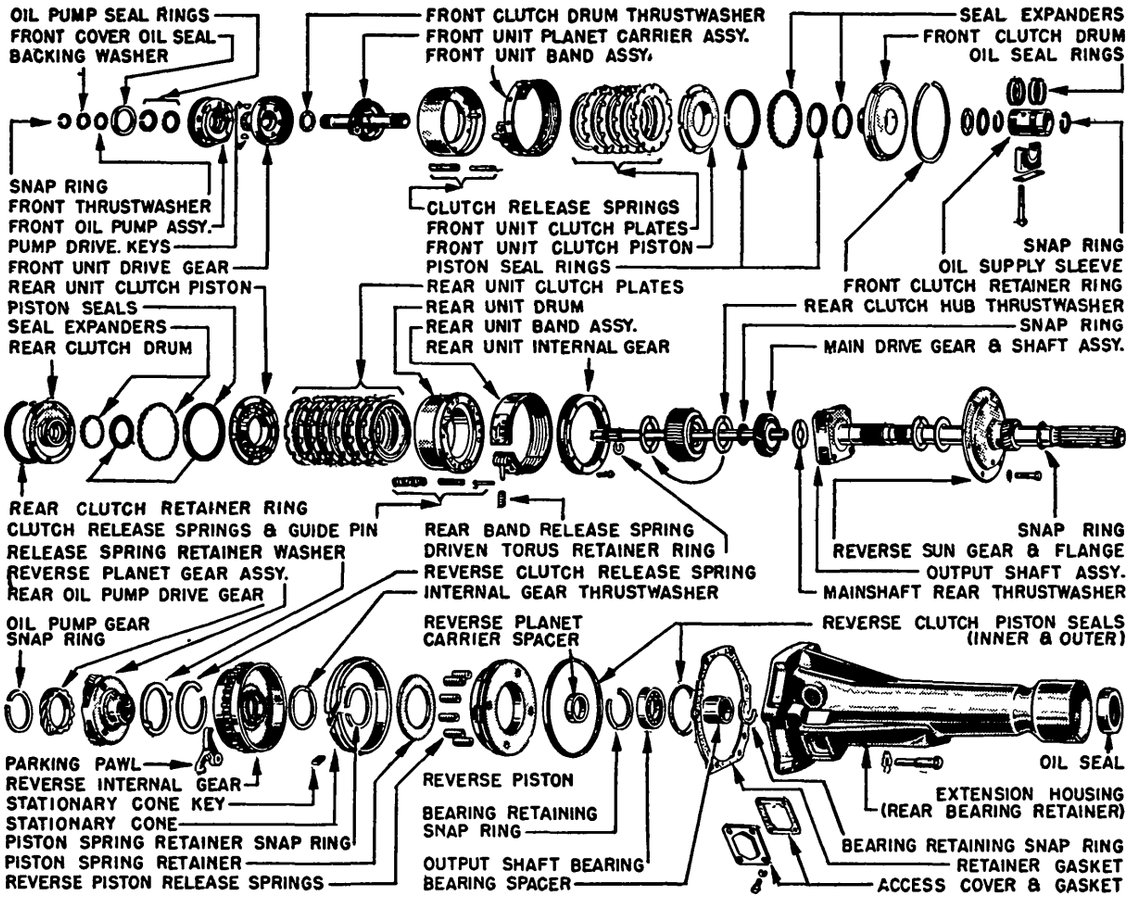
Slippage in "Dr. 3" Position—Check by running car up to 60 MPH. in "Dr. 4," then shift to "Dr. 3." Car should slow down and engine speed increase as engine acts as a brake. If compression braking not noted under these circumstances, slippage is indicated.

►*1952 REAR SERVO EXHAUST VALVE CHANGE:* New type valve used in later transmissions has shoulder cut in "Lo" oil apply end of valve to eliminate possibility of valve hanging up on servo body gasket. ***Either type valve may be used for service but gasket must be check for alignment when first type valve used to prevent valve hanging up on gasket.***

►*1952 MAIN LINE EXHAUST VALVE CHANGE:* **Two different types** used WHICH ARE NOT INTERCHANGEABLE. Valves are different length and must be used with correct length spring. See Line Exhaust Valve Removal (under Transmission Disassembly), and Installation (under Transmission Reassembly) for valve and spring identification. ***CAUTION—Same type Line Exhaust Valve and Spring must be used for replacement as were originally installed in transmission.***

►*1952 GOVERNOR PRODUCTION CHANGE:* Two types used in production: 1) Cast-iron, 2) Die-cast. Governors are interchangeable but cast-iron type is preferred as replacement unit.

►*NASH 1952 HYDRA-MATIC TRANSMISSION JUMPING OUT OF REVERSE CORRECTION* **(Cars before Serial R-656747):** To correct complaints of jumping out of reverse to low when accelerating rapidly, or backing up an incline, remove control valve detent plunger retainer and install a 3/16" ball bearing in the retainer under the plunger spring to increase the spring tension to hold the inside detent control lever in the reverse position. *See Control Valve Assembly Overhaul data.*



►*1953 TRANSMISSION CASE CHANGE:* Line exhaust valve now located in small valve body attached to front servo and is no longer located in case. Service of this valve is simplified as valve sleeve and special tool not required.

►*1953 FRONT SERVO CHANGES:* Front servo redesigned to include a valve body, one additional release cylinder attaching bolt, new piston assemblies, and a new 4-3 downshift valve.

Front Servo Valve Body Change—New valve body added to front servo contains the line exhaust valve formerly located in case, and overrun control valve formerly located in servo body.

Front Servo Releasing Cylinder—Three bolts are used to attach release cylinder to servo body and no gasket required.

Front Servo Piston Assembly Change—Assembly now consists of apply piston and compensator piston. Release piston is now separate. A booster spring has been added which acts on release piston to improve band release and clutch apply action.

1952-55 DUAL-RANGE HYDRA-MATIC TRANSMISSION

►*1953 CONTROL VALVE BODY CHANGE:* Valve body has been changed and is not interchangeable with previous model cars.

►*1953 PARKING BRAKE BRACKET SHIMS:* Shims used between transmission case and parking brake bracket on some early 1953 cars to insure correct alignment. DO NOT INSTALL SHIMS IF ORIGINAL TRANSMISSION CASE REPLACED.

►*1953 CENTER BEARING CAP PRODUCTION CHANGE:* Dowel pin hole has been drilled all the way through and dowel pin is press fitted so that upper end is flush with top of cap. If dowel pin is not indexed with hole in oil delivery sleeve, the dowel pin will push through rather than damage oil delivery sleeve when cap is tightened. CAUTION—Bearing cap lockplate must be flat with top of bearing cap after cap is tightened. **If it is raised up (over dowel pin), dowel pin is not indexed with oil delivery sleeve.**

►*1953 & EARLIER HYDRA-MATIC TORUS CHECK VALVE REPLACEMENT:* The check valve retainer and bolts are not necessary, and if desired, can be eliminated as follows: Slide torus check valve over driven hub to check freeness, then remove torus check valve from driven hub and install it and torus check valve spring over hub of driven torus. Locate driven torus against snap ring and install lock plate and locknut. Tighten locknut to 50-60 ft. lbs.

►*1953 CADILLAC REAR BAND SLIPPAGE CORRECTION (ON 3-2 DOWNSHIFT):* On a few early cars, slippage may be noted on the 3-2 downshift, when accelerating from speeds below 10 MPH. To correct, remove and disassemble the rear servo, and check rear servo check valve orifice. If found to be less than .048" diameter, enlarge orifice to .052" with a No. 55 size drill. This hole may be drilled without removing check valve from accumulator valve body, providing drill runs true and is held at right angles to valve. Clean unit thoroughly after drilling. Check accumulator check valve plunger for correct operation and full travel. Plunger travel should be 3/64" after it makes initial contact with check valve. If not correct, install a new accumulator body with

CONTINUED ON NEXT PAGE

OVERHAUL (Continued)

check valve. Check large servo spring for operating clearance within retainer. All pistons and pins should operate freely within their bores. Later production rear servo assemblies have a check valve orifice of .048-.052".

▷*1953 NASH—NO SHIFT TO REVERSE (AFTER WARM-UP) WITH ENGINE RUNNING:* Shift lever cannot be moved to Reverse with engine running, but can be shifted with ignition turned off. This condition can be caused by oil pressure passing rings in governor which is due to misalignment of governor in relation to parking brake bracket. Check ring travel in parking brake bracket. If ring travel indicates to outer or left side of oil hole in bracket, bracket must be shimmed away from case, using one or two shims Part No. 3113600 (See Parking Brake Shim Note above). If ring travel is to inner or right side of oil hole, then governor must be moved out (indicating that flange on rear oil pump not machined correctly or is too far on the shaft) in which case it will be necessary to install new oil pump assembly.

▷*1953 PONTIAC TORUS COVER-TO-FLYWHEEL LOCKWASHER PRODUCTION CHANGE:* Lockwashers have been eliminated at this point in production and are not required in service. Lockwashers may also be eliminated during service in all previous models.

▷*1953 PONTIAC THROTTLE VALVE REGULATOR SPRING CHANGE:* Regulator valve spring has been changed slightly and is no longer copper colored. Throttle valve spring can be distinguished from the double transition valve spring by the slightly heavier wire and 1/32" larger diameter.

▷*1953 PONTIAC CONTROL VALVE BODY PLATE CHANGE:* Early cars had a ⅛" thick plate attached to front valve body with four bolts. Later valve plate is 5/32" thick and attached with three bolts. When installing the early type plate make sure the shorter (⅜" long) screw is installed in the one middle hole closest to center of control valve body, otherwise it will interfere with front valve body to inner valve body attaching screw directly below it and cause a leak.

▷*1953 REAR CLUTCH HUB PRODUCTION CHANGE:* On the following cars (see below) a new clutch hub entered production as indicated. The new hub is relieved approximately .030" in front face of hub to allow space for thrust washer. New design eliminates possibility of wear between hub face and snap ring.

Cadillac—New type hub entered production in August 1953. A service kit, Part No. 8615451, containing Part No. 8615418 (Hub), and Part No. 8615419 (Thrust Washer) is available for service replacement on all 1946-53 cars.

Pontiac—New type clutch hub used beginning with Transmission Serial No. P53-271455. A Service Kit, Part No. 8615451 contains hub and thrust washer.

▷*1946—EARLY 1953 CADILLAC REAR CLUTCH HUB SERVICE REPLACEMENT:* Rear Clutch Hub changed in 1953 production and new clutch hub should be used for service replacement on earlier cars. See "1953 Rear Clutch Hub Production Change" above.

▷*1953 REVERSE INTERNAL GEAR PRODUCTION CHANGE:* On the cars indicated below, the Reverse internal Gear has been redesigned to provide a new retainer washer and spring. Later type spring retainer washer has four tangs instead of two on earlier type. Gap of later type spring is ¼" compared to ½" on earlier type.

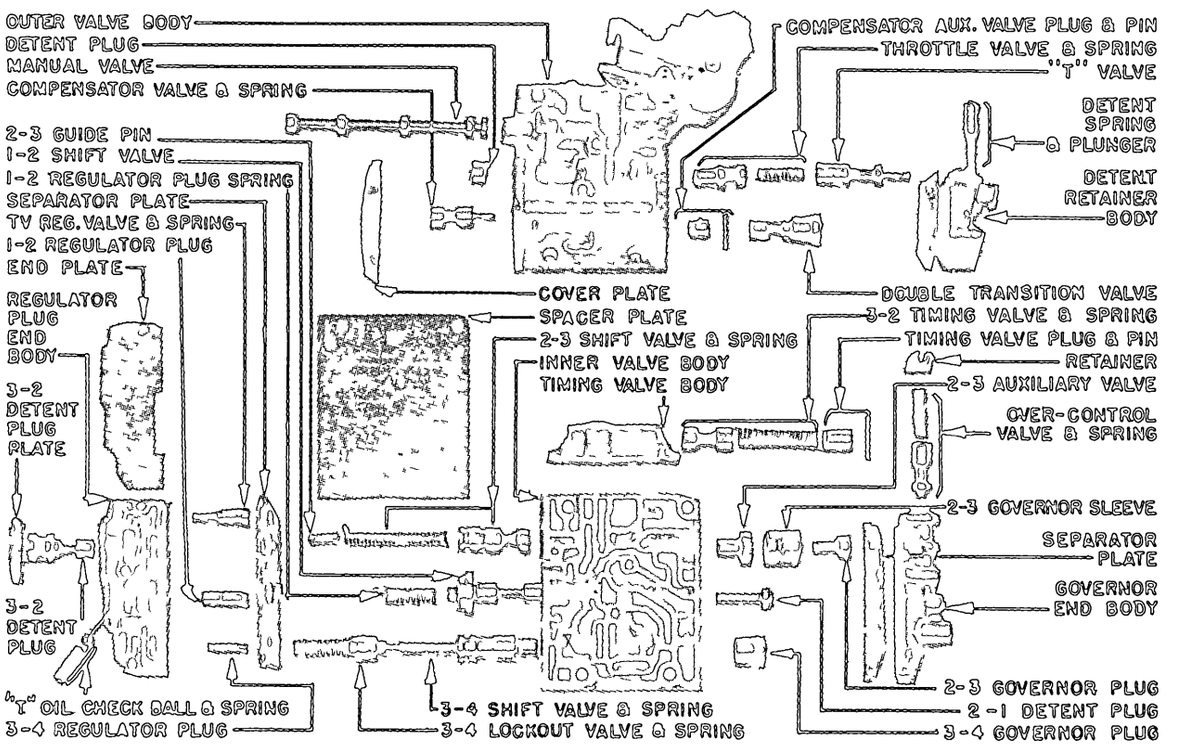
Cadillac—Beginning with Hydra-Matic Transmission Serial No. 83012 later type Reverse Internal Gear used. Service Replacement Kit Part No. 8615449, consisting of gear, washer, and spring furnished for service replacement on all 1951-53 model cars. CAUTION—Washer and spring are NOT interchangeable and must be used with their respective early and late type internal gears.

Oldsmobile—Late 1953 production cars incorporated the later type Reverse Internal Gear Assembly consisting of Gear Part No. 8615326, Retainer Part No. 8615316, Spring Part No. 8615314. Early and late type assemblies are interchangeable in complete assemblies only. Individual parts are NOT interchangeable.

Nash—Beginning with Hydra-Matic Serial Nos. NA-1001, NA-7001, E-1001, E-5001, Y-1001, Y-6001, later type Reverse Internal Gear used. Service Package Part No. 3114770, containing new gear, retainer, and spring is supplied for service replacement. Early type washers and spring are not interchangeable with later type.

▷*1951-53 REVERSE INTERNAL GEAR SERVICE REPLACEMENT: See "Reverse Internal Gear Production Change" above.*

▷*1953 & EARLIER LINCOLN THROTTLE SHAFT OIL SEAL SERVICE REPLACEMENT:* To improve seal between throttle shaft and detent lever, a new Inner Control Levers Service Kit, Part No. HEK-77211 containing a pin, seal and washer should be used to replace earlier type.



▷*1953 OLDSMOBILE TRANSMISSION CASE & FRONT PUMP GASKET PRODUCTION CHANGE:* Beginning with August Production the transmission case was changed to include the use of an "O" ring seal at the front pump instead of a flat gasket. "O" ring seal must be used with all later type cases. The front pump will fit either early or late type transmission case.

▷*1952-53 HUDSON 3-4 SHIFT VALVE SPRING INSTALLATION (to correct vibration and noise when accelerating from 16 to 20 MPH in 4th Gear):* Install new spring Part No. 307927 (not necessary to drain fluid or remove transmission) as follows: Raise car, disconnect TV line and control lever, remove side cover and control body assembly, remove front body and separator plate, install spring, reassemble transmission.

▷*1954 FRONT PUMP PRIMING SPRING PRODUCTION CHANGE:* Two pump priming springs are now being used. All previous models with vane type pumps can use the two springs for service replacement.

▷*1954 CADILLAC TRANSMISSION VENT LEAK (Caused by an Undersize or Out-of-round Pressure Regulator Valve):* Check this condition by transmission shift lever in "R" position, and with engine idling, observe breather vent hole. If oil appears, replace the

CONTINUED ON NEXT PAGE

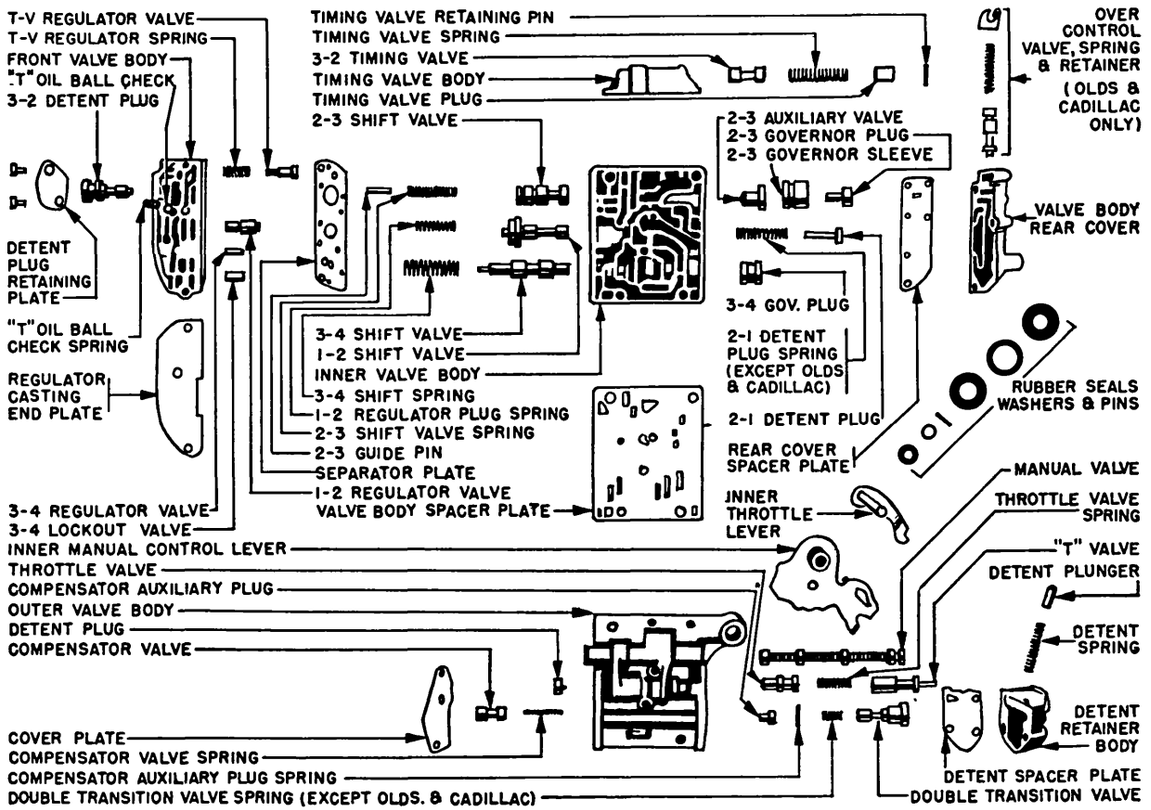
DUAL-RANGE HYDRA-MATIC 1952 CONTROL VALVE (TYPICAL)

OVERHAUL (C ntinu d)

Pressure Regulator Valve. Before installing new valve, check dimensions of the three wide valve lands, these should be .4990-.4985" in diameter. Do not install an undersize or out-of-round valve.

►*1954 OLDSMOBILE OVERRUN CONTROL VALVE CHANGE:* A later type overrun control valve with an increased diameter of the large shank end is now being used to avoid the possibility of installing the valve incorrectly.

►*1954 OLDSMOBILE REAR PUMP CHANGE (To eliminate noise in light throttle reverse operation):* This later pump, Part No. 8615329 can be used for service replacement to correct noise, as noted above, on earlier transmissions.



►*1954 PONTIAC GOVERNOR ASSEMBLY PRODUCTION CHANGE:* A new governor assembly having a relocated exhaust hole is being used in late 1954 production and as a service replacement on all 1952-54 transmissions.

►*1955 CADILLAC FRONT & REAR CLUTCH PRODUCTION CHANGE (Cars With Eldorado Engine):* Beginning with transmission Serial No. CE-6336, front and rear clutch drive and driven discs are thinner and an extra driving disc has been installed in both units. Due to this change, new front and rear clutch annular pistons are also used. If the later type discs are to be installed in transmissions before the above serial number, all clutch discs must be replaced and the new type annular piston must be used. The later type parts are as follows: Driven Disc (No. 8615593). Drive Disc (No. 8617317). Front Clutch Annular Piston (No. 8617332). Rear Clutch Annular Piston (No. 8615377).

►*1955 CADILLAC OIL LEAK CORRECTION (Oil Pan Drain Plug and Transmission Oil Cooler Fitting):* A new fibre gasket, Part No. 1307237 is available for service replacement. New gaskets should be placed in hot water a few minutes before installation.

►*1955 CADILLAC ROUGH SHIFTING CORRECTION (Usually encountered when accelerator pedal is pressed as the 3-2 shift occurs):* If correct throttle linkage adjustment and correct internal band adjustment fails to correct the condition, install a more flexible rear servo accumulator check valve, Part No. 8617281, with rivet, heavier rear servo spring, Part No. 8617217, and front servo unit booster spring, Part No. 8617274.

►*1955 HUDSON & NASH REVERSE OIL FEED SEAL PRODUCTION CHANGE:* In addition to the rear bearing retainer gasket, a new rubber "0" ring seal, Part No. 3117223, has been added to the rear of the transmission case to eliminate possibility of an oil leak at the reverse oil feed passage. Transmission case requiring this "0" ring seal can be identified by the counterbore around reverse oil feed hole in side of transmission. See "Pressure Test Point" illustration for location of hole.

1953-55 DUAL-RANGE HYDRA-MATIC CONTROL VALVE (TYPICAL)

►*1955 HUDSON & NASH REAR SERVO PRODUCTION CHANGE:* Starting with transmission Serial No. 55H-7460 (Hudson); 55N-12346 (Nash), the rear servo body was changed to incorporate a rear servo compensator pipe.

►*1955 HUDSON & NASH ROUGH 2-3 UPSHIFT CORRECTION:* After correct linkage and band adjustment, the rough 2-3 upshift condition remains, install Service Spring, Part No. 3119206 in the front servo body 4-3 downshift valve *(NOTE*—On Wasp models, it is also necessary to replace the pressure regulator spring, Part No. 3115705 which is identified by blue paint).

►*1955 OLDSMOBILE REAR PUMP DISCHARGE PIPE RETAINER:* A retainer bracket, Part No. 8615556, has been released for production and service on transmissions starting with Serial No. 55-R-65474. The new retainer is installed under the rear servo retainer attaching bolt, and replaces the pipe retainer clip formerly used.

►*1955 TRANSMISSION LEVER PRODUCTION CHANGE & 1954 REPLACEMENT PARTS NOTE:* A new "stamped" manual shift lever, Part No. 567316 is used in production and for service replacement on 1954-55 transmissions. A new "stamped" throttle lever is used in production and for service replacement on 1955 transmissions after Serial No. 55-R-76159. Do not use on transmissions before the above serial number as a longer throttle shaft is required for use with this lever.

DISASSEMBLY OF TRANSMISSION

►***TRANSMISSION DISASSEMBLY NOTE:*** ***Instructions below cover removal of sub-assemblies from transmission case. See "OVERHAUL OF UNITS" for disassembly, inspection, and reassembly of these sub-assemblies.***

Torus, Torus Cover, & Flywheel Housing: Remove oil level indicator (breather cap) from top of transmission case. With transmission on the bench, proceed as follows:

1) Move manual control lever on side of transmission case to Reverse (rear) position.
2) Straighten lockplate lip on mainshaft nut using a chisel and light hammer, remove mainshaft nut.
3) Slide torus driven member off front end of shaft. *CAUTION*—If torus member sticks, tap end of shaft with rawhide hammer while pulling on torus hub.
4) Remove driving torus snap ring, then remove torus driving member from shaft.

►***CAUTION—DO NOT attempt to remove driving torus and cover as a unit.***

5) Remove torus cover by working cover hub back through oil seals gently and then pulling cover off with quick jerk.

►***CAUTION—DO NOT pull or push on cover in rough manner which may cause broken or damaged oil seal ring.***

6) Remove four capscrews and lockwashers holding flywheel rear housing on transmission case, remove housing and gasket.

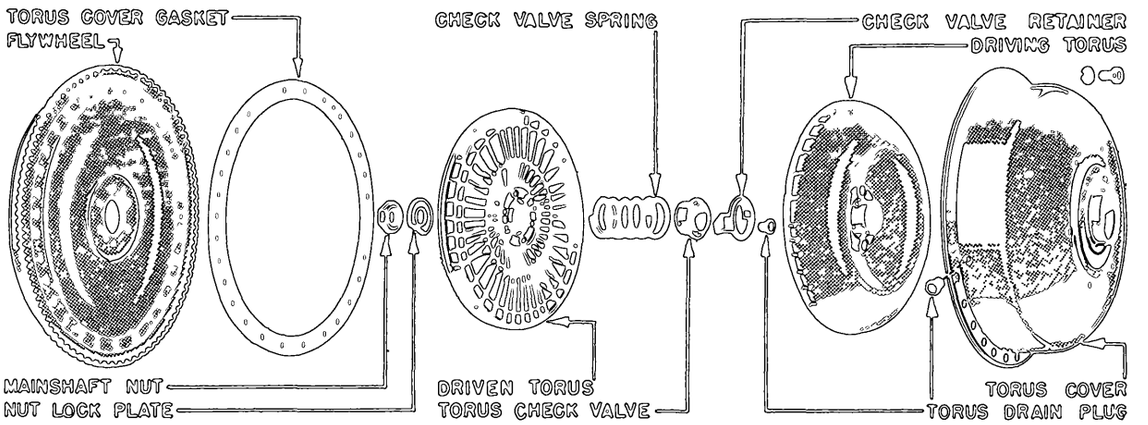
Manual Lever, Oil Pan, Oil Screen, & Side Cover:

1) Move shift lever on side of transmission case to "Lo" (next detent position forward from "R").

CONTINUED N NEXT PAGE

OVERHAUL (Continued)

2) Loosen clamp bolt retaining shift lever on shaft, remove lever.
3) Remove snap ring from groove at forward end of mainshaft using snap ring pliers.
4) Take out oil pan capscrews and lockwashers, remove oil pan and gasket. Lift oil pan screen and front pump intake pipe straight off as a unit (pipe will come out of front pump body and screen will pull off rear pump intake pipe).
5) Take out all side cover capscrews, remove side cover and gasket.



Control Valve & Parking Brake Bracket: Place inner detent lever in "Lo" position, loosen locknuts and back off front and rear band adjusting screws 5-6 turns. Then proceed as follows:
1) Remove pressure regulator reverse oil pipe by prying ends out evenly from control valve and case *(CAUTION—use light pressure to avoid bending pipe).*
2) Remove parking brake pawl support bolt (one of the rear bearing retainer mounting bolts on back of case), position pawl down in case as far as possible *(NOTE—pawl cannot be removed at this time).*
3) Unhook parking brake release spring from pin at front of parking brake bracket and remove spring.
4) Loosen two bolts mounting parking brake bracket on side of transmission case but DO NOT remove bolts at this time. *NOTE—Lockplate on lower mounting bolt also serves as parking blocker piston pin retainer.*
5) Take out four bolts mounting control valve assembly on side of transmission case, work control valve assembly toward front of case sufficiently to disengage two governor pipes and reverse clutch pipe *(CAUTION—Governor pipes may remain in either part but should be removed to prevent their being damaged),* lift control valve assembly out. Remove reverse clutch oil delivery pipe by pulling rear end out of hole in case.

▷*CAUTION—Control valve assembly should be kept wrapped in clean cloth or paper to prevent dirt entering valve body passages.*

6) Remove the two parking bracket mounting bolts (these bolts loosened in step 4 above), remove bracket by carefully sliding sleeve off governor *(CAUTION—Use extreme care not to damage governor oil rings when removing sleeve).* Do not lose roller from end of reverse shifter crank.
7) Lift parking brake pawl out of case.

Front & Rear Servos: *CAUTION—Front and rear band adjusting screws must be backed off approximately 5-6 turns to relieve servo spring tension before servos can be removed.*

1) Remove governor oil delivery pipe by carefully prying both ends up evenly out of front servo and governor.
2) Take out front and rear servo mounting bolts, lift out both servos as a unit *(CAUTION—rear pump discharge pipe will rotate in front fitting and slide free as units lifted off),* separate servos at oil transfer pipe leaving the pipe in one unit. Servos can be removed separately as follows: Move rear servo toward rear to disengage oil transfer pipe, lift servo off, then lift front straight up to disengage it from front pump oil delivery pipe. Remove rear pump discharge pipe and front pump oil delivery pipe by pulling pipe straight out.

DUAL-RANGE HYDRA-MATIC TORUS ASSEMBLY

Line Exhaust Valve: *(1953 & Later Note—This valve located in valve body attached to front servo unit and special tools are not required for its removal. Some early 1953 cars were same as 1952 models and are removed as follows:).*

1952 Line Exhaust Valve—This valve located in hole in case at front servo mounting face. Use special tool J-5177 (Manzell No. 77447 for Lincoln) to remove sleeve from hole (enter tool in sleeve with handle end facing nearest side of case and when tool bottoms against end of sleeve, rotate handle 180° to engage tool in sleeve, pull sleeve out). Then remove exhaust valve and spring (these parts can be popped out by applying air pressure at main line oil hole passage on side of case, or they will fall out if case inverted). *See Overhaul data (following) for inspection and re-installation of the valve.*

Governor & Rear Oil Pump: If these parts not to be removed, check governor run-out to make certain it is within limits. *See Transmission Reassembly data for procedure.* To remove assembly, proceed as follows (run-out is checked when unit re-installed):
1) Position governor so that large round governor weight is toward front of transmission, position reverse drive flange so that one attaching bolt is directly up.
2) Take out two bolts and lockwashers mounting assembly on transmission case.
3) Lift the assembly out by moving it toward the control valve side of the case and lifting pump end up to clear the case.

▷*MAINSHAFT ENDPLAY CHECK CAUTION—Mainshaft endplay should be checked at this point BEFORE removing drive units from transmission case to determine correct thrustwasher to be used when reassembling transmission. Check endplay as follows:*

Mainshaft Endplay Check—Install mainshaft endplay guide J-2587 (1952-53), J-2587-B (1954-55) over forward end of mainshaft and front planet carrier. Use special mounting fixture tool J-1465 to mount dial indicator on front of transmission case so that it contacts front face of guide tool. Insert a screwdriver between front clutch drum and center bearing cap to hold front planet unit forward, *(CAUTION—Place screwdriver at an angle to avoid damage to oil delivery sleeve).* Move mainshaft back and forth and record endplay as noted on dial indicator for use in selecting correct thrustwasher when assembling transmission. Endplay should be .004-.018". *See "Mainshaft Endplay Change" above.*

CAUTION—DO NOT force mainshaft when measuring endplay which will give inaccurate reading (the FREE endplay is the desired measurement).

Pressure Regulator: *CAUTION—This assembly is under spring pressure and should be held in while being unscrewed to prevent parts flying out.* Loosen regulator valve plug, unscrew plug by hand while holding pressure against outer end. Remove plug and valve assembly (plug, reverse booster plug, T.V. plug, spring, and valve should withdraw as an assembly).

Front Oil Pump & Drive Gear: Remove snap ring from front end of front planet carrier shaft, remove steel and bronze thrustwashers *(CAUTION—these are special washers with smaller O.D. and should be kept separately to insure re-installation at this point).* Take out two front pump mounting screws (in front face of case at edge of pump cover), remove locating washer from screw hole counterbore. Remove front pump, gasket and drive gear as an assembly *(NOTE—tap rear of pump with light hammer and brass drift if necessary).*

Reverse Assembly & Mainshaft Removal: Remove oil seal from rear bearing retainer. Take out six reverse center gear-and-drive flange attaching bolts *(NOTE—drive flange can be held from turning by wedging screwdriver under one drive flange bolt head).* Install screwdriver between center bearing cap and rear clutch drum to prevent drum moving forward *(CAUTION—place screwdriver at an angle to avoid damage to oil delivery sleeve),* take out all rear bearing retainer-to-transmission bolts, carefully withdraw bearing retainer and reverse assembly from rear end of case (if assembly sticks, tap on front end of mainshaft using rawhide or other soft hammer). Remove mainshaft endplay thrustwasher *(CAUTION—this washer may stick to mainshaft in case or remain in output shaft counterbore).* Remove stationary cone lock key (this key fits in keyway in cone and keyway in case). Remove mainshaft through rear end of case, remove bronze thrustwasher from rear clutch hub (this washer may come out on mainshaft). Install rear hub retainer tool J-2174 on rear face of rear clutch hub

CONTINUED ON NEXT PAGE

OVERHAUL (C ntinued)

(use one reverse drive flange attaching bolt to hold tool in place). Remove screwdriver from in front of rear unit.

Front & Rear Unit Removal: ***CAUTION—Make certain rear hub retainer tool J-2174 installed on rear unit to prevent parts coming out while units being removed.*** Straighten lockplate ears at center bearing cap attaching bolts using a chisel and light hammer, remove bearing cap bolts and lockplate (NOTE—if necessary, use blunt screwdriver between bearing cap or front and rear drum to equalize drum distances and permit socket wrench to be used on bearing cap bolts). Remove rear band and strut assembly (CAUTION—do not lose rear band release spring located between ends of band), wire ends of front band together to retain band on drum (brake wheel cylinder clamp can be used for this purpose). Lift entire assembly out of transmission case. Remove front band from front unit drum. Front and rear units can be separated for overhaul as follows:

Front & Rear Unit Disassembly—*Holding Fixture J-2187 will facilitate work on these units* (fixture engages front end of intermediate or planet carrier shaft and holds assembly vertical on bench). Remove rear clutch hub rear snap ring from groove at rear end of shaft, lift rear unit assembly off shaft. Remove rear clutch hub front snap ring from groove in shaft. Remove center bearing cap from oil delivery sleeve, lift sleeve and oil ring assembly off shaft. Remove snap ring from recess in front unit *(CAUTION—*hold snap ring open while removing it from shaft so that it does not score or otherwise damage bearing surface on shaft). Lift front unit assembly off shaft, remove bronze and steel thrustwashers from recess in front unit. ***See OVERHAUL data (following) for disassembly of each unit.***

DISASSEMBLY & REASSEMBLY OF UNITS

FRONT PLANETARY UNIT: Disassembly. Place front unit in arbor press with ram resting on block on front cover, apply just enough pressure to enable cover retaining snap ring to be removed from clutch drum, remove ring, remove unit from press. Separate drums by tapping front face of center gear using a rawhide or other soft hammer, remove front cover. Remove front clutch annular piston from cover by bumping front face of center gear on soft wood block. Remove clutch spring (six outer and six inner springs) and clutch plates (composition drive plates and steel driven plates—number varies on different transmissions) from the drum. Remove rubber piston seals and brass expanders from annular piston and clutch drum piston *(1955 CADILLAC NOTE—*Outer clutch piston seal is cast iron and can be removed by expanding slightly), using a blunt screwdriver to avoid damaging these parts.

Inspection: Clean all parts thoroughly. Inspect clutch drive pins and replace drum and drive pin assembly if pins scored, loose, distorted, or worn excessively (pins not furnished separately). Inspect drum for deep grooves or scoring on band surface or clutch plate surfaces; check piston bore, oil delivery sleeve bore and oil seal grooves for scoring; inspect gear teeth and thrust surfaces for wear or damage. Inspect clutch release springs for distortion or collapsed coils (free length should be 2 15/64"—slight wear as indicated by bright spots on side of outer springs where springs have contacted drums is permissible). Inspect clutch drive plates for damaged or loose facings (discoloration is permissible but plates should be replaced if flakes of facing material can be removed by scratching with the thumbnail), worn teeth, or lack of waving (these plates must be waved). Inspect clutch driven plates for scored or warped surfaces (these plates must be flat), or excessive wear. Inspect annular clutch piston for scoring and make certain oil seal grooves are thoroughly clean. Inspect planet carrier gears for damaged teeth or excessive roller bearing wear, inspect bearing surfaces of planet carrier shaft. Inspect all thrust washers for wear or damage.

Reassembly: *NOTE—*Clutch parts can be installed in front drum with drum on bench (driving pins upward) but assembly will be facilitated if planet carrier assembly placed vertically in fixture and front drum placed on planet carrier so that drum flange rests on pinion gears with drive pins upward. Install parts in following order:

1) Install driving (composition faced) and driven (steel) clutch plates alternately in that order *(CAUTION—*Engage **square** notches of driven plates over drum pins) and apply hydra-matic fluid to face of each plate as it is installed.

►***FRONT CLUTCH ANNULAR PISTON REPLACEMENT CAUTION—***Annular piston used with three composition and three steel plate clutch assembly is THICKER than piston used on four composition and four steel plate assembly. **Do not interchange pistons between the two types of assemblies.**

►***CLUTCH PLATE NOTE—***Clutch plate assemblies (equal number of drive and driven plates) differ on individual transmissions as follows:

►***1955 CADILLAC ELDORADO CLUTCH PLATE PRODUCTION CHANGE:*** Thinner plates used after Transmission Serial No. CE-6336, and one additional drive plate has been added. ***See "Cadillac Front & Rear Clutch Production Change" above, for installation of later type plates in early transmissions.***

Front Clutch—

3 Drive & 3 Driven Plates—Hudson (Exc. Hornet and 1954 Super Wasp); Kaiser; Nash (Exc. 1955 Ambassador); Rambler; and Willys.

4 Drive & 4 Driven Plates—Cadillac ***(See 1955 Cadillac Eldorado Note above)***; Hudson Hornet, 1954 Hudson Super Wasp; Lincoln; 1955 Nash Ambassador; Oldsmobile; and Pontiac.

2) Install six outer and six inner clutch release springs through plates and into spring holes in drum (install outer springs first).

3) Install new inner brass expander in ring groove in clutch drum with **expanding lips down,** then work new inner piston rubber seal into ring groove with lip down over brass expander *(CAUTION—*work expander well back into position so that brass edges are not exposed). Check installation by installing piston into clutch drum to insure proper seating of the seal and expander, inspect inner seal after piston removed.

4) On models with rubber outer seal on annular piston, place new rubber seal over annular piston with **lip up** so that it is beyond the seal groove, install new large brass expander in piston groove with **lips up,** work rubber seal up into groove and over brass expander, finally work expander well down into position under seal so that brass edges are not exposed. On models with cast iron outer seal on annular piston, slightly expand seal and slip into groove of piston. *(CAUTION—*Before installing seal on piston, check ring gap by inserting oil seal squarely into clutch drum assembly and checking with a feeler gauge. Clearance should be .001-.006" at O.D. of ring, and should not exceed .007" at I.D. of ring. File ring ends as necessary for correct gap).

5) Install annular piston and seal assembly on clutch drum by placing piston on drum so that it rests on outer seal (on pistons with cast iron seal ring, use Ring Compressor J-5608 to compress seal ring until assembly is positioned in clutch cover). Align square notches in piston with holes in drum. then apply slight hand pressure to piston and guide seal into drum with the flat side of a blunt screwdriver.

6) Install clutch drum and piston assembly in front drum with gear end in *(CAUTION—*make certain that springs enter recesses in annular piston). Place the assembly in a press with ram resting on block on top face of clutch drum, press clutch drum down to fully expose snap ring groove. Install snap ring in drum with open ends equally spaced between two drive pin holes *(CAUTION—*ring must be fully seated in groove). Release pressure slowly so that clutch drum seats solidly against snap ring, remove unit from press. Tap front face of center gear lightly with rawhide hammer to insure clutch drum seating properly against snap ring.

7) Install planet carrier assembly in drum assembly by rolling the drum assembly on the bench while pressing planet carrier firmly in place (NOTE—this will align clutch drive plate teeth and hub teeth). Place entire assembly in holding fixture which will support it vertically on bench with clutch drum end upward.

8) Install bronze thrustwasher and steel thrustwasher (in that order) on planet carrier shaft and seat the washers in the clutch drum recess (CAUTION—locating lug on steel washer must fit over flat portion of shaft). Install snap ring in ring groove on shaft directly above steel washer.

►***CAUTION—Use snap ring pliers to keep ring open while moving it down over shaft. DO NOT allow ring to score bearing surface of planet carrier shaft.***

9) Assembly is then ready for installation of rear unit assembly. ***See Front & Rear Unit Assembly below.***

OIL SLEEVE & OIL RING: Inspection. Inspect oil sleeve and babbitt bearing for scored surfaces or excessive wear, see that oil passages in sleeve are clean and not restricted. Check oil seal ring gaps with rings installed in bore of clutch drum. Gaps should be .001-.007".

REAR PLANETARY UNIT: Disassembly. Remove rear clutch hub retainer tool J-2174 (as used to hold parts together during removal from transmission case), lift out rear clutch hub and bronze thrustwasher. If rear internal gear to be replaced, take out two fillister-head screws retaining gear on rear drum and remove gear *(NOTE—*gear need not be disturbed unless replacement necessary). Place rear unit in arbor press with ram resting on wood block on clutch drum, apply just enough pressure to enable snap ring to be removed from groove in drum,

CONTINUED ON NEXT PAGE

OVERHAUL (Continued)

remove snap ring, relieve pressure and remove unit from press. Remove clutch drum from rear drum by inserting wood block through clutch and against rear thrust face of clutch drum and tapping on block lightly *(CAUTION*—use care not to damage clutch plate gear teeth). Remove clutch release springs and spring guide pins (six outer and six inner springs with guide pin in each spring group). Remove all clutch plates (composition drive plates and steel driven plates—number varies on different transmissions). Remove annular piston from clutch drum by tapping rear thrust face of drum on block of wood, remove rubber piston seals and brass expanders *(1955 CADILLAC NOTE*—Outer clutch piston seal is cast iron and can be removed by expanding slightly), from annular piston, and clutch hub drum.

Inspection: Clean all parts thoroughly. Inspect as for front planetary unit parts (see above) and also make following additional inspections: Inspect babbitt bushing in clutch drum for wear or scoring. Check spring guide pins for distortion and correct length (1⅝" ± .010"). Blow out drilled passages in clutch hub and see that they are not restricted.

Reassembly: If rear internal gear has been removed, install gear on drum with dowel pin properly engaged and tighten attaching screws securely. Place drum on bench with driving pins upward, install parts:

1) Install driving (composition faced) and driven (steel) clutch plates alternately in that order *(CAUTION*—Engage square notches of driven plates over drum pins) and apply hydra-matic fluid to face of each plate as it is installed.

▷*REAR CLUTCH ANNULAR PISTON REPLACEMENT CAUTION*—Pistons are different for the four types of clutch assemblies, and are not interchangeable.

▷*CLUTCH PLATE NOTE*—Clutch plate assemblies (equal number of drive and driven plates) differ on individual transmissions as follows:

▷*1955 CADILLAC ELDORADO CLUTCH PLATE PRODUCTION CHANGE:* Thinner plates used after Transmission Serial No. CE-6336, and one additional clutch plate is used. *See "Cadillac Front & Rear Clutch Plate Production Change" above for installation of later type plates in early transmissions.*

Rear Clutch—

5 Drive & 5 Driven Plates—Hudson Jet; Nash Statesman; Rambler; and Willys.

6 Drive & 6 Driven Plates—Hudson (Exc. Jet, Hornet, and 1954 Super Wasp); Kaiser; and 1952-54 Nash Ambassador.

7 Drive & 7 Driven Plates—Hudson Hornet and 1954 Super Wasp; 1955 Nash Ambassador; and Pontiac.

8 Drive & Driven Plates—Cadillac (See 1955 Cadillac Eldorado Note above); Lincoln; Oldsmobile.

2) Install six outer clutch springs, six inner springs, and six guide pins through rounded slots in clutch plates and into holes in drum.

3) Position new rubber seal with lip down on inner piston of clutch drum just above groove, install new brass expander in groove with expanding lips down, work rubber seal into groove with lip down over the expander and work expander well back under seal so that brass edges are not exposed.

4) On models with rubber outer seal on annular piston, place new rubber seal over annular piston with lip up so that it is beyond the seal groove, install new brass expander in piston groove with lips up, work rubber seal up into groove and over brass expander, finally work expander well down into position under seal so that brass edges are not exposed. On models with cast iron outer seal on annular piston slightly expand seal and slip into groove of piston.

5) Install annular piston and seal assembly on clutch drum by placing piston on drum so that it rests on outer seal (on pistons with cast iron seal ring, use Ring Compressor J-5608 to compress seal ring until assembly is positioned in clutch cover) Align square notches in piston with holes in drum, then apply slight hand pressure to piston and guide seal into drum with the flat side of a blunt screwdriver.

6) Install clutch drum and piston assembly over drive pins in rear drum. Place assembly in a press with ram resting on wood block on top of face of clutch drum, press clutch drum down until snap ring groove fully exposed. Install snap ring in drum with open ends equally spaced between two drive pin holes *(CAUTION*—ring must be fully seated in groove). Release pressure slowly so that clutch drum seats slodily against snap ring, remove unit from press. Tap front face of clutch drum (use light hammer on wood block inserted through internal gear and clutch assembly) to insure clutch drum seating properly against snap ring.

7) Install front bronze thrustwasher in deep counterbore of rear clutch hub (use vaseline to retain washer), install hub in drum assembly by rolling the drum on the bench while pressing hub firmly in place *(NOTE*—this will align clutch plate teeth and hub teeth).

8) Install holding tool J-2174 on drum to hold hub in place (use one reverse flange attaching screw to attach tool to drum).

9) Assembly is then ready for installation on front unit assembly. *See Front & Rear Unit Assembly (following).*

Front & Rear Unit Assembly: With front unit assembled on intermediate shaft (front planet carrier shaft) and mounted vertically in fixture, proceed as follows: Install oil rings on oil delivery sleeve *(CAUTION*—space oil ring gaps 180° apart to minimize oil leakage), install sleeve over intermediate shaft with long bearing upward, use Ring Compressor Tool J-1537 to compress lower oil rings and tap sleeve down into bore of front unit clutch drum using a rawhide or other soft hammer. Install rear unit clutch hub front snap ring in second groove of intermediate shaft. Compress upper oil rings with tool J-1537, install rear unit assembly over shaft (withdraw ring compressor after rings enter bore of rear unit clutch drum). Install rear unit clutch hub rear snap ring in groove in shaft. Assembly is then ready for installation in transmission case.

▷*CAUTION—Both front drum and rear drum should rotate freely when slight force applied. If either drum binds, disassemble unit and correct trouble before installing assembly in transmission.*

REVERSE UNIT: *NOTE—Various types of rear bearing retainers or extension housings (part of reverse unit assembly) used on these transmissions but data below applies to all types:*

Disassembly: Remove speedometer driven gear and sleeve assembly, remove retainer gasket and stationary cone lock key (flat key in cone gap). Remove oil seal from rear end of rear bearing retainer or extension housing, if not removed previously (use special puller). Remove snap ring from output shaft at rear of ball bearing within bearing retainer (on extension housing types, snap ring is "open" type and accessible through access cover opening on side of housing). On all models except Oldsmobile, remove bearing retainer or extension housing from output shaft by lifting on retainer while tapping end of shaft with rawhide hammer *(See OLDSMOBILE CAUTION below)*. Compress reverse stationary cone by hand and remove internal gear and stationary cone. On all models except Oldsmobile, remove rear bearing snap ring from within bearing retainer, remove bearing by tapping it out. Use Clutch Spring Compressor Tool J-4670 or J-4670-A mounted on front face of bearing retainer to compress clutch release springs, remove large snap ring from groove in end of retainer hub, relieve spring pressure, remove tool. Remove spring retainer and lift out the six clutch release springs. Lift reverse piston straight out *(CAUTION*—piston is located by four dowels and cannot be turned). Remove outer oil seal ring from reverse piston and inner oil seal ring from hub (remove inner ring by lifting lip up with the fingers and then using needle-nosed pliers). Lift large bronze thrustwasher from reverse internal gear. Remove reverse stationary cone from internal gear cone by expanding stationary cone slightly with snap ring pliers *(CAUTION*—do not expand cone more than necessary for removal), remove reverse clutch flat spring retainer and waved release spring by lifting straight out of reverse internal gear (to avoid damaging retainer tangs). Remove snap ring holding reverse planet carrier on output shaft (not used on all transmissions), remove carrier from shaft, remove planet carrier locating snap ring from shaft, then remove following parts: Sun gear and drive flange, steel thrustwasher, bronze thrustwasher.

▷*OLDSMOBILE REAR BEARING RETAINER REMOVAL CAUTION*—To avoid damage to bronze bushing, remove output shaft from rear bearing retainer as follows: Remove small snap ring from output shaft and large snap ring from groove in bearing retainer back of rear bearing. Tap output shaft out toward front of retainer until planet pinions just disengage from internal gear *(CAUTION—do not tap shaft any further from retainer)*. Remesh planet pinions in reverse gear and tap or push shaft back into retainer until bearing is moved back flush with retainer counterbore. Hold assembly vertically with bearing up and remove bearing with tool J-5139 (hooked wire which can be inserted in splines to engage bearing inner race). Remove lower snap ring from output shaft, re-install bearing on output shaft to protect bronze bushing, compress stationary cone and carefully remove retainer from reverse unit and output shaft, remove bearing from retainer.

Inspection: Clean all parts thoroughly. Oil the ball bearing and check for roughness by rotating it by hand *(CAUTION*—do not spin bearing with air). Inspect reverse internal gear for damaged teeth (including parking teeth), scored or damaged inside bearing surface, scored or burned cone surface Inspect planet carrier for worn or damaged teeth worn roller bearings, worn or damaged splines. In-

CONTINUED ON NEXT PAGE

OVERHAUL (C ntinued)

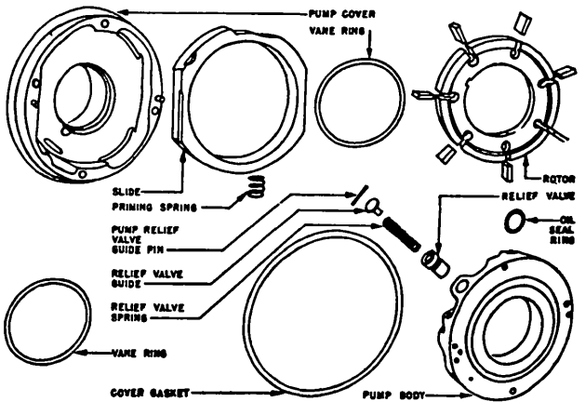
spect bronze oil pump drive gear for excessive wear or damaged teeth, see that gear is tight on carrier and that drive ball is in place. Inspect reverse center gear and flange assembly for damaged teeth or worn bushing *(NOTE—these parts must be replaced as an assembly)*. Inspect output shaft assembly for scored or worn thrust and bearing surfaces, nicked or burred splines, worn or damaged speedometer drive gear teeth (cut directly in shaft). Inspect all thrustwashers for excessive wear and scoring. Inspect clutch release spring and retainer for damage or burning. Check stationary cone for burning, excessive wear or worn keyway. Inspect reverse piston for scores, burned cone surface, see that oil seal grooves are clean, inspect piston seal inner and outer rubbing surfaces for scoring or roughness. Check piston guide pins in bearing retainer for distortion, looseness, and scores, inspect bushing for scoring or excessive wear and make certain that oil holes in retainer are clean and open. Inspect mainshaft for damaged gear teeth and worn or scored thrust surfaces. Check piston release springs for distortion or collapsed coils (free length of springs should be 1 11/32").

Reassembly: ***CAUTION—Parts must be installed exactly as follows and clearances checked as indicated:***

1) Hold reverse center gear with drive flange up, install steel and bronze thrustwashers in that order in drive flange recess, then insert output shaft through drive flange and center gear so that planet carrier bottoms on thrustwashers, **hold assembly tightly together** to keep thrustwashers from slipping out of place and invert assembly on the bench so that it rests on carrier with shaft upward.

►***CAUTION—Do not pick up this unit until it has been completely assembled and is being installed in rear bearing retainer (step 8 below) to prevent thrustwashers slipping out of place.***

2) Install reverse planet carrier locating snap ring in groove in shaft, install planet carrier over shaft with bronze pump drive gear **down** and mesh pinions with the sun gear *(CAUTION—make certain carrier bottoms against snap ring)*. On Cadillac and Lincoln, install small spacer on shaft. On all other models, install snap ring in shaft groove to position carrier (this snap ring not used on Cadillac and Lincoln).



3) Install clutch release wave spring and spring retainer on internal gear side of reverse internal gear, install stationary cone on internal gear cone using large snap ring pliers to spread cone just enough to permit installation *(CAUTION—do not spread cone more than necessary and see that small dowel on cone points toward gear teeth)*. Install large bronze thrustwasher over collar of reverse internal gear.

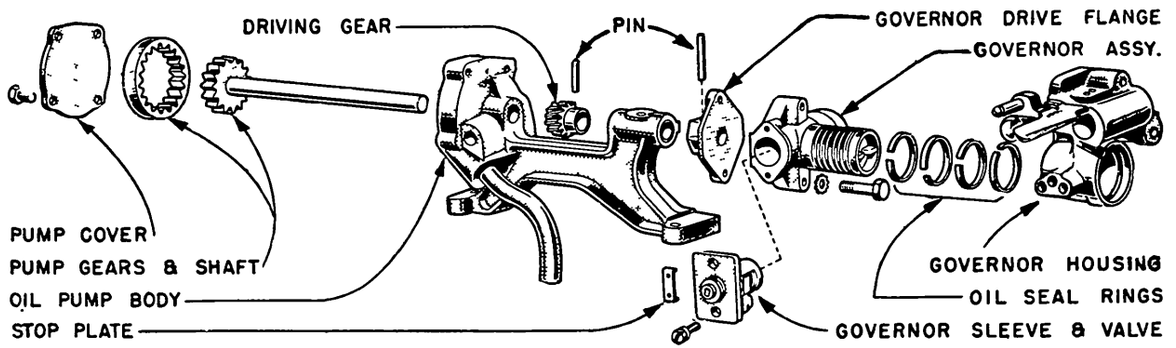
4) Install piston inner seal in groove in hub of bearing retainer or extension housing with lip inward, and outer seal in groove on outer rim of piston with lip down away from cone. Apply light coat of hydra-matic fluid to outer surface of seals.

5) Install the clutch piston in rear bearing retainer or extension housing so that it rests on the dowel pins *(CAUTION—do not align piston holes with dowels)*, insert Outer Seal Compressor Tool J-4752 (.025" shim stock) around seal and down against ledge in counterbore in retainer, rotate piston until holes line up with dowel pins and push piston into retainer using extreme care to avoid damage to seal, remove tool. Install six piston release springs and spring retainer, compress springs with Tool J-4670 or J-4670-A, install retainer snap ring, remove tool. Check for correct assembly and seating of the piston as follows:

Piston Assembly Check—Place a straightedge across the face of the piston and measure distance from straightedge to face of rear bearing retainer or extension housing on each side. This distance should be 3/8" to 13/32". **If less than 3/8",** dowel pins are too short and unit should be replaced. **If more than 13/32",** disassemble unit and make certain dowel pins pressed in fully (check in an arbor press). If height still greater than 13/32" when reassembled, replace rear bearing retainer.

►***OLDSMOBILE REASSEMBLY CAUTION:*** On these models, disregard steps 6 through 9 and use special reassembly procedure as follows: Install reverse internal gear and stationary cone assembly in rear bearing retainer, compressing stationary cone by hand and positioning cone keyway so that it will line up with keyway in case when assembly is installed later (CAUTION—use care that thrustwashers do not slip out of place). Position ball bearing in retainer counterbore to act as a guide, install rear bearing retainer over output shaft (CAUTION—use extreme care to prevent shaft damaging bushing and bearing in retainer). Remove ball bearing from retainer (use tool J-5139). Install inner snap ring in LOWER groove of output shaft, reinstall ball bearing using tool J-5138 to drive bearing in solidly against snap ring, install large snap ring in retainer groove to retain bearing, on 1952-54 models install outer snap ring in groove in output shaft back of bearing. On 1955 models place "O" ring around sleeve and slide sleeve on output shaft just past the snap ring groove in shaft; then using a small bladed screwdriver slide "O" ring from sleeve. Remove sleeve and push "O" ring against inner race of bearing. Slide sleeve into position over "O" ring *(NOTE—If sleeve not a free slide fit, tap sleeve into position using Tool J-5138. Install snap ring into groove in output shaft next to sleeve. Then proceed with step 10 below.*

DUAL-RANGE HYDRA-MATIC FRONT OIL PUMP ASSY.



6) On all models except Oldsmobile, install ball bearing in rear bearing retainer or extension housing using special installing tool to tap bearing in so that it is fully seated. Install NEW special snap ring in retainer to retain bearing.

7) On all models except Oldsmobile, install reverse internal gear and stationary cone assembly in rear bearing retainer, compressing the stationary cone by hand and positioning keyway in cone so that it will line up with keyway in transmission case when the assembly is installed later ***CAUTION—use care that thrustwashers do not slip out of place while installing this assembly.***

8) On all models except Oldsmobile, carefully install output shaft assembly in rear bearing retainer or extension housing, meshing the reverse planet gears with the internal gear and that bearing is fully seated on output shaft.

►***CAUTION—Use extreme care not to damage bushing and bearing when inserting output shaft through these parts.***

9) On Cadillac and Lincoln, install rear bearing spacer over end of ouput shaft so that it seats against bearing inner race, install open type snap ring in groove in output shaft to retain spacer and bearing (work through access opening on side of housing—then install gasket and cover to close this opening). On all other models except Oldsmobile, install special snap ring in output shaft groove directly back of bearing (no spacer used on these models).

DUAL-RANGE HYDRA-MATIC REAR OIL PUMP & GOVERNOR

CONTINUED N NEXT PAGE

OVERHAUL (Continued)

10) Install NEW rear oil seal in rear end of rear bearing retainer or extension housing using special tool to seat the seal (seal not used on all models). Install speedometer gear assembly. Place new gasket on mounting face of retainer. Install key in stationary cone keyway using Lubriplate to hold key in position until assembly installed in transmission case.

FRONT PUMP: *CAUTION—If pump rotor found to be broken when disassembled, completely disassemble and thoroughly clean transmission to remove all metal particles (may cause breakage of rear pump, parking brake bracket, and governor) and use NEW oil screen when reassembling transmission (all particles of metal cannot be removed from old screen).*

▷*1952-53 REPLACEMENT PUMP CAUTION:* Use only later type pump with improved rotor (as identified by "S" on face of pump opposite dowel pin. Mark "X" following serial number on transmission plate indicates later type pump used. *NOTE*—When installing later type pump on earlier cars, place an "X" following serial number (on Cadillac, place a daub of white paint on name plate and above body identification plate on cowl).

▷*PRIMING SPRING (FRONT PUMP) NOTE:* Two priming springs are used, replacing the single spring previously used. When overhauling earlier vane type pumps, replace single spring with later type springs.

Disassembly: Remove front pump from drive gear (tap gear out with rawhide hammer if necessary), remove gasket from pump cover. Take out four pump cover-to-body screws using J-2184-A pump holder *(CAUTION—Do not clamp pump in vise)*, carefully lift front pump cover from body, using care not to drop any of the internal parts. Mark face of rotor with prussian blue to be sure it will be reassembled properly. Remove upper vane ring and rotor, and remove vanes. Remove lower vane ring, slide, and two springs. Remove intake pipe rubber seal from pump body using a sharp awl. Compress pump relief valve spring with a screwdriver and remove retaining pin. Remove pump relief valve guide, spring and valve.

Inspection: Clean entire unit and make certain that all passages are clean and free from obstructions (run tag wire through two bleed holes in slide to make certain they are open). Check parts for scoring. See that slide is free in pump cover and does not bind. Check key in drive gear and key slot in rotor for burrs or wear. Check vanes for free movement in rotor slots and make certain they are not scored or burred. Check pump body bushing for scoring, flaking, or excessive wear (slight wear permissible). Check oil seal ring in pump cover to make certain it is free in groove and not broken or worn. Check oil seal in cover hub for wear or distortion. Make certain that relief valve and pressure regulator valve are free in pump body.

Reassembly: Reverse the disassembly sequence (above) and note the following important points:

Oil Seal Ring Replacement—If ring in groove on cover hub requires replacement, check gap of new ring in bore of torus cover before installing ring on pump cover. Gap should be .001-.007" with ring installed in torus cover.

Oil Seal Replacement—If oil seal in cover hub requires replacement, remove old seal with a small chisel, use special tool to install new seal with spring-loaded lip toward rear. Permatex #3 or similar sealer may be used to seal area between seal and cover.

▷*OIL SEAL CAUTION*—Two types used optionally. Seals differ in appearance but either type may be used and must be installed with lip toward rear.

Priming Spring & Slide—Spring must be properly installed under slide so that slide bottoms against lower stop in cover when spring compressed.

Rotor Vanes—Vanes should be installed in rotor after one guide ring and rotor installed (CAUTION—install rotor in accordance with marks made during disassembly). Install vanes with full polished edge facing slide (opposite edge will be polished only at points where vane contacts guide rings). Check rotor clearance with both guide rings installed by using feeler gauge between each vane and inside diameter of slide with vanes on opposite side contacting slide. Clearance must not exceed .003" (0-.003"), replace pump if excessive.

Pump Cover & Body Assembly—Lubricate all parts in cover with Hydra-Matic fluid before installing pump body. Body should fit freely over dowel pins in cover. Use holding tool J-2184-A and tighten cover-to-body screws to 12-15 ft.lbs. torque.

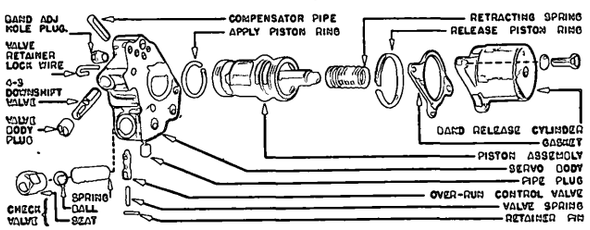
Final Assembly Check—With pump completely assembled, move rotor by hand to make certain that rotor, vanes and slide move freely. Priming spring should return slide to priming position after slide moved down to compress spring.

Drive Gear Assembly—Pump should be assembled to drive gear before assembly installed in transmission. Index rotor key slot with key on drive gear and slide pump on drive gear. *DO NOT FORCE PUMP ON DRIVE GEAR.*

REAR OIL PUMP & GOVERNOR: *GOVERNOR CHANGE NOTE*—Both die-cast and cast-iron governors have been used. Both types interchangeable but cast-iron type should be used for replacement.

▷*DISASSEMBLY CAUTION—Mark edge of governor body and drive flange before removing governor to insure re-installation in same position.*

Disassembly: Remove governor assembly from drive flange (two screws in governor body). Do not disassemble governor further except for cleaning or Oil Ring Replacement *(NOTE*—Governor serviced as complete unit except for Oil Rings). Remove pump cover (four screws), remove pump outer gear from body. This completes disassembly unless replacement of governor drive flange, pump and governor driven gear or shaft, or pump body is necessary in which case proceed as follows:



Replacement of Governor Drive Flange, Pump & Governor Drive Gear or Shaft, or Pump Body—Grind off end of lock pin in governor drive flange and in driven gear, drive pins out (use tool J-2183-1 clamped in vise to support shaft), remove burrs from shaft at pin holes, remove shaft through gear and body. Assemble parts in same manner using tool J-2183-1 to support shaft and peening tool J-2183-2 to peen ends of new locking pins to fill holes in shaft and gear or drive flange *(CAUTION*—height of peened end of pins must not exceed .070"). *See Transmission Reassembly data for governor drive flange run-out check (run-out must not exceed .002").*

Governor Disassembly (for cleaning or Oil Ring replacement)—Remove oil seal rings from governor body. Withdraw G1 and G2 stop plates from slots in body casting *(CAUTION*—do not attempt to remove G1 or G2 valves from body casting).

Inspection: Check governor G1 and G2 valves for free operation (if valves cannot be freed by operating them with governor immersed in cleaning fluid, replace governor assembly). Check governor oil rings for free movement in grooves, inspect ring lands and replace governor assembly if lands worn or damaged. Make certain all passages in governor body are clean and open. Check governor mounting face for nicks, burrs, or warped surface which would prevent securing oil-tight joint. Check pump body and cover for scoring or wear, check pump gears for wear or damaged teeth.

Reassembly: If new governor oil seal rings being installed, check ring gaps with rings installed in bore of parking bracket assembly. Gap should be .001-.007" and ring clearance in groove should be .001-.003". Install rings in governor grooves carefully. Install G1 and G2 stop plates in governor body grooves *(CAUTION*—valves must be correctly positioned so that stop plates enter freely without striking and damaging shoulders on valves). Install governor on drive flange with locating marks lined up, tighten two body-to-flange screws to 6-8 ft.lbs. Install oil pump driven gear in pump body, install cover and tighten cover screws securely.

FRONT SERVO: *(NOTE—1952 servos are not interchangeable with later type servos because of the addition of a Line Exhaust Valve & Overrun Control Valve Body. Some early 1953 models may have the same type servo as used in 1952 models).*

1952 DUAL-RANGE HYDRA-MATIC FRONT SERVO ASSEMBLY

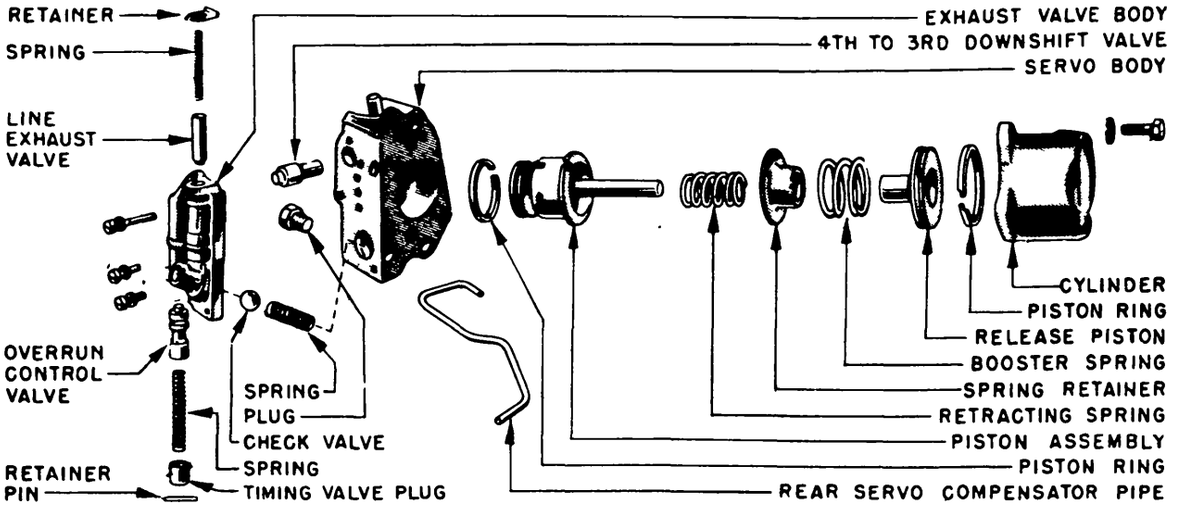
▷1952 Front Servo Production Change—(To provide better oil seal within release cylinder)—Two distinct production changes made: (1)—Gasket used between release cylinder and servo body on later transmissions and this gasket should be installed in first transmissions whenever servo disassembled. (2)—Improved piston assembly with longer shoulder diameter to provide better oil seal within release cylinder used on later transmissions. This later type assembly interchangeable with first type but DIFFERENT SERVO SPRING USED WITH EACH TYPE CYLINDER.

Disassembly (1952): Remove capscrews in front band

CONTINUED ON NEXT PAGE

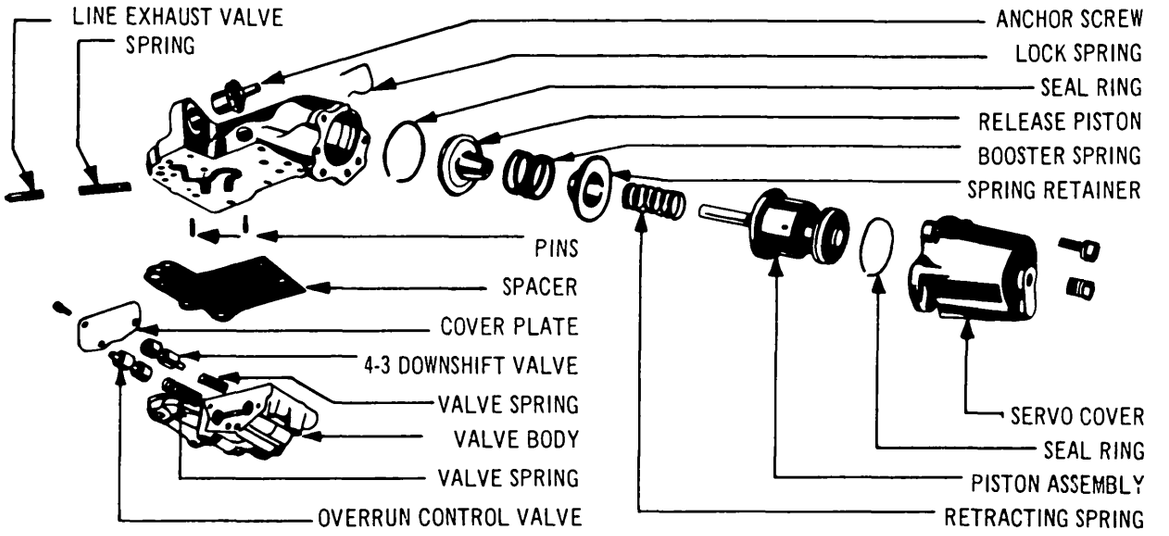
OVERHAUL (C ntinu d)

release cylinder, remove cylinder and servo spring from servo body. Remove servo release-and-apply piston assembly *(NOTE*—do not disassemble this unit—it is serviced as a complete assembly). Remove pipe plug and retainer spring holding 4-3 valve in place, remove valve. Remove rear pump check valve seat, ball, and spring. Clean up peened end of over-run control valve pin with a file, remove pin with pliers *(CAUTION*—keep finger over port to prevent spring flying out when pin removed), remove spring and over-run control valve. Remove compensator pipe from servo if this part loose. Take out ⅛" pipe plug from servo body (adjacent to over-run control valve port).



Disassembly: (1952-54 All Models. 1955 Chevrolet Truck, Hudson, Kaiser, Nash Rambler, & Willys)—Remove release cylinder to servo body attaching screws and lockwashers. Remove release cylinder, booster spring, retracting spring retainer, retracting spring and apply piston assembly. Remove release piston from cylinder. Remove three valve body to front servo body attaching screws and lockwashers and remove valve body. *(CAUTION*—Use care not to lose rear pump ball check spring from valve body). Remove rear pump ball check spring from servo. Remove 4-3 downshift valve by turning servo body over and catching valve in hand. Work overrun control valve pin out with needle nose pliers. Use care when removing pin to avoid losing overrun control valve spring plug. Remove spring and overrun control valve. Depress line exhaust valve spring and slide retainer out of valve body. Remove spring and line exhaust valve.

Disassembly: (1955 Cadillac, Oldsmobile & Pontiac)—Remove front band adjusting screw. Remove valve body to front servo attaching bolts and remove valve body and spacer plate. Remove front servo valve body cover plate attached to valve body by three screws. Remove 4-3 downshift valve and spring, and control valve and spring from valve body. With aid of needle nose pliers remove line exhaust valve retaining pin from servo body and remove spring and valve. Remove screws and lockwashers holding front servo apply cylinder. Remove servo retracting spring, retainer, booster spring and ban release piston. Remove piston assembly from apply cylinder.



Inspection: Inspect servo body and front band release cylinder for wear and scoring. See that all passages in servo body are clean and not obstructed and that two steel plugs which seal oil passages are tight and staked in place. See that servo piston locating pin in servo body is in place and tight and that outer end of pin is just below face of servo body. Check 4-3 valve and over-run control valve for wear and scoring and make certain valves are free in bore. Orifice in 4-3 valve must be clean and not obstructed. Inspect servo piston assembly for wear or scoring, obstructed passages, and worn or broken rings. Make certain rings are free in grooves and that compensator piston works freely in bore in servo piston. Check springs for distortion or collapsed coils by checking approximate free length. *See Control Valve Spring illustration.*

Reassembly (1952): Reverse disassembly procedure and particularly note following production change and other important points:

Servo Retracting Spring Note—Make certain that correct type spring used with first or later type piston assemblies.

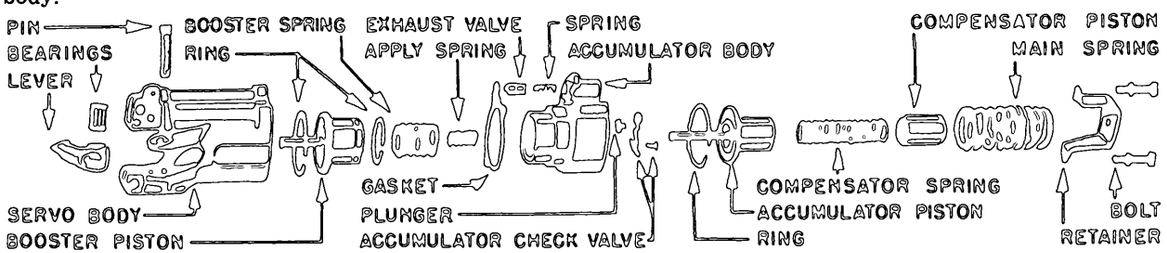
TYPICAL FRONT SERVO UNIT (1953-54 ALL MODELS; 1955 ALL MODELS EXC. CADILLAC, LDSMOBILE & PONTIAC)

TYPICAL FRONT SERVO UNIT (1955 CADILLAC, OLDSMOBILE & PONTIAC)

4-3 Valve Installation—After installing valve in body, align valve slot with spring retainer hole and install retainer. Check the valve for free operation after retainer installed.

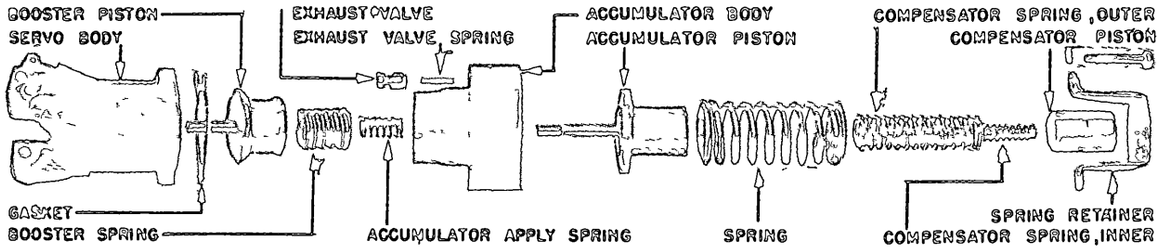
Overrun Control Valve Installation—Use only latest type valve (with groove on side at domed end) for replacement. *(NOTE—This valve will correct slippage in "Dr 3" when using engine as a brake).* Use new pin to retain valve and spring, peen end of pin to prevent it working out in service.

Servo Piston & Release Piston Installation—Compress oil seal rings and start these into body carefully to avoid breaking or damaging rings. Make certain that groove in servo piston engages locating pin in servo body.



Reassembly: (1953-54 All Models. 1955 Chev. Truck, Hudson, Kaiser, Nash, Rambler, Willys—*NOTE—Lubricate parts as installed.* Install ⅛" plug in bore of front servo body. If oil transfer pipe was previously removed, reinstall pipe in servo body bore, tapping

CONTINUED ON NEXT PAGE



OVERHAUL (Continued)

into place with a plastic hammer. Install oil rings on front servo piston and front band release piston. Insert stem of front servo piston assembly through bottom side (small hole) of band release cylinder. Stem of piston is to serve as a guide to install front band release piston in band release cylinder. Carefully compress oil ring on release piston; then install release piston in release cylinder over stem used as a guide. Push release piston and stem down evenly until piston is seated against bottom of cylinder. Remove servo piston and stem used as a guide. While carefully compressing oil seal ring on front servo piston, work piston into front servo body. Be sure groove in piston sleeve locates on positioning pin in servo body. Position retracting spring, release spring retainer, and booster spring over stem of front servo piston. Align drilled bosses in band release cylinder with tapped holes in servo body, then carefully guide band release cylinder down over piston stem, booster spring, spring retainer and retracting spring. Make sure band release cylinder seats squarely on servo body. Install three bolts and lockwashers. Tighten to 6-8 ft. lbs. Insert 4-3 valve in bore in servo body, small diameter of valve into body first. Install overrun control valve, spring and plug in bore of front servo valve body; then while compressing overrun control valve spring with a blunt screwdriver, press against plug and install new overrun control valve retainer pin. Install line exhaust valve in valve body. Compress spring and slide line exhaust valve spring retainer into slot in valve body. Position rear pump check valve ball in seat, and spring in bore of servo body. Make sure 4-3 valve is in bore of servo body; then align front valve body and check valve ball with servo body and check valve spring. Install and tighten three front valve body to servo body attaching screws.

Reassembly: (Cadillac, Oldsmobile, & Pontiac)—Install front servo piston assembly into front servo apply cylinder. Be sure to align slot in sleeve over the small dowel pin in cylinder. Install front servo band release piston into front servo valve body, being careful not to damage ring. Install booster spring over front band release piston. Place retracting spring retainer over piston stem, down onto booster spring. Place retracting spring in retainer. Position front servo apply cylinder and piston assembly on servo body and tighten in place with attaching screws and lockwashers. Install line exhaust valve, spring and pin retainer into servo body. Install 4-3 downshift valve and spring. Overrun control valve and spring, into respective bores in servo valve body. Attach valve body and plate to servo body. Install band adjusting screw into servo body.

1953-55 TYPICAL REAR SERVO ASSEMBLY

TYPICAL 1952 DUAL-RANGE HYDRA-MATIC REAR SERVO ASSEMBLY

▷*RELEASE CYLINDER-TO-SERVO BODY GASKET CAUTION*—Use a gasket at this point on ALL transmissions (this gasket not used on first transmissions but should be installed whenever servo disassembled to reduce oil leakage between machined surfaces of servo).

REAR SERVO: *CAUTION—Servo must be disassembled and reassembled in arbor press to control spring pressures.*

Disassembly: Place servo in arbor press with spring retainer up, bring ram down to rest on retainer. Take out two screws and lockwashers holding retainer on servo body, release press slowly until servo spring pressure relieved, remove assembly from press. Remove spring retainer, accumulator spring, compensator piston, spring, and accumulator body and piston assembly from servo body. Remove gasket, exhaust valve, and spring from accumulator body, then rest accumulator body on vise with copper jaws, tap accumulator piston through spring and body. Remove booster piston and spring from servo body. Take out cotter pin in each end of band actuating lever pivot pin on servo body bracket, push pin out (*CAUTION*—use care not to lose bearing needle rollers from lever), remove lever and needle bearings.

Inspection: Wash all parts in cleaning solvent and dry thoroughly with compressed air. Inspect parts and check clearances as follows:

Spring Retainer—Check for bending or distortion indicating severe strain, reshape retainer as required.

Compensator Piston—Piston clearance in accumulator piston bore should be .003-.005". Check with feeler gauge. Inspect compensator piston for wear, scores, nicks, or burrs which might interfere with free operation or cause oil leakage.

Servo Body & Accumulator Body—Inspect for nicks, burrs, scoring, wear, obstructed passages, and all conditions which might cause oil leakage or prevent free operation. Inspect accumulator check valve and make certain that rivet is tight, valve seats flat on accumulator body, hole in valve is open, and that check valve plunger is free. If required, replace check valve as follows:

Check Valve Replacement—Drive out rivet, remove check valve and plunger from accumulator body. Clean body and passages. Install plunger and check valve (engage plunger groove in notch in valve) so that bleed hole in valve is directly over hole in body, insert rivet through valve and into body. Support rivet head on steel bar clamped in vise and peen rivet securely. Make certain that plunger and valve work freely.

Accumulator Piston & Piston Rod—Inspect piston and rod for nicks, burrs, scoring, wear which might cause oil leakage or sticking. Check piston clearance in accumulator body with feeler gauge (with oil ring removed). Clearance should be .005-.009". Check piston ring gap (ring inserted in body) and side clearance in ring groove. Gap should be .010" maximum and side clearance .0005-.0025".

Booster Piston—Check piston clearance in accumulator body (use micrometer and telescopic gauge), and clearance in servo body (remove oil ring, insert piston in servo body, use feeler gauge to check clearance). Both clearances should be .006-.010". Check large piston ring gap (with ring inserted in servo body) and ring side clearance in groove (with ring installed on piston). Gap should be .010" maximum and side clearance .0005-.0025". Check booster piston rod for free operation in servo body.

Servo Exhaust Valve—*NOTE—Two types used but valves are interchangeable* (later type has shoulder at "Lo" oil apply end to eliminate possibility of valve hanging up on servo body gasket). Inspect valve and valve bore in accumulator body for scoring, make certain that valve operates freely. Check valve spring for distortion or collapsed coils.

Servo Springs—Inspect all springs for damage, distortion, or collapsed coils. *NOTE*—Double compensator springs (inner and outer) used on some models.

Reassembly: Lubricate pistons and rings with clean hydra-matic fluid before installing and use extreme care not to damage oil rings when inserting pistons in bore of accumulator and servo bodies. Install all parts in reverse order of disassembly sequence (above) and note following important points:

Servo Lever Needle Bearing Assembly—Use heavy grease to hold needle rollers in lever while installing lever and pivot pin.

Booster Piston Springs—Install smaller booster spring (accumulator apply spring) on accumulator piston rod with smaller tapered end of spring to-

CONTINUED ON NEXT PAGE

Form 568—1956-M

OVERHAUL (C ntinu d)

ward accumulator body and tap spring on rod until small end seats against shoulder.

Final Assembly—After all parts installed in servo and accumulator bodies, install gasket on accumulator body (use petrolatum to hold gasket) and position accumulator assembly on servo body in an arbor press with ram resting on spring retainer, compress spring to enable retainer screws to be tightened.

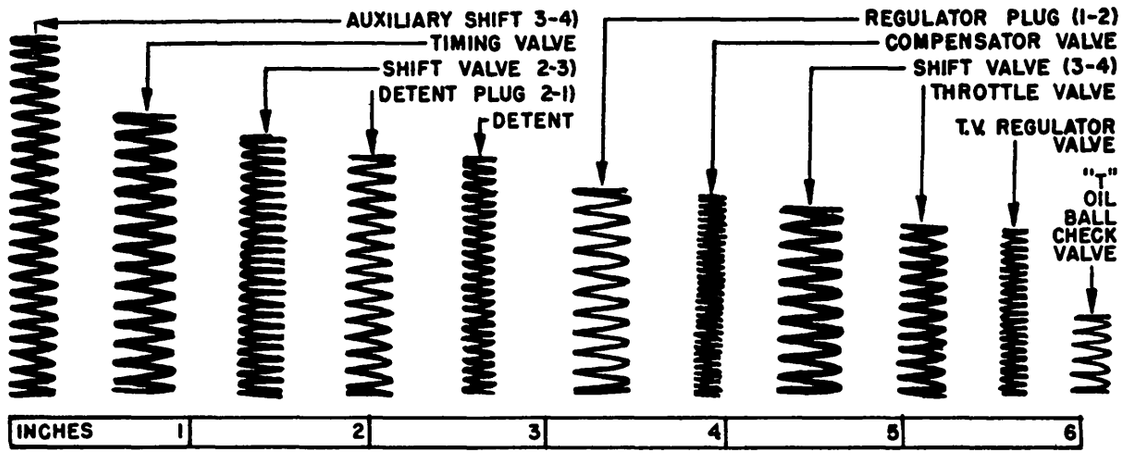
►*SERVO EXHAUST VALVE CAUTION*—If first type valve used (without shoulder at "Lo" oil apply end), make certain that gasket aligned so that valve will not hang up on edge of gasket when servo assembled.

PARKING BRAKE BRACKET: Disassembly—Compress the parking blocker piston spring and remove retaining pin with needle nose pliers *(CAUTION*—use care that spring does not fly out), withdraw spring and parking blocker piston. Round off peened head of reverse blocker piston stop pin with a file, pull pin out of bracket *(CAUTION*—use care that spring does not fly out), withdraw spring and reverse blocker piston. This completes disassembly (do not disturb welded crank assembly).

Inspection: Clean all parts thoroughly. Inspect both blocker pistons for scores, burrs, or excessive wear. Check fit of pistons in bores (slight vacuum should be created when piston pulled out with oil hole to sleeve closed by a finger). Check piston springs for distortion or collapsed coils (see spring specifications below). Check bracket mounting face for nicks, burrs, or warped surface which would allow oil leakage, make certain that ¼" plugs are in place in drilled blocker piston passages and that center hole of oil delivery sleeve is plugged and that plug is tight. Make certain governor feed passage is clean and open by running tag wire through passage. Check oil delivery sleeve for scoring or excessive wear. Inspect bracket and crank assembly for free operation of the crank without excessive wear, check crank roller and parking pawl for wear, check for cracks at point where pawl is welded.

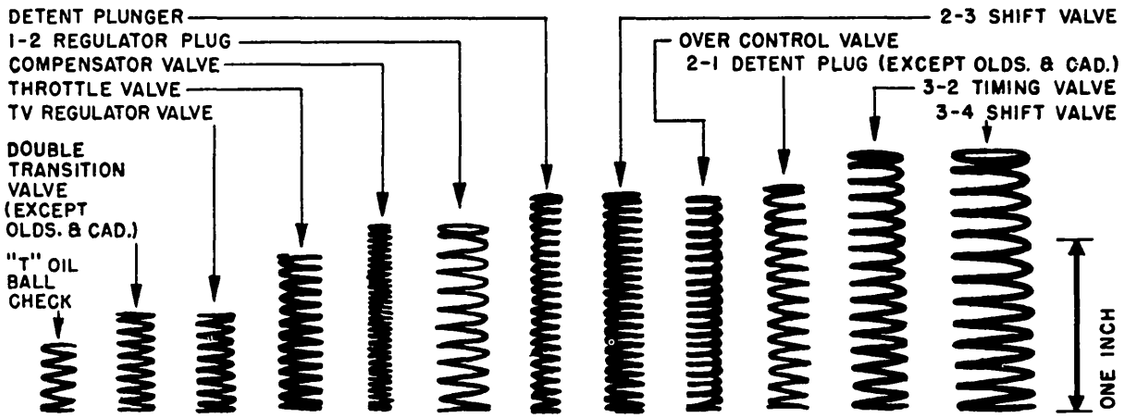
Reassembly: Install both blocker pistons and springs (slotted end of piston out), peen both ends of reverse blocker piston stop pin securely. *NOTE*—do not peen end of parking blocker piston retaining pin (this pin retained by pin retainer on lower mounting bolt when unit installed in transmission, pin retainer also seals off oil pressure in bolt hole).

CONTROL VALVE: *(DISASSEMBLY & REASSEMBLY NOTE): Service procedures on all control valves are similar. Refer to notes and production changes below for differences.*



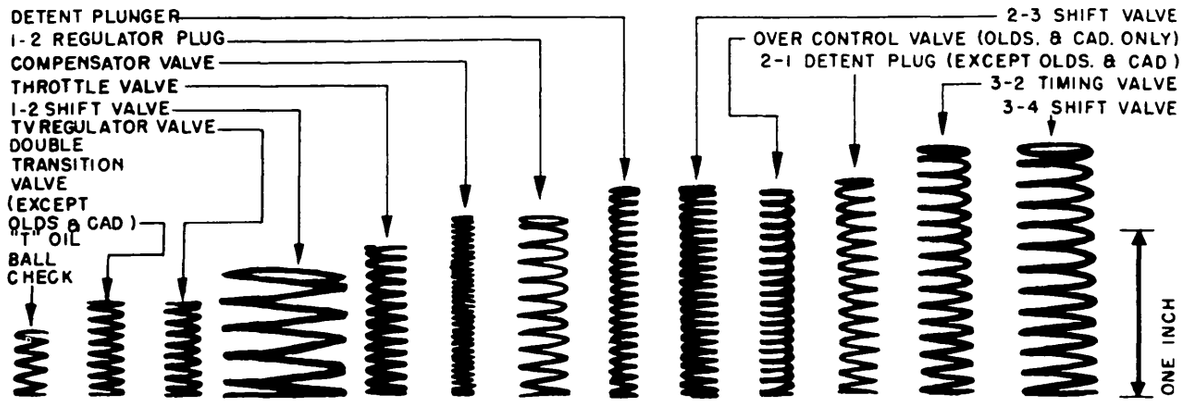
►*EARLY 1953 CONTROL VALVE ASSEMBLY IDENTIFICATION CAUTION*—1952 type control valve assemblies used on Early 1953 transmissions may be identified by a daub of yellow paint on transmission throttle lever shaft.

►*1954 & LATER CONTROL VALVE NOTE: "O" ring type seal used on throttle shaft.*



►*1955 CADILLAC, HUDSON, NASH CONTROL VALVE NOTE:* 1-2 regulator plug spring has been eliminated and a 1-2 shift valve spring has been added to the control valve assembly.

►*1955 CADILLAC, OLDSMOBILE, PONTIAC CONTROL*



CONTINUED N NEXT PAGE

1952 DUAL-RANGE HYDRA-MATIC CONTROL VALVE SPRINGS

1953-54 DUAL-RANGE HYDRA-MATIC CONTROL VALVE SPRINGS

1955 DUAL-RANGE HYDRA-MATIC CONTROL VALVE SPRINGS

OVERHAUL (Continued)

VALVE NOTE: The 3-2 detent plug is located between front valve body and inner valve body and is not accessible by removing the detent plug plate as on other models.

Disassembly: *See illustration for identification and location of valve parts.*

1) Remove two screws holding inner and outer valve body together. Remove washer on manual control shaft. Separate inner and outer valve bodies and remove spacer plate. Place outer valve body on bench with inside face up. Remove timing valve body assembly from inner valve body by removing two screws and lockwashers.

2) Compress spring and remove timing valve retainer pin, plug, spring and valve. Remove three governor end casting retaining screws and remove end casting, and separator plate. Compress over-control valve spring and remove retainer, spring and valve from governor end casting.

3) Remove 2-1 detent plug, 2-3 governor plug, sleeve, and auxiliary valve and the 3-4 governor plug. Remove front valve body plate (regulator plug end casting plate), "T" oil ball check valve and spring. (*CAUTION*—Front valve plate on some early production cars required four attaching screws, one being 1/16" shorter. Note location of this shorter screw, as a longer screw in its place will interfere with front valve body to inner valve body attaching screw, causing a leak).

4) Remove detent plug retaining plate from regulator plug end casting and remove the 2-3 detent plug, 2-3 shift valve spring and guide pin (On 1952-53 Oldsmobile and Cadillac, loosen the three regulator plug end casting screws approximately 3/16" to allow installation of Tool J-5157 over separator plate to hold springs compressed, then complete removal of regulator and casting. Remove tool by pressing down on spacer plate and sliding tool off to allow springs to expand gradually). On other cars remove three screws holding front valve body assembly to inner valve body and remove front valve body assembly and separator plate.

5) Remove following parts from inner valve body: 3-4 shift valve spring, 3-4 lockout valve assembly, 3-4 auxiliary shift spring, 3-4 shift valve, 1-2 regulator plug spring, 1-2 shift valve, 2-3 shift valve spring, 2-3 spring guide pin, 2-3 shift valve, 2-3 governor sleeve and 2-3 auxiliary valve (push these two parts out with pencil or wooden rod).

6) Remove manual valve from outer valve body. Remove detent plunger retainer from outer valve body (three screws), remove retainer plate. Then remove following parts from outer valve body: "T" valve, throttle valve spring, throttle valve, and double transition valve (NOTE—Double transition valve spring not used on 1953-55 Cadillac & Oldsmobile, 1955 Chevrolet Truck, & Pontiac.

7) Remove front plate from outer valve body (three screws, and remove compensator valve, spring and detent plug. Remove compensator auxiliary plug stop pin (needle bearing roller) holding compensator auxiliary plug in outer body. Remove compensator auxiliary plug by inserting 1/8" welding rod in hole in plug and using another rod, push plug from body. *CAUTION*—Because plug is short, be very careful not to drop it from between rods and have it become lodged in valve body.

Inspection: Clean valve body castings and valve parts in clean solvent (*CAUTION*—clean each valve singly using care not to nick or burr the valves). Inspect all valves carefully for burrs, scores, scratches, and wear. Burrs can be removed with a fine stone or crocus cloth (*CAUTION*—use care not to round off edges, these valves have sharp edges to prevent dirt wedging between valve and body). Inspect valve body castings for nicks, scratches, or warped mating surfaces (check for flatness on surface plate). Check valves and plugs for clearance in body by inserting in proper bore in body (both parts must be clean and dry). Valves should fall through bore of own weight when body tilted and shaken slightly. Check all valves springs for distortion (*NOTE—see illustration for identification of springs*). Check throttle valve inside lever and shaft for correct fit in hub of inside detent control lever on outer valve body. If shaft excessively worn, binds on shaft, or if oil seal damaged, replace parts.

▷*REPLACEMENT VALVE NOTE—Only the manual valve is furnished for service. If other valves or body casting being replaced, install new Control Valve Assy.*

Reassembly: 1) Install compensator auxiliary valve in outer valve body using 1/8" punch or rod to guide valve into place (*CAUTION*—use extreme care not to allow valve to drop down and lodge in body casting). Install pin to hold valve in place.

2) Insert compensator valve, spring, and detent plug in outer valve body, install front plate and secure with three attaching bolts.

3) Insert double transition valve, transition valve spring (spring not used on 1952-55 Cadillac & Oldsmobile, 1955 Chevrolet Truck & Pointiac), throttle valve, throttle valve spring, and "T" valve in outer valve body, install plate and detent plunger retainer and secure with three attaching screws.

4) Insert manual valve in outer valve body and detent spring and plunger in retainer, align manual valve with inside detent control lever and rotate control lever clockwise to index plunger on detent control lever assembly with groove in manual valve. Install manual shaft inner seal washer with small inside diameter over manual control shaft, dish up. Install manual shaft outer washer with large inside diameter over manual control shaft, dish down. Install rubber manual shaft seal over shaft with lip extending into inside of outer washer. Check to see that by-pass valve on inside of outer valve body seats against spacer plate. Visually perform this by placing plate on edge over by-pass valve.

5) Install following parts in inner valve body: 2-3 auxiliary valve and 2-3 governor sleeve (*CAUTION*—work valve stem into bore carefully so that it does not hang up on sleeve counterbore, check by shaking body assembly to make certain valve is free in bore), 3-4 governor plug (use brass rod in plug hole to assist in installation), 2-3 governor plug, 2-1 detent spring (not used on all transmissions), and 2-1 detent plug. On models with over-control valve, insert the over-control valve and spring in rear valve body and install retainer clip. On all models, install spacer plate and rear valve body on inner valve body and secure with three attaching screws. *CAUTION—Detent plug can be held in position against the spring tension with the spacer plate while starting the attaching screws.*

6) Complete assembly of inner valve body parts as outlined below. Assembly Clamp, Tool J-5157, will facilitate assembly as follows:

With Tool J-5157—Insert 2-3 shift valve, 1-2 shift valve, 3-4 shift valve, 3-4 auxiliary spring, 3-4 lock-out valve, and 3-4 shift valve spring. Depress 3-4 shift valve spring and install tool J-5157 over inner valve body, insert front valve body separator plate under tool tangs and carefully position plate on inner valve body. Insert 2-3 shift valve spring and spring guide pin, and 1-2 regulator plug spring through holes in separator plate. Assembly is then ready for front valve body installation (step 9).

Without using Tool J-5157—Insert 2-3 shift valve, spring, and spring guide pin; 1-2 shift valve and spring, 3-4 shift valve, 3-4 auxiliary shift valve spring, 3-4 lock-out valve, and 3-4 shift valve spring. Lay assembly on clean flat surface until front valve assembly has been completed.

7) Insert 3-2 detent plug in front valve body. On control valve assemblies with 3-2 detent plug plate, install plate and attach with two screws, making sure plate is installed correctly to cover bore in valve body.

8) Insert following parts in front valve body: "TV" regulator spring and valve, 1-2 regulator plug, 3-4 regulator plug, "T" oil ball check and spring, install cover plate and secure with three screws (CAUTION—Front valve plate on some early cars had four attaching screws, one being 1/16" shorter. This short screw must be installed in the one middle hole closest to center of control valve body, otherwise it will interfere with front valve body to inner valve body attaching screw directly below it and cause a leak). If Tool J-5157 not used, install separator plate on front valve body and insert three screws which attach front valve body to inner valve body. These two assemblies are now ready for joining as follows:

9) Place front valve assembly on clean flat surface in line with inner valve body assembly (see step 6 above) and bring the two assemblies together, aligning the springs protruding from the inner valve body with corresponding plugs in front valve body, start the attaching screws into the inner valve body to maintain alignment. If tool J-5157 being used, slide the tool off the inner valve body at this point. Tighten screws alternately to bring the two valve body assemblies together evenly.

▷*CAUTION—Make certain that 3-4 lock-out valve enters inner valve body and that all springs line up with their respective valves and plugs before tightening the screws. Tighten screws alternately and evenly to secure good alignment and contact of the valve bodies.*

10) Insert following parts in timing valve body: 3-2 timing valve, timing valve spring, and timing valve plug. Compress assembled parts and install plug retainer pin. Install timing valve body assembly on inner valve body assembly and secure with two attaching screws.

11) Install spacer plate and outer valve body assembly on inner valve body assembly. Align these parts by inserting four control valve-to-transmission mounting bolts, install and tighten the two attaching screws in the valve body assembly to 3-4 ft.lbs. Remove mounting bolts.

12) Install washers and seal on manual shaft in following order: Inner Spring Washer (washer with large hole—dished side out), Outer Spring Washer

CONTINUED ON NEXT PAGE

OVERHAUL (C ntinu d)

(washer with smaller hole—dished side in), Shaft Seal (lip in toward washers).

PRESSURE REGULATOR VALVE: *See Front Pump & Pressure Regulator illustrations for identification of valve parts.*

Disassembly: Separate regulator valve, plugs, and spring from regulator plug.

Inspection: Inspect reverse booster plug and T.V. pressure plug for nicks or scores and see that these plugs have free movement in regulator plug. Check regulator spring for distortion or collapsed coils. Check pressure regulator plug seal and gasket and replace if damaged or worn. Blow out passages in regulator plug with air to make certain these passages clean and open.

Reassembly: Install regulator valve in regulator spring with **small end of spring fitting in groove on valve.** Install T.V. pressure plug and reverse booster plug (chamfered end in) in regulator plug spring and install valve assembly in plug.

LINE EXHAUST VALVE (1952 CARS): *VALVE CHANGE CAUTION—Two different types used (different length valves and springs) and CORRECT type valve and spring must be used in each transmission (valve bore in case also changed so that VALVE ASSEMBLIES ARE NOT INTERCHANGEABLE). Replacement valve and spring must be same type as removed.*

Exhaust Valve Assemblies

	Valve Length	Spring Free Length
First Type	1 9/16"	2 27/64"
Later Type	1"	1 49/64"

Inspection: Inspect valve and valve bore in case for nicks or scores, check to make certain valve works freely in bore of case. Inspect valve sleeve for damage or distortion resulting from sleeve removal. Inspect valve spring for distortion or collapsed coils and make certain spring is correct type for valve (see spring data above).

Reassembly: *CAUTION—Install same type valve and spring as used originally (see Change Caution above).* After transmission case has been inspected (below), install valve spring and valve in valve bore in case, make certain that valve works freely and bottoms in valve bore by using ⅛" rod to work valve up and down. Install exhaust valve sleeve with flat on sleeve toward servo side of case (to provide clearance for servo attaching bolt) and tap sleeve in with a clean soft hammer until it bottoms in bore with edge of sleeve just below machined surface of case.

►*CAUTION—DO NOT force sleeve in deeper than bottoming shoulder in case (will interfere with valve operation).*

LINE EXHAUST VALVE (1953-55 CARS): Valve is located in valve body attached to front servo unit. *(NOTE*—Some early 1953 cars had same type valve as 1952 cars, above). *See "Front Servo Assembly" for installation of Line Exhaust Valve.*

TRANSMISSION CASE: Inspection—First remove band adjusting screws and oil pressure line plug on top of transmission case, clean case thoroughly with clean solvent. Blow out all oil passages (from underside of case to outside of case). Inspect case for cracks, restricted oil passages, nicked or burred mounting surafces. Check fit of oil delivery sleeve in center bearing cap (sleeve must be tight when bearing cap bolts tightened).

►*See "Pressure Test Point" illustration in TESTING for location of oil passages in case.*

FRONT & REAR BANDS: *CAUTION—DO NOT pry bands open or distort them in any manner. Bands are surface-ground for drum fit and will be damaged by rough treatment.*

Inspection—Inspect both bands for worn or burned linings, distorted or cracked bands, broken welds at anchor ends, or misaligned strut (rear band only—strut furnished as assembly with band and must pivot freely). Check band adjusting screws and screw hole in case for damaged threads, check adjusting screw locknuts for damage.

TORUS CHECK VALVE: *This assembly located in hub of driven torus.*

Disassembly (1952-53): Bend down ears on retainer at two torus check valve attaching bolts in driven torus hub, remove bolts, take out retainer, check valve and valve spring.

Disassembly (1954-55): *NOTE*—Torus check valve retainer and attaching screws no longer used.

Inspection: Clean all parts thoroughly. Inspect face and inside bearing diameters of check valve for scoring or nicks and make certain valve works freely on driven torus hub. Check valve spring for distortion or collapsed coils. Check end of planet carrier shaft for nicks or burrs that would restrict valve operation.

Reassembly (1952-53): Reverse disassembly procedure (above), tighten attaching bolts to 6-8 ft. lbs. and see that bolts are locked to prevent loosening. Check for free movement of valve.

Reassembly (1954-55): Slide torus check valve over driven hub to check freeness, then remove Torus Check Valve and Spring. Install Torus Check Valve onto mainshaft and at the same time locate Torus Check Valve Spring over hub of driven torus. Locate driven torus against snap ring and install lock plate and locknut. Tighten locknut to 50-60 ft. lbs.

TORUS COVER: *REPLACEMENT CAUTION—Before replacing cover to correct ring wear in torus cover neck, check the amount of wear as directed below.*

Inspection: Inspect inner and outer diameter of oil seal hub in cover for scoring, inspect grooved gasket surface for nicks or burrs (two continuous ridges should appear on sealing surface). Inspect splines in torus hub for wear or damage. Check for ring wear in hub, and check hub run-out as follows:

Torus Cover Ring Wear Check—Install a set of NEW front pump oil rings in the torus cover. If end gap of these new rings is NOT MORE THAN .025", cover is serviceable and can be re-installed.

Torus Cover Hub Run-out Check—Mount torus cover on flywheel without gasket using four attaching bolts evenly spaced (two adjacent to dowels and two between these points and 180° apart). Mount dial indicator so that indicating button contacts hub approximately ¼" from edge. Rotate flywheel and check run-out which should not exceed .005". If run-out greater than .005", rotate torus cover 180° on flywheel and recheck. If run-out still excessive, check flywheel run-out (if flywheel run-out less than .005", install new torus cover.

REASSEMBLY OF TRANSMISSION (INSTALLATI N OF UNITS)

AFTER SUB-ASSEMBLIES OVERHAULED (above) reassemble units in transmission cas in following order:

Front & Rear Units: With front band installed on front unit drum (band can be retained with wire or brake cylinder clamp), install assembly in case by lowering front end of planet carrier into case first. *CAUTION*—**Center hole in oil delivery sleeve must be centered between center bearing cap bolt holes and pointing upward. Remove clamp from front band and position anchor end of band over front adjusting screw. Install rear band on rear unit drum and position anchor end of band over rear adjusting screw. Install center bearing cap over oil delivery sleeve with dowel r gistering with dow l hole in sleeve, use new lockplate and tighten bearing cap bolts to 40-50 ft.lbs., secure bolts by bending lockplate up against bolt head (CAUTION—DO NOT pry lockplate corners up with a screwdriver which may damage edges of case).**

►*CENTER BEARING CAP PRODUCTION CHANGE:* Dowel pin hole has been drilled all the way through and dowel is press fitted so that upper end is flush with top of cap. If dowel pin is not indexed with hole in oil delivery sleeve, the dowel pin will push through rather than damage oil delivery sleeve when cap is tightened. *CAUTION*—Bearing cap lockplate must be flat with top of bearing after cap tightened. **If it raised up (over dowel pin), dowel pin is not indexed with oil delivery sleeve.**

Mainshaft Installation & Endplay Adjustment: Install correct thickness selective washer in counterbore of output shaft. If mainshaft had correct endplay of .004-.015" as measured before disassembly (see disassembly data), **use washer of same thickness as removed from this point. If mainshaft endplay was not correct,** select washer (see table below) **which will provide correct endplay of .004-.015". Use vaseline to retain washer. Install mainshaft in output shaft and mesh center gear with planet pinions.**

Mainshaft Selective Washer

Mark	Size	Mark	Size
1	.055-.059"	5	.087-.091"
2	.063-.067"	6	.095-.099"
3	.071-.075"	7	.103-.107"
4	.079-.083"	8	.111-.115"

Reverse Unit & Mainshaft Assembly Installation: Remove rear hub holding tool J-2174 from rear face of rear unit. Install rear clutch hub rear thrust washer in counterbore of rear hub (use vaseline to retain this washer). Install special tool or wedge screwdriver between center bearing cap and rear clutch drum to prevent drum moving forward *(CAUTION*—**insert screwdriver at an angle to prevent damage to oil delivery sleeve). See that new gasket in place on mounting face of rear bearing retainer or extension housing (gasket can be retained by vaseline) and that key is in place in keyway of stationary cone (key can be retained with lubriplate). Install the reverse unit and mainshaft assembly in rear end of transmission engaging the stationary cone key in keyway in case and meshing rear planet gears in rear unit (NOTE—revolving**

CONTINUED ON NEXT PAGE

OVERHAUL (Continued)

output shaft will facilitate meshing the gears). Align rear bearing retainer bolt holes with holes in case and just start the six bolts to align the assembly. Install the six reverse flange attaching bolts and lockwashers (remove wedging screwdriver after bolts finger-tight), tighten these bolts evenly to 10-13 ft.lbs. *(CAUTION*—use care not to distort flange and check for binding by holding output shaft and turning mainshaft). Tap or push rear bearing retainer solidly against case, tighten five rear bearing retainer bolts evenly to 28-33 ft.lbs. *(NOTE*—bolt which mounts parking pawl in case need not be torqued at this point). Check entire assembly for free operation by turning mainshaft, output shaft, and front and rear unit drums.

▷*MAINSHAFT ENDPLAY CAUTION—Check mainshaft endpay at this point BEFORE proceeding with reassembly:*

▷*NASH ENDPLAY GUIDE TOOL REWORK (For use with Statesman & Rambler 11" Torus)*—Revise the Endplay Guide Tool J-2587 for use with all Nash Transmissions as follows: Shorten tool 23/32" (from 5" to 4 9/32") by cutting off the necessary amount from mainshaft-bore end of tool, then deepen bore to 1 3/32", and chamfer sharp outer edge of tool.

Mainshaft Endplay Check—Install special tool or wedge screwdriver between center bearing cap and front clutch drum to hold front unit forward *(CAUTION*—insert screwdriver at an angle to prevent damage to oil delivery sleeve). Install mainshaft endplay guide J-2587 over forward end of mainshaft and front planet carrier. Use special mounting fixture tool J-1465 to mount dial indicator on front of transmission case so that it contacts front face of guide tool. Move mainshaft back and forth *(CAUTION*—do not force shaft) and note endplay. If endplay correct (.004-.018"), remove tool and install snap ring in forward end of shaft. If endplay not within limits, remove reverse unit assembly and change selective washer. *See Mainshaft Installation & Endplay Adjustment above.*

Front Pump & Drive Gear: Make certain that bronze thrustwasher in place on intermediate shaft against front planet carrier. Position front oil pump "O" ring seal in case and install pump and drive gear assembly on intermediate shaft (CAUTION—Align pump cover locating slot with locating washer counterbore in case), install locating washer in counterbore, install attaching bolts and tighten to 10-13 ft. lbs. Cover should protrude .003-.015" out of case. If pump cover protrudes less than .003", remove pump and add one of the earlier type gaskets (gaskets were replaced by "O" ring seals in 1954 transmissions). Install special bronze and steel thrust washers in that order over intermediate shaft and against front end of front drive gear, install snap ring to retain these washers.

Rear Pump & Governor Assembly Installation: Position reverse drive flange so that one attaching bolt is straight up, turn governor so that large round weight is forward, slide assembly into place in transmission entering governor end first through bottom of case and meshing driven gear with bronze drive gear on reverse planet carrier. Install attaching bolts and lockwashers and tighten to 15-18 ft.lbs. Check governor run-out (see below), then loosen attaching bolts (to assist in aligning governor and oil delivery sleeve during parking brake bracket installation below).

Governor Run-out Check—Mount dial indicator on side of transmission case so that indicating button contacts oil delivery sleeve approximately ¼" from end. Rotate transmission driven shaft by hand and note governor run-out. If run-out is less than .005", installation is OK. If run-out exceeds .005", remove governor assembly and check run-out at face of drive flange. If drive flange run-out is less than .002", re-install governor with body rotated 180° from previous mounting location and recheck governor run-out. If run-out still excessive, replace governor and sleeve. If drive flange run-out exceeds .002", one or more of following parts require replacement: governor drive flange, gear set, or complete rear oil pump assembly.

Parking Brake Bracket Installation: Remove rear bearing retainer bolt which mounts parking pawl (do not re-install this bolt until later), install parking pawl and position pawl as far down in case as possible. Turn rings so that gaps are aligned and pointing up. Install two oil delivery pipes in parking brake bracket and install assembly by rotating it back and forth as it is pushed on governor. *(CAUTION—Use care not to damage oil rings on governor).* Start bracket to case screws but DO NOT tighten screws at this point.

▷Parking Brake Bracket Shims—Shims used between transmission case and parking brake bracket on some early 1953 cars to insure correct alignment. DO NOT INSTALL SHIMS IF ORIGINAL TRANSMISSION CASE REPLACED.

(CAUTION—special parking blocker piston retainer must be used on lower screw). Install roller on parking brake pawl crank, raise pawl in position and install pawl support bolt with special lockplate under bolt head, tighten this bolt to 23-28 ft.lbs. and bend lockplate against bolt flat. Install parking pawl return spring *(CAUTION*—spring must be placed OVER inside oil delivery pipe to provide additional spring tension on manual lever when in reverse position). Install reverse clutch pipe with "L" end of pipe in rear of transmission case. Install special Governor Alignment Tool J-4731 between governor and sleeve and tighten the bracket screws (15-18 ft.lbs.) and rear pump attaching bolts (15-18 ft.lbs.) while turning the aligning tool to check for binding. Tool should turn freely and governor should rotate freely (within backlash limits). Check alignment at four points (turn output shaft to rotate governor shaft ¼ turn each time). If governor or tool binds at any point, loosen bracket and pump attaching screws and repeat tightening procedure. If free operation cannot be secured, check governor and drive flange run-out (above).

Control Valve Assembly Installation: Engage control valve on oil delivery and reverse clutch pipes by sliding valve assembly forward on transmission case. Set inner detent lever in "Lo" range, install four attaching bolts and lockwashers and tighten to 6-8 ft.lbs. Install pressure regulator reverse oil pipe in control valve and case.

Pressure Regulator Assembly Installation: Use new gasket on pressure regulator plug (install gasket with seam toward threaded end of plug) and new neoprene rubber seal, insert assembly in transmission case using extreme care not to damage rubber seal, tighten plug to 40-50 ft.lbs. If oil pressure line pipe plug not previously installed in hole between band adjusting screws, install plug using sealing compound (Permatex #3 etc.) on plug threads.

Front & Rear Servo Installation: Install front pump delivery pipe in front pump body and rear pump discharge pipe in hole in rear pump. Position front servo with piston stem in socket on end of front band, engage servo on front pump delivery pipe, insert end of rear pump discharge pipe in servo, lower servo into position on case, insert attaching screws and lockwashers *(CAUTION*—do not turn screws in more than 2-3 threads at this time). Install rear band release spring (between ends of rear band). Place rear servo in position on case, entering transfer pipe in servo and engaging actuating lever with rear band strut. Install two rear servo attaching bolts, then tighten all front and rear servo bolts evenly to 23-28 ft.lbs. Adjust front and rear bands *(see BAND ADJUSTMENT)*. After servos installed, tighten front pump attaching bolts to 10-13 ft.lbs. torque. Install front pump intake pipe (this pipe can be installed with oil screen later).

Side Cover & Outer Shift Lever Installation: Install side cover with new gasket over manual shaft, install side cover attaching screws and washers using NEW COPPER WASHERS on lower screws, tighten screws finger-tight, shift cover as necessary to centralize manual shaft in hole, then tighten screws to 10-12 ft.lbs. Install outer shift lever and tighten clamp bolt to 10-13 ft.lbs. *NOTE*—Outer throttle control lever will be installed after transmission installed in car.

Oil Screen & Oil Pan Installation: Install oil screen and front pump intake pipe as an assembly, entering pipe through "O" seal ring in front pump body and positioning screen on rear pump intake pipe. Install oil pan with new gasket, enter all oil pan screws to line up pan, tighten screws to 10-13 ft.lbs. Install drain plug with new gasket and tighten plug to 35-45 ft.lbs.

Torus Member Assembly & Rear Flywheel Housing Installation: Position rear flywheel housing on front of transmission case and tighten attaching bolts to 40-50 ft.lbs. torque. Install torus cover with splines in torus hub aligned with splines on front drive gear, push torus cover evenly into place *(CAUTION*—do not rock cover or handle it roughly which will damage oil seal rings). Install drive torus, aligning splines with splines on front planet carrier, install snap ring. Install driven torus on main shaft and make certain that it seats against snap ring. Use NEW lockplate under mainshaft nut, place shift lever in Reverse "R" position (extreme rear position), tighten nut to 50-60 ft.lbs. (except Cadillac 30-35 ft.lbs.), bend lockplate ears up against nut flats. Install oil filler cap (or breather where separate filler pipe used).

INSTALLATION IN CAR

TRANSMISSION IS NOW READY FOR INSTALLATION IN CAR. See Removal & Installation data.

1949-54 PACKARD ULTRAMATIC

All Models (1949-54)—See Note.

►*NOTE—Ultramatic is not standard equipment on all models.*

►CHANGES, CAUTIONS, CORRECTIONS

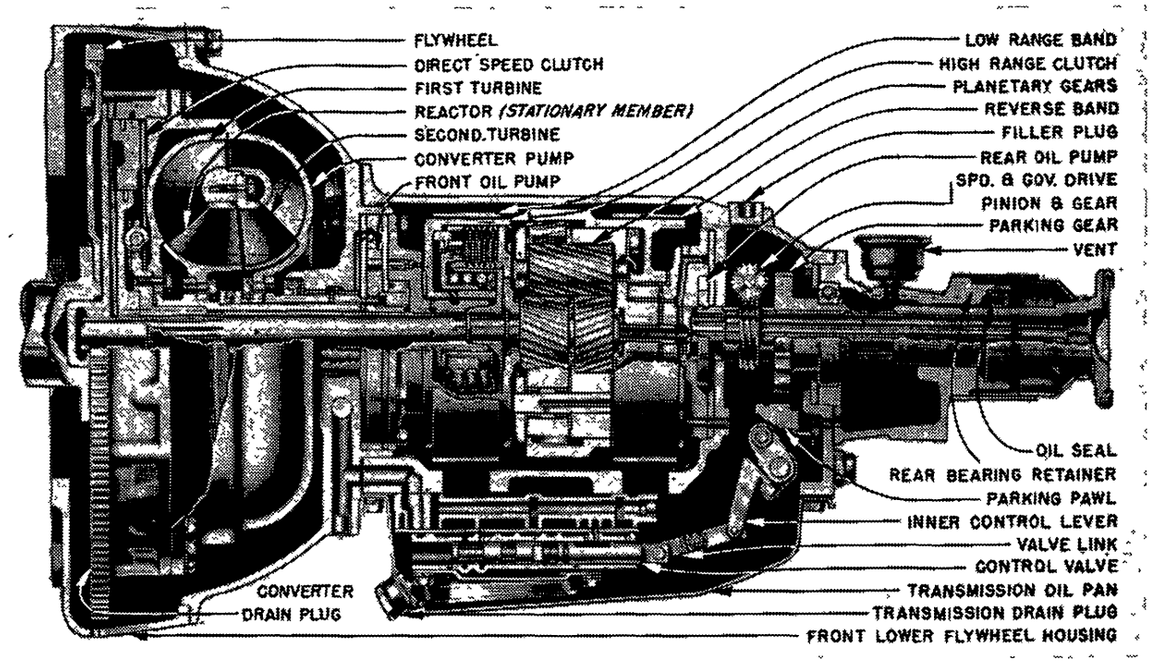
►*1953 BELL HOUSING-TO-TRANSMISSION BOLT PRODUCTION CHANGE (To Correct Leakage)*—The four lower bell housing-to-transmission attaching bolts have CONCAVE heads, and are used **without** lockwashers.

►*1953 DIRECT DRIVE CLUTCH PISTON PRODUCTION CHANGE (To Correct Clutch Slippage)*—Length of bore in piston (where it slides over housing hub and ring) increased from .281" to .406". Former piston allowed a drop-off in pressure to approximately 20 lbs., as clutch engaged, causing clutch to slip when engine accelerated. New type piston, Part No. 423413, will be furnished for service replacement.

►*1952 (25th SERIES) REVERSE NOISE CORRECTION*—Caused by vacuum in rear pump (when car operated in reverse), plus air admitted by governor vent valve. Correct by drilling 3/32" hole in rear half (flat side) of rear pump check valve. Drill hole directly in center, and remove all burrs. New type check valve Part No. 434527 has this hole drilled in it.

►*REVERSE BRAKE PISTON OIL PRESSURE NOTE*—Transmissions with 3/32" hole drilled in rear check valve (see Reverse Noise Correction above), will indicate a drop of approximately 20 to 30 lbs., in reverse brake piston oil pressure (130-150 lbs., instead of 150-180 lbs.).

►*1953 ULTRAMATIC SERIAL NUMBER NOTE—A new "block" of numbers starting with 20,001 used on 2611 Series only.*



►*1953 (Series 2611) SERVICE REPLACEMENT TRANSMISSION CAUTION—When installing service replacement transmission on 2611 Series cars, remove old speedometer drive gear and install it in new transmission.*

►*1951 CONTROL VALVE LINKAGE PRODUCTION CHANGES*—Following changes made in production require new settings and linkage adjustment procedures as detailed under LINKAGE ADJUSTMENT.

Control Valve Lever & Link Change—First type two-piece adjustable link superseded by one-piece solid link. With first type link, rear land of control valve should be ¾" out of control valve lower body. With second type solid link, rear land of control valve should be 5/16" out of control valve lower body with detent lever in reverse position. *See Control Valve Link Adjustment under Transmission Reassembly.*

Throttle Valve Lever Change—Beginning with Transmission unit No. 106958 (Eight), 6486 (Super & Cust. 8), woodruff key previously used to locate throttle valve outer lever on shaft in transmission case was eliminated to allow lever to be rotated on shaft for adjustment. On earlier transmissions, this key can be removed and discarded if new Throttle Valve Lever Adjusting Gauge PU-334 used to adjust lever. *See Throttle Linkage Adjustment.*

►**REACTOR SHAFT ENDPLAY CHANGE:** Original endplay setting of .018-.022" changed to .010-.015" to provide more running clearance for direct drive clutch driven plate and prevent any tendency of clutch to "hang on." Thrust washers for control of shaft endplay now furnished in .005" steps from .070" to .115" (superseding washers in .010" steps from .060" to .090"). *See Converter reassembly data.*

PACKARD ULTRAMATIC DRIVE SECTIONAL VIEW

►**REPLACEMENT OIL COOLER FITTING CAUTION (Early Custom Eight Cars):** Original 90° type elbow fittings not furnished for service (later 45° type, Part No. G444184, furnished for all cars) and following precautions must be observed when replacing flexible hose between oil cooler and intake and return lines on these cars: Turn a new 45° fitting into original 90° elbow at cooler (if necessary to replace oil cooler fitting, solder 45° elbow into cooler tank). Slack off the two forward tubing support brackets, force forward end of tubing back and fix its position so that flexible hose connections are as straight as possible (keep rear tubing brackets tight so that slack taken up by tubing without changing position of rear hose connections), tighten forward tubing support brackets.

►**PLANETARY ASSEMBLY PRODUCTION CHANGE**—Beginning with serial numbers 84130, 221200, & 26331, planetary assembly is balanced as a unit. Two sizes of weights spot welded to planetary cage bolt backplate. (If no weights required, a STAR is stamped on outside of cage). When unit disassembled, mark backplate with prick punch or scribber, and reassemble unit in same location.

►**STARTING ENGINE BY PUSHING CAR:** If this procedure required for Ultramatic cars, place selector lever in neutral "N" position, turn on ignition. When car has attained sped of 25 MPH., move selector lever to high range "H" position. The car will then crank the engine.

►**TOWING ULTRAMATIC DRIVE CARS:** Cars can be towed with selector lever in Neutral "N" position, **providing Ultramatic Drive unit is not damag d and oil level in unit is normal.** Car should not be towed at speed greater than 30 MPH., and should not be towed for any great distance (less than 300 miles). **If selector lever cannot be placed in Neutral,** or if transmission oil level low, disconnect drive shaft at rear end and securely fasten it up to frame so that it cannot move to the rear (CAUTION—rearward movement will allow front end to slip off transmission mainshaft splines and drop down).

►**GOVERNOR REMOVAL CAUTION:** Governor cannot be removed from Ultramatic transmission on car **as a unit** due to small clearance between governor and frame "X" member. Remove governor as follows: Take out governor housing-to-driveshaft retaining screws, remove housing. Then remove adapter by taking out retaining screws and maneuvering adapter out of transmission case. Install adapter and governor housing in same manner. Tighten adapter screws to 7½-8½ ft.lbs. and housing screws to 6-7½ ft.lbs. Pull screws up evenly and check valves in governor housing for free movement after screws tightened.

DESCRIPTION

Ultramatic Drive is a Torque Converter and Planetary Gear type transmission consisting of the following units:

Torque Converter & Direct Speed Clutch: This assembly is contained in a case mounted on the rear face of the flywheel and consists of the units listed below. Torque converter and direct speed clutch action is automatic and is controlled by the hydraulic system (see Operation—below, and Hydraulic Circuit illustration).

Converter Pump (Driving Member)—Integral

CONTINUED ON NEXT PAGE

PACKARD ULTRAMATIC (Cont.)

with rear section of torque converter case bolted directly on flywheel and positively driven at crankshaft speed. Pump is supported at rear end on hollow shaft carried in babbitted bearing in the bell housing (front oil pump is splined on rear end of shaft and shaft is grooved to provide oil channel into converter).

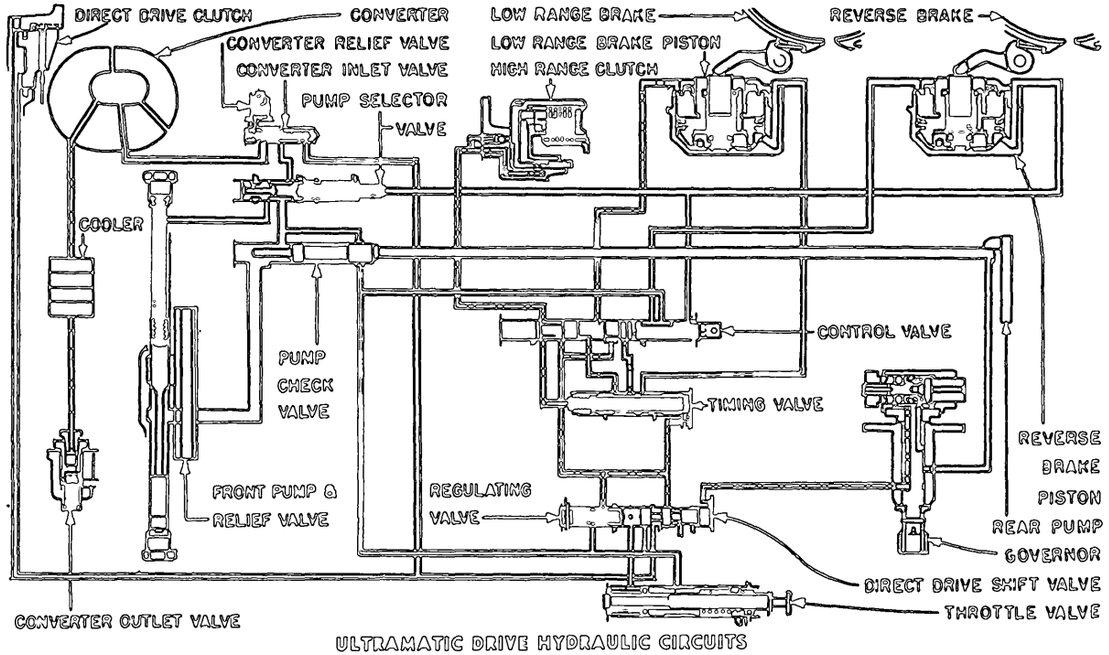
Turbine (Driven Member)—Two-section type consisting of a First Turbine bolted on a flanged hub which is splined on forward end of converter shaft (direct speed clutch driven member also bolted to this flanged hub), and a Second Turbine bolted to the first turbine with clearance between the two in which the Reactor is located.

Reactor (Stationary Member)—Consists of a set of curved vanes placed between the first and second turbines. Reactor is mounted on a short tubular shaft with an overrunning clutch in the mounting flange at the rear end of the shaft. Reactor is locked or held stationary when unit is operating as a Torque Converter but the overrunning clutch allows the reactor to "free-wheel" or rotate freely at steady car speeds so that the torque converter acts as a fluid coupling except when Direct Drive Clutch locks the entire unit for positive drive.

Direct Speed Clutch—Consists of a hydraulically operated oil-cushioned single plate clutch in forward section of torque converter housing. Clutch driven member is bolted to turbine mounting flange and clutch driving plates are locked in torque converter housing (lugs on plates engage slots in housing), so that the torque converter pump and turbine are positively locked together for positive drive when clutch is engaged. Clutch is engaged hydraulically by admitting oil into housing in front of forward driving plate (plate acts as a hydraulic piston).

Planetary Gear Unit: This assembly is contained in the transmission case directly behind the torque converter and is controlled by the driver through a selector lever directly below the steering wheel. It provides Emergency Low, Reverse, Neutral, and Parking (see Operation below). Operation and control of the transmission is through a hydraulic system for which oil pressure is supplied by two oil pumps built in the transmission (forward oil pump in recess in bell housing and driven by converter pump shaft, rear oil pump in recess at rear of transmission case and driven by output shaft). An oil cooler built in the lower tank of the radiator controls the temperature of the oil. Planetary assembly consists of the following units:

Sun Gears—Consist of two helical gears in tandem on drive (input) shaft with a ball thrust bearing between the gears. Front Sun Gear (Low Range Reaction Gear) is integral with a flange splined in the Low Range Drum so that the gear is locked to the shaft when the clutch is engaged (High Range) and is held stationary to serve as a reaction member for the short planetary pinoins which mesh with it when the low range drum band is applied (Low Range). Rear Sun Gear (Driving Sun Gear) is splined directly on the input shaft and meshes with the long planetary pinions.



Planetary Pinions—Consist of three short large gears and three long smaller gears mounted alternately around the planetary cage and all meshing together. The short pinions mesh with the forward sun gear (Low Range Reaction Gear) and with the Planetary Ring Gear which is integral with the Reverse Drum. The long pinions mesh with the rear sun gear (Driving Sun Gear). Planetary cage is integral with the output shaft.

Low Range Drum & High Range Clutch Assembly—Mounted on input shaft directly in front of planetary pinion cage. Inner clutch member is splined on input shaft and rotates with the shaft. Outer clutch member incorporates the Low Range Drum and front sun gear as well as the clutch engaging hydraulic piston and disengaging spring. Clutch driving plates (with facings) are waved to assist disengagement and spring-controlled oil vents in the hydraulic piston are also uncovered when clutch is disengaged.

Low Range Brake Band & Engaging Mechanism—Band holds Low Range Drum and front sun gear stationary when it is applied by the Low Range Brake Piston acting through a lever and strut engaging one end of the band. Opposite end of band is anchored by adjusting screw on side of case.

Reverse Drum Band & Engaging Mechanism—Same design as Low Range Band (above). Band holds reverse drum and Planetary Ring Gear Stationary when it is applied.

Parking Brake Mechanism: Consists of a gear splined on the transmission output shaft at the rear of the transmission case and a pawl which engages the gear to prevent rotation of the shaft when the selector lever placed in "P" parking position. Pawl is operated by a locking lever actuated by the control valve cross-shaft and lever in the transmission case.

ULTRAMATIC DRIVE HYDRAULIC CIRCUITS

OPERATION

The torque converter assembly automatically provides a torque multiplication ranging from approximately 2 1/3 to 1 (for Starting & Heavy Loads) to an equivalent "High" 1 to 1 ratio (for Steady Driving & Light Loads) and is locked out by the Direct Speed Clutch at speeds above 15 MPH. In High Range operation under normal driving conditions (can be unlocked or "kicked down" at car speeds under 50 MPH. at the will of the operator). Planetary Unit is controlled by the operator and provides definite gear ratios (in addition to the varying ratio of the Torque Converter) depending upon the selector lever position. This control is effected through the hydraulic control system (see illustration) by means of oil pressure supplied by the two oil pumps in the transmission case.

LUBRICATION

Check transmission fluid level every 1000 miles and add fluid as required to maintain level at FULL mark on dip stick. Drain and replace fluid at 25000 mile intervals (CAUTION—this 25000 mile interval supersedes original recommendation of 10000 or 15000 mile periods).

▷*CAUTION—Fluid must only be checked at normal operating temperatures and within 1 minute after engine has been idling at 800 RPM. for 1 minute with selector lever in Neutral "N" position.*

Checking Fluid Level—With fluid at normal operating temperature, place selector lever in "N" position, idle engine at 800 RPM. for at least 1 minute, check level by removing dip stick from filler hole on left side of transmission (accessible from beneath car—turn cap ½ turn counter-clockwise before withdrawing it). Add fluid as required to bring level up to FULL mark on stick.

▷Transmission Filling Note—Fluid can be installed through filler tube (from beneath car) if oil gun

CONTINUED ON NEXT PAGE

PACKARD ULTRAMATIC (C nt.)

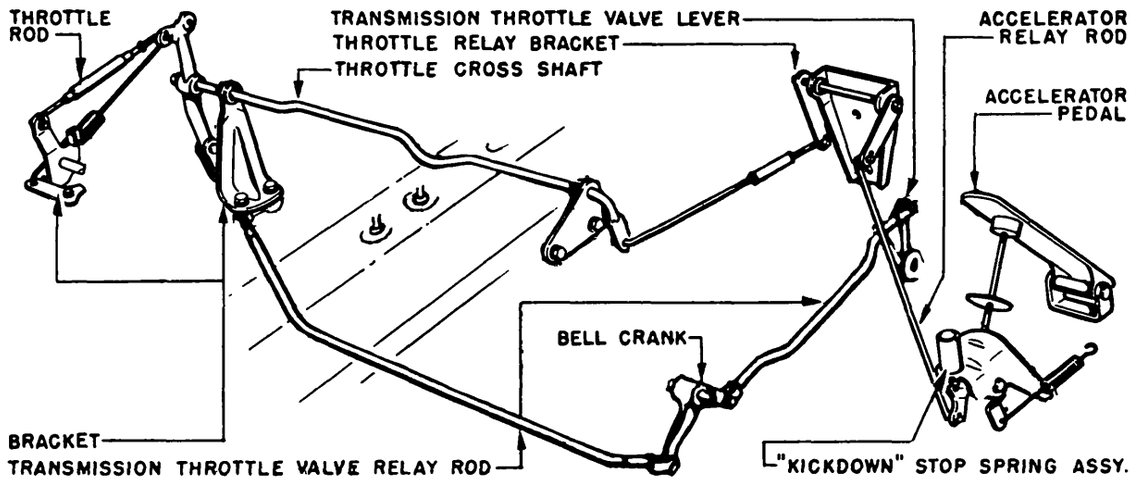
or pump with flexible hose or curved spout used. If this equipment not available, fold back rear corner of front floor mat, remove filler hole cover from transmission cover in floor, and remove filler hole plug in upper rear end of transmission case. Fluid can be poured in through this opening.

Draining & Replacing Fluid—Remove front lower flywheel housing. Loosen one converter drain plug (to act as vent), then rotate flywheel 180° to bring second drain plug to lowest point, remove this plug and drain converter case. Remove transmission case drain plug (at forward end of transmission oil pan), drain case. Replace and tighten all drain plugs, replace flywheel housing. Install 7 qts. of fluid through dipstick opening using curved oil gun (or through plug hole in top of case at rear, accessible by removing cover in transmission floor cover). Idle engine at 800 RPM for at least two minutes with selector lever in "N" neutral (to fill converter case). Check fluid level as directed above, add sufficient fluid to bring level up to FULL mark on dipstick (capacity is approximately 12 qts.). Run engine at 800 RPM for one minute, recheck level.

►***CAUTION—Amount of fluid installed should be determined by dipstick reading rather than actual number of quarts.***

Recommended Fluid—Packard Ultramatic Drive Fluid or any "Type A" Automatic Transmission Fluid which has an AQ-ATF number embossed on container.

LINKAGE ADJUSTMENT



►***ADJUSTMENT CAUTION***—Before adjusting linkage, check the transmission control and throttle linkage for free operation without binding or lost motion due to wear. Warm up engine and transmission. Set engine idle speed at 375 RPM. with choke valve wide open and fast idle inoperative and selector lever in "H" high range. Set hand brake to hold car. Then adjust linkage as follows:

Selector Control (All Models): Place selector lever in "L" Low Range position, see that detent plunger engages notch in sector (can be determined by feel). Adjust control rod by loosening locknuts and turning turnbuckle on rod until clearance between the steering column lever stop and the stop on the bracket is .030-.040" (measure with feeler gauge), tighten turnbuckle locknuts. Check adjustment by moving selector lever to other positions. Shifts to Neutral "N", Reverse "R", and Park "P" should be possible without permanent over-travel when contacting the stops.

1949-50 Throttle Linkage ("2300" & "2300-5" Series): ***CAUTION—Different checking gauges and special procedures required for some cars as follows:***

1) **Throttle Cross Shaft-to-Carburetor Rod**—Install Checking Gauge PU-333 (Eight), PU-332 (Super 8—see Note below), PU-312 (Custom Eight) over throttle cross shaft and end of carburetor rod. Adjust rod length by loosening locknut and turning the spring-loaded throttle override until forward end of gauge rests on upper milled surface of carburetor throttle body. Tighten locknut and remove gauge. This adjustment will provide correct angle of cross shaft lever.

►**Super 8 Gauge PU-332 Note—If gauge does not fit** properly due to interference between gauge and starter switch on carburetor, grind off inner edge of square end of gauge at 45° angle to distance of ⅛" from corner on each side.

ULTRAMATIC THROTTLE LINKAGE

►**Throttle Valve Lever Adjustment Note**—Procedure below is new and when applied to cars before Trans. No. 106958 (Eight), No. 6486 (Super & Cust.), it will be necessary to **remove and discard** the Woodruff key which positioned the throttle valve outer lever on shaft on right side of transmission case. This key is omitted on transmissions after above numbers.

2) **Throttle Valve Lever**—***CAUTION—First cars must be modified as follows before adjustment can be made:***

Adjustment—Use new Lever Adjusting Gauge No. PU-334 and proceed as follows: Disconnect both front and rear rods from relay lever on right side of transmission bell housing by taking out clevis pin. Move rear rod toward rear of car until throttle valve lever reaches rear limit of travel. Hold lever back against the stop in this position, install gauge over end of rod and relay lever, note whether pin on gauge enters these holes freely. If not, on first transmissions with woodruff key in valve lever shaft (see Note above), remove lever and discard key, replace lever. On all models, tighten lever clampscrew just enough so that lever will rotate with shaft until stop is reached and will then slip on shaft. Rotate lever toward front until stop is reached, **continue to rotate lever toward front ⅛ turn,** then rotate lever toward rear until stop is reached. Check lever position with gauge and continue to rotate lever toward rear until gauge pin enters lever rod hole freely, tighten lever clampscrew to 80 ft. lbs. torque, remove gauge, connect both rods to relay lever. Check throttle cross-shaft to throttle valve rod and adjust as follows:

Carburetor Throttle Rod—Adjust throttle cross-shaft to carburetor rod by loosening locknut and turning the spring-loaded throttle over-ride until cross-shaft bellcrank at manifold end of shaft leans forward 13½° at top from perpendicular through the shaft center-line. On Eight and Super Eight models, special gauges available for this adjustment: PU-333 (Eight), PU-332 (Super 8).

3) **Throttl Cross Shaft-to-Throttle Valve Rod**—Disconnect rod at upper (cross shaft) lever end, push rod downward lightly to seat transmission throttle valve plunger against stop. Adjust clevis on rod so that rod is **5/32" short** (pin hole in rod clevis 5/32" short of alignment with pin hole in lever—can be checked with Gauge PU-326). Tighten clevis locknut and connect rod. NOTE—The 5/32" movement of rod necessary to align holes for installation of clevis pin will move throttle valve plunger .050" from its stop.

4) **Relay Lever-to-Cross Shaft Rod**—Depress accelerator pedal until carburetor throttle is just wide open, check clearance between accelerator pedal push rod lever and spring-loaded stop on left side of engine. This clearance should be .050". Adjust by turning adjusting sleeve on relay lever end of rod.

1951-54 Throttle Linkage: Adjust linkage in following order.

►***CHECKING GAUGE (PU-364) CAUTION***—.050" has been added to Gauge PU-364 without changing gauge number. Identify gauges by measuring from base or lower flat surface to center of hole in gauge. **Early Type** will be 2 45/64". **Later Type** will be 2 3/4". If early type gauge used, lay a piece of shim stock .050" thick on each of the two milled surfaces on top of cylinder head and directly ahead of the bracket supporting throttle cross-shaft. Later type gauge has two holes, lower hole is used only for RHD cars.

1) Throttle Cross Shaft-to-Carburetor Rod—Install Checking Gauge PU-364 (all models) on milled surfaces on top of cylinder head directly ahead of cross shaft bracket. Adjust cross shaft lever-to-carburetor rod by loosening locknut and turning the spring-loaded throttle override until short bend at rear of rod protrudes through hole in lever and enters hole in gauge (upper hole in later type gauge). Tighten locknut and remove gauge. This adjustment will provide correct angle of cross shaft lever.

2) Throttle Valve Lever. Disconnect relay rod from throttle valve lever on right side at rear of transmission by taking out clevis pin. Loosen lever clampscrew just enough so that lever will rotate with shaft until stop is reached and will then turn

CONTINUED ON NEXT PA E

PACKARD ULTRAMATIC (Cont.)

on shaft. Rotate lever forward until it is horizontal, then rotate lever in opposite direction toward rear until valve is closed against the throttle valve spring but without compressing the spring. Using care not to compress the spring, continue to rotate lever toward rear until piece of 3/16" rod can be inserted through holes in lever and relay rod and when this rod is snug in both holes, tighten lever clampscrew to 80 inch pounds, or 6-7 ft. lbs. torque. Remove the 3/16" rod, connect relay rod to lever with regular clevis pin.

3) Accelerator Relay Rod-to-Cross Shaft Lever. Adjust rod length so that kick-down can only be accomplished when accelerator is pressed hard to floor.

Starter Safety Switch: Mounted on left side of transmission case. Circuit through switch should be completed (so that starter can be operated) with gearshift selector lever in "N" or "P" position.

BAND ADJUSTMENT

▷*ADJUSTMENT NOTE*—Adjusting screw and locknut for each band are located on outside of transmission case—left side (Low Range Band), right side (Reverse Band). Both bands are adjusted alike.

Adjustment—Loosen locknut on band adjusting screw, use Torque Wrench to tighten adjusting screw (clockwise rotation) to 20 ft. lbs. torque, then back off adjusting screw 1¾ complete turns, tighten locknut to torque of 25-30 ft. lbs.

TROUBLE SHOOTING

CAR FAILS TO MOVE (At all times or with selector lever in certain Ranges):

1. With Selector Lever in any position (appears to be in Neutral—rear wheels are free).

1) Low oil level in transmission or clogged oil inlet screen. Check oil level. Check front pump pressure (see Testing Hydraulic Units).

2) Front Oil Pump Relief Valve or Pump Selector valve sticking open. Check front pump pressure (see Testing Hydraulic Units).

3) Selector control linkage broken or disconnected.

4) Transmission output shaft broken at planetary unit in transmission case. Check by operating engine with selector lever in High Range and rear wheels jacked up. If engine accelerates and propeller shaft does not turn, broken output shaft is indicated (grating noise will be noted in transmission).

5) Rear axle shaft broken or other broken parts in rear axle (propeller shaft will turn but car will not move).

2. With Selector Lever in any position (Rear Wheels are Locked).

1) Parking gear lever spring broken (allowing pawl to remain engaged in parking gear).

2) Low & Reverse Bands adjusted too tight.

3) Bushing or bearings seized or other broken parts in transmission case.

4) Hand brake not released.

5) Broken parts in Rear Axle causing axle to be locked.

3. With Selector Lever in High Range (operation in Low and Reverse Ranges satisfactory).

1) Low oil level in transmission case.

2) Selector control linkage disconnected or out of adjustment (check by moving lever slightly to either side of "H" detent position).

3) High Range Clutch pressure low (may be caused by worn or sticking clutch piston rings or sticking or inoperative Modulating Valve). Check high range clutch pressure (see Testing Hydraulic Units).

4) High range clutch plates worn or burned.

4. With Selector Lever in Low Range (operation in High and Reverse Ranges satisfactory).

1) Selector control linkage out of adjustment (check by moving lever slightly to either side of "L" detent position).

2) Low Range Band worn, band end broken, or band strut dropped out of position (check Low Band adjustment, this trouble indicated if screw goes in too far).

3) Low Range Apply Piston jammed (check for loose Low Band adjusting screw with engine running and selector lever in "L", this trouble indicated if screw is found to be loose).

4) Low Range Fast Acting Piston Vent closed (check by running engine with selector lever in "L", this trouble indicated if car has tendency to move after several minutes operation).

5) Timing Valve stuck in "High Range" position (car will appear to be in neutral). Check as follows: disconnect carburetor throttle link rod from cross-shaft bellcrank, start and operate engine at 800 RPM., place selector lever in "L" range, depress accelerator pedal to floor to increase modulating pressure (to free timing valve). Reconnect carburetor throttle link rod and check operation in Low Range. If car now operates in Low Range, a sticking timing valve is indicated.

5. With Selector Lever in Reverse Range (operation in Low and High Ranges satisfactory).

1) Selector control linkage out of adjustment (check by moving lever slightly to either side of "R" detent position).

2) Reverse Band worn, band end broken, or band strut dropped out of position (check Reverse Band adjustment, this trouble indicated if screw goes in too far).

3) Reverse Apply Piston jammed (check for loose Reverse Band adjusting screw with engine running and selector lever in "R", this trouble indicated if screw is found to be loose).

EXCESSIVE SLIP WHEN TRANSMISSION OPERATING (At all times or with selector lever in certain Ranges):

1. In all Ranges (selector lever in "H", "L", or "R").

1) Low oil level in transmission case.

2) Selector control linkage out of adjustment.

3) Front Oil Pump Relief Valve or Pump Selector Valve faulty (valve sticking open, worn, or spring broken). Check Front Pump Relief Valve Boost Pressure (see Testing Hydraulic Units).

4) Front Oil Pump defective (check for worn or scored pump rotors).

2. In High "H" Range only (operation satisfactory in Low "L" and Reverse "R").

1) Control Valve Link out of adjustment.

2) High Range Clutch pressure low due to oil leakage in pressure passages, at low range drum bushing, check valve in reactor clutch housing, or at clutch piston rings. Check high range clutch pressure (see Testing Hydraulic Units).

3) High Range Clutch piston stuck in cylinder, piston rings broken or worn.

4) High Range Clutch plates worn, burned, or sticking on their splines.

3. In Low "L" Range only (operation satisfactory in High and Reverse Ranges).

1) Control Valve Link out of adjustment.

2) Timing Valve sticking. Check Low Range Application Pressure (see Testing Hydraulic Units). If pressure builds up slowly, this trouble is indicated.

3) Low Range Fast Acting Piston Vent closed (check by running engine with selector lever in "L", this trouble indicated if slippage disappears after several minutes).

4) Low Range Piston sticking or piston seals worn.

5) Low Range Band out of adjustment. Band or drum worn, burned, or scored.

4. In Reverse "R" Range only (operation satisfactory in High and Low Ranges).

1) Control valve link out of adjustment.

2) Reverse piston pressure low due to leakage in reverse hydraulic circuit.

3) Pump Selector Valve Boost Pressure low or lacking. Check Front Pump Relief Valve Boost Pressure (see Testing Hydraulic Units) in Reverse. Pressure should be 155 lbs. at 800-1000 RPM. If pressure low, check for obstruction or leak in boost passage.

4) Reverse Fast Acting Piston Vent closed (check by running engine with selector lever in "R", this trouble indicated if slippage disappears after several minutes).

5) Reverse Piston sticking or piston seals worn.

6) Reverse Band out of adjustment. Band or drum worn, burned, or scored.

EXCESSIVE DRAG WHEN TRANSMISSION OPERATING:

1. In High "H" Range or Reverse (operation satisfactory in Low "L").

1) Low Range Band adjusted too tight, low range piston jammed in "on" position, or band strut out of position. Check by loosening low range band and operating car in High "H" Range.

2) Timing Valve stuck in low range position (check by operating car below 15 MPH. in Low range, and shift into High range. If drag noted in High range, a stuck timing valve is indicated).

2. In High "H" Range and Low "L" Range (operation satisfactory in Reverse).

1) Reverse Band adjusted too tight, reverse piston jammed in "on" position, or band strut out of position. Check by loosening reverse band and operating car in reverse.

CAR CREEPS WHEN STANDING WITH ENGINE RUNNING:

1. With selector lever in Neutral "N".

1) Control valve link out of adjustment.

2) Low Range Band adjusted too tight.

3) High Range Clutch Pressure Line Vent stuck (ball check in reactor clutch housing). Creeping generally occurs only when engine speeded up.

4) High Range Clutch Plates sticking or binding on their splines.

2. With selector lever in High "H" Range (at Idle Speed).

1) Engine idling too fast. Set engine idle speed at 375 RPM. (hot or slow idle), 800 RPM. (fast idle).

3. With selector lever in Reverse "R" (creeps forward), or in Low "L" Range (creeps backward).

1) Control valve link out of adjustment.

CONTINUED ON NEXT PAGE

PACKARD ULTRAMATIC (C nt.)

EXCESSIVE LAG OR DELAY IN SHIFTING:

1. Low Range-to-High Range Shift Lag.

1) Timing Valve sticking or obstruction in metering passage at rear end of timing valve (causes slow release of low band so that band acts as a brake) Make pressure test (see Testing Hydraulic Units) and check time delay between high range engagement and low range release

2) Low Range Piston sticking in "on" position Install new seals after freeing piston.

3) Low Range Fast Acting Piston Vent Valve stuck (preventing dumping pressure as soon as pressure is cut off).

2. High Range-to-Low Range Shift Delayed.

See (1), (2), (3) under low-to-high shift lag above

4) Low Range Band out of adjustment

SHIFTS ARE SEVERE OR ROUGH:

1. Low Range-to-High Range Shift Severe at Light Throttle only (normal with greater throttle opening).

1) Throttle Valve Linkage out of adjustment (see Linkage Adjustment).

2) Throttle Valve sticking in bore in valve body.

2. Low Range-to-High Range Shift Severe regardless of throttle position.

1) Throttle valve linkage out of adjustment (see Linkage Adjustment).

2) Throttle Valve sticking open or Modulating Valve defective Check throttle valve pressure (see Testing Hydraulic Units).

3) Low Range Band out of adjustment

4) High Range Clutch plates worn, scored, or damaged.

5) Cover at rear end of timing valve in control valve body loose.

3. High Range-to-Low Range Shift Severe.

1) Low Range Band out of adjustment.

2) Timing Valve sticking. Make Low Range Application Pressure test (see Testing Hydraulic Units) and note pressure build-up rate of low range piston.

3) Cover at rear end of timing valve loose.

4) Low Range Band or drum worn, scored, or rough.

CHATTERS WHEN STARTING:

1. When starting in Low "L" or High "H" Range.

1) Low Range Band out of adjustment (dragging band will cause High Range chatter).

2) Reverse Band out of adjustment and dragging.

3) Low Range Band or Drum worn, scored, or rough.

4) High Range Clutch plates worn, scored, burned, or sticking. Clutch Piston sticking.

2. When starting in Reverse "R".

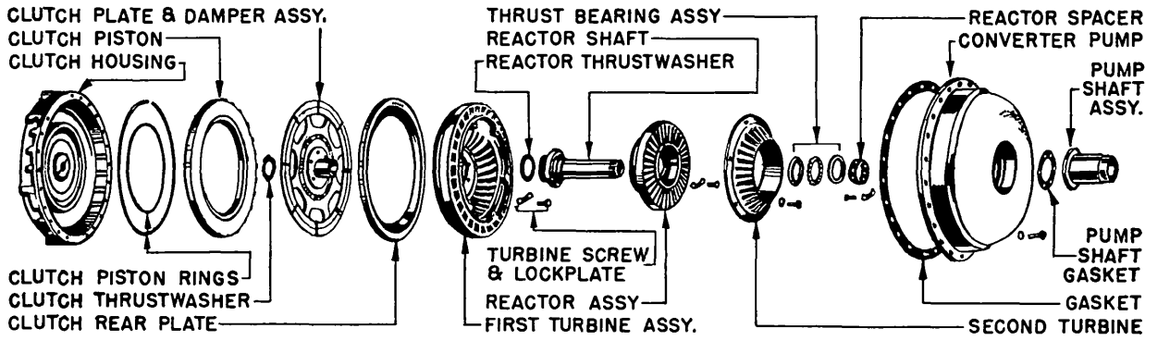
1) Reverse Band out of adjustment.

2) Low Range Band dragging.

3) Reverse Band or Drum worn, scored, or rough.

4) Reverse Drum Bushing or Thrustwasher worn or scored.

5) High Range Clutch plates worn, scored, burned, or sticking. Clutch Piston sticking.



TRANSMISSION "CLUNKS" WHEN CAR STOPPED:

1. Direct Drive Clutch Disengagement Noisy.

1) Direct Drive Shift Valve sticking Check Direct Drive Clutch Pressure (see Testing Hydraulic Units).

2) Governor Vent Valve sticking or defective. Check Hydraulic Governor Pressure (see Testing Hydraulic Units). Governor pressure should cut off at 11 MPH. or above on deceleration.

3) Direct Drive Clutch Moveable Driving Plate sticking or facing groove too shallow in driven plate facing (facing should have groove .062" wide through the full depth of the facing).

PACKARD ULTRAMATIC TORQUE CONVERTER ASSEMBLY

ENGINE STALLS WHEN CAR STOPPED:

1. Direct Drive Clutch fails to disengage.

1) Governor defective. Check Hydraulic Governor pressure (see Testing Hydraulic Units).

2) Direct Drive Shift Valve sticking.

3) Converter Inlet Valve or Converter Relief Valve sticking. Check Converter Inlet Pressure (see Testing Hydraulic Units) and also check converter pressure when operating in direct drive.

4) Direct Drive Clutch Moveable Driving Plate sticking or Driven Plate facings broken or torn.

NO "DIRECT DRIVE" (or Direct Drive operation erratic or noisy):

1. Direct Drive Clutch fails to engage (or engages and disengages erratically).

1) Governor defective, Vent Valve sticking or clogged, Governor Drive Pinion teeth worn or chipped (causing erratic operation of the governor). Check Hydraulic Governor Pressure (see Testing Hydraulic Units).

2) Direct Drive Shift Valve sticking. Check Direct Drive Clutch Pressure (see Testing Hydraulic Units).

3) Direct Drive Clutch Moveable Drive Plate sticking. Install new piston rings after freeing up plate.

NO "KICK-DOWN":

1. Direct Drive Clutch fails to disengage.

1) Throttle Valve Linkage out of adjustment (see Linkage Adjustment).

2) Throttle Valve Piston stuck. Check Throttle Valve Pressure (see Testing Hydraulic Units).

3) Governor defective, or governor pressure too high. Check Hydraulic Governor Pressure (see Testing Hydraulic Units).

4) Direct Drive Shift Valve sticking. Check Direct Drive Clutch Pressure (see Testing Hydraulic Units). Pressure should cut off on kick-down if shift valve operating correctly.

5) Throttle Rod Operating Bellcrank (on bell housing) incorrectly installed or reversed. Check and adjust throttle linkage (see Linkage Adjustment).

OVERHEATING ON HILLS (Converter and Transmission).

1. Insufficient oil flow through Converter and Oil Cooler.

1) Converter Inlet Valve or Relief Valve sticking, oil cooler clogged, or Converter Outlet Valve stuck Check Converter Inlet Pressure (see Testing Hydraulic Units). If pressure OK. when converter operating, check flow through converter as follows: Disconnect hydraulic line at converter outlet valve, use clean container to catch oil flowing through line. Operate engine at 600 RPM. for 15 seconds. Oil flow should be 1¾ quarts in 15 seconds.

NOISE IN TRANSMISSION OR CONVERTER:

1. Scraping Noise in Converter.

1) Broken Direct Drive Clutch driven plate (will also cause faulty direct drive clutch disengagement).

2) Reactor Shaft Bearings or Thrustwashers worn or broken (allowing converter parts to rub or scrape together).

2. Rattle in Transmission (in Neutral or High "H" Range).

1) Rough engine performance (noticeable at idle speed).

2) Low Range or Reverse Band Struts rattling due to bands being too loose. Adjust bands.

3. Vibration in Drive Line (at 20 MPH. or higher speeds in Direct Drive).

1) Direct Drive Clutch Driven Plate friction lag incorrect (replace driven plate).

2) Extension Housing Bearing worn, scored, or burned out.

4. Excessive backlash (noticeable when accelerating or decelerating in Direct Drive).

1) Transmission Thrust Bearings and Thrustwashers worn.

2) Drive line or rear axle backlash excessive.

5. Knock or grating noise (in Neutral, Low Range, or Reverse).

1) Planetary Unit Gears chipped or broken. Pinion roller bearings broken.

6. Whine in Planetary Unit (below 35 MPH.).

1) In Low Range or Reverse—Planetary gears and pinions worn, scored, or burned. Pinion endplay excessive.

2) In Neutral or High Range below 35 MPH. (disappears at higher speeds)—Air leak in front oil pump intake line, front oil pump rotors noisy, oil foaming in transmission.

7. Whine r Hum in transmission (above 30 MPH.).

1) Front Oil Pump Relief Valve stuck (preventing front pump from idling normally). Check Front Pump Regulated Pressure (see Testing Hydraulic

C NTINUED N NEXT PAGE

PACKARD ULTRAMATIC (Cont.)

Units) at speeds above 30 MPH. If pump does not cut out, free up relief valve.

2) Rear oil pump noisy due to worn or scored pump rotors.

TESTING HYDRAULIC UNITS

▷*CAUTION*—Before making following tests, check fluid level in transmission, road test car by driving under conditions simulating heavy traffic and highway operation, (frequent stops and starts, low speed, medium speed, and accelerating). If transmission does not operate satisfactorily after engine and transmission thoroughly warmed up, make the hydraulic test outlined below exactly as directed.

NOTE—Hydraulic pressure gauge with 0-100 psi. scale and flexible line 48" long with ⅛" male pipe fitting are required for these tests (except Reverse Application Test for which 0-200 or 0-300 psi. gauge MUST BE USED. Pressure Test Set No. PU-300, provides all gauges needed for these tests.

Front Pump Regulated Pressure: Remove floor mat and inspection cover in floor panel, remove pipe plug on lower left side of transmission bell housing, install ⅛" pipe reducer and connect gauge line, support gauge in front compartment so that it can be read while running engine. Start engine and operate it at 600 RPM. Gauge reading should be 80-90 lbs. If pressure correct, disconnect gauge, remove reducer, replace pipe plug.

If pressures not correct, check the following: Front Pump Relief Valve or Selector Valve sticking or valve spring broken, Pump Check Valve not seating (front pump pressure will be lost through rear pump), Air Leak in pump intake passage, Bore in control valve body at Control Valve, Modulating Valve, or Throttle Valve worn or scored or has excessive clearance allowing pump pressure to be lost, Piston Seals in control valve upper body worn or leaking allowing pump pressure to be lost at release side of low or reverse piston.

▷Gauge Fitting Note—Pipe plug (above) is ¼" (first cars), ⅜" (later cars), and the correct ¼" to ⅛" or ⅜" to ⅛" reducer must be used to connect gauge.

High Range Clutch Pressure: Remove ⅛" pipe plug at center of lower rear end of transmission bell housing (just to right of front pump outlet passage plug), connect gauge at this point. Test car on road with gearshift lever in "H" High Range. Pressure should be approximately 35-43 lbs. (throttle closed), and approximately 85 lbs. with throttle wide open. Repeat test with gearshift lever in Low Range, then shift to High Range and again repeat test. If pressures correct, disconnect gauge and replace plug.

If pressures not correct, check the following: Throttle Valve Linkage out of adjustment, Throttle Valve or Modulating Valve sticking, Ball Check Valve in high range pressure passage (in reactor housing) sticking, High Range Clutch Piston Rings worn or leaking, Low Range Drum Bushing worn or scored.

Direct Drive Clutch Pressure: Remove ⅛" pipe plug just to right of center on lower rear end of transmission bell housing (just to right of high range passage plug), connect gauge at this point. Test car on road with gear shift lever in High Range. Accelerate car slowly with light throttle opening. At speed of 15 to 18 MPH, with light engine load and steady driving, clutch should engage and gauge reading should be approximately 33-41 lbs. at this point (See "Direct Drive Clutch Piston Production Change" following). With full throttle, clutch should engage at 56 MPH and gauge reading should be approximately 85 lbs. If pressure correct, disconnect gauge and replace plug.

▷DIRECT DRIVE CLUTCH PISTON PRODUCTION CHANGE (To correct clutch slippage)—Length of bore in piston (where it slides over housing hub and ring) increased from .281" to .406". Former piston allowed a drop-off in pressure to approximately 20 lbs., as clutch engaged, causing clutch to slip when engine accelerated. New type piston, Part No. 423413 will be furnished for service replacement.

If pressures not correct, check the following: Throttle Valve Linkage out of adjustment, Throttle Valve or Modulating Valve sticking, Direct Drive Clutch Piston Rings worn or leaking, Input Shaft Pilot Bushings worn, Reactor Shaft and Reactor Over-running Clutch Housing Bushings worn.

Front Oil Pump Relief Valve Boost Pressure: Remove ⅛" pipe plug, at lower right rear end of transmission bell housing, connect gauge at this point. Start engine and run at 600-1000 RPM. Gauge reading should be 65-75 lbs. If pressure correct, disconnect gauge and replace plug.

If pressures not correct, check the following: Front Pump Relief Valve or Pump Selector Valve sticking or valve spring broken.

Hydraulic Governor Pressure: Remove ⅛" pipe plug at right rear end of transmission case (just to rear of governor housing), connect gauge at this point. Test car at road speeds above 15 MPH. Gauge reading should be in direct proportion to car speed and range from 31 lbs. at 15 MPH. to 65 lbs. at 56 MPH. If pressure in proportion to car speed, disconnect gauge and replace plug.

If pressures not correct, check the following: Governor Valve or Vent Valve sticking, Governor Housing loose on shaft (attached by two cap-screws), Valves or Valve Support worn.

Converter Inlet Pressure: Remove the ⅛" pipe plug at upper left side of bell housing, connect gauge at this point. Start engine and operate it at 600 RPM. Gauge reading should be 65-80 lbs. If pressure correct, disconnect gauge and replace plug.

If pressures not correct, check the following: Converter Pump Shaft Bushings (in bell housing) worn or clearance excessive. Converter inlet valve sticking or defective (if pressure exceeds 22 lbs. when operating in direct drive, sticking valve is indicated and may be accompanied by slipping direct drive clutch).

▷*CAUTION FOR MAKING FOLLOWING TESTS: Gauge must be connected within transmission case as follows:* Drain oil from case, remove oil pan, insert flexible gauge line through oil filler opening on left side of case, connect gauge at correct plug hole for each test, reinstall oil pan, fill transmission case with fluid so that car can be operated. After tests completed, pan must be removed to disconnect gauge.

▷*NOTE—Following three tests can be made at one time if three gauges used.*

Throttle Valve Pressure: See Caution above. Remove ⅛" pipe plug from throttle valve body (right side of control valve lower body in transmission case), connect gauge at this plug hole. Test car on road at various throttle openings. Gauge reading should be in direct proportion to throttle opening and should range from 24-28 lbs. at closed throttle to 55-63 lbs. at full or wide open throttle. If pressure correct and in proportion to throttle opening, disconnect gauge and replace plug.

If pressures not correct, check the following: Throttle Valve Linkage out of adjustment, Throttle Valve sticking.

Low Range Application Pressure: See Caution above. Remove ⅛" pipe plug from low range cylinder body (right front end of control valve upper body in transmission case), connect gauge at this plug hole. Test car on road under heavy traffic conditions (frequent stops, starts in Low Range, acceleration, and shifts to High Range). Gauge reading should be approximately 35-45 lbs. when low band application starts at light throttle and 80-90 lbs. at full throttle. If pressures correct, disconnect gauge and replace pipe plug.

If pressures not correct, check the following: Leaks in low range pressure passages (entire passage from timing valve to low range cylinder body), Loose Range Cylinder Body, Low Range Piston Rings worn or leaking.

Reverse Application Pressure: *CAUTION—0-200 psi. gauge required for this test.* See gauge connection Caution above. Remove ⅛" pipe plug from reverse cylinder body (at left rear end of control valve upper body), connect gauge at this point. Test car on road by making frequent stops and engaging Reverse in normal manner. Gauge reading should be 160-180 lbs. (with early type rear pump check valve without 3/32" hole in flat side of valve); 130-150 lbs. (with later type valve with 3/32" hole in flat side of valve), with gearshift lever in Reverse and car moving backwards with engine speed of 1500 RPM. If pressure correct, disconnect gauge, replace plug.

If pressures not correct, check the following: Leak in reverse pressure passages (entire pressure system from control valve to reverse cylinder), Loose Reverse Cylinder Body or Upper & Lower Valve Bodies, Reverse Piston Rings worn or leaking, Pump Selector Valve sticking (see Note).

▷Pump Selector Valve Sticking Note—Check for sticking valve by checking Front Pump Relief Valve Boost Pressure (see above) in Reverse at 1500 RPM. Boost pressure should be 135-165 lbs. and low boost pressure indicates that pump selector valve is at fault.

▷*If above tests indicate that transmission not operating satisfactorily, see Disassembly data.*

REMOVAL FROM CAR

NOTE—The Transmission and Converter assembly are removed from the car as an assembly. Proceed as follows:

1) Place control lever in "N" Neutral position, remove front seat cushion, install cover on front seat back and door trim panels, remove front floor mat and floor transmission inspection cover.

2) Raise both ends of car and support it securely at all four wheels.

3) Remove lower flywheel housing and drain both Torque Converter and Transmission case (see Draining Data) under "Lubrication" above

4) Disconnect gear selector linkage and transmission throttle linkage, oil cooler lines, speedometer cable, and starter safety switch leads.

5) Disconnect propeller shaft at front and rear universal joints, remove propeller shaft assembly.

CONTINUED ON NEXT PAGE

PACKARD ULTRAMATIC (C nt.)

6) Support rear end of engine with a hydraulic jack placed under rear end of oil pan (CAUTION—use block of wood on jack to prevent damage to oil pan), or use auxiliary support beam (hung under frame side rails with engine support studs located on each side to rear of oil pan flange). Raise engine and transmission just enough to remove load from engine rear mounting and remove the mounting as follows:

1949-50—Disconnect and remove engine rear support channel and bracket assembly, remove transmission steady rest and insulator, remove both support insulators from transmission case by taking out attaching screws in mounting bosses on case.

1951-54—Remove nuts on insulator studs (on lower face of support cross-member), remove engine support cross-member by taking out attaching screws in frame cross-member.

7) Lower engine and transmission assembly until universal joint flange almost rests on lower face of frame X-member, remove the two extreme upper bell housing-to-upper flywheel housing screws, then raise engine and transmission to normal position.

8) Place transmission lift under transmission or use special hoist (see note), make certain that lift adapter fits properly around transmission oil pan. Take up transmission weight on lift or hoist.

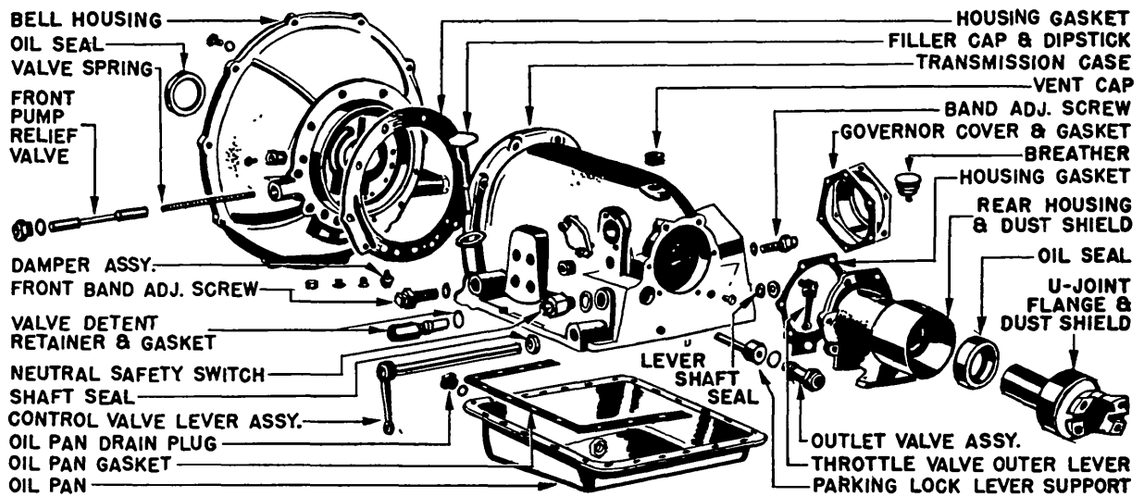
►**Transmission Hoist Note**—If the special hoist is used, install special lift bracket on transmission case or use sling around case, install lifting hoist over opening in floor panel, connect hoist cable to bracket or sling, take up transmission weight with hoist by tightening cable just enough until cable is taut.

9) Mark flywheel and converter housing to insure re-installation in same relative positions, remove flywheel-to-direct drive clutch housing bolts, tap clutch housing to loosen it from flywheel and slide transmission to rear.

10) Remove transmission bell housing-to-flywheel housing bolts. Secure converter to bell housing to prevent it falling out during transmission removal. Slide transmission to rear until clutch housing is clear of flywheel.

11) Lower transmission and at the same time tilt front end down until transmission bell housing is clear of flywheel and housing, then move transmission forward until universal joint flange clears frame X-member, lower transmission to floor.

12) Remove converter assembly from transmission.



OVERHAUL—TORQUE CONVERTER

►***TRANSMISSION OVERHAUL NOTE***—**Converter and transmission are disassembled and serviced separately as follows:**

►***CAUTION—Check Reactor Shaft Endplay before disassembling converter to determine if new Thrust Washer needed for reassembly.***

Reactor Shaft Endplay Check: With converter on bench pump end up, mount dial indicator on pump (use special clamp PU-306) with pointer contacting end of reactor shaft, measure reactor shaft endplay. Should be .010-.015". Note actual endplay for use in selecting thrust washer of correct thickness for installation between reactor and front turbine when reassembling converter.

►***BALANCE LUG CAUTION***—Balance lugs (flat plates under converter pump-to-clutch housing capscrews) are not attached by drive screws (except on replacement converter pumps) and should be marked by scribed line or paint mark to insure re-installation in exact same position. ALL BALANCE LUGS MUST BE RE-INSTALLED IN CORRECT LOCATION TO MAINTAIN BALANCE.

PACKARD ULTRAMATIC TRANSMISSION CASE ASSEMBLY

Disassembly: ***See balance lug caution above.*** Take out all converter pump-to-clutch housing capscrews *(CAUTION*—These are special capscrews and must not be interchanged with others of same size). Loosen pump by tapping with plastic hammer, lift off converter pump and thrust spacer. Take out all second turbine-to-first turbine bolts, loosen second turbine by tapping it with a plastic hammer and lift it off. Remove reactor and shaft assembly, ball thrust bearing, and reactor thrust washer *(NOTE*—this is the selective washer which controls reactor endplay). Lift first turbine and hub assembly off splines of clutch driven plate. Mark face of direct drive clutch stationary plate and clutch housing (use paint or scratch-awl) to insure re-installation in same position. Take out capscrews and washers attaching stationary plate and clutch piston to bosses in clutch housing, remove stationary driving plate and clutch driven plate. Mark one lug of direct drive clutch piston and clutch housing (use paint or scratch-awl) to insure re-installation in same position, remove the piston. Remove spacers from bosses in clutch housing *(NOTE*—spacers used at four mounting screw locations to compensate for drive strap height at other mounting screw holes).

►***CAUTION—Use care not to damage piston rings located on inner diameter of clutch housing and on outer diameter of piston.***

Cleaning & Inspection: Wash all parts in clean gasoline or kerosene and dry with compressed air. Inspect all contact and mounting surfaces for nicks, burrs, distortion, warping or low spots. Inspect all bolts and capscrews for worn threads, see that bolt holes not worn or cracked. Inspect machined area around vanes, torus ring, and turbine hub for wear or rubbing condition indicating worn bearings or thrust plates. Check clutch driven plate for worn facing, loose springs, worn splines or thrust bearing. Inspect clutch movable plate and piston ring. Check ring gap with feeler gauge (gap should be .002-.016", with .012" preferred). Inspect all bearing surfaces for wear, pits, and scores. Clean and inspect oil passages leading from input shaft bearing to direct drive clutch piston.

Reassembly: Place clutch housing on bench with rear open face upward, check rings in housing and piston to make certain they are free, install clutch piston in housing *(CAUTION*—align marks made before disassembly). Use five pilot studs (5/16" x 18) inserting one stud in each of the threaded holes in the housing bosses adjacent to holes where piston driving straps are attached, install one stud through piston driving strap and into housing boss hole to prevent piston moving out of position. Install special spacer on each of the four studs which do not pass through driving straps. Install clutch driven member. Install stationary driving plate over studs in housing *(CAUTION*—align marks made before disassembly). Remove all studs *(CAUTION*—use care not to disturb spacers or to move piston and driving plate out of position), install capscrews and washers (total of eight) and tighten evenly to 20-25 ft. lbs. torque. Centralize clutch driven member housing, install first turbine and hub and engage hub in splines of clutch driven plate. Coat reactor thrust washer with cup grease and install it in turbine hub *(CAUTION*—If new washer being installed this should be selected on basis of endplay noted before disassembly—See washer data below). Install reactor and shaft assembly. Install second turbine and tighten mounting capscrews evenly to 12-15 ft.lbs. torque. Lubricate ball thrust bearing with Ultramatic Drive fluid and install it on reactor shaft, coat bearing spacer with clean cup grease and install it in forward end of converter pump shaft. Place a new converter pump gasket on pump flange (use film of cup grease to hold gasket in place), install converter pump *(CAUTION*—Make certain that balance lugs installed in same position from which removed), install four converter pump

CONTINUED ON NEXT PAGE

PACKARD ULTRAMATIC (Cont.)

mounting capscrews and washers and recheck shaft endplay (see above). If endplay is correct (.010-.015"), install remaining capscrews and washers and tighten all screws evenly to 20-25 ft. lbs. torque. Check assembly for free movement of the clutch driven plate by spinning it with a dummy input shaft. Plate must rotate freely without any drag.

▷Converter Pump-to-Pump Shaft Screw-Tightening Note—If converter pump shaft removed from converter pump, tighten screws (5/16") to 20-25 ft. lbs. torque when shaft reinstalled on converter pump.

▷Reactor Shaft Thrustwasher Note—This washer furnished in .005" thickness steps from .070" to .115". (Part Nos. 423190 to 423199 inclusive).

▷Converter Pump & Clutch Housing Clearance Check: With converter pump installed on clutch housing without the gasket, measure clearance between pump mounting flange face and face of clutch housing around entire circumference with a feeler gauge. Clearance must be .007" or less and uniform within .002" all around the flange. If clearance varies more than .002", rotate cover ¼ turn and recheck clearance. When a point is found where clearance is within these limits, mark both the pump and clutch housing with a centerpunch on the edge of the flange between the bolt hole bosses (CAUTION—use only a centerpunch or paint for marking—DO NOT use a chisel, and use great care not to mar the bolt hole bosses). If no position can be found where clearance is uniform and within limits, clearance can be reduced on the high side by carefully dressing down pump shoulder with a mill file. If clearance is uniform but greater than .007", dress the pump shoulder down carefully around entire circumference.

DISASSEMBLY—TRANSMISSION

Disassembly: Remove oil pan and gasket. Install hold-down tool PU-308 on Low and Reverse band levers (will prevent band struts dropping when valve assembly is removed), then remove oil screen. Disconnect control valve link, remove control valve lower body, separator, and upper body as an assembly (this assembly need not be disassembled further unless required). Take out 8 capscrews and remove bell housing and gasket. Loosen low range band adjusting screw, remove high range clutch assembly, remove front sun gear thrust bearing. Remove the hold-down fixture from low range band lever (CAUTION—use care that struts do not drop down in case), remove low range band struts, then remove low range band. Remove governor cover on right side of case, take out governor adapter attaching screws, remove governor assembly. Remove speedometer drive pinion and retainer. Take out rear bearing retainer capscrews, and remove housing and extension shaft as an assembly. Remove converter outlet valve. Remove parking gear, speedometer drive gear and spacers (note position of spacers to insure correct installation—spacer with grooved face at rear). Remove entire planetary unit and output shaft assembly through front end of transmission case. Loosen reverse band adjusting screw, lift out reverse drum and planetary ring gear. Remove hold-down fixture from reverse band lever, lift out reverse band struts, remove reverse band. Take out attaching capscrews and remove rear oil pump from recess in rear of case. This completes routine removal of units from case (see Transmission Case data under Overhaul if case is to be stripped). For further disassembly and overhaul of units, proceed as follows:

OVERHAUL (ALL TRANSMISSION UNITS)

After disassembling transmission (above), the various units can be disassembled for inspection and overhaul as follows:

▷*DISASSEMBLY CAUTION—Cleanliness is extremely important when disassembling and overhauling transmission. Make certain that workbench, tools, parts containers, and cleaning solvent are CLEAN.*

▷*PLANETARY ASSEMBLY PRODUCTION CHANGE*—Beginning with serial numbers 84130, 221200, &26331, planetary assembly is balanced as a unit. Two sizes of weights spot welded to planetary cage bolt backplate. (If no weights required, a STAR is stamped on outside of cage). When unit disassembled, mark backplate with prick punch or scriber, and reassemble unit in same location.

Planetary Unit—Remove ring gear *(CAUTION*—use care not to lose dampers or springs which may fly out as ring gear removed). Remove capscrews attaching forward and rear halves of planetary cage, remove forward half of cage by tapping it sharply with a plastic hammer. Move short planetary pinion shaft to rear and remove locking woodruff key. Remove the three short planetary pinions, shafts, thrust washers, and roller bearings as an assembly. Remove rear (driving) sun gear and thrust washer. Move long planetary pinion shaft to rear and remove locking woodruff key. Then remove the long planetary pinions, shafts, thrust washers, and roller bearings as an assembly.

High Range Clutch—Remove large snap ring from low range drum, remove low range reaction sun gear and flange from drum. Remove clutch hub and input shaft, and clutch plates (see Note below). Use Tool PU-304 to compress clutch piston return spring, remove retaining snap ring, relieve spring tension, remove spring and seat. Dislodge and remove clutch piston by bumping low range drum on a wooden block (piston side down). Remove outer piston ring from piston and inner piston ring from inner hub of low range drum. Remove snap ring on input shaft at rear of clutch hub, remove clutch hub from shaft.

▷*HIGH RANGE CLUTCH PLATE CAUTION—10 Plate clutch used on Series 2601 & 2633. All other series use 12 plate type, which is also furnished for service replacement. 12 plate clutch can be used to replace 10 plate type, but DO NOT USE 10 plate type to replace 12 plate type.*

Bell Housing—Take out eight capscrews, remove front oil pump and reactor overrunning clutch housing assembly (CAUTION—do not disassemble the overrunning clutch). Remove front pump relief valve and spring, and oil pressure passage plugs (threaded plugs).

Front Oil Pump—Take out two screws retaining pump on reactor overrunning clutch housing. Remove front cover plate, pump body, and rotors. Separate pump body and rotors, separate pump rear plate from reactor housing.

Rear Oil Pump—Remove cover plate, lift out inner and outer rotors (CAUTION—Keep these rotors separate from front pump parts, rear pump rotors are smaller and are not interchangeable).

Reactor Overrunning Clutch—Do not disassemble this unit (replace if worn or inoperative). See Inspection data.

Control Valve—CAUTION—use extreme care to keep working area and all parts CLEAN when working on control valve assembly. Separate lower valve body, separator, and upper valve body (CAUTION—do not clamp valve body or parts in a vise which may mar contact surfaces or crack body). Remove throttle valve piston spring seat screws, remove the throttle valve, piston, spacer, spring, and seat. Remove control valve and link using slight twisting motion. Remove plate at rear end of timing valve bore, remove timing valve and spring. Remove plate at rear end of direct drive shift valve bore, remove shift valve piston. Remove pins at the forward end and at the center of the modulating valve bore, remove modulating valve, guide, and direct drive shift valve. Remove low range and reverse cylinder bodies, and pistons from the upper valve body. Remove plate at forward end of upper valve body, remove the two pump check valves from slots in valve bore in lower side of upper valve body, remove converter relief valve and valve springs.

Hydraulic Governor—Take out two capscrews attaching governor housing to drive shaft flange, separate housing from flange. Check governor drive shaft-to-adapter endplay which should be .0005-.002". If clearances not correct, disassemble driveshaft by driving out pin in driving gear, press gear off, remove shaft from adapter. Check governor valves for free operation by pressing valve in to inner limit of travel and noting whether spring pushes it out to outer limit of travel without drag when released. If valves stick or excessive looseness noted, disassemble valves as follows: Pull vent valve to outer limit of travel, remove small snap ring, remove flyweight. Remove valve support snap ring, remove valve support, outlet valve and springs, lift governor valve out through vent valve support opening.

Transmission Case—If case being stripped for cleaning or replacement, remove starter safety switch and selector detent. Loosen lockscrew on selector detent sector and remove lockscrew from control valve inner lever, then slip control valve outer lever and cross-shaft from the case (CAUTION—use care not to damage oil seal), lift out detent sector, inner lever, and parking lock operating lever. Low Range and Reverse Band Levers can be removed by driving out lever pivot pins and lifting out the levers, then remove pivot pin and lift out parking gear pawl and lever.

Extension Housing: *CAUTION—Different type housing and bearing assembly with extension shaft used on 1951 and later models.*

1949-50 Bearing Retainer & Extension Housing: Retainer has oil seal at rear end which can be replaced by pulling old seal with a seal puller and driving new seal into place.

1951-54 Extension Housing—To disassemble, clamp housing in a vise, remove universal joint flange nut, pull flange, tap rear end of shaft with soft hammer to free shaft from ball bearing and remove shaft through front end of housing. Remove oil seal using a seal puller or drive seal out with a drift inserted through forward end of housing. Remove snap ring at rear of ball bearing, press bearing out of housing toward rear. If babbitt bearing

CONTINUED ON NEXT PAGE

PACKARD ULTRAMATIC (C nt.)

in forward end of housing requires replacement, remove old bearing with puller PU-335 (used with adapter PU-357). Press new bearing in place with tool PU-357.

Cleaning: Clean all transmission parts (except the ball bearing) in solvent cleaner such as clear gasoline or naptha. Wash all valve parts in separate container. Dry all parts with compressed air, and blow out all valve passages (CAUTION—Do not use wire or drills to clean out passages and ports which would damage metering openings and change calibrations).

Inspection: Inspect all parts for wear and defects with special attention to the following:

Gears—Inspect teeth for wear, scores, nicks, burrs, pits, and chipped teeth. Inspect bearing surfaces and splines for wear and scoring.

Bearings & Thrust Washers—Check for roughness, flat spots, pits, and scores. Check bearings for excessive looseness due to wear. See Reassembly data for selection of thrust washers for correct clearances or endplay.

Drums & Bands—Check for wear, scoring, nicks, or out-of-round. Check low range drum clutch plate splines and inner hub surfaces.

Pistons & Rings—Inspect pistons and rings for wear, scores, nicks, and burrs. Check ring gap of all piston rings with **rings in full contact with cylinder walls.** Rings can be filed if gaps too small.

Piston Ring Gaps

High Range Inner Ring	①.007-.012"
High Range Outer Ring	②.007-.012"
Direct Drive Rings (Inner & Outer)	③.002-.016"

①—Supersedes previous gap of .007-.015".
②—Supersedes previous gap of .010-.020".
③—.012" or less preferred.

Valve Body & Valves—Check all valve body bores for wear with plug gauges PU-324. Check mating surfaces of lower body, separator plate, and upper body for evidence of oil leakage caused by low spots or unevenness (lap on a surface plate using 4OOA wet or dry sandpaper and kerosene). Valves should be free from scores, must not bind, or be excessively loose (valves should move through entire travel in bore of own weight).

High Range Clutch—Inspect clutch plates for wear, scores, nicks, burrs, and for correct "wave."

►***CLUTCH ASSEMBLY CAUTION—10 plate clutch (Series 2601 & 2633); 12 plate clutch (all other series), used in production. 12 plate type clutch used for service replacement on all series cars. 10 PLATE TYPE MUST NOT BE USED TO REPLACE 12 PLATE TYPE.***

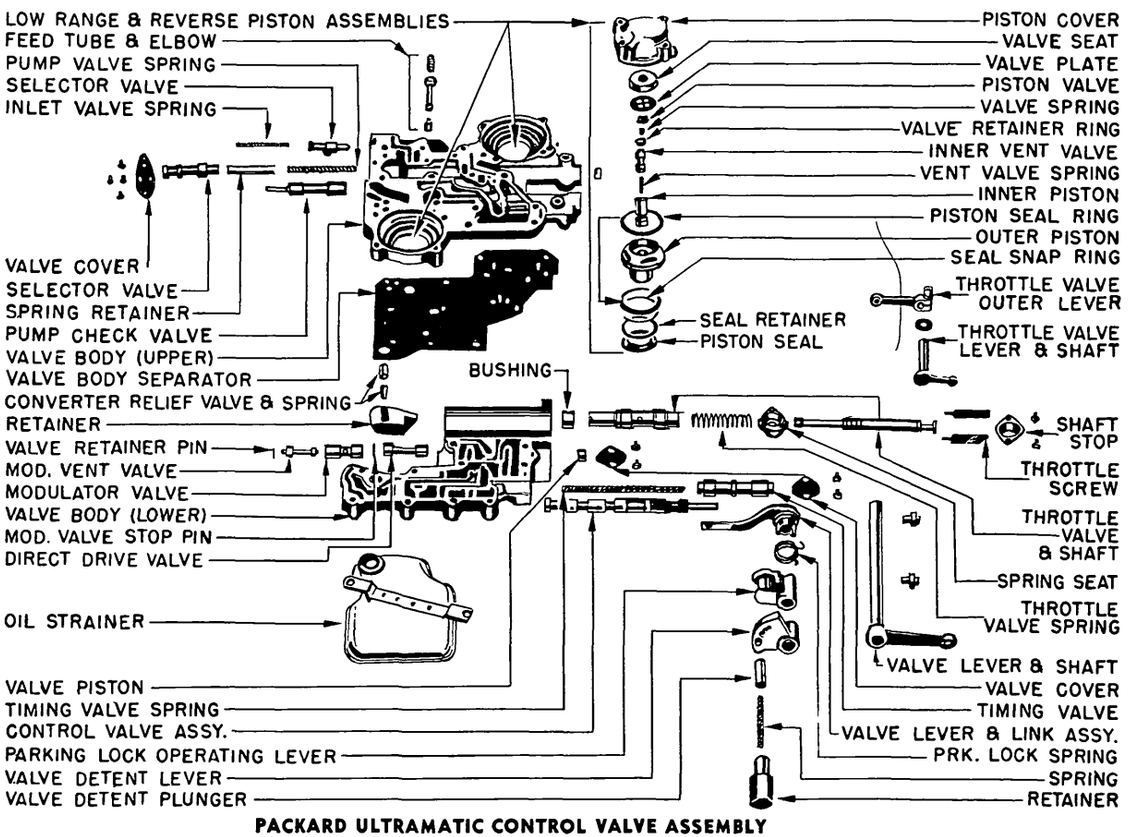
►**Clutch Identification Note**—10 plate type assembly marked with a star. 12 plate type unmarked.

Reactor Overrunning Clutch—Inspect condition of sprags and clutch races (slip circular coil spring from front end of sprags and withdraw one sprag with long-nosed pliers to make this inspection). If worn, pitted, or brinelled, install new assembly.

Reassembly of Parts: Reassemble all sub-assemblies by reversing disassembly directions and note following important details:

►***OIL SEAL & GASKET CAUTION***—Use all new seals and gaskets. **Do not open** gasket package until ready to install (gaskets will absorb moisture and expand so they will not fit). If gaskets have absorber moisture, dry them out in an electric oven at 175° to 200° F. (do not use gas oven which emits moisture from combustion).

Transmission Case—Install following parts in case before installing sub-assemblies: Parking gear lever, pawl, and linkage; low range band lever and pivot pin; reverse band lever and pivot pin. Install throttle valve operating cross-shaft seal in case, then install throttle valve inner operating lever and shaft, woodruff key and outer lever, lock lever with clamp bolt. Install new control valve operating cross-shaft seal in case, then install cross-shaft, (CAUTION—work shaft through oil seal carefully so that seal not damaged). Install selector detent sector, control valve inner lever, and parking lever spring-loaded cam. Lock inner operating lever in place with lockscrew and nut. Install selector detent. Install starter safety switch. Install converter outlet valve.



Hydraulic Governor—If new shaft being installed, insert shaft and flange in adapter, press on driving gear until endplay between gear and adapter is .010-.018", drill ⅛" hole in shaft and press in new pin to retain gear. After all parts installed, see that valves operate freely (see disassembly check). Make certain housing seats firmly and evenly on drive shaft flange, tighten the two attaching screws evenly to 6 ft. lbs.

Control Valve Assembly—Install converter inlet valve and spring, pump selector valve and spring, and pump check valve in forward end of upper valve body; install retaining plate and screws. Install direct drive clutch shift valve through the rear end of bore in lower valve body, install stop pin at center of bore; install modulating valve and guide, install retaining pin, install direct drive shift valve piston at rear of bore, install retaining plate and screws. Install timing valve and spring, install retaining plate and screws. Install control valve and link (use slight twisting motion). Install throttle valve, piston, spacer, spring and seat, tighten seat attaching screws evenly. Assemble upper and lower valve bodies and separator plate (CAUTION—make certain correct length screws installed in each position), tighten all screws to 5 ft. lbs. torque. Install the low range and reverse piston upper seals and retaining rings, assemble fast-acting pistons, seats and retainers in the low range and reverse pistons and install seals on both pistons, then install these assemblies in cylinder body (CAUTION—moisten seals with Ultramatic fluid). Assemble pistons and cylinder bodies on control valve upper body (CAUTION—see that piston does not damage upper seal) using round-headed Phillips screws.

►***NOTE*—All valves not spring-loaded should move within control valve body of own weight.**

Reactor Overrunning Clutch—***See Bushing production change & replacement bushing note.*** If clutch dis-

CONTINUED ON NEXT PAGE

PACKARD ULTRAMATIC CONTROL VALVE ASSEMBLY

PACKARD ULTRAMATIC (Cont.)

assembled, install in following order: Hold inner race facing the front face, install the sprags with curved side at top toward left, and curved side at bottom toward right (use rubber band to hold them in place) and see that sprags lean counter-clockwise or toward left at top. Install coil spreader spring at each end of sprags. Install assembly in housing allowing housing to slip off rubber band (CAUTION—make certain that spreader springs remain in place). Check for correct assembly by making certain that inner race will rotate in clockwise direction (viewed from front) but locks when turned in counter-clockwise direction.

▷Reaction Clutch Housing Bushing Note—*Three types of Housing & Bushing Assemblies have been used as follows:*

1—No. 421641 with non-replaceable thin wall bushings. This type superseded by No. 423220.

2—No. 423220 with non-replaceable thin wall bushings (housing bore less than 1.250"), and replaceable thick-wall bushings furnished under Part No. 410989 and can be replaced with bushing tools. This bushing, Part No. 423220 superseded by No. 410986.

3—No. 410986 with replaceable thick-wall bushings. Bushings are No. 410989 (same as second type housing) and can be replaced with bushing tool.

Front Oil Pump—Assemble pump rear plate on the reactor overrunning clutch housing (journal end of reactor cluch housing down), install pump body in correct position on rear plate (CAUTION—make certain all oil passages are aligned), install outer and inner rotors in pump body (CAUTION—make certain that centering ring in place and that inner groove in inner rotor is DOWN). Check rotors for correct assembly (rotors should mesh at the bottom), install pump front plate (CAUTION—align oil passages), use two reactor clutch housing capscrews to hold parts in alignment, install two pump attaching screws and tighten evenly to 8-9 ft. lbs.

Rear Oil Pump—Install outer and inner rotors in pump body (output shaft will line up inner rotor), install rear plate, install two attaching screws and tighten evenly to 8-9 ft. lbs.

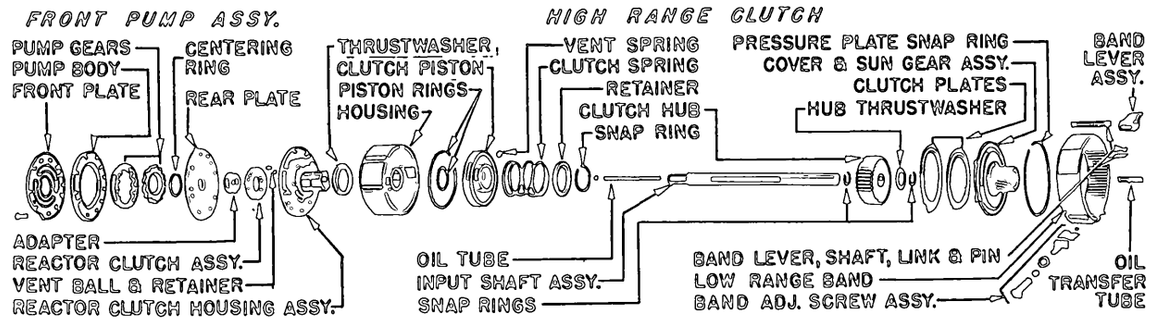
Bell Housing—*CAUTION*—Do not tip assembly down after overrunning clutch installed (will allow assembly to fall out). Install front pump relief valve and check for free operation in valve bore, then install valve retaining plug, valve spring, and plug. Install front oil pump and reactor overrunning clutch assembly (CAUTION—make certain that oil passages line up), install eight attaching screws and tighten evenly to 15-18 ft. lbs. Install oil passage plugs and tighten securely, install new converter pump shaft seal in housing.

▷Bell Housing-to-Transmission Bolt Production Change (To correct leakage)—The four LOWER bell-to-transmission attaching bolts have CONCAVE heads, and are used without lockwashers.

High Range Clutch—*See the Bushing Production Change & Replacement Bushing Note below.* Install outer piston ring on piston and inner ring on drum journal and centralize inner ring on hub, use ring compressor PU-314 to guide outer ring and install high range clutch piston in cylinder of low range drum. Install clutch release spring with one end seating in piston. Use tool PU-304 to compress the spring, install spring retainer and snap ring. Coat clutch hub thrustwasher with cup grease before installing, install snap ring on input shaft ahead of clutch hub, then install clutch hub, thrust washer, and rear snap ring. Install clutch hub and input shaft in low range drum. Install clutch plates (start with steel plate, install driving and driven plates alternately). Install front sun gear and flange, and retaining snap ring (CAUTION—make sure snap ring seated in groove).

▷High Range Clutch Housing Note—*Two types of Housing and Bushing Assemblies (requiring different Clutch Piston Inner Ring) have been used as follows:*

1—No. 421638 Housing Assembly (with replaceable thick-wall bushings) used with Piston Inner Ring No. 421072. If bushing wear excessive, replace above parts with Kit No. 410987 (consists of second type housing No. 423366 and later design Piston Ring No. 423367).



2—No. 423366 Housing Assembly (with replaceable thick-wall bushings) *used with new No. 423367 Clutch Inner Piston Ring* (this ring can also be used with first type housing but first No. 421072 ring must not be used with the second type housing). This housing has bushing bore of 2.000" ± .0005" (.062" larger than first type). Replacement bushings are furnished (No. 410990) and can be installed with regular bushing tools.

Planetary Unit—Assemble each planetary pinion with spacer, roller bearings, and thrust washers on its shaft (spacer at center, 19 rollers and thrust washer at each end—use clean cup grease to hold rollers and thrust washers in place). Hold output shaft horizontal, install long planetary pinion assemblies in planetary cage with chamfered end of each pinion to the front, push shafts far enough in to insert woodruff key, then push shafts forward so that they are locked by keys. Install rear thrust washer in cage (hold in place with clean cup grease) and then install rear sun gear (CAUTION—see that thrustwasher seats in cage). Install short planetary pinion assemblies with chamfered end to front and lock shafts with woodruff keys in same manner as long pinions. Make certain that all thrustwashers are in place, then install front half of planetary cage (CAUTION—line up marks on both halves). Tighten attaching capscrews to 25-30 ft. lbs. (large screws), 15-18 ft. lbs. (small screws), lock all screws by bending up tabs on lock plate. Install damper and spring assemblies exactly as follows:

▷*DAMPER ASSEMBLY INSTALLATION*—Assembly must be made with ring gear supported on flat surface over 2" hole which will allow planetary cage shaft to pass through as cage is assembled to ring gear (bore hole in bench or in piece of 4x4" clamped in vise). Position ring gear directly above this 2" hole, position Planetary Cage Installer PU-371 in ring gear. Assemble springs and dampers in planetary cage as follows: Install two springs (bowed-out center of springs outward) in the side of the "V" groove in the planetary cage (on side which has a lip), position bronze damper on springs with widest side of damper facing outward, use rubber band to hold assembly in place. Install remaining spring and damper assemblies similarly. Position planetary cage assembly in ring gear with dampers lined up with legs of Damper Installer. Tap dampers with a soft hammer until planetary unit starts downward into tool sleeve, then remove rubber band. If necessary, rotate planetary cage slightly to line up pinion clearance recesses in retaining collar of tool with pinions and to mesh pinion teeth with ring gear teeth, slide planetary unit down in ring gear.

Extension Housing & Shaft—Press the rear ball bearing in rear end of housing, install bearing snap ring, press rear oil seal in, install extension shaft in housing making certain that shaft pressed in until shoulder on shaft is against bearing inner race. Install universal joint flange, washer, and nut. Tighten nut securely to 90 ft. lbs. torque. Lubricate parking gear hub with film of Ultramatic Drive Fluid, install parking gear in forward end of housing temporarily with thrust spring omitted (necessary for measurement of endplay to determine correct thrustwasher thickness between high range clutch housing and reactor clutch housing).

▷*CAUTION—Parking Gear Thrust Spring must be installed in final assembly (after endplay adjustment).*

PACKARD ULTRAMATIC FRONT PUMP & CLUTCH PISTON ASSEMBLY

REASSEMBLY—TRANSMISSION (AFTER OVERHAUL OF UNITS)

Reassembly of Transmission: Reverse disassembly procedure and note the following:

Rear Oil Pump: Install pump in case, line up all oil passages, tighten capscrews evenly to 15-18 ft.lbs.

Planetary Unit Installation—Coat reverse drum thrust washer with cup grease and place it on rear oil pump body journal. Install reverse band and struts, install band lever holding fixture PU-308 to retain these parts. Install reverse drum using care not to score the drum bushing. Install new seal ring on output shaft and lubricate seal and shaft with Ultramatic Drive Fluid. Install the planetary unit through the front of the case using care not to

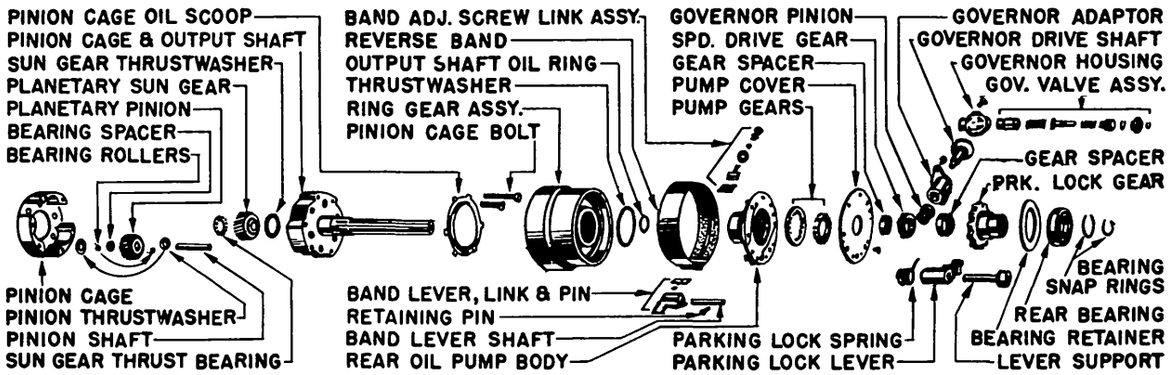
CONTINUED ON NEXT PAGE

PACKARD ULTRAMATIC (C nt.)

score the drum bushing (CAUTION—make certain that seal ring enters front bore of rear pump body and that planetary unit is all the way back against the reverse drum thrust surface). Install speedometer driving gear parts (see Note below for production changes). Install rear bearing retainer (1949-50) or rear housing assembly (1951-54 parking gear thrust spring must be **omitted**) with new gasket, tighten attaching capscrews evenly to 12-15 ft. lbs. (1949-50), 15-18 ft. lbs. (1951-54). Install hydraulic governor and tighten attaching screws in governor adapter to 8-9 ft. lbs., then install governor cover with new gasket and tighten cover screws to 8-9 ft. lbs. Install speedometer drive pinion and retainer.

►**Speedometer Drive Gear Assembly Note**—Different type assemblies (gear, spacers, washers, etc.) used which must be correctly installed as follows:

1949-50—Install parts on rear end of output shaft in following order: Speedometer driving gear spacer, parking gear spacer, parking gear, output shaft rear bearing, parking gear snap ring.



1951-54—Install parts on rear end of output shaft in following order: Speedometer drive gear sleeve, spring, spacer (smooth face against gear), speedometer driving gear, rear spacer (grooved face against gear).

Extension Housing & Shaft Assembly and Installation—Press rear bearing into rear end of housing, install retaining snap ring, press oil seal into rear end of housing, insert extension shaft through front end of housing and press shaft through bearing until shoulder on shaft is seated against bearing inner race. Install universal joint flange, washer, and nut, tighten nut securely to 90 ft.lbs. torque. Coat parking gear hub with film of Ultramatic Fluid, install parking gear in forward end of housing OMITTING THE THRUST SPRING TEMPORARILY (this spring must not be installed until after endplay adjusted as directed below). Install housing assembly on rear of transmission case using a new gasket and tightening attaching capscrews to 15-18 ft.lbs. torque. Install hydraulic governor and tighten adapter attaching screws evenly to 8-9 ft.lbs. torque. Install governor cover using new gasket, tighten cover attaching screws to 8-9 ft.lbs. Install speedometer drive pinion and retainer.

High Range Clutch Installation & Endplay Adjustment—Install low range band, and driving sun gear front thrust ball bearing (use cup grease to hold bearing in place). Install high range clutch unit through front of case and make certain that it is seated against thrust bearing with sun gear in mesh with planetary pinions. Install low range band struts and install band lever holding fixture PU-308 to retain parts. **Then check and adjust endplay:**

►*CAUTION—On 1951 & Later cars, extension shaft and rear housing MUST BE INSTALLED and planetary unit and output shaft must be solidly up against end of extension shaft when following measurements are taken (false reading will be obtained if measured otherwise).*

(1) Mount gauge PU-302 on transmission mounting face of bell housing **with gask t removed,** set gauge

PACKARD ULTRAMATIC PLANETARY & OUTPUT SHAFT ASSEMBLY

to measure distance from milled rear face of bell housing to milled surface at rear face of reactor overrunning clutch cylinder, lock gauge cylinder. (2) Invert gauge on front face of transmission case, measure distance from forward face of low range drum thrust surface to milled front face of transmission case. Gauge micrometer reading will indicate endplay which must be adjusted by installing thrustwasher of correct thickness (this washer furnished in .010" steps from .085" to .135" thick). **From the gauge reading (above),** select a thrustwasher .010" less in thickness than gauge reading, coat thrust washer with cup grease to hold it in place, install bell housing on transmission using a NEW GASKET (see gasket caution below). Install all attaching capscrews and tighten evenly to 55-60 ft.lbs. torque. Remove rear extension housing, **install parking gear thrust spring** on end of extension shaft (to rear of parking gear), re-install rear housing and tighten attaching screws to 15-18 ft.lbs.

►*BELL HOUSING GASKET CAUTION*—End clearance is controlled by the thickness of this gasket (in conjunction with thrust washer) and should be .018-.028". NEW GASKET AND CORRECT THICKNESS THRUST WASHER MUST BE USED WHEN ASSEMBLING TRANSMISSION.

Control Valve Assembly—Install control valve assembly (CAUTION—Make certain that control valve collar engages valve operating lever), using correct length capscrews in each hole and omitting the two which attach the oil screen, tighten all screws (except brake piston screws) to 9 ft. lbs. Tighten brake piston screws to 15-18 ft. lbs. Connect control valve link to inner lever, install the spring lock. Adjust control valve (see below). **After control valve adjusted,** install oil screen, tighten attaching capscrews to 15-18 ft. lbs. Remove holding fixture PU-308 from low range and reverse band levers.

Control Valve Link Adjustment (1949 & Early 1950 Type Two-Piece Adjustable Link): Place selector control valve inner lever in Reverse "R" position and make certain that detent fully engaged in detent well. Use Gauge PU-316 installed on rear land of control valve, adjust link (loosen clamp bolt holding link sections together), so that rear land of valve is ¾" out of control valve lower body. In this position, distance from center of link pin to control valve lower body should be 1.28". Make certain that link clamp bolt is securely tightened.

Control Valve Adjustment (Late 1950-54 Type Solid Link): Place selector control valve inner lever in Reverse "R" position and make certain that detent fully engaged in detent well. Use Gauge PU-316B installed on the control valve, loosen detent lever capscrew, position control valve so that distance from face of valve body to shoulder on valve is exactly 5/16", tighten lever clampscrew to 50 ft. lbs. torque. Control lever shaft should have approximately .045" endplay (controlled by detent lever position on shaft). If necessary to adjust endplay, loosen detent lever clampscrew and move lever, using care **not to disturb valve setting of 5/16".**

Oil Pan Installation—Use new gasket, tighten attaching capscrews evenly to 10-12 ft. lbs.

Band Adjustment—See Adjustment data.

INSTALLATION IN CAR

After transmission completely assembled, install converter on transmission input shaft and **fasten** converter to bell housing to prevent it falling off while transmission being installed. Install transmission and converter assembly by reversing the removal procedure and note the following:

Transmission Pilot Studs—Use two pilot studs in clutch housing to guide it into place.

►*CAUTION—Make certain that converter drain plug lined up with opening in flywheel.*

Tightening Torques—Tighten clutch housing-to-flywheel capscrews to 25-30 ft. lbs. Tighten transmission bell housing-to-flywheel housing capscrews to 25-30 ft. lbs. (CAUTION—bell housing must be held tightly against flywheel housing while tightening these screws).

Filling Transmission—See Lubrication data.

►*CAUTION—Transmission must have at least 7 qts. of fluid before engine is started.*

Adjusting Linkage—See Linkage Adjustment.

TWIN ULTRAMATIC DRIVE

Packard (Lat 1954-55). *See Note below.*
Huds n H rn t V8 (1955).
Nash Ambassad r V8 (1955).

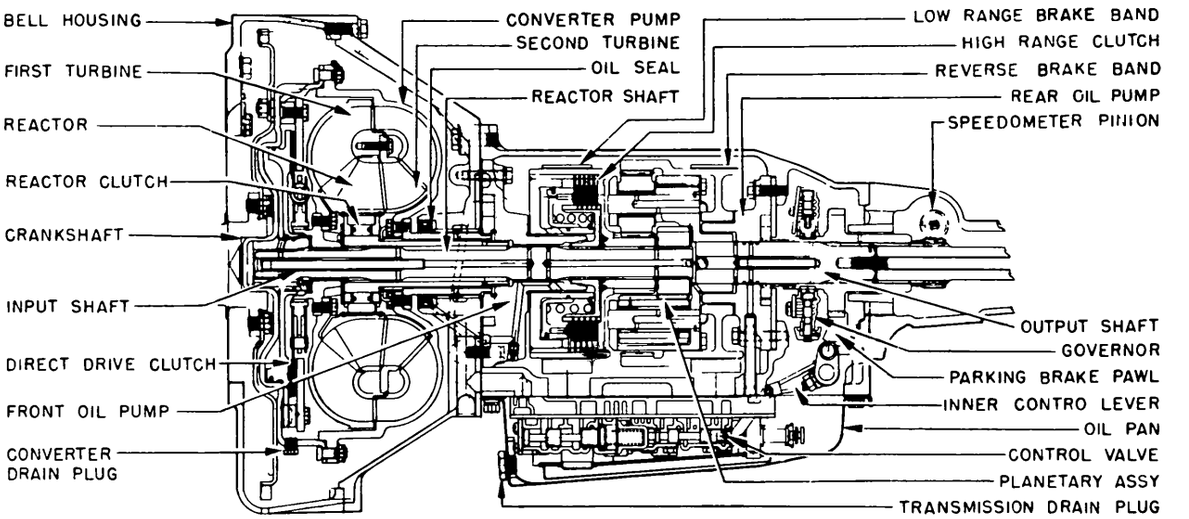
►CHANGES, CAUTIONS, CORRECTIONS

►*1954 PACKARD TWIN ULTRAMATIC NOTE. Twin Ultramatic Transmission replaced previous type in production beginning in August. The control valve assembly in the first 1954 cars with Twin Ultramatic differs from that used in Late 1954 and 1955 cars. See "Control Valve" below for identification and service procedures.*

►*SLIPPAGE OR DELAYED LOW RANGE BRAKE APPLICATION (after coming to a stop or after shifting to either "D" or "L" position).* May be caused by a distortion of the low range brake assembly cap. Part No. 6470266, Low Range Brake Housing Cap (made of heavy machined aluminum stock) replaced the earlier stamping. This change effective on Hudson & Nash at Transmission No. 5-A-11289. *See "Trouble Shooting" below for other causes of excessive slippage.*

►**TOWING TWIN ULTRAMATIC TRANSMISSION CARS:** Cars can be towed with selector lever in Neutral "N" position providing the Twin Ultramatic unit is not damaged and oil level in unit is normal. **Do not tow car at a sp ed great r than 30 MPH., or for any great distanc .** If selector lever cannot be placed in Neutral, or if transmission oil level low, disconnect drive shaft at rear end and securely fasten to frame so it cannot move to the rear *(CAUTION*—Rearward movement will allow front end to slip off transmission main shaft splines and drop down).

►**STARTING ENGINE BY PUSHING CAR:** If this procedure required for Twin Ultramatic Cars, place selector lever in Neutral "N" position and turn on ignition. When car has attained a speed of 25 MPH., move selector lever to LEFT HAND "D" position. Engine will then crank.



DESCRIPTION

Twin Ultramatic Transmission consists of a torque converter, direct drive clutch, and a hydraulic operated planetary transmission. Transmission assembly components are as follows

Torque C nv rter & Direct Speed Clutch: This assembly is mounted on rear face of flywheel and consists of the units indicated below. Torque converter and direct speed clutch is automatic and is controlled by the hydraulic system *(see "Operation", and the Hydraulic Circuit Illustration below).*

C nv rt r Pump (Driving Member)—Integral with rear section of torque converter case bolted directly on flywheel and driven at crankshaft speed. Pump is supported at rear end on hollow shaft carried in bearing in bell housing (front oil pump is splined on rear end of shaft and shaft is grooved to provide oil channel into converter).

Turbine (Driven M mb r)—Two-section type turbine. First section is bolted on a flange hub splined on forward end of converter shaft (direct speed clutch driven member also bolted to this flange hub). Second turbine bolted to first turbine with clearance between the two in which the Reactor is located.

TWIN ULTRAMATIC DRIVE SECTIONAL VIEW

Reactor (Stationary Member)—Reactor consists of a set of curved vanes placed between the first and second turbines and is mounted on a short tubular shaft with an overrunning clutch in the mounting flange at rear end of shaft. Reactor is locked or held stationary when unit is operating as a torque converter but the overrunning clutch allows reactor to free wheel or rotate freely at steady car speeds so the torque converter acts as a fluid coupling except when the direct drive clutch locks the entire unit for positive drive.

Direct Speed Clutch—Single plate clutch hydraulically operated located in forward section of torque converter housing. Clutch driven member is bolted to turbine mounting flange and clutch driving plates are locked in torque converter housing (lugs on plate engage slots in housing) so that torque converter pump and turbine are locked together for positive drive when clutch is engaged. Clutch is engaged hydraulically by admitting oil into housing in front of forward driving plate (plate acts as hydraulic piston).

Planetary Gear Unit: In transmission case directly behind torque converter and is controlled by driver through a selector lever. This assembly consists of the following units

Sun Gears—Two helical gears in tandem on drive (input) shaft with a ball thrust bearing between the gears. Front Sun Gear (Low Range Reaction Gear) is integral with flange splined in Low Range Drum so that gear is locked to the shaft when the clutch is engaged (High Range) and is held stationary to serve as a reaction member for the short planetary pinions which mesh with it when the low range drum band is applied (Low Range). Rear Sun Gear (driving sun gear) is splined directly on the input shaft and meshes with the long planetary pinions.

Planetary Pinions—These pinions are three short (large diameter) gears and three long (small diameter) gears mounted alternately around planetary cage (in mesh with pinion on each side). The short pinions mesh with forward sun gear (Low Range Reaction Gear) and with the Planetary Ring Gear which is integral with the Reverse Drum. The long pinions mesh with the rear sun gear (Driving Sun Gear). Planetary cage is integral with the output shaft.

Low Range Drum & High Range Clutch Assembly—Mounted on input shaft directly in front of planetary pinion cage. Inner clutch member is splined on input shaft and rotates with shaft. Outer clutch member includes the Low Range Drum and front sun gear as well as the clutch engaging hydraulic piston and disengaging spring. Clutch driving plates (with facings) are waved to assist disengagement, and when clutch is disengaged, allows the spring controlled oil vents in the hydraulic piston to be uncovered.

Low Range Brake Band & Engaging Mechanism—This band holds Low Range Drum and front sun gear stationary when it is applied by the Low Range Brake Piston acting through a lever and strut engaging one end of the band. Opposite end of band is anchored by adjusting screw in side of case.

Reverse Drum Band & Engaging Mechanism—Same design as Low Range Band (above). Band holds reverse drum and Planetary Ring Gear stationary when applied.

Parking Brake Mechanism: Consists of a gear splined on transmission output shaft at rear of transmission case and a pawl which engages gear to prevent rotation of shaft when selector lever is placed in "P" parking position. Pawl is operated by a locking lever actuated by the control valve cross-shaft and lever in the transmission.

CONTINUED ON NEXT PAGE

TWIN ULTRAMATIC (C nt.)

OPERATION

The torque converter assembly automatically provides a torque multiplication ranging from approximately 2-1/3 to 1 (for starting and heavy loads) to a 1 to 1 ratio (for steady driving and light loads) and is locked out by the Direct Speed Clutch at speeds above 15 MPH in High Range operation under normal driving conditions (can be "Kicked down" at car speeds under 60 MPH). Planetary unit is manually controlled and provides definite gear ratios (in addition to the varying ratios of the Torque Converter) depending on selector lever position. This control is effected through the hydraulic control system by means of oil pressure supplied by front and rear oil pumps in transmission case.

LUBRICATION

Check transmission fluid level every 1000 miles and add fluid as required to maintain level at FULL mark on dipstick. Drain and replace fluid at 25,000 mile intervals.

►*CAUTION: Fluid must only be checked at normal operating temperatures after 1 minute operation at 800 RPM with selector lever in "N" position.*

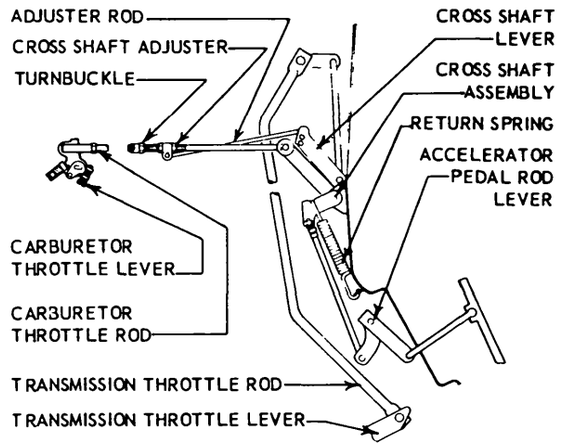
Checking Fluid Level–With fluid at normal operating temperature, place selector lever in "N" position, idle engine at 800 RPM to fill system, then run engine at low idle while level is being checked, using dipstick in engine compartment on left side.

►*NOTE:* If fluid level doubtful due to bent or distorted dipstick tube, check actual fluid level in transmission as follows: Place car on level floor and allow engine to run at idle speed for five minutes in "N" (Neutral). Place a pan under rear of transmission and remove plug in rear of transmission case. If no oil runs out of opening, add oil until it begins to run out, install plug, then ADD ONE QT. If oil does run out when plug removed at rear of transmission, allow to drain to level of hole, then ADD ONE QT.

Draining & Refilling–Remove flywheel housing lower cover and turn flywheel to bring a converter drain plug to the bottom. Place a container under converter and transmission oil pan and then loosen but do not remove converter drain plug. Rotate flywheel to bring the other drain plug to the bottom and remove this drain plug and also the oil pan drain plug and drain fluid. Remove oil filler tube, oil pan, and strainer and thoroughly clean and dry these parts (use compressed air to dry). Reinstall strainer, pan, and tube using new gaskets. Reinstall and tighten converter and oil pan drain plugs (make sure that the drain plug previously loosened is also tightened securely). Install flywheel housing lower cover and tighten retaining screws to 15-18 ft. lbs. (1954 cars), 25-30 ft. lbs. (1955 cars). Pour seven qts. of Automatic Transmission Fluid Type A through filler tube in engine compartment. Start engine and allow to run at HIGH IDLE speed for five minutes with transmission selector lever in "N" (Neutral) position. Bring engine to slow idle speed and add approximately two to three qts. of fluid, and then continue to add only enough to bring level to FULL mark on dipstick.

►*CAUTION: Determine amount of fluid installed by mark on dipstick rather than by number of qts. installed.*

Recommended Fluid–Packard Twin Ultramatic Transmission Fluid or any Automatic Transmission Fluid Type "A" having an AQ-ATF number and symbol embossed on the container.



LINKAGE ADJUSTMENT

►*ADJUSTMENT NOTE:* Before adjusting linkage, check transmission control and throttle linkage for free operation without binding or lost motion due to wear. Warm up engine and transmission. Adjust engine idle speed to 400 RPM with choke valve wide open and selector lever in a "D" (Drive) position (Block choke valve wide open with a piece of cardboard after engine is stopped to prevent linkage returning to fast idle position while adjustments are being made).

HUDSON & NASH

Selector Control Linkage Adjustment (Hudson & Nash V8): Place selector lever in "R" (Reverse). Disconnect transmission control lever from control rod at rear of transmission. Move transmission control lever to rear as far as it will go (do not force lever as it may bend stop plate within transmission). Adjust clevis on transmission control rod so that clevis pin fits freely in hole of clevis and transmission lever. Replace cotter key and tighten locknuts on control rod. *NOTE*– If necessary to align selector lever point on steering column, place selector lever in "N" (Neutral) position (noting position of pointer). Remove shroud from jacket tube by removing retaining screw at lower end of shroud and sliding shroud downward and turning upper end toward the right. Lift out of jacket tube. Hold pointer shaft with pliers and move pointer toward right or left on shaft to line it up directly under center of letter "N".

Throttle Linkage Adjustment (Hudson & Nash V8): (Before adjusting transmission throttle rod, check the distance between hole centers (in a straight line). This distance should be 25-15/16". If necessary, bend rod at first bend forward of transmission connecting hole to obtain correct length. Disconnect transmission throttle rod at throttle valve shaft outer lever at side of transmission. Hold a straightedge across milled surface at rear of transmission case. The taper end of the lever should just contact straightedge. If adjustment is necessary loosen the clamp screw nut and turn shaft to left (counter-clockwise) until valve has reached its stop. With shaft held in this position, rotate lever on shaft so that taper on shaft lines up with milled surface on transmission case when checked with a straightedge. Tighten clamp screw nut and reconnect rod to lever. Raise hood and remove carburetor air cleaner. Disconnect upper throttle rod from center hole in throttle cross shaft lever. Lightly hold cross shaft lever forward so that throttle lever in transmission is against its stop (do not spring linkage). Adjust rod by loosening the nuts at each end of throttle rod adjuster so that end of rod will enter center hole in cross shaft lever, then reconnect rod in center hole of lever. Tighten adjuster locknuts. Adjust accelerator rod at forward end (turnbuckle) so that rod is 15½" (measured in a straight line) between

1955 PACKARD THROTTLE LINKAGE

ball joint at carburetor throttle lever and hole in bellcrank where rod is attached. Tighten locknuts on turnbuckle.

Neutral Safety Switch Adjustment: Adjust switch so starter is operative only in "N" and "P" position.

PACKARD

Selector Control Linkage Adjustm nt (All Packard): Disconnect forward end of transmission control rod at bellcrank (attached to frame side rail). Pull control rod to its full forward limit which will place the control manual valve in the reverse position. Pull lever at lower end of selector shaft downward to its full limit of travel so it contacts stop on lever bracket. Adjust turnbuckle in lower lever to bellcrank link so that the forward end of the control rod will enter bellcrank, and secure in this position.

Throttle Linkage Adjustment (1954 Packard): Disconnect rod at throttle valve shaft outer lever at right rear side of transmission. Move lever rearward to its stop. Hold a straightedge across milled surface at rear of transmission case. The taper end of the lever should just contact the straightedge. If adjustment is necessary, loosen the lever clamp screw nut and turn shaft to the left (counter-clockwise) until valve has reached its stop. With shaft held in this position, rotate lever on shaft so that taper end on lever lines up with the milled surface on case when checked with a straightedge, and then tighten clampscrew nut. Reconnect rod to lever. Disconnect upper end of throttle cross shaft return spring on left side of engine. Disconnect rear end of carburetor throttle rod from cross shaft lever on right side of engine. Lightly hold the cross shaft lever in a forward position so that throttle valve in transmission is against its stop (do not spring the linkage). Adjust length of throttle rod at over-ride spring housing (in center of carburetor throttle rod) so that end of rod will enter center hole in cross shaft lever and then **l ngth n throttl rod 1/2 turn** and reconnect it to center hole in cross shaft lever. Adjust turnbuckle in accelerator pedal-to-cross shaft rod on left side of engine so that clearance of 1/2" to 9/16"

CONTINUED ON NEXT PAGE

TWIN ULTRAMATIC (C nt.)

exists between lower section of accelerator rod and hinge pin in accelerator lever bracket. Reconnect cross shaft return spring in rear hole in cross shaft.

Thr ttl Linkag Adjustm nt (1955 Packard): Disconnect rod at throttle valve shaft outer lever at right rear side of transmission. Move lever rearward to its stop. Hold a straightedge across milled surface at rear of transmission case. The taper on the end of the lever should just contact the straightedge. If necessary, loosen lever clamp screw nut and turn shaft to left (counterclockwise) until valve has reached its stop. With shaft held in this position, rotate the lever on the shaft so that taper on lever lines up with the milled surface on the case when checked with a straightedge and then tighten clamp screw nut. Reconnect rod to lever. Loosen both locknuts positioning the carburetor-transmission cross shaft adjuster and make sure the adjuster is free to move back and forth. Make sure the adjuster rod is in the upper hole of cross shaft lever. With carburetor idle adjusting screw against the stop, adjust carburetor throttle rod turnbuckle so that accelerator pedal rod lever just touches underside of toe board. Re-adjust turnbuckle by turning it out one full turn to prevent accelerator pedal rod lever touching toe board. Tighten lock nut on turnbuckle. Apply a light rearward pressure on cross shaft adjuster rod and move up the rear adjuster locknut to the adjuster then move up the front locknut to the adjuster and tighten securely. Make certain that alignment of adjuster does not cause lever to bind.

Neutral Saf ty Switch Adjustment: Adjust switch so starter is operative only in "N" and "P" position.

BAND ADJUSTMENT

ADJUSTMENT NOTE: Adjusting screw and locknut for each band are located on left side of transmission case (Low Range Band), right side (Reverse Band). Both bands are adjusted alike as follows:

Adjustment: Loosen locknut on band adjusting screw and use a torque wrench to tighten adjusting screw (clockwise) to 20 ft. lbs. torque, then **back off adjusting screw 1-3/4 turns.** Tighten locknut.

TROUBLE SHOOTING & DIAGNOSIS

CAR FAILS TO MOVE (Under conditions indicated bel w):

1) Car fails t m v r gardless of selector lever position.
(a) Insufficient oil or clogged inlet screen.
(b) Converter valve stuck or pump valve stuck.
(c) Selector control linkage disconnected.
(d) Transmission output shaft broken loose from planetary cage.
( ) Parking gear lever broken which may allow pawl to remain engaged in parking gear.
(f) Low and reverse bands adjusted too tight.
(g) Bushings or bearings seized in the transmission. Noise may or may not be present.

2) Car fails t m ve in "D" (Drive) rang with s l ctor l v r in th gear starting p sition.
(a) Insufficient oil or clogged inlet screen. Loss of pressure to apply side of low range brake.
(b) Selector control linkage disconnected or out of adjustment.
(c) Low range brake band strut out of position or low range brake band badly worn.

3) Car fails to move in "D" (Drive) range with selector lever in high range clutch start position.
(a) Rubber lip seal on high range clutch piston out of position causing piston to leak.
(b) Shift regulator valve stuck or clutch plates worn or burned.
(c) Selector control linkage disconnected or out of adjustment.

4) Car fails to move with selector lever in "L" (Low) position.
(a) Selector control linkage disconnected or out of adjustment.
(b) Worn low range band or band strut out of position.
(c) Low range brake piston jammed or insufficient oil supply to apply side of low range brake.

5) Car fails to move with selector lever in "R" (Reverse) position.
(a) Selector control linkage disconnected or out of adjustment.
(b) Worn reverse brake band or strut out of position.
(c) Manual valve stop inside transmission not adjusted properly allowing the manual valve to over-travel.
(d) Lack of oil to apply side of reverse brake piston caused by a stuck reverse shuttle valve.
(e) Reverse brake piston stuck in housing.

6) Excessive slippage in all driving ranges.
(a) Insufficient oil or low front pump pressure due to sticking pump valve.
(b) Low front oil pump pressure due to ball plugs being out of low range and reverse brake housings, or worn or badly scored pump rotors.
(c) Low oil pressure to the converter caused by a stuck converter valve.

7) Excessive drag in "D" (Drive) range using high range clutch start. Also drags in reverse but is all right on "L" (Low) range.
(a) Low range brake band too tight, or low range brake piston stuck and holding brake partly applied.
(b) Transfer tube to release side of low range brake out of position.

8) Excessive drag in both "D" (Drive) ranges. All right in "R" (Reverse) range.
(a) Reverse brake band too tight, or reverse brake piston stuck holding brake partly applied.

9) Car creeps forward in "N" (Neutral).
(a) Low range brake band too tight, or High range clutch plates sticking on splines.
(b) High range clutch piston rubber lip seal out of position causing piston to stick and partly engage clutch.
(c) Low range brake piston stuck holding brake partly applied.

10) Car creeps excessively in any driving range with the engine idling.
(a) Engine idling too fast.

11) Car cre ps forward wh n s l ct r l v r is in "R" (Rev rs).
(a) Manual valve linkage out of adjustment.

12) Car d s n t m v with th s l ct r l v r in "R" (Rev rs) p sition.
(a) Reverse shuttle valve stuck preventing the oil above the reverse brake piston from venting.
(b) Reverse brake band strut out of position.

13) Chatter when starting in "D" (Drive) range using high clutch start.
(a) Low range band dragging, or reverse band dragging.
(b) Worn, burned, or distorted high range clutch plates. Could also be caused by sticking plates or piston.

14) Chatter when starting in "L" (Low) range.
(a) Low range brake band out of adjustment, or reverse range band dragging.
(b) Sticking high range clutch plates or pistons.

15) Chatter when starting in "R" (Reverse) range.
(a) Reverse brake band out of adjustment, or low range band dragging.
(b) Reverse drum (ring gear) bushing badly worn.

16) Drive Clutch fails to engage.
(a) Sticking high speed governor valve, low speed governor valve or direct shift valve. Could also be caused by direct shift throttle valve sticking.
(b) Direct drive clutch piston sticking.

17) Direct drive clutch "hangs on" or fails to releas on deceleration.
(a) Sticking direct shift valve or low speed governor valve.

18) Direct drive clutch engages late and disengages early.
(a) Direct shift valve spring "cocked" in valve bore.
(b) Direct shift throttle valve sticking open.

19) Direct drive clutch slips.
(a) Excessive slippage in direct drive clutch circuit.
(b) Sticking converter valve resulting in high converter pressure while in direct drive.

20) Transmission remains in low range using gear start "D" (Drive) position. Will not upshift from low range converter to high range converter.
(a) Sticking low-high shift valve or sticking governor valves.
(b) Sticking throttle valve.

21) Incorrect front oil pump pressure.
(a) Low oil level or sticking pump valve.
(b) Ball plugs missing in reverse brake housing.
(c) Sticking pump check valves, or incorrect valve spring. Sticking modulator valve.

22) Incorrect high range clutch pressure.
(a) Sticking shift regulator valve, or sticking low-high shift valve. Incorrect pump pressure.

23) Incorrect low range brake top pressure.
(a) Ball plug missing in low range brake housing.
(b) Sticking low-high shift valve, or incorrect pump pressure.
(c) Threaded plug missing in low range brake housing.

24) Incorrect converter "IN" pressure.
(a) Incorrect front pump pressure.
(b) Sticking converter valve.
(c) Loss of pressure in the converter circuit caused by loose or worn bushings.

25) Incorrect direct drive clutch pressure.
(a) Sticking low or high speed governor valves.
(b) Worn or leaking direct drive clutch piston rings.
(c) Loss of pressure through direct drive clutch circuit caused by loose or worn bushings.

26) Incorrect g vernor pressure.
(a) Sticking low or high speed governor valves.

CONTINUED ON NEXT PAGE

TWIN ULTRAMATIC (C nt.)

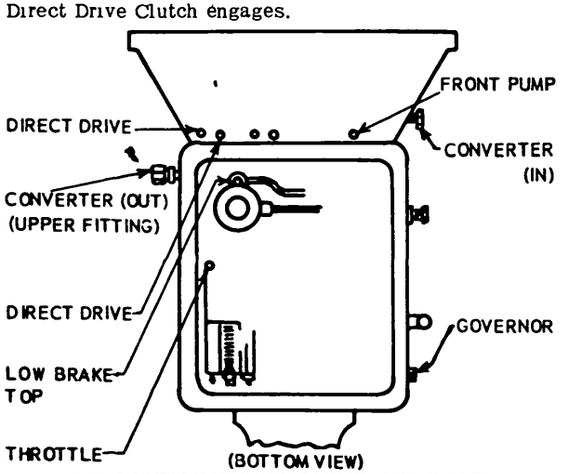
(b) Governor plate not properly installed

27) Incorrect throttle pressure.

(a) Throttle pressure adjusting screw not properly set.
(b) Throttle linkage not properly set or is binding.
(c) Throttle valve sticking.

HYDRAULIC PRESSURE TESTS

►*NOTE:* Before making following tests, check fluid level in transmission. Road test car by driving under conditions simulating heavy traffic and highway operation (frequent stops and starts, low speed, medium speed, and accelerating). If transmission does not operate satisfactorily after engine and transmission thoroughly warmed up, make hydraulic tests as outlined below.



►*SPECIAL HYDRAULIC TESTING TOOL NOTE:* For Nash & Hudson, use Tool Set J-5975. For Packard models, use Tool Set PU-300, and Pan Adapter PK-23. These tool sets are comprised of gauges, fittings, flexible tubing, and special pan adapters.

TEST GAUGE INSTALLATION (HUDSON & NASH): Fold floor mat away from left side of front seat to uncover floor hole cover. Remove cover and insert flexible pressure gauge lines supplied with Tool J-5875 to the transmission. Remove plug in transmission and connect line fitting to correct passage for desired hydraulic test (see Test Plug Location in illustration)

TEST GAUGE INSTALLATION (PACKARD): Remove flexible tubing from left hand fresh air duct and thread gauges through the fresh air grille, out of air duct and down to transmission. Attach hoses to desired points on transmission (see Test Plug Location in illustration).

FRONT PUMP PRESSURE: Connect gauge to front pump test point at front of transmission case (left side). On all models, operate engine at 400 RPM. Normal oil pressure should be 80-95 lbs. (1954 Packard). 80-110 lbs. (Others), with selector lever in all positions.

With Selector Lever in •D Range—Drive car at 15-20 MPH. Maximum pressure should be 150-160 lbs. (1954 Packard). 150-170 lbs. (Others), at full throttle before Direct Drive Clutch engages.

TWIN ULTRAMATIC HYDRAULIC TEST P INTS

With S l ct r L v r in D• Rang—Maximum pressure should be 140-150 lbs. (1954 Packard). 80-120 lbs. (1955 Packard). 140-160 lbs. (Nash & Hudson), at full throttle before Direct Drive Clutch engages.

With Selector Lever in L Range (1955 Packard): Drive car at 25 MPH. Pressure should be 120-130 lbs., at full throttle.

HIGH RANGE CLUTCH PRESSURE: *(NOTE—Leave gauge connected for "Front Pump Pressure" test above).* Connect another gauge to high range clutch pressure point at front of transmission (right side). In the following tests, High Range Clutch Pressure should be the same or not more than 10 lbs. under Front Pump Pressure.

With Selector Lever in •D Range: Operate engine at 400 RPM. High Range Clutch Pressure should be 75-90 lbs. (1954 Packard). 70-100 lbs. (1955 Packard). 70-110 lbs. (Hudson & Nash). Front Pump Pressure should be 80-95 lbs. (1954 Packard). 80-110 lbs. (Others).

With Selector Lever in •D Range: Drive car at 15-20 MPH (Converter Drive). High Range Clutch Pressure should be 145-155 lbs. (1954 Packard). 145-165 lbs. (Others). Front Pump Pressure should be 150-160 lbs. (1954 Packard). 150-170 lbs. (Others).

With Selector Lever in D• Range: Operate engine at 400 RPM. High Range Clutch Pressure should be at Zero pressure. Front Pump Pressure should be 80-95 lbs. (1954 Packard). 80-110 lbs. (Others).

With Selector Lever in D• Range: Drive car at 20 MPH (Direct Drive) with a steady throttle. High Range Clutch Pressure should be 55-65 lbs. (All Models).

LOW BRAKE TOP PRESSURE: *(NOTE—The pressure point for this test and for Throttle Pressure is located on the control valve assembly. A special oil pan adapter is used and a special procedure is required. Connections for both tests should be made at the same time. See "Low Brake Top Pressure & Throttle Pressure Test Connection Note" below).* Pressure should be the same or not more than 10 lbs. under Front Pump Pressure.

With Selector Lever in •D Range: Operate engine at 400 RPM. Low Brake Top Pressure should be 75-90 lbs. (1954 Packard). 70-100 lbs. (Others). Front Pump Pressure should be 80-95 lbs. (1954 Packard). 80-110 (Others).

With Selector Lever in D• Range: Operate engine at 400 RPM. Low Brake Top Pressure should be at Zero pressure. Front Pump Pressure should be 80-95 lbs. (1954 Packard). 80-110 lbs. (Others).

With Selector Lever in D• Range: Immediately after upshift, Low Brake Top Pressure should be 40-65 lbs. (All Models). Front Pump Pressure should be 50-70 lbs. (All Models).

CONVERTER "IN" PRESSURE: Connect gauge to converter "in" test point at left side of converter housing.

With Selector Lever in D• Range: Operate engine at 400 RPM. Pressure should be 60-70 lbs. (1954 Packard). 30-50 lbs. (Others).

With Sel ctor Lever in D• Range: Drive car at 15 MPH., (before Direct Drive). Pressure should be 70-80 lbs. (1954 Packard). 55-80 lbs. (Others).

With S l ctor L v r in D• Range: Drive car at a speed to engage Direct Speed Clutch. Pressure should be 15-25 lbs. (All Models) with Direct Drive engaged.

With S lect r L ver in D Range: In "kickdown" position, converter pressure should be 70-80 lbs. (1954 Packard). 70-85 lbs. (Others).

CONVERTER "OUT" PRESSURE: To check converter "out" pressure a special tee connection is required (install and braze a 1/8" nipple into one end of the 1/8" tee). Remove upper oil cooler tube adapter from side of bell housing. Install oil cooler tube adapter in the tee and reconnect cooler tube. Connect gauge to tee connection.

With Selector Lever in D• Range: Drive car at 15-18 MPH. In "Converter Drive" pressure should be 30-40 lbs. (1954 Packard). 25-40 lbs. (Others). In "Direct Drive" pressure should be 10-20 lbs. (All Models).

DIRECT DRIVE PRESSURE: Connect gauge to direct drive test point at front of transmission (right side), and another gauge to front pump test point at front of transmission (left side). Direct drive pressure should be the same or not more than 10 lbs. under front pump pressure.

With Selector Lever in D• Range: Drive car at 15-18 MPH. Front Pump Pressure should be at Zero pressure (All Models), before Direct Drive Clutch engagement. Front Pump Pressure should be 80-95 lbs. (1954 Packard). 70-100 lbs. (Others). After Direct Drive Clutch engagement, pressure should be 55-65 lbs. (All Models). After "kickdown", Direct Drive Pressure should be at Zero pressure. Front Pump Pressure should be 140-160 lbs. (All Models).

GOVERNOR PRESSURE: Connect gauge to governor pressure test point on left side of transmission case (rear). Pressures should be as follows:

1954 Packard, Hudson & Nash—15-20 lbs. at 13 MPH. 30-35 lbs. at 28 MPH. 55-65 lbs. at 56 MPH.

1955 Packard—15-18 lbs. at 13 MPH. 35-40 lbs. at 28 MPH. 62-69 lbs. at 56 MPH.

THROTTLE PRESSURE: *(NOTE—The pressure point for this test and for Low Brake Top Pressure is located on the control valve assembly. A special pan adapter is used and a special procedure is required. Connections for both tests should be made at the same time. See "Low Brake Top Pressure & Throttle Pressure Test Connection Note" below).* Operate engine at 400 RPM. Throttle pressure should be 20-25 lbs. (1954 Packard). 23-26 lbs. (Others). At Full Throttle, pressure should be 65-72 lbs. In "kickdown" (before downshift), pressure should be 80-95 lbs. (All Models).

Throttle Pressure Adjustment: Before adjusting throttle pressure, check all of the throttle linkage adjustments (see "Throttle Linkage Adjustment" above). The throttle pressure adjusting screw can be reached from the right side of the transmission case with the Oil Pan Adapter, PK-23 (Packard), or Oil Pan Adapter, J-5975 (Nash & Hudson) in place as described in "Low Brake Top Pressure & Throttle Pressure Test Connection Note" below. Use two wrenches through opening. Loosen locknut and turn adjusting screw to obtain correct throttle pressure (see "Throttle Pressure" above). Be sure to recheck throttle pressure after locknut is tightened.

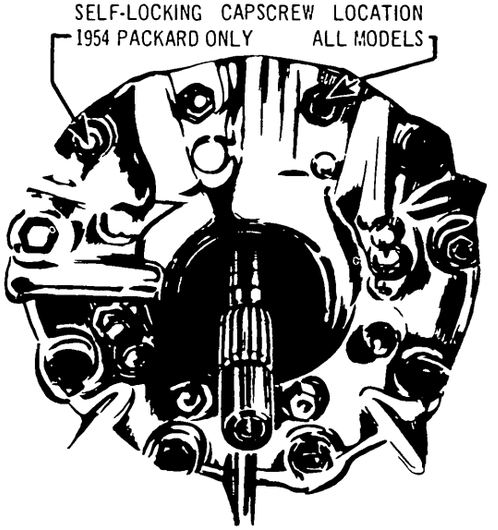
CONTINUED ON NEXT PAGE

TWIN ULTRAMATIC (C nt.)

►*LOW BRAKE TOP PRESSURE & THROTTLE PRESSURE TEST CONNECTION NOTE:* These two connections are located on the throttle control valve assembly within the transmission oil pan. Drain transmission fluid and remove transmission oil pan and screen. Install special test pan adapter, PK-23 (Packard), J-5975 (Nash & Hudson), with the adapter tube on the left side and toward front of car. Thread two of the gauge hoses through elbow tube on the adapter. Remove the 1/8" pipe plug from bottom of low brake housing and install a 1/8" elbow. Connect gauge hose. Remove 1/8" pipe plug from throttle valve body, install a 1/8" elbow and connect other gauge hose. On Packard, install the two oil suction tube extensions to suction tubes, install oil pan and gasket and replace transmission fluid.

TRANSMISSION REMOVAL

HUDSON & NASH



►*NOTE: The transmission and converter are removed from the chassis as an assembly.*

1) Raise car on lift or raise car at both ends and support it with jack stands under side sills. Drain fluid from transmission and converter assembly *(see "Draining & Refilling" above).*

2) Disconnect torque tube and propeller shaft from transmission. Disconnect throttle valve linkage and selector control linkage at transmission. Disconnect speedometer cable and cooler lines at transmission.

3) Support engine at rear using a support beam across frame channels or with a large block and hydraulic jack under rear end of engine oil pan. Raise engine and transmission just enough to take load off rear support under transmission rear housing. Remove the insulator to support nuts and washers and then remove the support to cross member bolts and remove support.

4) Place a transmission lift under transmission with the lift adapter properly positioned around oil pan.

TWIN ULTRAMATIC BELLHOUSING TO TRANSMISSION ATTACHING SCREWS

Pick up transmission load by slightly raising the lift.

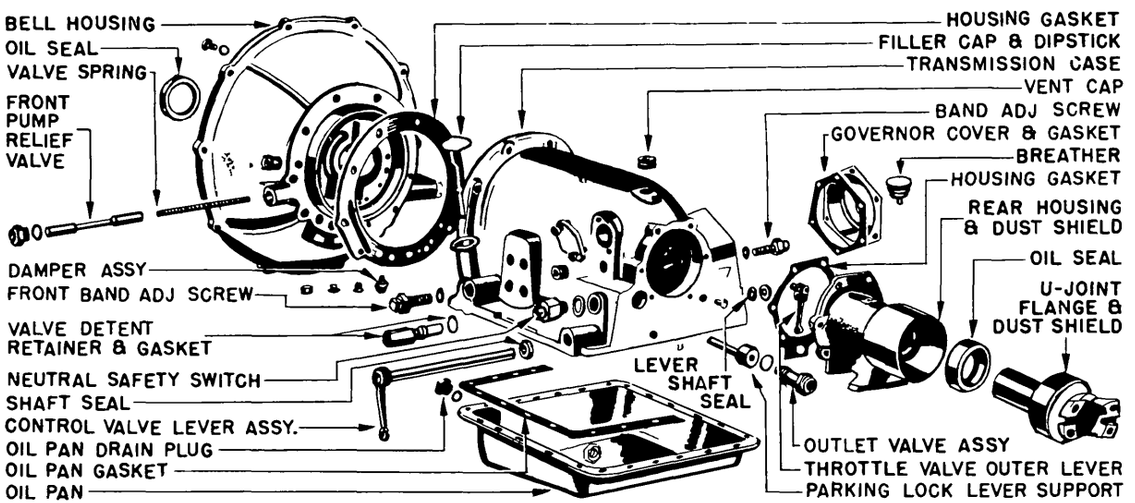
5) Remove direct drive clutch housing to flywheel retaining nuts and slide converter assembly toward transmission. Remove the bell housing to flywheel capscrews and then move transmission rearward until the direct drive housing is clear of the flywheel. Wire converter assembly to bell housing so that it cannot accidentally slide off the input shaft.

6) Lower transmission lift and pull it from under car. Transfer transmission assembly to a reconditioning stand.

PACKARD

►*NOTE: Transmission and converter are removed from chassis as an assembly.*

1) Raise car on lift or raise car at both ends and support with jack stands under side sills. *(CAUTION– Do not place jack or other lifting device under rear load arms or any other part of Torsion Level Suspension assembly).*



2) Disconnect propeller shaft at both ends and remove shaft. Disconnect throttle valve linkage and selector control linkage at transmission. Disconnect speedometer cable and cooler lines at transmission.

3) Support engine at rear using a support beam across frame channels or with a large block under rear of engine oil pan and a hydraulic jack. Raise engine and transmission just enough to take the load off rear support under transmission rear housing. Remove insulator to support nuts and washers and then remove the support to "X" member bolts and remove the support.

4) Place a transmission lift under transmission with lift adapter properly positioned around the oil pan. Pick up the transmission load by slightly raising the lift. Remove direct drive clutch housing to flywheel retaining nuts and slide converter assembly toward transmission.

5) Remove the bell housing to flywheel housing capscrews and then move transmission rearward until the direct drive clutch housing is clear of flywheel. Wire the converter assembly to bell housing so it cannot accidentally slide off input shaft.

6) Lower transmission lift and pull it from under the car.

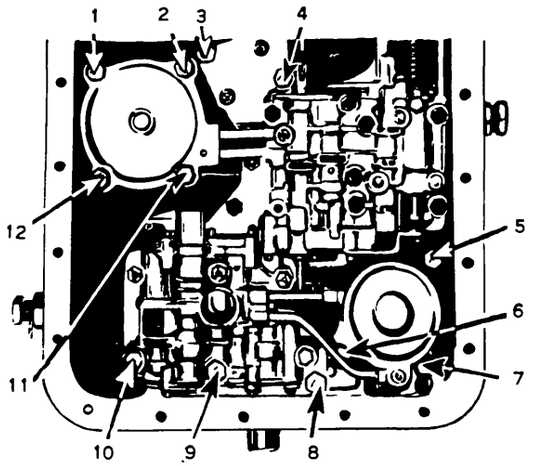
TWIN ULTRAMATIC TRANSMISSION CASE ASSEMBLY

TORQUE CONVERTER OVERHAUL

►*TORQUE CONVERTER OVERHAUL CAUTION: This unit is accurately balanced at the factory by welding lugs to the direct drive clutch housing. It is very important that the original balance be maintained at overhaul by marking the various parts of the converter during disassembly to insure their being installed in the same relative position at reassembly.*

►*SERVICE REPLACEMENT CONVERTER CLUTCH BALANCING NOTE:* These units are individually balanced and may or may not have balance lugs attached to the flange with drive screws. A new pump with a balance lug may be installed with the balance lug at any position in relation to the lug on the direct drive clutch housing without affecting converter assembly balance.

►*REACTION SHAFT ENDPLAY CAUTION:* Before disassembling torque converter, check the reaction shaft endplay to determine if a new thrust washer is needed for reassembly.



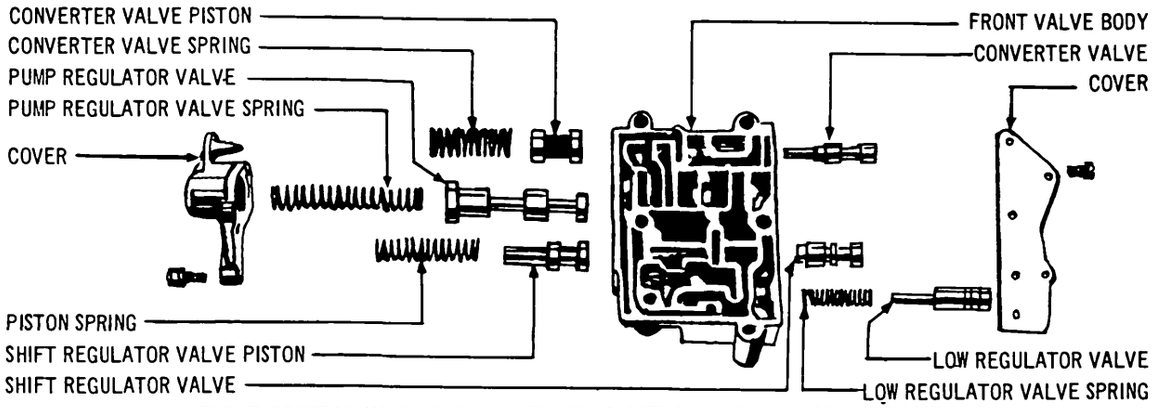
Reaction Shaft Endplay Check: With converter on bench, measure reaction shaft endplay. On Packard, use Dial Indicator and Special clamp, PK-306 along with Reactor Checking Tool PK-27. Insert tool PK-27 through reactor shaft and expand tool so it grips the first turbine hub. Attach clamp and indicator, then raise the checking tool and note indicator reading. Make a note of the indicator reading to be used as reference when reassembling the unit. The specified endplay is .010" to .017".

Disass mbly: Scribe a line on converter pump and clutch housing. Remove converter pump to direct drive clutch

CONTINUED ON NEXT PAGE

TWIN ULTRAMATIC (C nt.)

housing nuts, washers and bolts. Tap the pump with a plastic tipped hammer to loosen it, then lift off pump and remove the reactor thrust spacer. Remove large rubber "O" ring from pump. Remove the second turbine to first turbine capscrews and washer and lift off second turbine. Remove the reactor thrust washer from shaft and lift out the reactor shaft and reactor as an assembly. Remove the reactor shaft front thrust washer. Lift out the first turbine and the first turbine hub thrust washer. Using a scratch-awl, scribe marks on the clutch housing and the pressure plate to insure reassembly in the same position, and then remove the plate retaining screws and lift out the pressure plate and driven plate. Scribe a mark on clutch piston to line up with the mark made on the clutch housing. Lift out four pressure plate spacers and lift out the clutch piston. Remove the four large piston rings from piston and also remove the small inner ring from hub



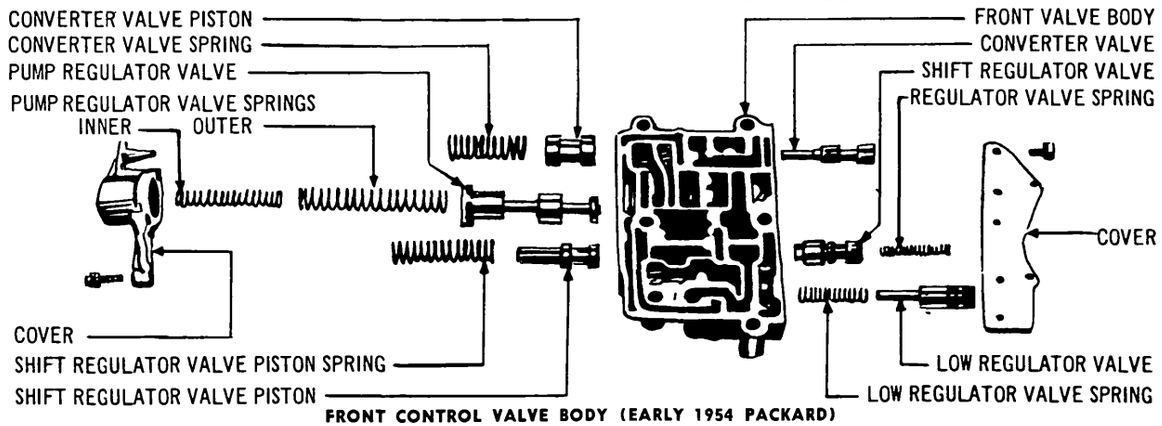
CONTROL VALVE ASSEMBLY RETAINING SCREW DIAGRAM

of clutch housing. Lift reactor shaft out of reaction clutch in hub of reactor. Remove reaction clutch bearing plate and a retaining ring. Remove reaction clutch bearing plates, washers, springs and sprags and then lift the reaction clutch outer race out of hub of reactor.

Cleaning & Inspection: Wash all parts in clean solvent and dry with compressed air. Inspect all contact and mounting surfaces for nicks, burrs, distortion, warping or low spots. Inspect all bolts and capscrews for worn threads and see that bolt holes not worn or cracked. Inspect machined area around vanes, torus ring, and turbine hub for wear or rubbing conditions indicating worn bearings or thrust plates. Check clutch driven plate for worn facing, loose springs, worn splines or thrust bearing. Inspect clutch movable plate and piston ring. Inspect all bearing surfaces for wear, pits, or scores. Clean and inspect all oil passages leading from input shaft bearing to direct drive clutch piston.

Reassembly: 1) Install reaction clutch bearing plate and a retaining ring in hub of reactor at coned or forward end. Place reactor on bench with coned end downward

FRONT CONTROL VALVE BODY (LATE 1954 & 1955 PACKARD, HUDSON & NASH)

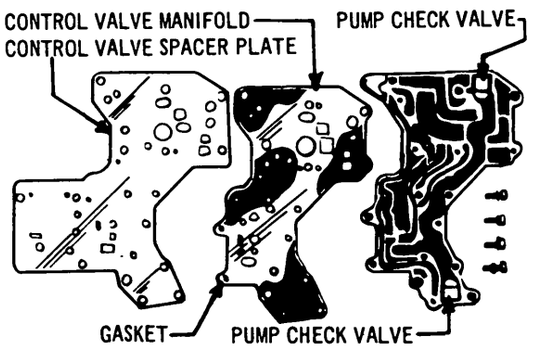


and insert the outer race. Place one of the washers in the race and then place one of the circular springs on top of the washer. *(NOTE–*Before installing the sprags check direction of groove as follows: The centerline of the spring groove in the sprag is at an angle less than 90° in relation to the flat back portion of the sprag. In other words, the groove is pointing toward the left when viewed facing the flat back portion of the sprag. Sprags must be installed in the correct direction for proper operation). Place the first sprag in the race at approximately the three o'clock position, with the bottom groove over the spring, the top groove pointing inward toward the left or center and the nose of the sprag pointing in a counter-clockwise direction. Follow this procedure to install the rest of the sprags *(CAUTION–The reactor must be on the bench with the coned side down when installing the sprags as described above).* Install circular spring in the sprag grooves and place the large washer over the sprags. Install bearing plate and lock ring.

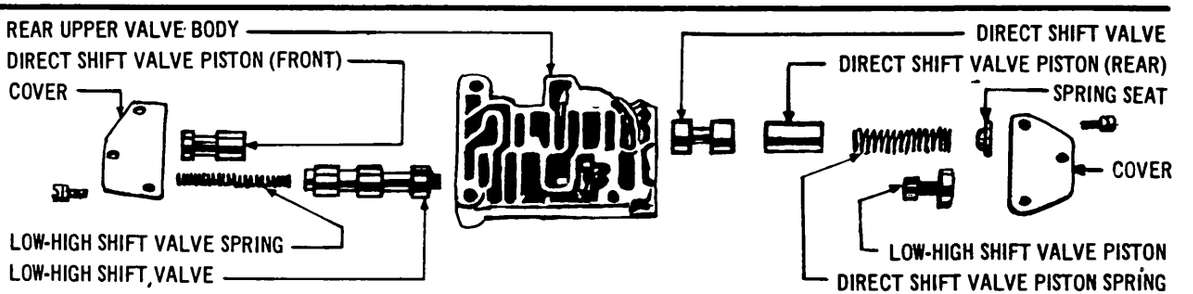
2) Insert the reactor shaft into the overrunning clutch with smooth bearing surface of shaft in contact with the sprags *(NOTE–If shaft cannot be inserted into the clutch, one or more of the sprags have been installed incorrectly).* When shaft has been installed, hold the reactor and rotate the shaft. The shaft should turn freely when rotated clockwise and should lock up when rotated counter-clockwise.

3) Insert the direct drive clutch piston inner ring into the piston bore and check the gap. Specified ring gap is .005-.010". Install the ring in its groove on the hub of the direct drive clutch housing and make certain it is free in the groove. Install the four piston outer rings on the piston and rotate them on installation so that the gaps are 90° apart. Centralize the inner ring in its groove in hub of the clutch housing and then push the piston into housing lining up the marks scribed at disassembly. Place the four spacers in the clutch housing locating them on the bosses provided. Place the driven plate on the piston lining up the marks scribed at disassembly (make certain that the spacers have not been knocked off the bosses). Install and tighten the retaining screws to 18-20 ft. lbs.

4) Place first turbine hub thrust washer on hub of direct drive clutch housing *(CAUTION–This thrust washer controls reactor shaft endplay. Seven thrust washer sizes are available in .008" graduations ranging from .062" to .110" in thickness. Ref r to reactor endplay note made on disassembly and select a washer to provide .010" to .017" endplay).* Centralize the driven plate in clutch housing and insert the first

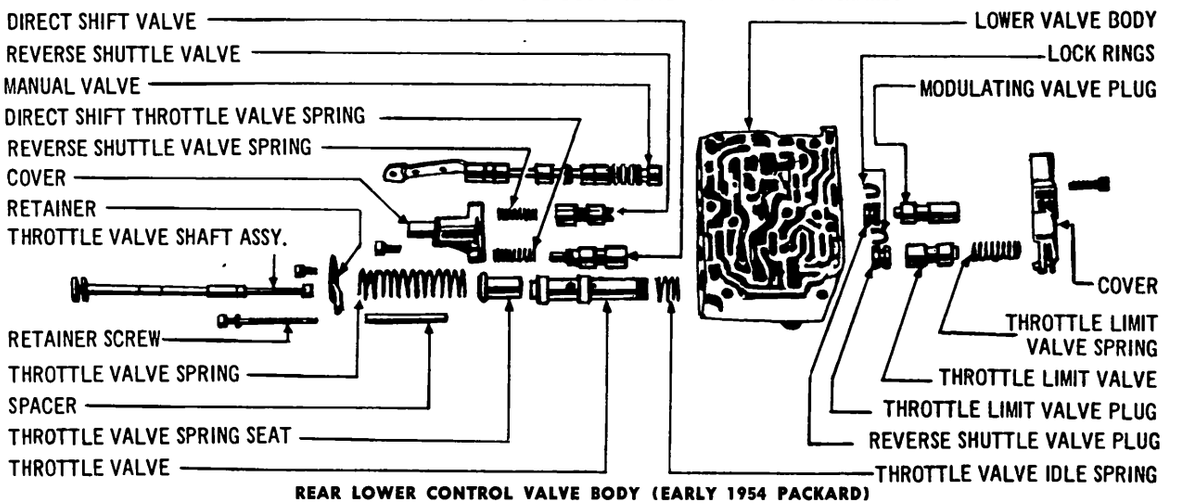


CONTINUED ON NEXT PAGE



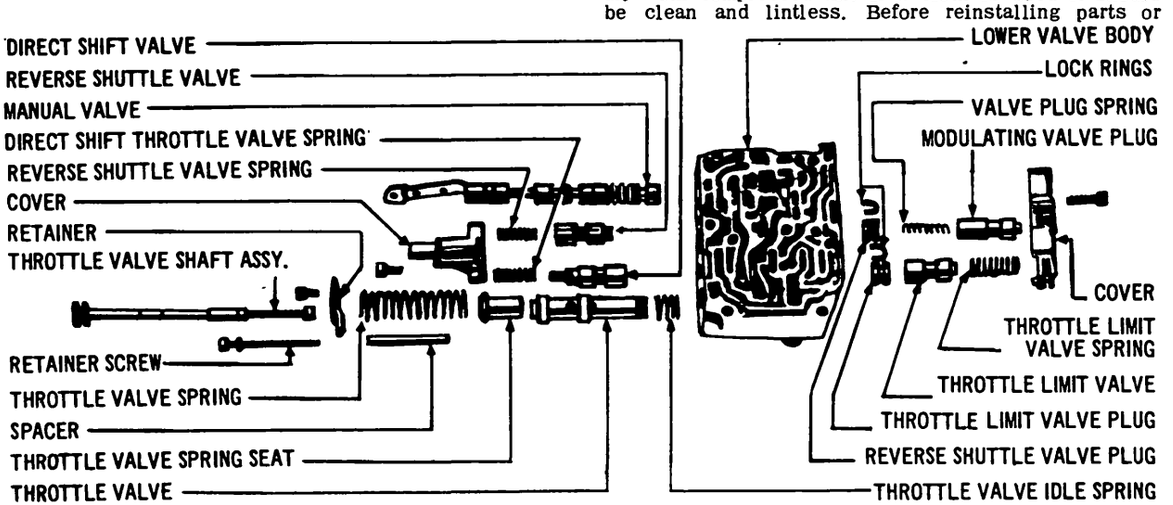
FRONT CONTROL VALVE BODY (EARLY 1954 PACKARD)

TWIN ULTRAMATIC (C nt.)



turbine splined hub into driven plate hub. Place reactor shaft front thrust washer on hub of first turbine and install reactor shaft and reactor as an assembly. Install second turbine, attaching screws and washers and tighten screws to 12-15 ft. lbs. Install reactor rear thrust washer. Place a new "O" ring around pump flange and install converter pump on clutch housing lining up the marks scribed in housing and pump at disassembly. Install four retaining bolts, nuts and washers approximately 90° apart and finger tighten the nuts. Using a wrench, tighten the nuts 1/4 turn at a time until pump flange is fully seated on the clutch housing flange *(NOTE–It is important that the above tightening proc dure be followed to prevent undue str ss b ing placed on pump flange at any one point).* Check reactor shaft endplay and if not within limits of .010-.017", a new first turbine hub thrust washer of the proper thickness must be installed to bring endplay within correct limits. When endplay is correct, install the remaining bolts, washers, and nuts and torque tighten evenly to 20-25 ft. lbs.

MANIFOLD BODY ASSEMBLY



REAR UPPER CONTROL VALVE BODY (LATE 1954 & 1955 PACKARD)

REAR LOWER CONTROL VALVE BODY (EARLY 1954 PACKARD)

TRANSMISSION DISASSEMBLY

►*TRANSMISSION CLEANING & INSPECTION CAUTION:* When a part of assembly is removed or disassembled it should be thoroughly cleaned in solvent and blown dry with compressed air. If a cloth is used it should be clean and lintless. Before reinstalling parts or reassembling units, all parts should be thoroughly inspected. When inspecting gears, pinions, or splined shafts, check all teeth for nicks or burrs and clean up as necessary, using an abrasive stone having a fine grit. Check the fit of all mating parts. Excessive clearance should not exist nor should parts be excessively tight. When inspecting any part having oil passages, blow compressed air through these passages. The friction facings and linings in clutch plates and brake bands should not be loose, have excessive wear, or be improperly bonded. Areas in contact with facings and linings should be inspected for scores or distortion. Check all castings for cracks or sand holes. Gasket contact area should be clean, smooth and free from deep scratches which would permit oil to pass gasket. Use new gaskets when reassembling transmission. Control valves should be very closely inspected for nicks and burrs and if necessary, cleaned up with a fine abrasive stone. Check to see that each valve moves freely of its own weight in its respective bore.

REAR LOWER C NTR L VALVE B DY (LATE 1954 & 1955 PACKARD, HUDSON & NASH)

TRANSMISSION OVERHAUL (TRANSMISSION UNITS)

1) Invert transmission and remove oil pan. Remove oil cooler tube adapter and then extract oil transfer tubes from side of transmission housing. Remove the transmission to bell housing retaining bolts and remove bell housing and front oil pump assembly.

CONTINUED ON NEXT PAGE

TWIN ULTRAMATIC (Cont.)

2) Place selector lever on side of transmission in "Park" position to lock output shaft then remove the long through bolt from end of output shaft. Remove the six rear housing to case retaining screws and washers and remove the rear housing assembly. Extract rear housing spacer from inside parking gear hub.

3) Rotate parking gear so that governors are in line with openings in case and then lift out parking gear and governors as an assembly. Loosen brake band screw lock nuts and then back out and loosen both the low and reverse band adjusting screws. Pull out the rear oil pump suction jumper tube.

4) Remove manual valve lever to link pin. Remove the five capscrews holding control valve assembly to case, and the seven screws holding the low range brake and reverse range brake to case. Lift control assembly and brakes out of case as an assembly.

5) Remove high range clutch assembly working it out through front of transmission case. Remove low range brake band through front of case. Using a dummy input shaft, lift the planetary assembly out through front of case and remove the reverse range brake band.

6) Extract rear oil pump governor jumper and discharge jumper oil tube from case with long nose pliers. Remove rear oil pump retaining screws and lock washers and lift out the pump noting the planetary ring gear thrust washer on pump hub. With a small punch, tap out the parking lock operating lever index pin.

7) Remove manual valve inner lever set screw locknut, remove stop plate, and then back out setscrew. Loosen manual valve outer lever setscrew locknut at end of shaft on outside of case, then back out setscrew and nut and remove lever. Using a long punch, tap inner end of manual valve lever shaft to start shaft and seal out of case. Hold inner lever, spring and operating lever and pull shaft, seal, washer, and retaining ring out of case.

8) If parking lock lever is to be removed, work through front of case and release lever support retaining ring using a pair of tru-arc pliers. With a long punch, tap front end of lever support to start it out of case and then remove the support, lever, and spring. Tap inner end of throttle valve inner lever to push seal out of case, and remove seal, washer and retaining ring. Slide lever out of case. Back out brake band adjusting screws and pull out anchor pins from inside of case. Remove breather from side of case.

CONTROL VALVE

►*CONTROL VALVE ASSEMBLY NOTE: Valve assemblies for 1954 Packard, 1955 Packard, Hudson & Nash are different. Appearance and service procedures are similar, the difference being in the valves, valve springs and passages.*

Disassembly: Remove front valve body assembly retaining screws, washers and lockwashers and remove body assembly. Remove rear lower body to rear upper body and to manifold screws, washers and lockwashers and remove the two body assemblies. Remove separator plate to manifold screws and washers and lift off plate and gasket (Note front & rear pump check valves in manifold).

►*THROTTLE VALVE ADJUSTING SCREW CAUTION: The setting of this screw should never be changed and should be left intact in the detent housing when disassembling and assembling the control valve assembly. Special equipment is required to set the throttle pressure which must be adjusted with transmission in the car and operating. If adjustment made necessary by removal, see adjusting procedure outlined in "Hydraulic Pressure Test" above.*

►*NOTE:* It is not necessary to remove the Reverse Shuttle Valve Plug and Throttle Limit Valve Plug in Rear Lower Valve Body. These plugs are held in place with lock rings located in elongated holes.

Valve & Valve Spring Removal (from the three valve housings): It is recommended that each control valve sub-assembly be disassembled, thoroughly cleaned, inspected and reassembled one at a time. To facilitate reassembly, the sub-assembly details should be placed on the bench in the order in which they were removed. See Control Valve Assembly illustrations for location of valves and springs.

Late 1954 & 1955 Packard
Rear Upper Valve Body

Valve Spring	Free Length	No. Coils	O.D.

Direct Shift Valve (Late)	1-27/32"	13-1/2	.440"
Low High Shift Valve	2-5/64"	33	.250"

►*DIRECT SHIFT VALVE PISTON SPRING PRODUCTION CHANGE: The Direct Shift Valve Spring Part No. 6470186 replaced in production and for service by Part No. 6470055.*

CONTROL VALVE ASSEMBLY SPRINGS: The springs used in the various valve housings are different and are identified as follows:

1954 Packard (Early)
Rear Lower Valve Body

Valve Spring	①	Free Length	No. Coils	O.D.
Reverse Shuttle		1-3/32"	13	.330"
Direct Shift Throttle		1-17/32"	15	.400"
Throttle Valve Idle		21/32"	5	.654"
Throttle Valve		2-25/32"	14	.784"
Throttle Limit Valve		1-7/32"	9-1/2	.550"

1954 Packard (Early)
Front Valve Body

Valve Spring	Free Length	No. Coils	O.D.
Converter Valve	1-3/4"	11-1/2	.580"
Pump Regulator Valve ②	2-7/32"	19	.400"
Pump Regulator Valve ③	3-1/4"	19	.525"
Shift Regulator Valve Piston	2-3/16"	16	.477"
Shift Regulator Valve	1-1/2"	24	.250"
Low Regulator Valve	1-17/32"	16	.400"

① —Approx. ② —Inner Spring. ③ —Outer Spring.

1954 Packard (Early)
Rear Upper Valve Body

Valve Spring	Free Length	No. Coils	O.D.
Direct Shift Valve Piston	2-5/32"	17	.440"
Low High Shift Valve	2-5/64"	33	.250"

Late 1954 & 1955 Packard
Rear Lower Valve Body

Valve Spring	Free Length	No. Coils	O.D.
Reverse Shuttle	1-3/32"	13	.330"
Direct Shift Throttle	1-13/32"	13-1/2	.412"
Throttle Valve Idle	21/32"	5	.654"
Throttle Valve	2-25/32"	14	.784"
Throttle Limit Valve	1-9/32"	9-1/2	.550"
Modulating Valve	1-3/32"	13	.330"

Late 1954 & 1955 Packard
Front Valve Body

Valve Spring	Free Length	No. Coils	O.D.
Converter Valve	1-3/4"	11-1/2	.580"
Pump Regulator Valve	3-21/32"	19	.650"
Shift Regulator Valve Piston	2-3/16"	16	.477"
Low Regulator Valve	1-17/32"	16	.400"

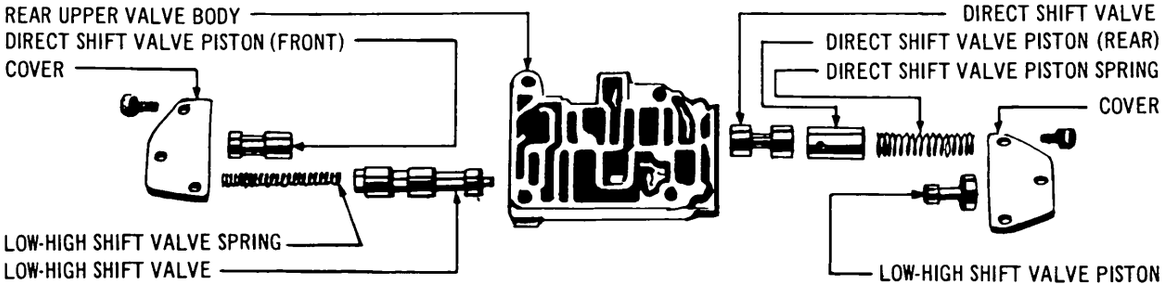
Reassembly: Place check valves in the manifold (if removed) and then assemble gasket and separator plate to manifold. Assemble valve, plugs and springs to the valve bodies. Assemble valve bodies to manifold but do not tighten retaining screws at this time as they will be torqued when assembled to the transmission case.

REVERSE BRAKE

Disassembly: Remove brake housing cap retaining ring with a screw driver and lift out cap, piston, seal and guide pin as an assembly. If cap sticks in housing, invert and support assembly on blocks and lightly tap end of guide pin with a fibre or brass drift. Using a sleeve approximately 7/8" long and 1" inside diameter, clamp piston and guide pin in a vise to compress the spring washer and then remove retaining snap ring. Remove from vise and take out piston and ring

CONTINUED ON NEXT PAGE

TWIN ULTRAMATIC (C nt.)



assembly and dished spring washer

Reassembly: Place piston seal or ring in housing bore and check ring gap (Packard 002" to 007"), (Nash & Hudson 002" to 014") Drop the spring washer in the housing with the concave or "dished" side upward Place the ring on the piston and make certain the ring is free in ring groove Install piston and ring in housing by tilting piston to compress ring while pushing piston downward Using the same sleeve used for removal, compress spring washer in a vise and install retaining ring

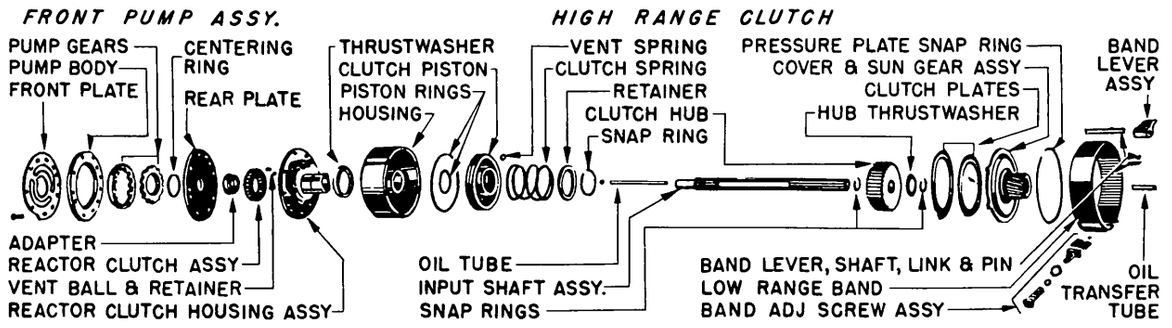
LOW RANGE BRAKE

Disass mbly: Position Piston Remover & Replacer Tool PK25 (Packard), J-5977 (Hudson & Nash) so that open lower end of tool clears forward edge of bench Drill two holes in bench and attach tool Place low range brake in tool and secure it with the two special screws Place cupped adapter on the center of brake housing cover turn down the adjusting screw making sure that the lower end enters hole in adapter Tighten adjusting screw a turn or two to relieve the pressure on the retaining ring and then remove retaining ring with a screw driver Slowly loosen adjusting screw taking particular note that brake piston cover raises as adjusting screw is loosened If cover is sticking in brake housing, use a punch and hammer and tap lower end of piston shaft upward to loosen cover Slowly loosen screw until brake piston and springs are free Remove assembly from tool and take out cover, piston, seal, washer, shaft and inner and outer springs

R ass mbly: Place piston ring in housing bore and check the gap (Packard 002" to 007"), (Nash & Hudson 002") Place the low range brake housing in tool and secure it in place with the two allen screws Install the two springs in the housing and make sure they are level and on their seats Place the ring compressor in top of brake housing and install piston, piston ring and rod assembly on top of springs Place the cupped adapter on top of piston and turn down adjusting screw of tool, make sure that lower end enters hole in adapter Slowly turn adjusting screw to compress springs, and guide piston and ring into ring compressor while tightening screw Be careful when tightening the screw to make sure that lower end of piston shaft enters freely into small bore in brake housing Tighten adjusting screw until springs are compressed and piston is at bottom of brake housing Install brass clamp on the section of piston shaft extending below brake housing Push clamp upward as far as it will go and securely tighten the clamp screw This is important as the clamp holds the piston down while releasing the tool to install cover and retaining ring Back off the adjusting screw and remove ring compressor Install piston cover, place cupped adapter on top of cover and tighten screw to hold cover in place Install retaining ring After making sure retaining ring is properly installed, loosen screw in clamp and release piston Remove brake assembly from tool

REAR UPPER CONTROL VALVE BODY (EARLY 1954 PACKARD, HUDSON & NASH)

HIGH RANGE CLUTCH



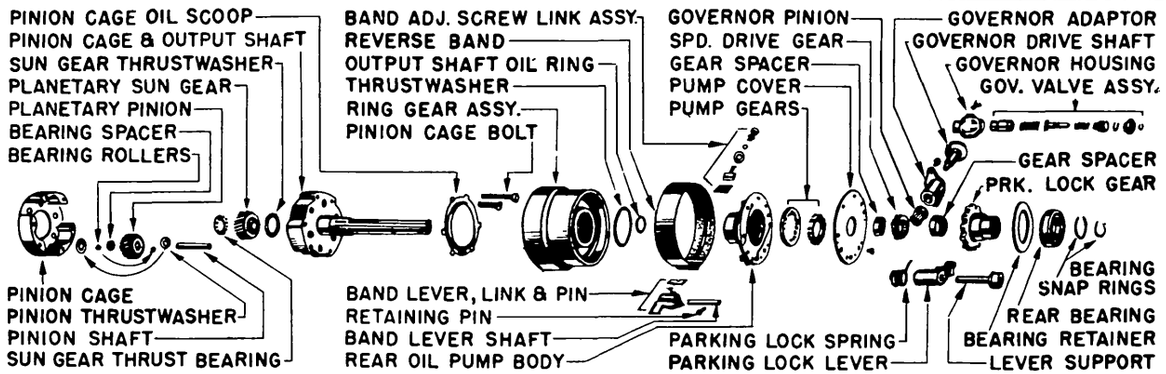
Disassembly: *(NOTE*—A 1-1/2" hole drilled in a bench will facilitate servicing the high range clutch. If a vise is used, lead jaws should also be used to prevent marring the input shaft) Remove planetary sun gear thrust bearing Remove plate snap ring with a screwdriver and remove plate and sun gear assembly Lift out the input shaft along with the clutch hub Invert clutch housing to permit the clutch plates to drop out Using Clutch Spring Compressor PK-304 (Packard), J-5943 (Hudson & Nash), compress clutch spring and release the spring retainer snap ring using expander snap ring pliers Back off compressor screw stem and remove the tool, snap ring, retainer and spring. Sharply rap or drop the housing on the bench, open end downward to dislodge piston In the event the rubber seal has swelled, it may be necessary to rap housing on bench more than once Remove lip seal from piston and also remove piston inner ring from clutch housing hub Clamp input shaft in a vise and remove clutch hub snap ring with snap ring pliers Remove hub thrust washer, hub and rear snap ring

Reassembly: Insert piston inner ring into bore of piston and check ring gap 004" to 018" (Early 1954 Packard), .007" to .015" (Late 1954 & 1955 Packard), .005" to 0085" (Hudson & Nash). Place the ring in groove in hub of clutch housing and make certain it is free in groove. Place a new piston lip seal on piston with the lip toward front face of piston. Centralize piston inner ring in its groove in hub of clutch housing. Lubricate lip seal and piston bore with Ultramatic oil and lower piston into housing. Push piston downward to start it over the inner ring and then use a feeler gauge to start lip seal into its bore while pushing downward on the piston. Care should be exercised so as not to tear or cut lip while performing this operation. Using Clutch Spring Compressor PK-304 (Packard), J-5943 (Hudson & Nash), install piston return spring, retainer and snap ring. Remove tool. Install clutch hub snap ring on input shaft and then slide hub on shaft with open end of hub toward snap ring. Slide clutch hub thrust washer on the shaft and against hub and then install the rear snap ring. Place the input shaft in the clutch housing and then install the driven and driving plates. When installing plates, first install a steel driven plate and then a waved, friction faced driving plate and continue installing the plates in this manner. Install sun gear and plate assembly and then lock the snap ring in place. Install planetary sun gear thrust bearing on shaft.

PLANETARY UNIT

Disassembly: With assembly on bench, shaft end upward, slowly lift off planetary ring gear *(CAUTION—This should be done slowly so that the three cage dampers and six damper springs are not scattered and lost).* Scribe alignment marks on the planetary cage and on the oil scoop. This must be done to insure installing scoop in its correct position on reassembly to maintain proper planetary balance. Remove planetary cage bolts then remove the end plate. Using a dummy planetary pinion pin, butt one end of the pin against a pin which carries a short pinion. Hold thrust washers the pinion and slide pinion, bearings and washers onto dummy shaft. Slide these parts off dummy shaft

CONTINUED ON NEXT PAGE



TWIN ULTRAMATIC FRONT PUMP & CLUTCH PISTON ASSEMBLY

TWIN ULTRAMATIC (C nt.)

into a clean container exercising care not to lose any rollers. Remove the other two pinions in the same manner. Pull out planetary sun gear and lift out rear thrust washer. Remove the planetary long pinions following the same procedure outlined for removing the short pinions. Using a pointed tool, unhook interlocking ends of the oil ring and slide rings off the shaft. It is seldom necessary to remove the pinion shaft from the cage; however they can be removed by tapping the shaft and woodruff keys out toward splined shaft.

Reassembly: Slide planetary cage shaft oil rings on shaft and into ring grooves. To lock ends of rings, push one end down into groove and push upward on opposite side of ring to raise other end while pushing inward toward shaft. Assemble planetary pinions and bearing rollers and install on their shafts in cage. A dummy pinion shaft and a dummy long pinion bearing spacer can be used to aid assembly of rollers into pinions *(NOTE–38 bearing rollers are used in each pinion.* The long pinions have 19 rollers at each end separated by a spacer. No spacer is used with the short pinions in Early 1954 Series. In Late 1954 & 1955 Packard, Hudson & Nash, some units have a spacer between the bearings in the short pinions while other units have no spacer. When a spacer is used in the short pinions, the bearings are not as long as when used without a spacer). Insert the dummy pinion shaft and two spacers into the long pinion and then insert 19 rollers. Install a small washer *(NOTE–There are a total of 12 washers required for the pinion shaft, 9 small size and 3 large size. Each long pinion uses a small washer at both ends. Each short pinion uses a small washer at the forward end of cage, and a large washer at rear or cage end).* After the 19 rollers have been installed, remove dummy spacer and insert 19 rollers. Add another small washer at this end. While holding the small washers against the ends of the pinion, butt end of dummy shaft against a long pinion shaft in cage and slide pinion, rollers, and washers onto pinion shaft *(NOTE–Beveled ends of pinion teeth should be toward the plate or cover end of the cage).* Assemble the two remaining long pinions in the same manner as described above. Place the rear sun gear thrust washer in the cage with oil grooves in washer toward front or open end of cage. Install rear sun gear in cage with the end of the sun gear having the teeth ground flush with the gear, toward front or open end of cage. Use the dummy shaft and spacer and insert 19 rollers in each end of the short pinions. A small washer is used at beveled end of pinion and a large washer is used at opposite end. Install short pinions with the beveled end toward plate or cover end of cage. Line up the alignment marks (small "O" on each part) on cage and end plate and install end plate onto pinion shafts. Position oil scoop on cage so that previously scribed marks on scoop and cage are in register. Start planetary cage into ring gear (note that planetary cage damper groove has a lip on one side). Place two damper springs into lip side of the groove. Tilt planetary cage and slide a damper into the groove and on top of the springs. Install remaining springs and dampers in the same manner. After all springs and dampers are installed, place the assembly on the bench, shaft upward and rotate the ring gear to engage pinions and seat the ring gear.

TWIN ULTRAMATIC PLANETARY & OUTPUT SHAFT ASSEMBLY

GOVERNOR

Disassembly: Remove low speed and high speed governors from parking gear assembly using an Allen wrench. Remove high speed governor plate. Press inward and tilt spring seat to release it and remove spring and seat. NOTE–The low speed governor is serviced as an assembly and should not be disassembled if the valve works freely in the body. If valve is sticking because of dirt, remove plate, and wash out passages.

Reassembly: Slide high speed governor valve into its bore in body and make sure it moves freely. Install valve spring and seat and attach plate. Assemble governors to parking gear.

FRONT & REAR OIL PUMPS

Disassembly: Remove rear oil pump cover plate and rotors. Remove front oil pump cover plate, rotors, and outer rotor spacer ring. Also remove two oil rings from the high range clutch journal of front pump.

Reassembly: Place the rear oil pump rotors in the rear pump body and check rotor tooth nose clearance (One side of rear pump inner rotor has an undercut and this should be installed toward front or hub end of pump body). Tooth nose clearance should not exceed .008". Check side clearance between outer rotor and the pump body bore. This clearance should not exceed .011". Check rotor end clearance using a straightedge placed across face of pump body. Clearance between straightedge and rotors should not exceed .006". If clearances not within these specifications, install a new pump assembly. Install the front pump rotors and spacer ring in front pump body and repeat the clearance checks that were made for the rear pump. Clearances are the same. Place rotors in the pump bodies in the same position in which clearances were checked and then install the cover plates. When assembling the front pump, install two oil rings on high range clutch journal.

REAR HOUSING

NASH & HUDSON

Disass mbly: Remove speedometer driving gear spring from forward end of output shaft. Remove speedometer adapter snap ring from transmission rear housing. then remove speedometer pinion gear and adapter assembly. Remove output shaft snap ring from rear of output shaft and remove shaft from rear ball bearing by tapping end of shaft with a plastic hammer. Remove speedometer drive gear from output shaft. Remove rear ball bearing snap ring from transmission rear housing using Tru-Arc pliers. Tap bearing out of housing with the handle end of plastic hammer. Remove transmission rear housing spider front bushing by tapping with hammer handle. Slide speedometer drive gear off splines of output shaft and remove snap ring.

Reassembly: Install rear ball bearing and Tru-Arc snap ring with flat side of snap ring against bearing outer race. Install speedometer drive gear snap ring on output shaft. With a plastic hammer tap the output shaft in the ball bearing through front end of the housing, then install rear bearing snap ring and output shaft. Install rear housing oil seal using Oil Seal Installer J-1354. Tap front spider bushing retainer assembly in front end of housing. The transmission rear housing spider retainer has the word "top" cast on retainer: this end faces toward front of transmission and to top of case. Install speedometer drive gear and spring on front end of output shaft. Install the speedometer pinion and adapter lining up notch in adapter with index pin in housing. Install speedometer adapter retaining ring with ring gap toward top of housing.

PACKARD

Disassembly: Slip speedometer driving gear and spring from forward end of output shaft and remove adapter retaining ring with snap ring pliers. Remove adapter and speedometer pinion assembly. Install universal joint flange plate (part of Tool PK-22), place assembly in arbor press and press out the input shaft. Remove rear housing seal with Tool PK-352 and PK-361. Remove rear bearing retaining ring and press or knock out the rear bearing.

Reassembly: Press rear bearing onto output shaft and press this assembly into rear housing. Install rear bearing retainer ring. Install a new rear housing oil seal and drive into place with Tool PK-367. Place the rear housing assembly in an arbor press with Housing Support (part of Tool PK-22) under housing. Start universal joint flange on output shaft splines. Place Installing Tool (part of Tool PK-22) and press flange onto output shaft. Install speedometer pinion

CONTINUED ON NEXT PAGE

TWIN ULTRAMATIC (Cont.)

and adapter, lining up notch in adapter with index pin in housing. Install speedometer adapter retaining ring with the ring gap toward top of housing. Install speedometer driving gear and spring on forward end of output shaft.

TRANSMISSION REASSEMBLY

1) Install breather in side of case with breather cap toward top of case. Place new "O" rings on brake band anchor pins and slide pins into case from inside and then start adjusting screws into case.

2) Install throttle valve inner lever and add the retainer ring and washer. Slide the oil seal over outer end of shaft with lip of seal toward case. Using a 1/2" socket, tap seal into case until it bottoms. Install outer lever but do not tighten clamp bolt nut.

3) Install parking lock lever with end of spring hooked over the operating lever stop pin and push lever support into case. Install lever support retaining ring. Install retaining ring and washer on outer end of manual lever shaft and then slide new oil seal onto shaft so that lip of seal will be toward case. Start shaft through case and add the parking lock lever, spring and manual valve inner lever. Tap operating lever index pin into shaft and then line up the setscrew in manual valve lever with the hole in the shaft and install setscrew, stop plate and locknut. Using a 11/16" deep socket, bottom the oil seal in the case. Attach manual valve outer lever to shaft so that the offset in lever is toward the case.

4) Place planetary ring gear thrust washer on hub of rear oil pump and place pump in case. Install rear pump retaining screws and washers with the long screw at upper left hand position on pump flange (looking through case from front to rear). Tighten capscrews to 15-18 ft. lbs. Install new "O" ring seals on rear oil pump governor jumper and discharge jumper oil tubes, lubricate seal rings with Ultramatic oil and press tubes into pump and case.

5) Place reverse brake band in case with the band strut with the notch in it on the same side as band operating lever. Engage band struts in operating lever and in the anchor pin and tighten adjusting screw just enough to hold band in place. Using a dummy input shaft, install planetary assembly. Exercise care to avoid breaking the planetary shaft sealing rings when they enter bore in rear pump.

6) Place low range brake band in case with the band strut with the notch in it on the same side as band operating lever. Engage band struts in operating lever and in anchor pin and tighten adjusting screws just enough to hold band in place. Install high range clutch assembly.

7) Assemble front oil pump to bell housing and tighten the retaining screws to 15-18 ft. lbs. Place high range clutch thrust washer on hub of pump with ball indentations in washer against rear face of pump.

8) Lightly apply clean cup grease in three or four places around transmission case side of bell housing-to-case gasket. Line up capscrew holes in gasket with those in the case and stick gasket to case. Assemble bell housing and front pump assembly to case and tighten screws to 55-60 ft. lbs. *(NOTE–On 1954 Packard, two self-locking screws are used. On 1955 Packard, Hudson & Nash one self-locking screw is used. The remaining attaching screws are standard type with lockwashers. See illustration for location of self-locking screws).*

►*PARKING GEAR NOTE: If a new parking gear is to be installed, transfer the snap ring from inside of parking gear hub to the new gear.*

9) Insert parking gear lug ring into hub of parking gear and install parking gear and hub assembly on end of planetary gear shaft being sure to line up index pin in end of planetary shaft with missing tooth in parking gear hub. Rotate planetary cage shaft so that parking gear assembly can slide onto shaft when governors are lined up with openings in transmission case. Place rear housing spacer in hub of parking brake. Using a new gasket, assemble complete rear housing assembly to case and install and tighten two or three retaining screws. Insert long bolt into end of output shaft and tighten bolt.

10) Attach dial indicator to input shaft with the indicator against bell housing flange. Check high range clutch and planetary endplay by using a screwdriver behind high range clutch housing. Push input shaft toward the rear and set indicator dial and then pry clutch housing forward noting the endplay, which should be .023-.036". If endplay not within these specifications it will be necessary to change the rear housing spacer located in hub of parking gear assembly. Spacers are available in thicknesses ranging from .020" to .085" in .013" graduations. Select and install a spacer which will bring endplay within specified limits and recheck endplay.

11) Install all rear housing retaining screws and lockwashers and torque tighten screws to 15-18 ft. lbs. On Hudson & Nash tighten the long output shaft bolt to 35-40 ft. lbs. On Packard, remove the long output shaft bolt and inspect threaded end of bolt. If bolt does not incorporate a nylon plug, install a new bolt with a nylon plug. Tighten bolt to 35 ft. lbs., then back off bolt one or two turns and then re-tighten it to 50 inch lbs.

12) Install control valve assembly to case and just start the five capscrews. Insert oil jumper tubes into their respective openings in valve bodies. Push reverse brake band operating lever down so that the jumper tubes can enter brake housing, then push the brake assembly into position and start the capscrews. Repeat the foregoing operation to attach low range brake assembly (NOTE—It may be necessary to slightly raise or tilt the control assembly to engage the jumper tubes when installing low range brake assembly.

13) Tighten the five capscrews in control valve assembly to **nine ft. lbs.**, and the remaining screws in the two brake assemblies to **five ft. lbs.** *CAUTION–It is very important that capscrews in the control valve assembly be tightened evenly and to nine ft. lbs. torque to prevent distortion of control valve assembly.*

14) Tighten both reverse and low range brake band adjusting screws to 20 ft. lbs., then back screws out 1-3/4 turns and tighten locknuts. Connect manual valve link to shaft inner lever. Lubricate "O" ring on rear oil pump suction jumper tube and install the tube. Install the oil strainer. Using a new gasket, install the oil pan and tighten retaining screws to 10-12 ft. lbs.

15) Install the front oil pump transfer tubes and tube adapters. The adapter with the small metering hole should be installed in the opening toward top of case. Using a screwdriver in the end of the throttle valve shaft, rotate shaft counter-clockwise until valve reaches its stop. With valve against its stop, use a straightedge to position angled end of lever flush with machined rear face of transmission case.

TRANSMISSION INSTALLATION

HUDSON & NASH

1) Wire converter assembly to bell housing to prevent it from slipping off input shaft while moving transmission. Install transmission on lift or jack. Place under car and raise it until pilot at front of direct drive clutch housing is in a line with bore in crankshaft. Move transmission forward so that pilot enters crankshaft while at the same time the four studs on clutch housing enter holes in flywheel. Start two of the converter to flywheel retaining nuts and remove wire holding converter to bell housing.

2) Raise transmission until pilot around top of bell housing flange is right to top of flywheel housing. Install the lower flywheel housing cover and starting motor. Install all bell housing to flywheel housing retaining bolts and tighten to 25-30 ft. lbs. Install the other two converter to flywheel nuts and tighten to 25-30 ft. lbs.

3) Attach rear cross member to the engine supports and side sills. Connect torque tube and universal joint to rear transmission housing and output shaft. Remove the support from under engine and lower the jack from under transmission.

PACKARD

1) Wire converter assembly to bell housing to prevent it from slipping off input shaft while moving transmission. Using a jack or other lifting device, place transmission under car and raise it until the pilot on front of direct drive clutch housing is in direct line with bore in crankshaft. Move transmission forward so pilot enters the crankshaft while at the same time the four studs on clutch housing enter holes in flywheel. Start two of the converter to flywheel retaining nuts and remove wire holding converter to bell housing.

2) On 1954 models, raise transmission until the pilot around top of bell housing flange is tight to the top of flywheel housing. On 1955 models, the dowel in the flywheel housing positions the bell housing properly in relation to flywheel housing. Install all bell housing to flywheel housing retaining bolts and tighten to 25-30 ft. lbs. Install the two remaining converter to flywheel retaining nuts and tighten to 25-30 ft. lbs.

3) Assemble flywheel housing lower cover to flywheel housing and tighten the bolts to 15-18 ft. lbs. (1954 Packard), 25-30 ft. lbs. (1955 Packard). Attach engine rear support to "X" members. Lower transmission lift and the jack supporting the engine and then install transmission rear housing insulator to support nuts and washers. Remove jack from under engine and the lift from under transmission.

STUDEBAKER AUTOMATIC TRANSMISSION

Studebaker Champion (1950-55)
Studebaker Commander (1950-55)
Studebaker Land Cruiser (1950-54)
Studebaker President (1955)
Hudson (Exc. Jet) (1954)

►CHANGES, CAUTIONS, CORRECTIONS

►*AUTOMATIC TRANSMISSION MODEL IDENTIFICATION & APPLICATION (Different transmission models used as follows):*

Car Model	①Trans. Model
Champion (1950-Early 1955)②	DG-150
Champion (Late 1955)③	DG-150M
Commander (1950-Early 1955)④	DG-200
Commander (Late 1955)⑤	DG-200M
Commander (1955 2nd Series)⑥	DG-250M
President (1955)	DG-250M
Hudson (1954)	DG-200

①—On model plate on left side of transmission case.
②—Before 1955 Engine No. 1,147,699.
③—After 1955 Engine No. 1,147,699.
④—Before 1955 Engine No. V-318,899 (Early 1st Series).
⑤—After 1955 Engine No. V-318,899 (Late 1st Series).
⑥—1955 2nd Series. *See "Starting Engine Numbers" for 2nd Series on Car Model pages.*

►**STARTING ENGINE BY PUSHING CAR: Turn ignition key ON, depress and release accelerator pedal once (to set automatic choke), place transmission selector lever in Neutral "N" position. Push car until speed of 15-20 MPH. is reached, then move selector lever to Drive "D" or Low "L" position.**
CAUTION—Pushing to start engine recommended rather than towing (car may overtake tow car).

►**TOWING CARS WITH AUTOMATIC TRANSMISSION: Place transmission selector lever in Neutral "N" position and do not tow car in excess of 30 MPH.**

►**TRANSMISSION SERIAL NO. NOTE—Separate Torque Converter Nos. and Transmission Nos. used:**

Torque Converter—Stamped on engine side of flywheel adjacent to flywheel ring gear.

Transmission—On metal plate on left side of transmission case below oil level gauge.

►*1951 COMMANDER ACCELERATOR LINKAGE CHANGE (Serial No. 8133626 Up):* Following parts changed to provide smoother accelerator operation: Accelerator Bell-Crank Lever & Bracket Assembly, Accelerator Bell-Crank Lever-to-Transmission Rod, Accelerator Cross Shaft Assembly.

►*CAUTION—See Linkage Adjustment Directions for connection at this lever (rod must be connected in proper hole and all cars not connected alike).*

►*1951 TRANSMISSION OIL PAN PRODUCTION CHANGE:* Beginning Champion Serial No. 20171, Commander No. 45792, oil pan reinforced flange used. This pan requires ⅛" longer oil pan screws and can be installed on earlier cars if Kit No. 529975 used (includes 14 new longer screws No. 31-0510).

►*1951-52 REPLACEMENT TRANSMISSION DESIGN CHANGES*—Several changes have been made in design and should be noted when installing these assemblies:

Parking Brake Pawl Pivot Pin Case Change Beginning Trans. Serial No. SCO-124103 (1951-52 Commander), No. SCO-1715R (1950 Commander), No. SCH-35085 (1950-52 Champion). As follows:

(1) Parking pawl pivots provided with 5/16" x 24 tapped hole in end to facilitate removal.
(2) Extension cases which have through pivot pin hole in case have blind bushing installed on open side.
(3) "O" ring omitted from parking pawl pivot pins ("O" ring groove retained for interchangeability of parts).

NOTE—Complete extension case assemblies are interchangeable regardless of above changes.

Parking Pawl Toggle Arm Fiber Washer—Beginning Trans. Serial Nos. SCO-124523 (1951-52 Commander), No. SCO-1804R (1950 Commander), No. SCH-35086 (1950-52 Champion). A fiber washer is installed on parking pawl toggle arm splined shaft (between pawl and rear of extension case) to align linkage and prevent bindings. ***CAUTION—This washer must be re-installed in all transmissions in which it is found on disassembly (see NOTE following for use of STEEL washer).***

Parking Pawl Toggle Arm Steel Washer—Beginning Trans. Serial No. SCO-133019 (1951-52 Commander), No. SCO-2119R (1950 Commander), No. SCH-37545 (1950-52 Champion). STEEL washer used in place of fiber washer (above). This steel washer or similar washer .067-.071" thick must be used on parking pawl toggle arm splined shaft on these transmissions.

CAUTION—Steel washer cannot be used to replace fiber washer used in previous transmissions.

►*STUDEBAKER ERRATIC MULTIPLE CLUTCH ACTION CORRECTION:* May be caused by oil distributor tube being loose or improperly located. This aluminum distributor tube is located behind the bronze lubricator valve in the main shaft. Check by visual inspection and if found to be loose or improperly located, replace main shaft assembly. Distributor tube is not serviced separately.

►*STUDEBAKER FAILURE TO MOVE FORWARD (AFTER REVERSE OPERATION) CORRECTION:* May be caused by loss of front oil pump prime. The loss of front oil pump prime is caused by rear pump blowing air out of rear pump inlet hole and at the same time blowing oil away from front pump inlet hole. To check and correct this condition, take front pump pressure after a long reverse operation. If pressure is zero, remove rear oil pump cover and idler gear. Reinstall rear pump cover and again operate car in reverse. After stopping, shift to "D" or "L" position. Car should now move forward under acceleration. This will confirm that the condition described above is the cause of the forward operation condition. Reinstall rear oil pump idler gear. To correct, remove transmission oil pan and screen and install a new screen with baffle. Before replacing oil screen shroud, drill a ⅛" hole at a point ½" above and slightly to the left of the smaller of the two rectangular holes in the shroud (this will place the hole approximately in the corner of the shroud near flanged edge).

►*HUDSON "BUZZING" CORRECTION:* Increasing the amount of fluid in the transmission *(See "Oil Level Change" below)*, will in most cases correct this condition. On transmissions with Serial No. HA-4275 and lower, where the increased oil capacity does not correct the condition, it will be necessary to install the later type Front & Rear Pump Relief Valve *(See "Front & Rear Pump Relief Valve Production Change" below).*

►*OIL LEVEL CHANGE (ALL HUDSON AUTOMATIC TRANSMISSIONS):* Increase the oil capacity from 11 qts. to 12 qts. A new dipstick, with revised markings has been released for service replacement and later production cars.

►*HUDSON BAND ADJUSTING SCREW PRODUCTION CHANGE:* Beginning with transmission Serial No. HA-9930, a new band adjusting screw is being used in production and for service replacement on older transmissions. The brake anchor strut has also been revised to use the new screw. When replacing the adjusting screw with the later type, it will be necessary to also use the revised anchor strut. The early type adjusting screw can be used with the revised anchor strut. Later type adjusting screw is identified by the ½" radius between threaded portion and screw head.

►*HUDSON DETENT SPRING PRODUCTION CHANGE:* Beginning with transmission Serial No. HA-10109, a new detent spring, Part No. 311892, is used to provide a more positive selector lever positioning.

►*HUDSON FRONT OIL PUMP COLLECTOR RING PRODUCTION CHANGE:* A one-piece alloy iron collector ring replaces the two-piece type formerly used in production and for service replacement.

►*HUDSON REAR PLANET CARRIER PRODUCTION CHANGE & REPLACEMENT PARTS CAUTION:* Beginning with transmission Serial No. HA-6005 a new rear planet carrier assembly entered production. The new planet carrier, Part No. 311406, can be used for service replacement on earlier transmissions when Spacer Washer, Part No. 311412 is also used. The later type carrier can be identified by the machined counterbore in rear hub face to receive the spacer washer.

►*TRANSMISSION ASSEMBLY SERVICE REPLACEMENT CHANGE (1951 TO 1953 COMMANDER)*—Service replacement transmission assembly (with "Part Throttle Downshift") Part No. 533568 used on 1953 Commander Models, replaces service transmission Part No. 529973 previously furnished for replacement on 1951 & 1952 Commander Models.

►*EXTENSION CASE ASSEMBLY REPLACEMENT NOTE (COMMANDER)*—Extension Case assembly, Part No. 529984 is furnished as service replacement for all 1951 to 1953 Commander models. *See "Part Throttle Downshift" option (with service replacement extension case) following.*

►*"PART THROTTLE DOWNSHIFT" OPTIONAL WITH SERVICE REPLACEMENT EXTENSION CASE (1951-52 COMMANDER MODELS)*—Extension case assembly can be installed to provide "Part Throttle Downshift" if desired. Extension case is furnished with the direct drive lock-pawl in place, and to prevent "Part Throttle Downshift," install extension case exactly as received. To retain, or convert to "Part Throttle Downshift," remove the Direct Drive Lock-up Pawl (located directly below transmission main shaft bearing bore on machined face of extension assembly).

►*EXTENSION CASE REPLACEMENT (1953 COMMANDER)*—Direct Drive Lockup Pawl must be re-

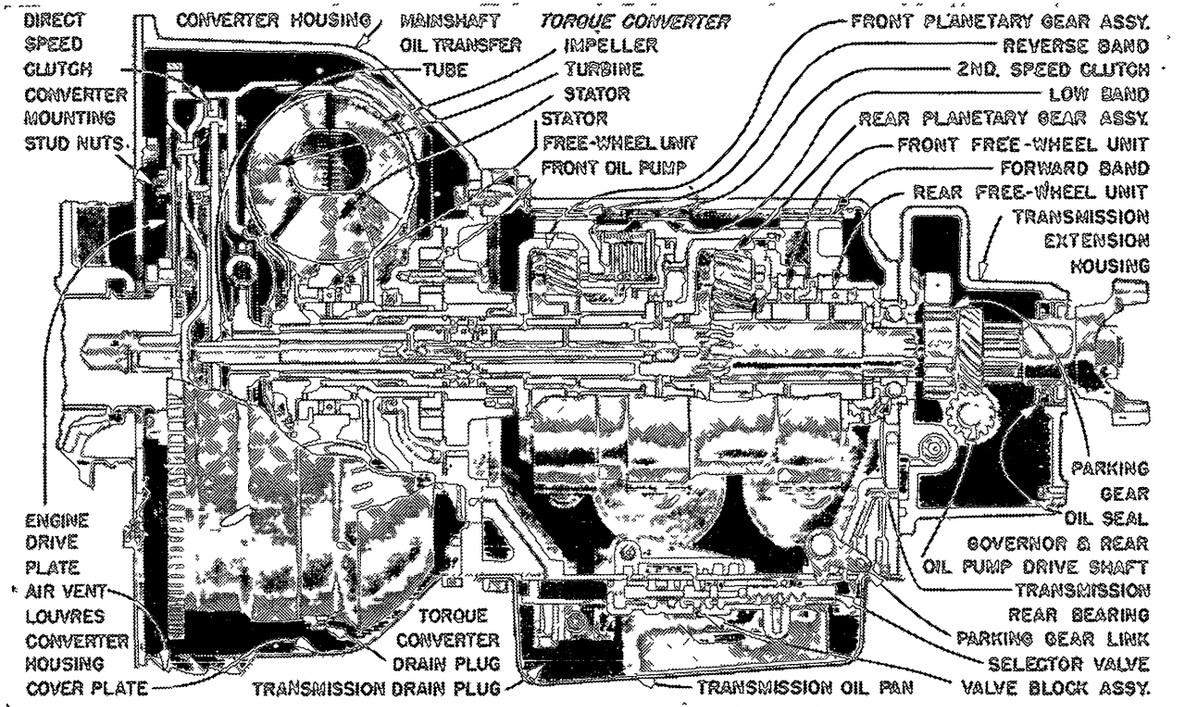
CONTINUED ON NEXT PAGE

STUDEBAKER AUTOMATIC TRANSMISSION (Cont.)

moved before installation of extension case assembly service replacement (see "Part Throttle Downshift Option" above).

▷*1955 SLOW REVERSE ENGAGEMENT CORRECTION (When shifting from either "D" or "L" range to "R" range):* There are two possible causes for the condition, both of which require rework of valve block assembly. *See "Sub-Assembly Overhaul" below.*

▷*1955 REMOTE CONTROL SHIFT LEVER ENDPLAY & LOOSENESS CORRECTION:* A new spacer is available for replacement in the remote control gearshift lever spring housing. Installation of this later type spacer will reduce endplay and looseness, and will make it easier to make proper adjustment.



▷*1950-55 MULTIPLE DISC CLUTCH SERVICE REPLACEMENT CAUTION & 1955 PRODUCTION CHANGE:* Sintered friction discs and flat separator plates are used in 1955 production and for service replacement on all 1950-55 models. Previously the separator plates were slightly "dished." The early type friction discs were thicker, therefore when installing the new type discs in early transmissions it is necessary that Spacer Plate, Part No. 537720 be used. When it is necessary to replace either a disc or a disc plate, all discs and plates should be replaced in complete sets.

▷*1955 CONVERTER VALVE PRODUCTION CHANGE:* Starting with the following transmission serial numbers, the converter valve was changed so that the shuttle valve is regulated by the multiple disc clutch pressure instead of direct drive clutch pressure. Serial numbers SCH-2101 (DG-150M Trans.), SP-10801 (DG-250M Trans.), this change made to provide a more positive shift from drive-intermediate into direct drive. The converter pressures with the later type valve is 50-70 lbs., in low gear, and 20-30 lbs., in drive-intermediate or direct drive.

▷*1955 COMMANDER & PRESIDENT LOW UPSHIFT & LOW "KICK-DOWN" SPEED CORRECTION:* If transmission has a low upshift speed (approx. 60 MPH) from drive-intermediate to direct drive at full throttle "kickdown" or a low maximum "kickdown" speed from direct drive to drive-intermediate (approx. 48 MPH) check accelerator-to-governor linkage adjustment and inspect governor spline shaft and governor valve for burrs or roughness, smoothing up parts as necessary. *NOTE*—If correction cannot be made as indicated above, install a new governor tension spring, Part No. 537066 (free length 2 21/32").

DESCRIPTION

Transmission consists of Torque Converter Assembly (torque converter and Direct Speed Clutch) and a planetary type transmission (3-speed and Reverse) which is hydraulically controlled. Transmission has a pawl-and-gear Parking lock mechanism (Studebaker models are fitted with an electrically controlled, solenoid operated "Anti-Creep" device by which the brakes are held "ON" while car is standing. This unit is operative whenever ignition switch turned on). Direct drive clutch is hydraulically operated, and consists of driven member, backing plate and a hydraulically operated pressure plate. Oil pressure to direct drive clutch, locks these three units together allowing engine torque to be transmitted directly to rear wheels.

STUDEBAKER AUTOMATIC TRANSMISSION SECTIONAL VIEW

▷Champion & Commander Differences: Transmissions are similar but have following differences:

Torque Converter—11" diameter (Champion), 12" (Comm.). Direct Drive Clutch is also proportionately smaller on Champion. Torque converter cooling air intake has screened opening on left side (Champion), flexible air duct (Comm.).

Transmission Oil Capacity—Approx. 9½ qts. (Champion), 11½ qts. (Comm.). *See Lubrication data.*

Low Band Servo—Single piston type (Champion), double piston type (Comm.).

Planetary Multiple Disc Clutch—Three-disc type (Champion), four-disc type (Comm.).

Extension Housing—Champion governor extension housing does not have direct drive latching mechanism (used on Comm.), and has heavier governor spring. Speedometer pinion has 27 teeth (Champion), 24 teeth (Comm.).

Torque Converter & Direct Speed Clutch: Assembly is mounted in a case which replaces the flywheel used on cars with standard transmission and consists of the units listed below. Torque converter is air-cooled by air drawn in through duct on left side of case (vanes on outer surface of converter case circulate air) and discharged through louvres on bottom of housing. Torque converter and direct speed clutch action is automatic and controlled by the hydraulic system (see Operation—below, and Hydraulic Circuit illustration).

Converter Impeller (Driving Member)—Integral with rear section of converter case bolted on engine drive plate on end of crankshaft. Impeller is supported at rear end by sleeve extending through bushing in forward end of front oil pump housing (behind oil seal). This sleeve engages the inner gear of the front oil pump and drives the pump. Impeller rotates at engine speed.

Turbine (Driven Member)—In converter case directly in front of impeller and driven by oil flow from the impeller. Turbine hub is splined on tubular driveshaft which is integral with the front planetary ring gear so that power is transmitted to this unit when the converter is operating.

Stator (Stationary Member)—Consists of a set of curved vanes placed between the inner ends of the turbine and impeller vanes. Stator is mounted on a free-wheeling unit which is mounted on a stationary shaft carried in the front retainer of the transmission case. Stator is locked or held stationary when unit is operating as a torque converter and acts to "boost" the oil returned to the impeller thus supplying the torque multiplication. When turbine speed equals impeller speed, stator rotates freely with the other members (rotation permitted by free-wheel unit) without any torque multiplication.

Direct Drive Clutch—Consists of a hydraulically operated single plate clutch in forward end of torque converter housing. Clutch driven member is splined on forward end of transmission mainshaft and clutch driving plates are locked in converter housing (plates engage dowels and studs in housing), so that the transmission mainshaft is driven directly by the crankshaft when the clutch is engaged, thus locking out the torque converter. Clutch

CONTINUED ON NEXT PAGE

STUDEBAKER AUTOMATIC TRANSMISSION (C nt.)

is engaged hydraulically by oil under pressure in chamber in front of forward pressure plate (oil enters and leaves this chamber through oil channel in hollow mainshaft).

Planetary Transmission: Consists of planetary gear sets, bands, and servo mechanisms, multiple disc clutch, free-wheeling units, governor, oil pumps, and control valves located in transmission case.

Front Planetary Unit & Clutch—Gears are conventional (inner sun gear, planetary pinion assy. and outer ring gear) with outer ring gear driven by torque converter turbine, planetary pinion assembly driving rear planetary ring gear, and sun gear controlled by Low Band and Multiple Disc Clutch. Sun gear is held stationary by the Low Band (in Low position) so that power is transmitted through the gears, or is locked to the planetary pinion assembly by the multiple disc clutch (in Intermediate and Direct positions) so that the entire planetary unit revolves as an assembly to transmit power directly without gear reduction. In reverse position, the planetary pinion assembly is held stationary by the Reverse Band and power is transmitted through the gears and in a reverse direction.

Rear Planetary Unit—Gears are conventional (inner sun gear, planetary pinion assy. and outer ring gear) with outer ring gear driven by front unit planetary pinion assembly, planetary pinion assembly driving transmission mainshaft (pinion plate splined on shaft), and sun gear controlled by the Low Band or Forward Band through free-wheel units on the gear hub. Sun gear is held stationary by the Forward Band in all forward speeds (Low, Intermediate, and Direct positions) so that power is transmitted through the gears with these modifications: In Intermediate position, the forward free-wheel unit permits the front planetary unit (which is locked out) to over-run the rear planetary sun gear (which is held stationary). In Direct drive position, gears are by-passed by the engagement of the Direct Speed Clutch and the sun gear turns freely with the other gears although the Forward Band is applied (this rotation permitted by the rear free-wheel unit in the forward band drum hub). In Reverse position, the sun gear is driven by the front planetary unit and the ring gear is held stationary by the Reverse Band (along with the front planetary pinion assy.) so that power is transmitted through the planetary pinion assembly.

Parking Brake Mechanism—Consists of a pawl controlled by the transmission selector lever which engages a gear on the rear end of the transmission mainshaft and locks the shaft when selector lever is placed in Parking "P" position. An interlock piston (see illustration) operating from oil pressure supplied by the rear oil pump prevents engagement of the pawl if car is moving forward at speed greater than 3-5 MPH. to prevent accidental engagement of the parking lock.

Anti-Creep System (Studebaker Only): Consists of a solenoid controlled valve in the hydraulic brake line to the rear wheels which is controlled by the pressure switch in the transmission and an Idle Adjustment Screw Switch on the carburetor (replaces regular throttle stopscrew) or on accelerator across shaft bracket.

See "ANTI-CREEP" in Brake Section for data.

Oil Pumps: Two pumps used to provide oil pressure for hydraulic controls, oil supply for torque converter, and transmission lubrication:

Front Pump—External-internal gear type, in front of transmission case and driven by the engine. Pump starts to operate as soon as engine started and supplies oil to torque converter and for transmission lubrication. Also supplies oil pressure for hydraulic controls during Idling, Low Speed, and Reverse operation. Pump pressure is controlled by Front Pump Relief Valve.

Rear Pump—Mounted externally on right side of transmission extension housing and driven from same cross-shaft as governor. Pump is driven from the propeller shaft and operates whenever rear wheels are turning. Supplies oil pressure for transmission operation when pushing car to start engine, and at higher car speeds (when rear pump takes over, rear pump relief valve by-passes front pump output to oil pan so that front pump idles).

Hydraulic Controls: Consist of a governor in the transmission extension housing, and a valve assembly contained in the Valve Block mounted on lower face of transmission case within oil pan.

Governor—Fly-ball type. Actuates governor valve to control Direct Speed Clutch operation. A governor lever is linked to the accelerator linkage so that governor action can be overridden for "kick-down" to intermediate gear, or upshift to Direct speed delayed by the operator.

Front Pump Relief Valve—Regulates front pump pressure at 80 lbs. for all forward driving ranges (P, N, D, L) and boosts pump pressure to 200 lbs. for reverse (R) operation.

Rear Pump Relief Valve—Regulates rear pump pressure at 80 lbs. Also by-passes front pump output to oil pan (so that front pump idles) when rear pressure sufficient to operate transmission.

Converter Valve—Supplies oil to converter assembly at pressure of 27 lbs. to maintain oil level.

Selector Valve—Linked to transmission selector lever on steering column and controls oil pressure supply to servo mechanisms, multiple disc clutch, and direct drive clutch as required for operation in each range (P, N, D, L, R depending on selector lever position).

Reverse Shuttle Valve—Provides for smooth engagement of reverse band. *NOTE*—Reverse shuttle valve is not used on 1954-55 Champion models. An orifice in the reverse servo plate provides the smooth engagement of the reverse band.

Reverse Interlock Valve—Prevents application of reverse band when car is moving forward.

Parking Interlock Piston—Blocks engagement of parking gear pawl when car is moving forward and prevents accidental engagement of parking lock.

OPERATION

Torque Converter Assembly automatically provides a torque multiplication ranging from 2.16-1 (maximum when turbine stationary and impeller turning at 1450 RPM. or normal stall speed) to 1-1 (when turbine and impeller speeds approximately equal. At car speed of 18 MPH. (depending on throttle position—see table), engagement of Direct Speed Clutch locks out the torque converter completely. The planetary transmission is controlled by the operator and provides the following gear ratios:

Neutral "N" Position—All bands and clutches are released so that no power is transmitted through transmission. Car can be moved freely if brakes not applied (will be held on by Anti-creep after they have once been applied but can be released by turning ignition off or by opening the throttle).

Low "L" Position (used primarily for extra power on steep grades, engine braking when descending grades, fast acceleration from standing start, or "rocking" car out of sand or snow). The Low and Forward bands are applied and power is transmitted through both planetary gear sets in tandem providing a total ratio of approximately 4.6-1 (converter torque multiplication of approximately 2-1 plus gear reduction of 2.3-1).

►***OPERATION CAUTION*—When Low used for engine braking on grades, car speed should b brought below 40 MPH. before moving selector lever to "L" position. When Low used for fast starts, selector lever should be moved to "D" position bef re reaching car speed of 40 MPH. and without releasing acc lerator.**

Drive "D" Position (Model DG-200 Trans.)—Provides two ratios depending on car speed and throttle position as follows: ***(Intermediate)*—**Forward Band & Multiple Disc Clutch applied so that forward planetary gear set is locked out and power is transmitted through rear planetary gear set providing a total ratio of approximately 2.9-1 (converter torque multiplication of approximately 2 to 1, plus gear reduction of 1.4-1). ***(Direct)*—**The Direct Speed Clutch engages and this locks out the Torque Converter and also the Planetary Gear unit to provide positive drive of 1 to 1. ***(Direct-to-Intermediate Downshift)*—**At car speeds below approximately 60 MPH, the transmission can be "Kicked-Down" from Direct to Intermediate for additional power for hill climbing on passing by fully depressing accelerator pedal. Transmission will remain in Intermediate until throttle released momentarily or Lockout Speed reached.

Drive "D" Position (Models DG-150 & DG-150M Trans.)—Provides for three automatic forward drive range as follows: ***(Low)*—**Forward Band applied, locking forward drive drum to transmission case. All other units free to rotate. ***(Intermediate)*—**Forward Band & Multiple Disc Clutch applied. ***(Direct)*—**Direct Speed Clutch engages and this locks out the Torque Converter and also the Planetary Gear unit to provide a direct drive. ***(Direct-to-Intermediate Downshift)*—**At car speeds below approximately 60 MPH, the transmission can be "Kicked-Down" from Direct to Intermediate for additional power by fully depressing the accelerator pedal. Transmission will remain in Intermediate until throttle released momentarily or Lockout Speed reached.

Drive "D" Position (Models DG-200M & DG-250M Trans.)—Provides for three automatic forward drive ranges as follows: ***(Low)*—**Forward Band & Low Band applied. ***(Intermediate)*—**Forward Band & Multiple Disc Clutch applied so that forward planetary set is locked out and power is transmitted through rear planetary gear set. ***(Direct)*—**Forward Band, Multiple Disc Clutch & Direct Drive Clutch applied locking out the Torque Converter and forward planetary set to provide a direct drive. ***(Direct-***

STUDEBAKER AUTOMATIC TRANSMISSION (Cont.)

to-Intermediate Downshift)—At car speeds below approximately 60-64 MPH, the transmission can be "Kicked-Down" from Direct to Intermediate for additional power. Transmission will remain in Intermediate until accelerator pedal momentarily released or Lockout Speed reached. *(Low-to-Intermediate Downshift)*—At car speeds below 10-12 MPH, the transmission can be "Kicked-Down" from Intermediate to Low by fully depressing the accelerator pedal. Transmission will remain in Low until pedal momentarily released or car speed exceeds Lockout speed.

Reverse "R" Position—Reverse band is applied in two stages ("boosted" oil pressure of 200 lbs. on servo inner piston applies band, shuttle valve then directs oil pressure to servo outer piston also to assist band in absorbing the high reaction torque). Power is transmitted through both planetary units in tandem to provide reverse rotation and a total ratio of approximately 4-1 (converter torque multiplication of 2-1 plus gear reduction of 2-1). *(1954-55 Champion Note*—Shuttle valve not used. A restriction in reverse servo plate replaces the shuttle valve).

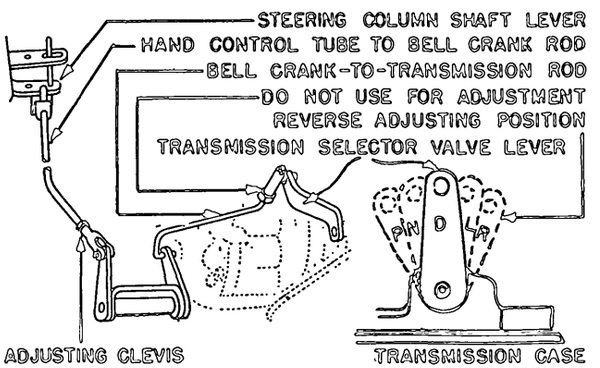
Parking "P" Position—Similar to neutral position (all bands and clutches released) and in addition the parking pawl (linked to selector lever) is engaged in parking gear on rear end of mainshaft so that propeller shaft and rear wheels locked.

▷Holding on Hills Note—With selector lever in Drive "D" Position and engine running, the transmission prevents rollback when car is stopped on normal upgrades. This is due to action of free-wheeling units which prevent reverse rotation of transmission main shaft when multiple disc clutch and forward band are engaged.

Anti-Creep System—System consists of Solenoid valve (located on brake master cylinder), which holds pressure on rear wheel brake whenever anti-creep circuit is closed. A Pressure Control Switch (located on rear of transmission extension case), which is operated by rear pump pressure to open anti-creep circuit when car is moving forward and to close this circuit when car is stationary or moving in reverse. The anti-creep Release Switch (located in engine compartment, adjacent to throttle linkage), opens and closes anti-creep circuit as accelerator pedal is depressed or released.

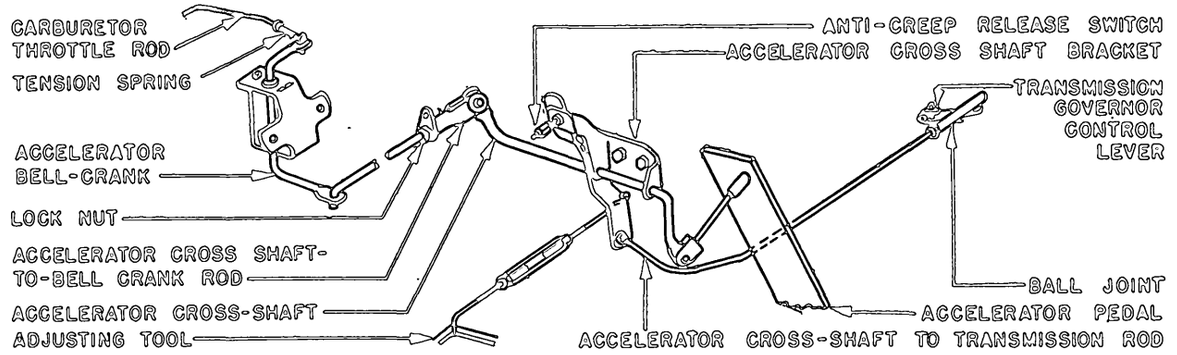
LUBRICATION

Check transmission fluid every 1000 miles and add fluid as required to maintain level at "Full" mark on dipstick. Drain and refill every 15,000 miles.



▷*FLUID LEVEL CHECKING NOTE (To obtain accurate level reading): To prevent oil spray and torque converter drain-back, causing inaccurate dipstick reading, fluid level must be checked as indicated below, immediately after engine stopped.*

Checking Fluid Level—With car on a level floor, set hand brake firmly. Place selector lever in "L" position and allow engine to warm up to normal operating temperature and then run engine at idle speed. Clean area around inspection hole and top of fluid level gauge. Remove gauge and wipe it dry. *Stop engine and immediately insert and withdraw gauge.* If any additional fluid is required, add it and then repeat the checking procedure. Use only Automatic Transmission Fluid Type "A," bearing an AQ-ATF symbol on container.



▷*CAUTION: Under no circumstances should transmission be filled above "Full" mark on dipstick.*

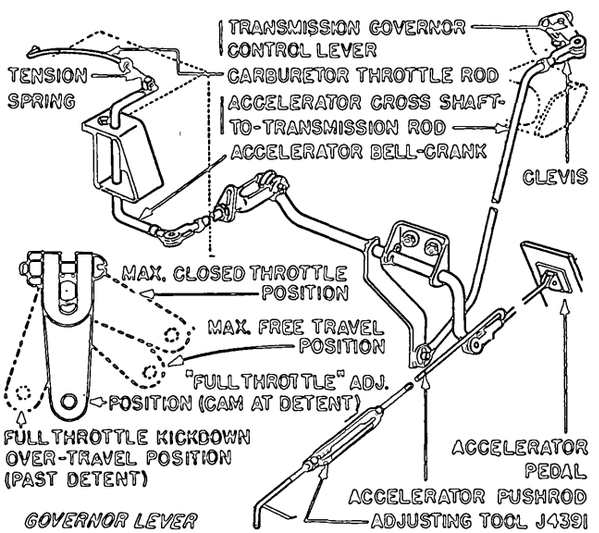
Draining & Refilling—Oil must be warm (set parking brake, place selector lever in "L" position, idle engine until normal operating temperature reached). Stop engine, remove inspection hole cover in front floor carpet, clean all dirt from around inspection hole, remove oil level gauge dipstick. Drain transmission oil pan by removing drain plug at left front corner of pan. Remove converter housing lower cover plate, turn converter until drain plug down, drain converter by taking out this plug (draining facilitated by removing converter pressure take-off plug on left side of transmission case. If two plugs on case (early type), remove upper plug. If only one plug (later type) located at bottom of boss, remove this plug. Re-install all drain plugs, install converter housing plate. Install 5 quarts oil (all models), through the dipstick hole in top of transmission case. Start engine and allow to idle for approximately 1 minutes with selector lever in "L" position to fill converter housing, then add 3 additional quarts of oil, finally check oil level with engine idling and selector lever in "L" position, add oil to bring level up to FULL mark on dipstick.

Oil Pan & Oil Screen Removal & Installation: Drain transmission case (see above).

SELECTOR CONTROL LINKAGE (ALL MODELS)

CHAMPION ACCELERATOR LINKAGE

Removal & Cleaning—Remove parking brake bellcrank from crossmember under transmission case (not necessary on Champion). Remove all oil pan capscrews, remove oil pan. Remove spring clip holding oil screen in screen housing on bottom of valve block assembly, remove screen and clean with compressed air.



Installation—Install oil screen in housing and see that spring clip installed properly to hold screen in place. Use a new pan gasket but DO NOT use any type of sealing compound when installing pan (heavy mineral grease or Lubriplate may be used to hold gasket in place). Tighten all oil pan mounting screws to 10-13 ft.lbs. Install parking brake bellcrank.

LINKAGE ADJUSTMENT

▷*LINKAGE ADJUSTMENT CAUTION—Champion and Commander Accelerator Linkage adjusted differently as follows:*

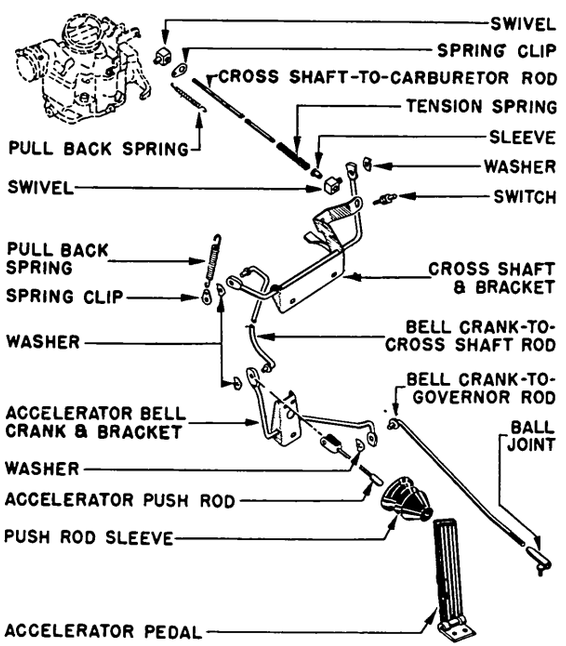
Accelerator-To-Carburetor Linkage Adjustment (Champion 1950-55): Make certain that engine idle

CONTINUED ON NEXT PAGE

1950 COMMANDER ACCELERATOR LINKAGE

STUDEBAKER AUTOMATIC TRANSMISSION (Cont.)

speed set at 500-550 RPM (engine at normal operating temperature with choke valve wide open and fast idle inoperative).



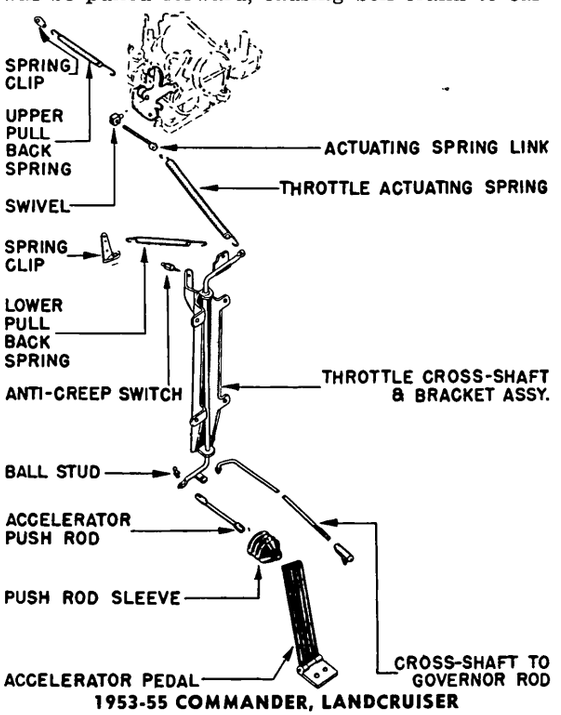
1) Disconnect accelerator cross shaft-to-bellcrank rod by removing clevis pin at cross shaft end of rod. Disconnect wire at Anti-creep Switch on cross shaft bracket.

2) Hold contact plate on cross shaft lever firmly against end of Anti-creep Switch, measure distance between contact plate and cross shaft bracket. If this measurement not ¼", adjust switch by loosening locknut and turning switch in or out of bracket, tighten locknut after correct ¼" clearance secured.

NOTE*—If ¼" clearance cannot be secured by adjusting switch, disconnect accelerator cross shaft-to-transmission rod at transmission end and check push rod and cross shaft for interference. *Do not bend contact plate or cross shaft bracket to secure correct switch setting.

3) Connect accelerator cross shaft-to-bellcrank rod by installing clevis pin but do not install cotter pin at this time. Make certain that carburetor throttle valve in fully closed position (stopscrew on low end of fast idle cam and choke valve wide open).

4) With accelerator control fully released, and carburetor throttle in fully closed slow idle position, check position of spring-loaded swivel on accelerator bellcrank end of carbureor throttle rod. Swivel should be close to but not touching the swivel sleeve on the carburetor side of the rod. If swivel position not correct, disconnect accelerator cross shaft-to-bellcrank rod by removing clevis pin, loosen locknut on bellcrank rod clevis, adjust clevis on rod until carburetor rod swivel position is correct, tighten clevis locknut, connect bellcrank rod and install clevis cotter pin.



1951-52 COMMANDER THROTTLE LINKAGE

5) Place selector lever in Park "P" position. Set Adjusting Tool J-4391 at maximum length, hook one end of tool over cross shaft lever to which the transmission rod is connected, hook opposite end of tool over upper right rear corner of battery box (this will rotate lever and partially open carburetor throttle). Shorten tool length by turning the turnbuckle until carburetor throttle valve is just wide open (at this point further movement will compress spring on throttle rod without changing throttle position). Leave tool in place to hold throttle linkage in this position while making adjustments outlined under "Accelerator-To-Governor Linkage Adjustment" below.

Accelerator-To-Carburetor Linkage Adjustment (Commander 1950): Set engine idle speed to 500-550 RPM. (Warm engine with choke valve wide open and fast idle inoperative). Then proceed as follows:

1) With accelerator pedal fully released, measure distance between the center of the clevis pin at accelerator cross-shaft and flat portion of the firewall (not at the rib). This distance should be 3 1/16". Adjust the distance, if necessary, by turning clevis at accelerator pedal lever.

2) With Accelerator-to-Transmission Control Adjusting Tool No. J-4391 at its maximum length, install the tool between lower end of accelerator push rod just above the fixed clevis and lower right rear corner of battery box. In doing so, the push rod will be pulled forward, causing bell crank-to-carburetor throttle rod to partially open carburetor throttle valve.

1953-55 COMMANDER, LANDCRUISER & PRESIDENT THROTTLE LINKAGE

3) Adjust length of tool by turning turnbuckle until accelerator push rod is brought forward just enough to put carburetor throttle valve in its wide open position. This position is the point at which the bell crank-to-carburetor throttle rod reaches the end of its travel and any further forward motion of pushrod only results in compressing the overtravel spring on bell crank-to-carburetor rod. NOTE—Accelerator linkage must be held exactly at this position to allow a correct setting of accelerator cross shaft-to-governor control linkage. Leave tool in place while making adjustments outlined under "Accelerator-To-Governor Linkage Adjustment" below.

Accelerator-To-Carburetor Linkage Adjustment (Commander 1951-52): Loosen anti-creep release switch locknut. Disconnect wire from switch and back off switch a few turns. Adjust engine idle speed to 500-550 RPM (Warm engine with choke valve wide open and fast idle inoperative).

1) With accelerator fully released and throttle stop screw on low step of cam, check clearance between end of cross shaft-to-carburetor rod and the firewall. This clearance should not be less than ⅛" and not more than ¼". This measurement must be made between end of rod and reinforcing rib of firewall. If clearance is not within limits, loosen locknut and adjust length of rod.

2) After making linkage adjustment, adjust position of the anti-creep release switch. Screw switch into bracket until plunger just contacts the plate when accelerator pedal is fully released. Install wire, turn on ignition, and adjust the switch as required until a click is heard in the solenoid. Tighten locknut.

3) Use special tool hooked over accelerator pedal shaft and into hole in cowl flange directly above wiring harness to hold carburetor throttle valve in wide open position (this tool must be made up in shop) or hold accelerator linkage in this wide open position as follows: Disconnect accelerator pull back springs, place sufficient weight on accelerator pedal to fully open carburetor throttle valve but make certain over-travel spring on cross-shaft-to-carburetor rod not compressed (swivel sleeve on rod should just start to move away from washer).

NOTE—Leave tool in this position while making adjustments outlined under "Accelerator-To-Governor Linkage Adjustment" below.

Accelerator-To-Carburetor Throttle Linkage Adjustment (Commander & Landcruiser 1953-54): Adjust engine idle speed to 500-550 RPM (engine at normal operating temperature with choke valve wide open and fast idle inoperative).

►***ACCELERATOR CROSS SHAFT-TO-CARBURETOR ACTUATING SPRING PRODUCTION CHANGE (To Correct Unintentional Engagement of Kickdown):*** A new stiffer spring Part No. 534230 (painted green) will be used in production, and can be used on earlier models to assure proper "feel" of accelerator pedal and prevent unintentional kickdown. New spring has a load of 9-11 lbs., at 9" length.

1) Place the idle adjusting screw on the fourth step of the fast idle cam (the lowest step being the first step) .Adjust throttle check screw until it just contacts the pad on the throttle shaft lever.

CONTINUED ON NEXT PAGE

STUDEBAKER AUTOMATIC TRANSMISSION (Cont.)

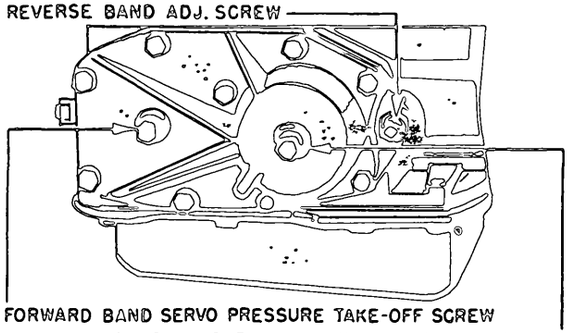
2) Disconnect anti-creep release switch wire at switch. Remove anti-creep release switch from accelerator bellcrank bracket. Leave all three springs attached.

3) Loosen the two threaded locknuts (for adjusting throttle actuating spring tension) several turns. Hold cross-shaft arm against bracket and at the same time tighten forward locknut on threaded rod until spring is taut. The idle adjusting screw will just start to break contact with lower step of fast idle cam. Back off forward threaded rod lock nut just enough to let the idle adjusting screw lightly contact low step of fast idle cam.

4) Install anti-creep release switch in cross shaft bracket. Turn it in until idle adjusting screw again starts to break contact with low step of fast idle cam. Back off anti-creep switch 3 complete turns and secure with locknut.

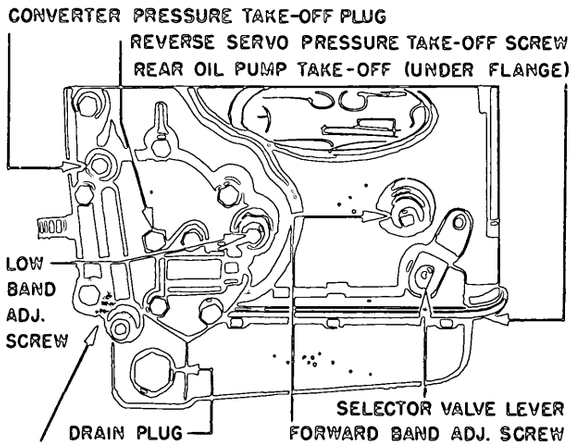
5) Back off the forward threaded rod locknut 3 complete turns. This will allow approximately ⅛" to 3/16" sag in throttle actuating spring. Tighten the rear threaded rod locknut.

6) Throttle valve must be held in the wide open position for Accelerator-to-throttle linkage adjustment (following). Use a piece of ½" x ¾" angle iron 15¼" long. Pull hand brake control handle out 4 or 5 inches. Position the angle iron between hand brake plunger, just forward of handle, and the accelerator pedal. Then slowly push hand brake in until carburetor throttle valve is just to its wide open position. This is the point where any further movement of accelerator pedal will only result in operating the overtravel spring. The angle iron will now hold linkage in this position while governor linkage is adjusted (following).



Accelerator-To-Carburetor Throttle Linkage Adjustment (Commander & President 1955): Disconnect anti-creep release switch wire at switch and remove switch from bracket (leave all three springs attached).

1) With selector lever in "P" or "N" position, adjust engine idle speed to 550 RPM with the choke valve wide open. Make sure throttle return check is operating correctly.



2) Install Anti-creep switch and adjust it in the bracket so throttle actuating spring is taut and the idle adjusting screw just breaks contact at the wide open choke position. Back off Anti-creep switch one-half turn.

3) Loosen throttle return check assembly locknut and adjust assembly in bracket until the plunger just breaks contact with tab on throttle lever. Mark position of the check assembly relative to the bracket, then turn the check assembly 1¾ to 2 complete turns toward the lever. Tighten locknut.

4) Throttle valve must be held in the wide open position for Accelerator-to-Governor Linkage Adjustment (following). Use a piece of ½" or ¾" angle iron 13½" long to hold throttle valve in its wide open position. Pull hand brake control handle out 4" or 5". Position angle iron between hand brake plunger, just forward of the handle, and accelerator pedal. Depress accelerator pedal to near the wide open position and at the same time slide the lower end of the angle iron up near top of accelerator pedal. Then slowly push hand brake in until the carburetor throttle valve is just to its wide open position (this is the point where any further movement of the accelerator pedal will result in operating the over-travel spring). The angle iron will now hold the linkage in this position while accelerator cross shaft-to-governor linkage is adjusted (following).

LEFT SIDE OF TRANSMISSION CASE
CHECKING & ADJUSTING POINTS

RIGHT SIDE OF TRANSMISSION CASE
CHECKING & ADJUSTING POINTS

Accelerator-To-Governor Linkage Adjustment (All Studebaker Models): Disconnect accelerator rod ball joint from governor lever (note whether it is taken from inner or outer hole if lever has two holes). *CAUTION—Ball joint must be installed in OUTER hole on all models, except Commander models prior to 1951 Serial No. 8133626, where the inner hole is used.*

1) Turn governor control lever (on transmission) forward or clockwise until resistance of the detent is felt, then check adjustment of the rod. If the linkage is correctly adjusted, the stud of the ball joint will easily slip into the proper hole of governor lever. If adjustment is required, loosen ball joint locknut and turn ball joint until stud is aligned with proper hole in lever. Make sure that lever is still at point where resistance of detent is felt. After making adjustment, tighten locknut securely. **Do not install ball joint stud at this time.**

3) Remove tool from accelerator pedal, then check linkage as follows:

(a) With floor mat properly in place and accelerator pedal fully depressed (kickdown position), slip ball joint stud out of governor lever and check to make sure that governor lever is at end of its forward travel.

(b) With the accelerator fully released check to make sure there is at least ¼" of free travel of governor lever before spring pressure is felt as it is turned forward. If adjustment is correct, install and tighten ball joint stud.

(c) If full forward travel or the correct amount of free travel of governor control lever is not obtained, recheck linkage adjustment. If proper travel is still not obtained, check for and eliminate any bind, distortion or interference in linkage which would affect proper operation or adjustment. A possible point of interference could be between accelerator bellcrank-to-transmission rod and the car floor pan. Remove front splash pan from frame side rail by removing the small screw and loosening the body bolt, and check for this condition. Correct by bending floor pan out of the way; **do not bend linkage.** Check all linkage mounting bolts for tightness.

Accelerator-to-Governor Linkage Adjustment (Hudson): Set engine idle speed to 490-510 RPM. With carburetor linkage properly adjusted and with engine shut off, hold the throttle control bell crank operating rod so that throttle is wide open. This is point where any further movement would only result in operating the throttle rod over travel spring. Adjust length of governor control rod so when governor lever is held at detent, the trunnion pin will enter bell crank freely (this detent is located approximately 1½" of rod travel from the rear, the resistance felt at ¼" to ½" of travel is the governor spring pick-up and not the detent). Tighten lock nut securely, but do not install cotter pin at this time.

2) Hold accelerator pedal against its stop with pedal jack or other means. With governor control rod pulled forward until governor lever bottoms against its stop in transmission, adjust the accelerator pedal rod length until the governor rod trunnion pin can be entered freely into throttle bell crank. (NOTE—On some Hornet models, it may be necessary to release the accelerator to facilitate adjustment; however, final check should be made with accelerator pedal against its stop, at which time the governor control lever should be at maximum travel). Tighten all lock nuts securely and install cotter pins. Do not make any readjustment of the governor control rod trunnion to accommodate pedal rod adjustment.

Selector Hand Control Linkage (1950-52 Champion & Commander): Adjust as follows:

1) Place selector lever in Reverse position. Remove clevis pin from bellcrank end of steering column tube-to-bellcrank rod.

2) Measure length of bellcrank lever-to-transmission rod. This length must be 7 5/16" (all 1950 cars); 7 9/16" (1951 & 1952 cars—See Note below) measured from center of fixed end of bellcrank (forward end of rod) to center of adjustable joint at trans-

CONTINUED ON NEXT PAGE

STUDEBAKER AUTOMATIC TRANSMISSION (Cont.)

mission (rear) end of rod. Adjust by loosening locknut and turning adjustable joint on rod.

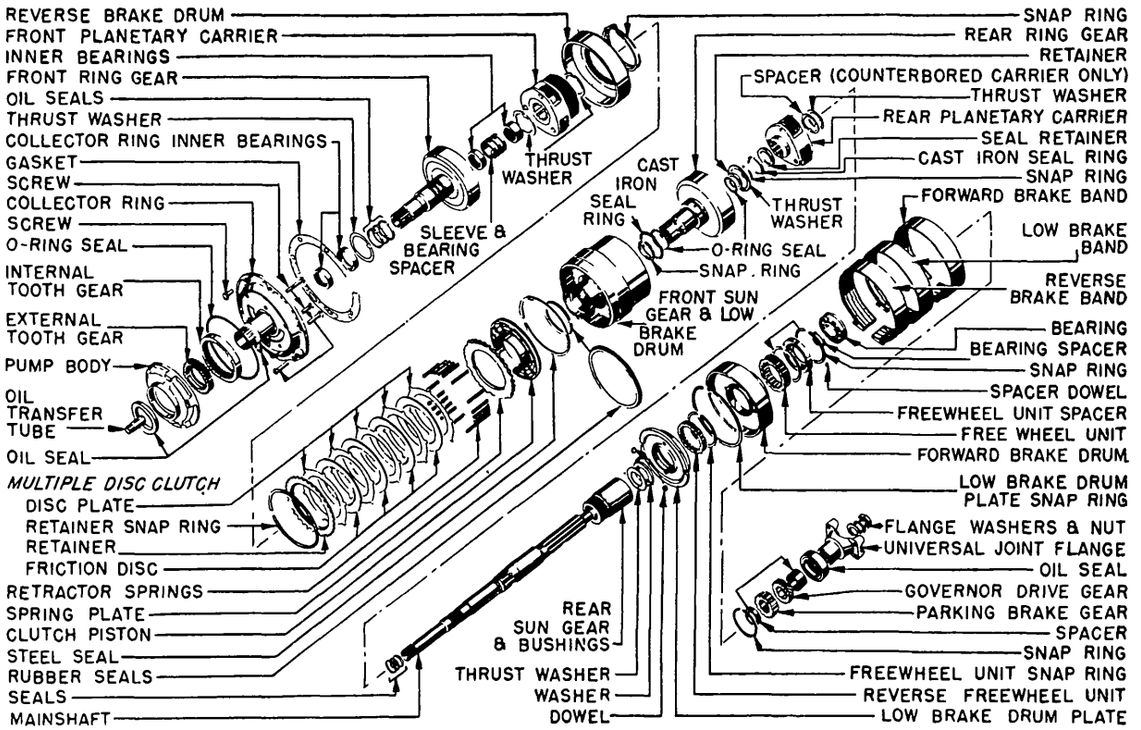
►*1951-52 SETTING NOTE*—This 7 9/16" setting supersedes specifications on earlier 1951 cars. Tool J-4602 (for 7 9/16" setting) can be used to make this adjustment if ball joint is turned back one full turn after having been set to 7⅝" with the tool (this will give 7 9/16" setting).

►***CAUTION—After rod length correctly set (above), DO NOT change rod length when making adjustments.***

3) Disconnect steering column tube-to-bellcrank rod by taking out clevis pin at bellcrank, move valve selector lever on transmission case to reverse (extreme rear position). Adjust length of steering column tube-to-bellcrank rod by turning clevis on bellcrank end of rod until clevis pin enters hole in clevis and bellcrank freely (CAUTION—Do not change length of bellcrank-to-transmission lever rod). Do not install clevis at this time.

4) Set selector lever on steering column in Parking "P" position, move selector lever on transmission case to park (extreme forward position) and check to see that parking pawl engaged (propeller shaft should be locked). Check adjustment by slipping clevis pin through clevis at rear end of steering column tube-to-bellcrank rod and bellcrank. If pin enters both holes freely, connect rod. If not, readjust as follows:

5) If adjustment not correct in parking position (4 above) after having been set in reverse position (3 above), readjust rod by turning clevis **not more than ½ turn** in either direction for best possible compromise in both reverse and park position. If satisfactory setting not possible within these limits, check entire linkage for wear, looseness, or distortion.



Selector Hand Control Linkage (All Studebaker Models 1953-55): Adjust as follows:

1) Disconnect hand control bellcrank-to-transmission rod from bellcrank and selector control shaft lever.

2) Measure the diagonal distance from center of cotter pin hole at the bellcrank end, to center of ball at the ball joint end. This measurement should be 10 13/16" (for all 2-Door, 4-Door, and Land Cruiser models); 14 7/16" (for all Hard Top Convertibles, and 5-Passenger Coupes). On cars equipped with power steering, measurement should be 10 9/16" (for all 2-Door, 4-Door, and Land Cruiser Models); 14 3/16" (for all Hard Top, and 5-Passenger Coupes). After rod is adjusted, tighten the locknut and install rod. Once set, adjustment of the rod must not be changed during subsequent linkage adjustments.

►***CAUTION—After rod length correctly set (above), DO NOT change rod length when making adjustments.***

3) Disconnect steering column tube-to-bellcrank rod by taking out clevis pin at bellcrank, move valve selector lever on transmission case to reverse (extreme rear) position. Adjust length of steering column tube-to-bellcrank rod by turning clevis on bellcrank end of rod until clevis pin enters hole in clevis and bellcrank freely (CAUTION—do not change length of bellcrank-to-transmission lever rod). Do not install clevis pin at this time.

TRANSMISSION INTERNAL PARTS ASSEMBLY

4) Set selector lever on steering column in Parking "P" position, move valve selector lever on transmission case to park (extreme forward) position and check to see that parking pawl engaged (propeller shaft should be locked). Check adjustment by slipping clevis pin through clevis at rear end of steering column tube-to-bellcrank rod and bellcrank. If pin enters both holes freely, connect rod. If not, readjust as follows:

5) If adjustment not correct in parking position (4 above) after having been correctly set in reverse position (3 above), readjust rod by turning clevis not more than ½ turn in either direction for best possible compromise in both reverse and park position. If satisfactory setting not possible within these limits, check entire linkage for wear, looseness, or distortion.

Selector Hand Control Linkage Adjustment (Hudson): Check upper and lower control tube brackets and make sure they are securely tightened on steering column jacket tube and that selector lever tube is parallel with the jacket tube. Disconnect the transmission shift rod at the selector tube lower level. Place selector control lever against the stop in the "D" position on the quadrant and the selector control shaft outer lever at the transmission in the "D" position (No. 3 detent on the selector valve) and adjust the transmission shift rod until the clevis pin freely enters the clevis of the selector rod and the hole in the selector control lower lever

ANTI-CREEP ADJUSTMENT: For adjustments other than Release Switch (part of linkage adjustment above), *see "Anti-Creep" in Brake Section.*

►***ANTI-CREEP RELEASE SWITCH REPLACEMENT CAUTION—When switch is replaced for any reason, the accelerator-to-transmission control linkage must be checked and adjusted (see Adjustment above).***

BAND ADJUSTMENT

►***CLIMATIZER DUCT INTERFERENCE (Low Band Adjustment) NOTE***—If Band Adjusting Tool J-4285 cannot be used for low band adjustment, because of interference with Climatizer duct, make adjustments as follows: Loosen and back off low band adjusting screw nut. Using a small wrench approximately 5" long, turn adjusting screw in until snug. Then back screw out FOUR COMPLETE TURNS. Tighten adjusting screw locknut securely, making sure that adjusting screw does not turn.

BAND ADJUSTMENT: Check and adjust all bands (Forward, Low, Reverse) in same manner using Band Adjusting Tool J4285 (plug gauge) to check the band setting before making adjustments.

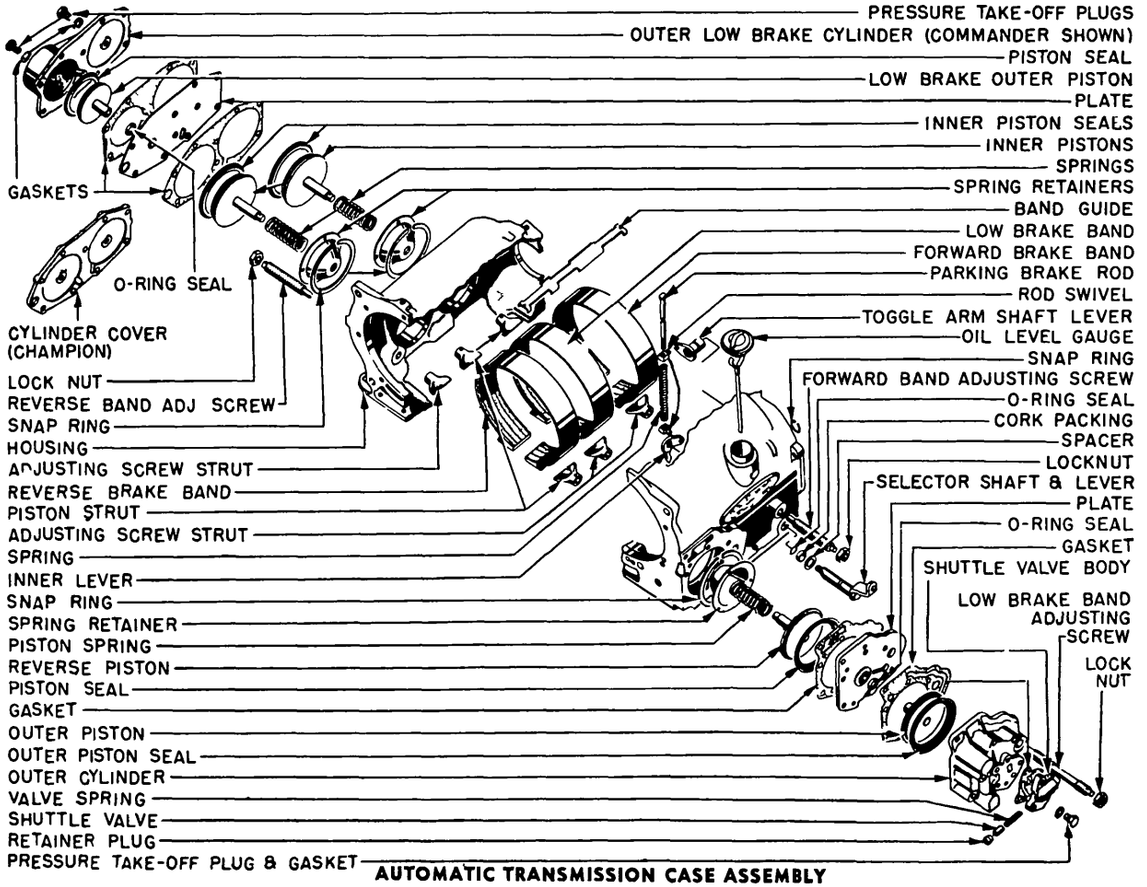
Checking Bands—Remove capscrew and copper gasket from pressure take-off hole in servo mechanism of band being checked (see illustration). Insert tool J4285 into the pressure take-off hole as far as it will go and exert slight pressure to start tool threads in hole (see Caution below if threads do not start readily), screw tool into the hole until tool shoulder rests against transmission case noting that indicator plug in tool handle moves outward as tool is turned in (if plug reaches a position flush

CONTINUED ON NEXT PAGE

STUDEBAKER AUTOMATIC TRANSMISSION (Cont.)

with tool handle BEFORE tool turned in fully, see Caution below). Indicator should be FLUSH with end of tool handle when tool fully installed if bands correctly adjusted. If not, adjust bands as directed below.

►*CAUTION*—If tool threads cannot be readily engaged in the Forward Band Servo pressure take-off hole, or if indicator plug reaches a position flush with tool handle before adjusting tool fully screwed into transmission case, **BACK OFF band adjusting screw on opposite side of case 2 turns** before screwing tool fully into position. This is an indication that the band adjustment was too tight and tool will be damaged if indicator plug forced out beyond end of tool handle.



Adjusting Bands—With adjusting tool in place to check band setting (above), loosen locknut on band adjusting screw (see illustration), turn adjusting screw in until indicator plug in adjusting tool handle is just flush with end of handle, tighten locknut being careful that adjusting screw does not turn. Remove adjusting tool and replace capscrew using new copper gasket under screw head.

►***CAUTION—Do not use any type of sealing compound on this capscrew.***

TESTING TRANSMISSION OPERATION

►***CAUTION—When testing with transmission selector lever in one of the driving positions, and with rear wheels held stationary, ENGINE MUST NOT BE OPERATED AT HIGH SPEED for more than 10 seconds, or for a TOTAL time more than ONE MINUTE in any half hour period.***

Hand Control Linkage: With engine running at a speed slightly greater than idle speed, set the hand brake, then place selector lever in "D" position Slowly move selector lever from "D" position to "N" position, noticing change in engine speed The shift to neutral will be accompanied by a sudden increase in engine speed, and should take place just before selector lever reaches detent of "N" position Shift lever to "L" position, then slowly move selector lever to "R" position An increase in engine speed, indicating the shift out of low, should occur when selector lever has moved approximately two-thirds of distance from "L" to "R" Then, when selector moved slightly closer to "R" position detent, the shift into reverse should take place, accompanied by a decrease in engine speed For adjustment see "Selector (Hand Control) Linkage" above.

AUTOMATIC TRANSMISSION CASE ASSEMBLY

1950-EARLY 1954 CHAMPION & 1950-EARLY 1955 COMMANDER

Stall Speed Test: With engine in good operating condition, connect tachometer to engine. Set hand brake, start engine, then move selector lever to "D" position Apply the service brakes, and operate the engine at full throttle and note tachometer reading. Repeat this procedure with selector lever in "L" position and in "R" position. ***(CAUTION—Do not operate engine with wheels held stationary and selector lever in one of the driving positions for more than 10 seconds at a time, or for a total time more than one minute in any half-hour period).*** With engine in good operating condition, normal stall speeds are as follows:

Stall Speeds

Car Model	①Stall Speed
Studebaker Champion (1950-55)	1500-1600
Studebaker Commander (1950)	1400-1500
Studebaker Commander (1951-55)	1550-1650
Studebaker President (1955)	1550-1650
Hudson 232" Engine	1350-1600
Hudson 263' Engine	1450-1700
Hudson 308" Engine	1600-1900

①—A lower stall speed (900-1000 RPM), is caused by slippage of torque converter stator free-wheel unit. A higher speed indicates slipping in transmission

1950-53 Transmission Shift Speeds

Champion Models—	①1950-51	②1952-53
Light Throttle Upshift	21-23 MPH	18-20 MPH
Full Throttle Upshift	40-42 MPH	36-38 MPH
Kickdown Upshift	62-65 MPH	57-60 MPH
Closed Throttle Downshift	17-19 MPH	15-17 MPH
Limit of Kickdown Downshift	52-55 MPH	49-50 MPH
Commander Models—	**① 1950**	**①1951-53**
Light Throttle Upshift	18-20 MPH	18-20 MPH
Full Throttle Upshift	34-36 MPH	39-41 MPH
Kickdown Upshift	55-58 MPH	67-70 MPH
Closed Throttle Downshift	12-14 MPH	13-15 MPH
Limit of Kickdown Downshift	48-51 MPH	57-60 MPH

①—With 3 54-1 Rear Axle Ratio
②—With 4 10-1 Rear Axle Ratio

1954 Transmission Shift Speeds

Studebaker Champion	①2 to 3
Light Throttle Upshift	18-20 MPH
Full Throttle Upshift	36-38 MPH
Kickdown Upshift	57-60 MPH
Closed Throttle Downshift	15-17 MPH
Limit of Kickdown Downshift	49-50 MPH
Studebaker Commander	**①2 to 3**
Light Throttle Upshift	18-20 MPH
Full Throttle Upshift	39-41 MPH
Kickdown Upshift	67-70 MPH
Closed Throttle Downshift	13-15 MPH
Limit of Kickdown Downshift	57-60 MPH

Hudson (All Models)	②1 to 2	①2 to 3
Light Throttle Upshift	10-12 MPH	22-24 MPH
Full Throttle Upshift	31-34 MPH	48-52 MPH
Kickdown Upshift	43-46 MPH	70-75 MPH
Closed Throttle Downshift	20-19 MPH	8-7 MHP
Limit of Kickdown Downshift	65-60 MPH	72 MPH

①—Intermediate to Direct Drive
②—First speed to Intermediate

TESTING HYDRAULIC UNITS

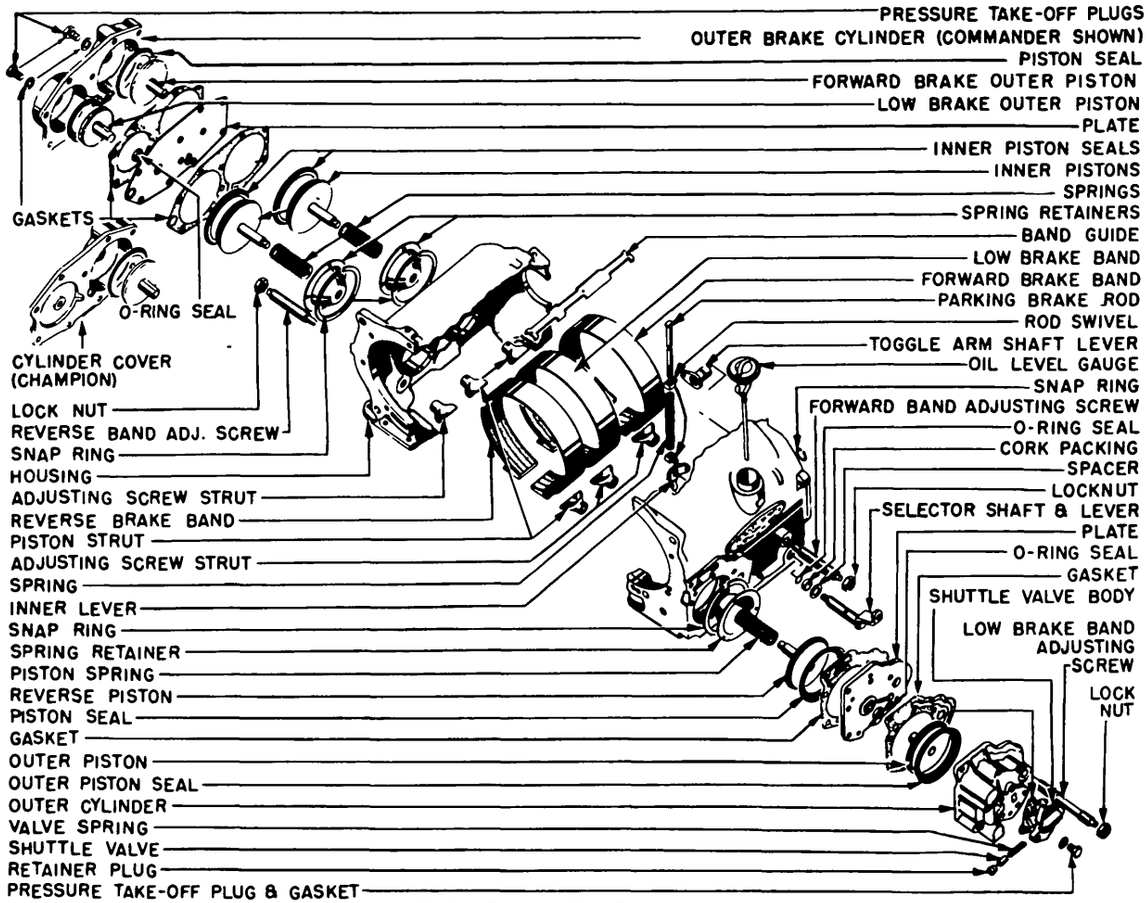
If transmission operation not satisfactory, check operation of oil pumps and control units by testing hydraulic control pressures.

Testing Tool Note—Pressure gauge and fittings for connecting gauge at various points on transmission are required for these tests. This equipment furnished as Tool No. J4270 (gauge & fittings).

►***CAUTION—When testing with transmission selector lever in one of the driving positions, and with rear wheels held stationary, ENGINE MUST NOT BE OPERATED AT HIGH SPEED for more than 10 seconds or for a TOTAL time more than ONE MINUTE in any half-hour period.***

Front Oil Pump Pressure: With engine stopped, remove Allen-head pipe plug in oil pan flange on front of transmission case, install pressure gauge fitting and connect gauge at this point. Connect electric tachometer to engine. Place selector lever in "P" or "N" position and bring speed up to 1000 RPM. At this speed gauge reading should be 60 lbs. min (DG-150, 150M, 200, 200M transmissions). 15-25 lbs. (DG-250M transmission). On DG-250M transmission, apply parking brake and foot brake firmly. Move hand control lever to "D" or "L" position. At 1000 RPM, gauge should show 60-90 lbs. pressure. Place selector lever in "R," and at 1000 RPM, the gauge reading should be 160-250 lbs pressure Stop engine. Remove test equipment and reinstall plug. Tighten to 15-18 ft lbs

►***CAUTION—Do not use white lead or any type of sealing compound on these plugs.***



Forward Band Servo Pressure: With engine stopped, remove capscrew and copper washer from forward band servo coverplate (see illustration). Install pressure gauge fitting and connect gauge at this point. Connect electric tachometer to engine. With engine running, apply foot brake and hand brake firmly to hold car, move selector lever to "D" position. Gradually increase engine speed to 1000 RPM. At this speed gauge reading should be 60 lbs. (Studebaker), 70 lbs (Hudson) minimum Stop engine, disconnect gauge, replace capscrew, using a new copper gasket, tighten screw to 28-33 ft lbs.

►*See TESTING CAUTION above.*

Reverse Band Servo Pressure: With engine stopped, disconnect bellcrank-to-transmission selector valve lever rod at bellcrank, move selector valve lever on transmission to reverse "R" position. Remove capscrew and copper washer from reverse band servo cover (see illustration), install pressure gauge fitting and connect gauge at this point. Connect electric tachometer to engine. Apply foot brake and hand brake firmly to hold car before starting engine. Start engine and increase speed to 1000 RPM. At this speed gauge reading should be 160 lbs. (Studebaker), 180 lbs. (Hudson) minimum. Stop engine, disconnect gauge, replace capscrew, using a new copper gasket, tighten screw to 28-33 ft. lbs.

►*See TESTING CAUTION above.*

CONTINUED ON NEXT PAGE

AUTOMATIC TRANSMISSION CASE ASSEMBLY (DG-150, DG-150M, DG-250M)

STUDEBAKER AUTOMATIC TRANSMISSION (Con..)

Low Band S rvo Pressure: With engine stopped, remove capscrew and copper gasket from low band servo cover (see illustration), install pressure gauge fitting and connect gauge at this point. Connect electric tachometer to engine. With engine running, apply foot brake and hand brake firmly to hold car, move selector lever to "L" position. Increase engine speed to 1000 RPM. At this speed gauge reading should be 60 lbs. (Studebaker), 70 lbs. (Hudson) minimum. Stop engine, disconnect gauge, replace capscrew, using a new copper gasket, tighten screw to 28-33 ft. lbs.

Multiple Disc Clutch Pressure (Studebaker)—With engine stopped, remove ⅛" pipe plug from mounting flange on rear end of extension housing on transmission case, install pressure gauge fitting and connect gauge at this point. Connect electric tachometer to engine. With engine running, apply foot brake and hand brake firmly to hold car, move selector lever to "D" position. Increase engine speed to 1000 RPM. At this speed, gauge reading should be 60 lbs. minimum. Stop engine, disconnect gauge, replace pipe plug, tighten plug to 15-18 ft. lbs.

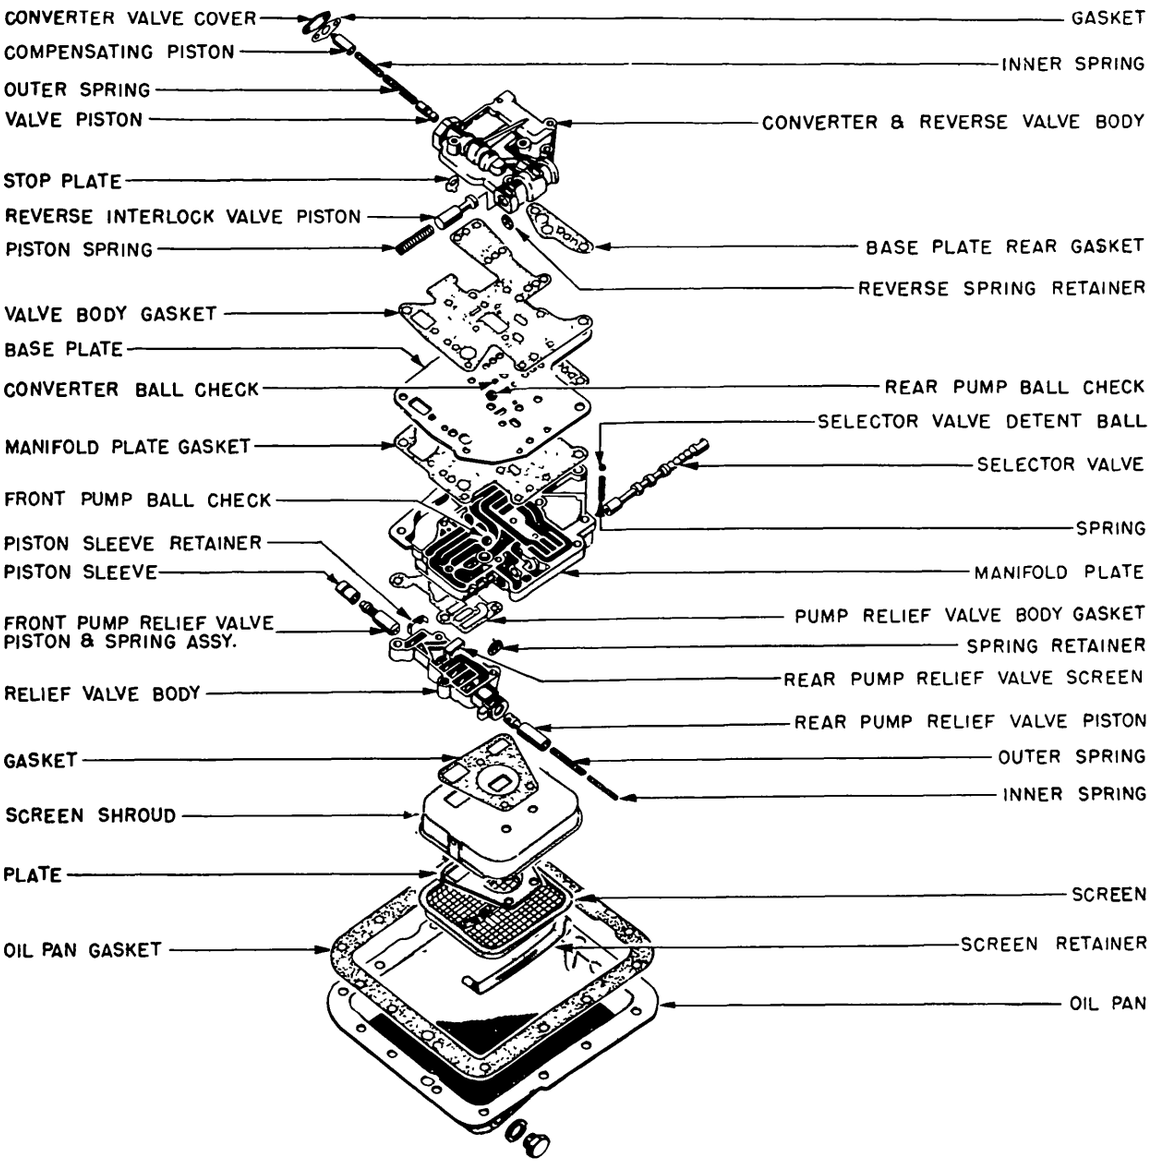
►*See TESTING CAUTION above.*

Multiple Disc Clutch Pressure (Hudson)—With engine stopped remove the ⅛" pipe plug from transmission extension case and install the pressure gauge fitting. Connect tachometer to engine. Place car on jacks and speed up to 15 MPH. At this speed, gauge reading should be 70 lbs. minimum. Stop engine, disconnect gauge, replace pipe plug and tighten to 15-18 ft. lbs.

►*See TESTING CAUTION above.*

►*1955 TORQUE CONVERTER VALVE & PRESSURE CHANGE:* Beginning with the following transmission serial numbers, the converter shuttle valve is regulated by multiple disc clutch pressure instead of direct drive clutch pressure. Serial Numbers SCH-2101 (DG-150 Trans.), SP-10801 (DG-250M Trans.). This change was made to provide a more positive shift from drive-intermediate to direct drive. The converter pressures with the later type converter valve is 50-70 lbs. in low gear, and 20-30 lbs. in drive-intermediate or direct drive.

Torque Converter Pressure: With engine stopped, remove ¼" pipe plug at torque converter pressure take-off point (early transmissions have two plugs, later transmissions have one plug). On transmissions with two plugs connect to upper hole, and on transmissions with one plug located at bottom of boss, connect to this point. (NOTE—selector valve lever rod may be disconnected for ease in making this connection). Connect electric tachometer to engine. Place selector valve lever in neutral "N" position. Run engine at 1000 RPM. At this speed, gauge reading should be 25-35 lbs. For further check, jack up wheels so they are free to rotate, place selector lever in drive "D" position, run engine at 1500 RPM. At this speed, gauge reading should be the same (25-35 lbs.). Stop engine, disconnect gauge, replace pipe plug, tighten to 6-7 ft lbs.



►***CAUTION—Do not use white lead or any type of sealing compound on these plugs.***

Direct Drive Clutch Pressure: With engine stopped, remove Allen-head pipe plug in oil pan flange on rear of transmission case, install pressure gauge fitting and connect gauge at this point. Connect electric tachometer to engine. Block up rear end of car securely so that wheels are free to rotate. Run engine at idle speed, place selector lever in "D" position. Gauge reading should be 0 lbs. Increase engine speed to 1500 RPM. while watching the gauge. At approximately 1200 RPM., gauge should indicate rapid pressure rise (shift to direct drive) and gauge reading should be 60 lbs. (Studebaker), 70 lbs. (Hudson) minimum. Decrease engine speed and again watch gauge. When speedometer indicates 10-12 MPH, gauge reading should drop to 0 (downshift to intermediate drive). Stop engine, disconnect gauge, replace pipe plug, tighten plug to 15-18 ft. lbs.

►***CAUTION—Do not use white lead or any type of sealing compound when installing pressure switch.***

Rear Pump Pressure: With engine stopped, disconnect leads and remove Anti-Creep Pressure Switch (Studebaker), or remove ¼" pipe plug (Hudson) at rear of transmission. Install pressure gauge fitting

CONTINUED ON NEXT PAGE

AUTOMATIC TRANSMISSION CONTROL VALVE ASSEMBLY (DG-150, DG-200)

STUDEBAKER AUTOMATIC TRANSMISSION (C nt.)

and connect gauge at this point Run engine with brakes set to hold rear wheels stationary Gauge reading should be 0 lbs with rear wheels not turning Block up rear of car securely so that rear wheels are free to rotate With engine idling, place selector lever in "D" position, increase engine speed while watching gauge Pump pressure should build up steadily as indicated by increasing gauge pressure, and should be 60 lbs (Exc Hudson & DG-250M Trans), 70 lbs. min (Hudson & DG-250M Trans), at 20 MPH Stop engine, disconnect gauge, install Anti-Creep Switch

►*CAUTION—Do not use white lead or any other type of sealing compound when installing pressure switch.*

TROUBLE SHOOTING & DIAGNOSIS

SLIPPING EXCESSIVELY (Or Not Operative, in All Ranges Below 25 MPH): 1) Low front oil pump pressure caused by Sticking front pump relief valve Leakage in valve block assembly Excessive wear of front pump or damaged front pump drive fingers Excessive oil leakage in passage from front pump-to-valve block oil passage Rear oil pump check valve out of position Blocked oil passage from valve block-to-front pump 2) Broken fins in converter, indicated by noisy converter operation

SLIPPING EXCESSIVELY (Or Not Operative, in Low & Intermediate Drive): 1) Forward band slippage caused by Incorrect band adjustment Damaged or worn lining Low pressure at forward servo because of blocked passage Stuck forward brake piston Broken forward band 2) Forward free-wheel unit slipping

SLIPPING EXCESSIVELY (Or Not Operative, in Reverse): 1) Reverse band slipping caused by Incorrect band adjustment Damaged or worn lining Low pressure at reverse servo because of blocked passage Broken reverse band or stuck reverse brake piston 2) Reverse free-wheel unit slipping (NOTE—Transmission will slip in reverse and will also lose its hill-holding characteristic

NO ENGINE BRAKING (Deceleration in Low): Low band slipping caused by Incorrect band adjustment or worn or damaged lining Low pressure at low servo because of blocked passage Stuck low brake piston or broken brake band

SLIPPING EXCESSIVELY (During Acceleration in Intermediate Drive and Loss of Hill-Holding): Multiple disc clutch slipping caused by Damaged or worn disc facings Blocked oil passage to multiple disc clutch Stuck multiple disc clutch piston NOTE —Retractor spring retainer may have been used to replace retractor spring plate at rear of multiple disc clutch assembly when transmission overhauled

FAILURE TO SHIFT TO DIRECT DRIVE (Or Slips After Direct Drive Clutch Is Engaged): 1) Improper governor operation caused by Damaged governor Governor sticking on governor shaft Governor valve sticking closed 2) High converter pressure preventing engagement of the direct drive clutch caused by Sticking converter valve Leaking direct drive clutch piston seals Main shaft lubricator valve assembly loose and twisted out of correct location Leaking transfer tube "O" ring seal 3) Leakage in direct drive clutch passage 4) Blocked direct drive oil passage in collector ring

ENGINE WILL NOT START BY PUSHING (Also Reverse and Park Interlocks Inoperative): Rear pump pressure low caused by Damaged or worn rear pump parts Damaged rear pump drive gear Sheared rear pump drive gear pin Valve block assembly incorrectly assembled Leaking valve block assembly gaskets Porous valve block castings Leaking extension case gaskets Porous extension case castings Blocked rear pump passage-to-valve block

CAR ROLLS (With Selector Lever in "P" Position): 1) Parking pawl does not engage, caused by Incorrect adjustment of hand control linkage or parking pawl linkage Extension case misaligned on transmission case Parking pawl interlock piston stuck in locked position Parking pawl linkage binding or broken

ENGINE STALLS OR LABORS (When Selector Lever Shifted to "D" Range): 1) Incorrect adjustment of accelerator-to-transmission control linkage 2) Improper governor valve operation, caused by Governor binding Governor sticking on governor shaft Governor valve sticking open because of governor control detent piston sticking or installed backwards, or by a blocked governor drain passage Accelerator control plunger and linkage binding Check governor sleeve for correct position in extension case 3) Damaged main shaft oil seal rings or front planetary set ring gear oil seal rings.

ENGINE SHUDDERS OR STALLS (When Car Is Stopped While Selector Lever is in "D"): 1) Incorrect adjustment of accelerator-to-transmission control linkage 2) Improper governor valve operation caused by Damaged governor or governor sticking on governor shaft Governor valve sticking open (This condition can be caused by governor control detent piston sticking or installed backwards—governor valve sleeve out of position—blocked governor drain passage—damaged main shaft oil seal rings or front ring gear oil seal rings—no groove on end of transfer tube or main shaft lubricator valve assembly out of position) 3) Sticking or damaged direct drive clutch plate or clutch piston

NO DOWNSHIFT AT KICKDOWN (Or Kickdown Shift Speed Range Incorrect): 1) Incorrect accelerator-to-transmission control linkage adjustment 2) Interference between ball joint nut at the governor control lever and extension case 3) Improper governor valve operation (see "Engine Shudders or Stalls" above) 4) High oil level.

TRANSMISSION SHIFTS TO REVERSE (Immediately When Selector Shifted to "R", Above 5 MPH): 1) Rear pump inoperative 2) Reverse interlock inoperative caused by Blocked reverse interlock valve oil passage Interlock valve sticking

PARKING PAWL ENGAGES IMMEDIATELY (When Selector Lever is Shifted to "P", Above 10 MPH): 1) Rear pump inoperative 2) Parking pawl piston inoperative, caused by Oil passage to parking pawl interlock piston blocked or not drilled Parking pawl interlock piston sticking.

ENGINE LABORING & TRANSMISSION OVERHEATING IN FORWARD RANGES (Reverse Operation Normal, but Car Creeps Rearward in Neutral When Anti-Creep Released): Reverse band dragging, caused by Incorrect band adjustment Leaking valve block assembly gaskets Porous casting in valve block assembly Reverse brake piston sticking or reverse band damaged or distorted

ENGINE LABORING & TRANSMISSION OVERHEATING IN ALL RANGES EXCEPT "L" RANGE: Low band dragging, caused by Incorrect band adjustment Leaking valve block assembly gaskets or porous castings in valve block assembly Low brake piston sticking or low band damaged or distorted Leaks between Low and Forward brake cylinders in Low brake cylinder or Forward and Low brake cylinder cover Leaks between Low and Forward brake cylinders in transmission case

ENGINE LABORING & TRANSMISSION OVERHEATING IN REVERSE RANGE (Low & Forward Operating Normal, but Car Creeps Forward in Neutral When Anti-Creep Released): Forward band dragging, caused by Incorrect band adjustment Leaking valve block assembly gaskets or porous castings in valve block assembly Forward brake piston sticking or forward band damaged or distorted

ENGINE LABORING & TRANSMISSION OVERHEATING IN ALL RANGES EXCEPT "D" RANGE· Multiple disc clutch dragging caused by Leaking valve block assembly gaskets or porous castings in valve block assembly Multiple disc clutch piston sticking Improper operation of main shaft assembly. Broken or damaged multiple disc clutch release springs

NORMAL OPERATION IN DIRECT DRIVE (Poor Performance With Transmission Overheating, in Other Ranges—Low Stall Speed): Caused by torque converter free-wheel unit slipping.

NORMAL OPERATION AT LOW SPEEDS (Poor Performance with Transmission Overheating in Direct Drive): Torque converter free-wheel unit sticking

TRANSMISSION NOISY (With Selector Lever in "D", "L", or "R", and Car Standing Still): 1) Low fluid level 2) Fluid intake screen clogged 3) Damaged front pump fingers, or worn or damaged front pump parts 4) Air leaks in front pump intake passages in transmission case or front pump and collector ring assembly 5) Improper valve action 6) Broken connector fins 7) Loose direct drive clutch backing plate or drive fingers on converter.

TRANSMISSION NOISY (When Car Is Moving): 1) Damaged or worn rear pump parts or drive gear 2) Damaged or worn speedometer drive gear or pinion (not to be confused with drive line or rear axle noise). 3) Damaged or worn rear planetary gears (if only in low, front planetary gear is bad) 4) Damaged governor assembly.

FLUID LEAK (Between Torque Converter and Transmission): 1) Front pump oil seal damaged by front pump drive fingers 2) Leaking collector ring gasket or leaking pump-and-collector ring assembly 3) Leaking torque converter

FLUID LEAK (At Brake Cylinders): Damaged gaskets, uneven or warped gasket surfaces Sand holes in castings

FLUID LEAK (At Extension Case): Damaged gaskets or warped or uneven gasket surfaces Sand holes in castings Improperly seated governor control shaft bushing Leaking governor control cam stopscrew. Damaged "O" ring seal on parking pawl pivot pins

C NTINUED ON NEXT PAGE

STUDEBAKER AUTOMATIC TRANSMISSION (Cont.)

FLUID LEAK (At Selector Control Shaft): Damaged control shaft "O" ring seal Bore out-of-round or too large diameter Damaged selector control shaft packing

FLUID LEAK (At Transmission Oil Pan): Damaged gasket Damaged or warped gasket surfaces Interference between oil pan and pressure take-off plugs

TRANSMISSION REMOVAL

1950-55 CHAMPION
1950-54 COMMANDER
1955 COMMANDER (FIRST SERIES)

▷*CAUTION—Transmission Assembly and Torque Converter Assembly are removed SEPARATELY as follows:*

1) Drain oil from transmission case and torque converter housing. See LUBRICATION data.

2) Disconnect propeller shaft at front and rear ends by taking out bearing cup U-bolts (CAUTION—wire bearing cups in place to prevent them dropping off), and removing nuts from center bearing support-to-crossmember studs. Move entire propeller shaft assembly to the rear and out of the way.

3) On Champion, disconnect parking brake, cable clevis at parking brake bellcrank. On Commander, disconnect parking brake forward cable from bellcrank on cross member, disconnect bellcrank bracket by taking out mounting bolts, move bellcrank and cable assembly to rear and fasten up out of the way.

4) Disconnect transmission control rods by taking out clevis pins at selector valve lever and governor control lever on transmission case.

5) Remove speedometer cable and pinion assembly from transmission. Disconnect Anti-creep cables from solenoid switch on rear of transmission, free Anti-creep harness from clip on transmission case.

6) Remove converter housing lower cover plate. Remove nuts from two lower transmission case-to-converter housing studs (accessible from within converter housing with cover off).

7) Place transmission lift with adapter in position under transmission case (see NOTE). Do not disturb adapter adjustment knobs after saddle-to-transmission oil pan flange alignment has once been set.

Lift & Adapter Note—Two types available: Model 63 (Lift Type Hoist J4385 & Adapter J4287), and Model 27 (Floor Type Hoist J3389 & Adapter J4287). This tool essential to maintain transmission alignment during removal and installation and to handle transmission weight of approximately 220 lbs.

8) Take out two upper transmission case-to-converter housing capscrews, install Pilot Studs No. J4284 in these holes.

9) Slide transmission assembly to rear out of converter housing and torque converter, then lower transmission and remove from beneath car.

NOTE—If main shaft oil transfer tube (in forward end of transmission mainshaft) does not come out with transmission, remove tube from converter using a long-nosed pliers.

1955 COMMANDER (SECOND SERIES)
1955 PRESIDENT

▷*CAUTION: Transmission Assembly and Torque Converter Assembly are removed SEPARATELY as follows:*

1) Drain transmission and torque converter assemblies On 5 Pass Coupe and Convertible models, remove body front pillar post cross-member assembly Remove complete propeller shaft

2) Disconnect hand control bellcrank-to-transmission rod from selector control shaft lever Disconnect accelerator cross shaft-to-transmission rod ball joint from the governor control lever Remove speedometer cable retaining screw and remove cable and pinion

3) Disconnect Anti-Creep cables from Anti-Creep Pressure Switch and remove wiring harness from clip holding the harness to transmission Remove the two lower transmission case-to-converter housing stud nuts using tool J-5413

4) Place transmission lift, with the transmission adapter as far forward in tracks as possible Adjust knobs on the adapter to align the saddle to transmission oil pan flange

5) Remove the two upper transmission case-to-converter housing capscrews Remove transmission assembly by sliding it rearward on the saddle out of converter housing and torque converter assembly If mainshaft oil transfer tube does not come out with the transmission, remove it from torque converter assembly with long nose pliers

▷*NOTE*—If converter is to be removed, remove pilot studs from converter housing

1954 HUDSON

1) Raise car and drain transmission and converter Remove cotter pin and disconnect governor control rod at governor control lever Disconnect speedometer cable at speedometer gear housing and remove driven gear

2) Remove attaching nuts, washers and "U" bolts and disconnect propeller shaft from transmission companion flange (wire propeller shaft to frame out of the way)

3) Place hydraulic hoist with transmission adapter in position under transmission oil pan and adjust fixture knobs on adapter to align the saddle-to-transmission oil pan flange so that the weight of the transmission case is supported by hoist

4) Remove the two transmission case-to-converter housing upper bolts and install two pilot studs, J-4284 into capscrew holes Remove the two lower transmission case-to-converter housing stud nuts With hydraulic hoist cradle adjusted so transmission case is in alignment with converter housing, pull transmission with hydraulic hoist rearward to disengage transmission from converter housing and converter assembly *CAUTION*—If transmission sticks to converter housing, do not rock the transmission case A small pry bar between rear end of oil pan flange and converter housing can be used to carefully pry the two units apart

5) The mainshaft oil transfer tube must be removed from the converter if it does not come out with the transmission

TRANSMISSION INSTALLATION

ALL MODELS

1) Place transmission selector valve lever in "Neutral" position Align splines on transmission shafts with Spline Alignment Fixture J-4283 Loosen fixture thumbscrew, install fixture over shaft splines on front end of transmission case, inserting fixture as far as possible into transmission and aligning positioning arm sector with one of the transmission lower mounting studs, move arm and shaft (turn universal joint companion flange) until positioning pin slips easily over mounting stud, tighten thumbscrew to lock positioning arm in place on sector Remove fixture from transmission case carefully and without moving shaft splines out of position. Install oil transfer tube in end of mainshaft

2) Align splines in Torque Converter Assembly by installing alignment fixture (after positioning arm has been set in (1) above), working the fixture into the converter until all splines are lined up on the fixture Rotate torque converter members and spline alignment fixture until positioning pin slips easily into transmission mounting stud hole corresponding to same lower transmission case stud on which fixture was aligned in (1) above. Remove fixture carefully and without moving splines out of position.

3) Install two Transmission Pilot Studs J4284 in upper transmission mounting screw holes in converter housing. Raise transmission assembly to correct height and angle (on special hoist), carefully slide transmission into place using pilot studs as a guide and using care not to disturb spline alignment (CAUTION—do not disturb universal joint companion flange position).

▷*CAUTION* Do not force transmission into converter by using transmission retaining screws to draw transmission into position as this may cause damage to converter or front pump Make sure that transmission fits firmly against converter housing If transmission stops at a distance greater than ¼" from converter housing, turn companion flange a little in each direction and at the same time apply pressure to rear of transmission If transmission stops less than ¼" from converter housing, turn converter a little in each direction and at the same time apply pressure to rear of transmission

4) Remove pilot studs and install two upper mounting capscrews, tighten to 23-28 ft lbs (Studebaker), 40-50 ft lbs (Hudson) Install nuts on lower mounting studs and tighten these to 23-28 ft lbs (Studebaker), 35-40 ft lbs (Hudson)

5) On Studebaker, install Anti-Creep wiring harness and connect wires to pressure switch on transmission Install speedometer pinion and cable assembly Install parking brake bellcrank on crossmember and connect parking brake cable Install propeller shaft, connect front and rear universal joints and center bearing support stud nuts

6) On Hudson, install speedometer driven gear and speedometer cable, making sure that cable is entered over the rear motor support, between support and converter housing Move propeller shaft into position and attach to transmission companion flange, installing U-bolts and lockwashers and nuts

7) On all cars, install transmission control rods

CONTINUED ON NEXT PAGE

STUDEBAKER AUTOMATIC TRANSMISSION (C nt.)

(selector valve lever rod and governor control lever rod) and adjust linkage *See LINKAGE ADJUSTMENT data.*

8) Fill transmission with oil *See LUBRICATION.* Check transmission operation

TORQUE CONVERTER REMOVAL

1950-53 STUDEBAKER

1) On all Champion Models and 1950 Commander, remove converter housing bolt hole cover and remove housing-to-block screws Raise car On 1951-53 Commanders, remove starter On 1950 Commander, loosen screws holding converter housing air intake hose clamp to frame side rail and pull hose free of clamp

2) Remove clevis pin holding hand control tube-to-bellcrank rod to bellcrank On 1950 Commander, disconnect parking brake conduit from conduit hook On 1950 Commander and 1950-53 Champion, disconnect exhaust pipe from engine manifold and loosen bolts and nuts from clamp holding the exhaust pipe to converter housing bracket

3) On 1951-53 Commander, disconnect tail pipe supports and remove U bolt from exhaust pipe support at converter housing Then disconnect rear exhaust pipe from front right exhaust pipe and pull muffler and pipe assembly rearward After disconnecting pipe, move assembly to side out of the way

4) The engine rear support must be removed to permit removal of torque converter housing, but before removing cross member engine weight must be lifted off cross member Place engine support saddle (see Note below) under engine approximately 3-5" forward of rear engine plate, support engine weight with jack under support saddle (hydraulic jack should be used to permit engine lowering for converter removal)

►**Support Saddle Note**—Saddle can be made up from iron or wood block capable of supporting 600 lbs Dimensions of wood saddle made from 4" plank Width 14½", Height 9¼" at front edge, 8¾" at rear (top surface should slant down ½" from front to rear) Center cut-out 9" wide and 7" high (so that saddle clears oil pan and weight is carried on oil pan flanges)

5) Remove engine rear insulator stud nuts and raise engine just enough to have separation between insulators and cross members Remove engine rear support cross member bolts and, on 1950 Commander, disconnect fender-to-cross member brace Remove cross member

6) On all models remove converter housing-to-engine capscrews On All Champions and 1950 Commander, remove the small filler plate On 1951-53 Commander, remove converter housing front plate Remove converter housing from dowels, taking care not to damage or distort converter housing dowels or converter blower

7) Lower rear of engine approximately 3" to provide clearance for converter housing removal

►***CAUTION*—Do not allow oil pan to strike steering bellcrank and tie rod ends. If additional clearance required, loosen nuts holding bellcrank to engine front crossmember, drop bellcrank down.**

8) Remove the nuts and plain washers holding torque converter assembly to crankshaft-to-converter drive plate and remove converter assembly

1954-55 STUDEBAKER

1) With transmission removed, proceed as follows On Champion, remove converter housing bolt hole cover and remove housing-to-block screws, raise car On other models, remove starter, then raise car

2) Remove clevis pin holding hand control tube-to-bellcrank rod to bellcrank On Commander & President, disconnect tail pipe support and remove U-bolt from exhaust pipe support at converter housing Then disconnect rear exhaust pipe from front right exhaust pipe and pull muffler and pipe assembly rearward After disconnecting pipe, move assembly to the side out of way On Champion, disconnect exhaust pipe from engine manifold and loosen bolts and nuts from clamp holding exhaust pipe-to-converter housing bracket

3) On all models the engine rear support must be removed to permit removal of torque converter housing, but before removing cross-member engine weight must be lifted off cross-member Place engine support saddle (see below) under engine approximately 3-5" forward of rear engine plate, support engine weight with jack under support saddle (hydraulic jack should be used to permit engine lowering for converter removal)

►**Support Saddle Note**—Saddle can be made up from iron or wood block capable of supporting 600 lbs Dimensions of wood saddle made from 4" plank Width 14½", Height 9¼" at front edge, 8¾" at rear (top surface should slant down ½" from front to rear) Center cut-out 9" wide and 7" high (so that saddle clears oil pan and weight is carried on oil pan flanges)

4) Remove engine rear insulator stud nuts and raise engine just enough to have separation between insulators and cross-member. Remove engine rear support cross-member bolts.

5) On all models, remove converter housing-to-engine capscrews On Champion, remove the filler plate On Commander & President, remove converter housing front plate Remove converter housing from dowels, taking care not to damage or distort converter housing dowels or converter blower Lower rear of engine approximately 3" to provide clearance for converter housing removal

►***CAUTION*—Do not allow oil pan to strike steering bellcrank and tie rod ends. If additional clearance required, loosen nuts holding bellcrank to engine front crossmember, drop bellcrank down.**

6) Remove the nuts and plain washers holding torque converter assembly to crankshaft-to-converter drive plate and remove converter assembly

1954 HUDSON

HUDSON TORQUE CONVERTER REMOVAL (With Transmission Removed From Car): 1) Install engine holding fixture J-4651, positioning the "U" shaped section around engine oil pan and enter one adjusting hook in the frame just below steering gear housing support and the other hook in the corresponding hole on the opposite frame side rail This will place the fixture approximately 5" from rear end of engine oil pan Raise engine so that rear motor supports are raised ½" above the brackets on No 3 cross-member Make sure that engine weight is supported by holding fixture Remove nuts and washers attaching No 3 cross-member to frame

***CAUTION*—Cross-member will drop out when bolts removed.**

2) With cross-member removed, lower engine approximately 1" by backing off engine holding fixture This will make the upper converter housing bolts accessible from below car NOTE—These upper converter housing bolts can also be removed from the front driving compartment by removing the two floor opening covers under the floor mat

►***CAUTION*—The amount the engine can be moved depends on the clearance between oil pan and center steering arm and tie rod ends. Do not allow weight to rest on center steering arm.**

3) Remove converter housing right hand lower bolt first, then with a ⅝" socket and universal with a 10" extension remove converter to engine bolts

►***CAUTION*—Converter housing is doweled to cylinder block and should be pulled rearward carefuly to avoid damage to dowels during removal.**

4) Remove converter drain plug and drain converter assembly (if not already done) Remove the six nuts and plain washers attaching converter assembly to flywheel

TORQUE CONVERTER INSTALLATION

►**NEW TORQUE CONVERTER HOUSING INSTALLATION:** If new housing installed, bore and face run-out must be checked and corrected BEFORE torque converter assembly installed. Install the housing on the dowels in the flywheel housing and tighten all mounting bolts and capscrews. Use Clutch Aligning Gauge J-2045 installed in end of crankshaft to mount a dial indicator, check and correct run-out as follows:

Bore Run-out—Revolve crankshaft slowly and check total run-out. If run-out exceeds .004", housing must be repositioned and dowels relocated as follows: Remove housing, remove dowel pins, reinstall housing and tighten mounting bolts just enough to hold housing in position. Recheck bore run-out and use a lead hammer to shift housing, as required until run-out is less than .004", then tighten all mounting bolts and capscrews securely to hold this position and make final run-out check. If run-out within limits, drill a new dowel hole through the thin section of the flange near each production dowel hole using a 11/32" drill and then reaming holes to .376-.377". Install service dowels in these holes.

***NOTE*—Above instructions supersede earlier dowel installation data on Champion & Commander H Models.**

Face Run-out—With housing installed on dowels and all mounting bolts and capscrews securely tightened, use Clutch Aligning Gauge J-2045 to mount dial indicator, check face run-out at a 4¼" radius throughout entire revolution of the crankshaft. If total indicated run-out exceeds .006", replace housing.

Torque Tightening—Tighten converter housing-to-engine bolt nuts and capscrews to 28-32 ft. lbs.

1950-53 STUDEBAKER

1) On 1950 Commander, be sure that one of the

C NTINUED N NEXT PAGE

STUDEBAKER AUTOMATIC TRANSMISSION (Cont.)

aligning marks (0) on torque converter is aligned with the aligning mark (0) on crankshaft-to-converter drive plates. Install torque converter assembly on the crankshaft-to-converter drive plate and loosely install the plain washers and nuts.

2) Clean engine rear plate and the mating surface of converter housing and install converter housing, taking care not to damage dowel or the converter blower. Be sure converter housing is installed on dowels. Install lower converter housing capscrews. If engine has been lowered, raise it to normal position.

3) Position Converter Aligning Flange J-4286 into bore of converter housing and over pump drive fingers on torque converter assembly. Install two top transmission capscrews to hold aligning flange in position and rotate torque converter assembly through two complete revolutions to center torque converter assembly.

4) Tighten converter-to-drive plate nuts to 28 ft. lbs. On all models except 1951-53 Commander, install converter filler plate. On 1951-53 Commander, install converter housing front plate.

5) Install the cross member and on 1950 Commander connect the fender-to-cross member braces and install parking brake conduit. On all models connect hand control tube-to-bell crank rod.

6) On 1950 Commander and all Champions, connect the exhaust pipe to engine manifold and tighten exhaust pipe to converter housing bracket bolts and nuts. On 1951-53 Commander, install exhaust pipe muffler and tail pipe assembly, making sure that proper alignment exists between assembly and supports.

7) On 1950 Commander, install converter housing air intake hose in clamp at frame side rail and tighten clamp screws.

1954-55 STUDEBAKER

1) On all models, install converter assembly on crankshaft-to-converter drive plate and loosely install plain washers and nuts. Clean engine rear plate and the mating surface of converter housing and install converter housing, taking care not to damage dowels or the converter blower. Be sure converter housing is installed on dowels. Install lower capscrews in converter housing. If engine has been lowered, raise it to normal position.

2) Position Converter Aligning Flange J-4286 into bore of converter housing and over pump drive fingers on torque converter assembly. Install two transmission top capscrews to hold aligning flange in position and rotate torque converter through two complete revolutions to center torque converter assembly. Tighten converter-to-drive plate nuts to 28 ft. lbs. On Champion, install converter filler plate. On Commander & President, install converter housing front plate.

3) On all models, install the frame crossmember and connect hand brake control tube-to-bellcrank rod. On Champion, connect the exhaust pipe to engine manifold and tighten exhaust pipe to converter housing bracket bolts and nuts.

1954 HUDSON

1) Install torque converter assembly on flywheel and loosely install attaching plain washers and nuts. Clean cylinder rear support plate and machined faces of converter housing. Install converter housing and engage dowels, using care not to damage dowels or converter. Install right and left hand lower capscrews and tighten finger tight.

2) Position Converter Aligning Flange J-4286 into bore of converter housing and over converter hub (front pump drive fingers on converter assembly). Install the two transmission upper attaching bolts to hold aligning flange. With aligning flange in position, tighten converter-to-flywheel attaching nuts to 23-28 ft. lbs. Install remaining converter housing capscrews, and tighten all capscrews.

3) Install converter housing dust pan (if previously removed). Raise engine approximately 1" with Engine Holding Fixture J-4651. Position the No. 3 cross-member and install all attaching screws before tightening any screws to assure proper alignment. Then tighten all screws to 25-30 ft. lbs.

4) Lower engine and install rear engine support bolts at the No. 3 cross-member. Remove engine holding fixture.

OVERHAUL

▷*1951-52 COMMANDER "PART THROTTLE DOWNSHIFT" OPTION (WITH SERVICE REPLACEMENT EXTENSION HOUSING)*—Extension case assembly can be installed to provide "Part Throttle Downshift" if desired. Extension case is furnished with the direct drive lock pawl in place, and to prevent "Part Throttle Downshift," install extension case exactly as received. To retain, or convert to "Part Throttle Downshift," remove the Direct Drive Lockup Pawl (located directly below transmission mainshaft bearing bore on machined face of extension assembly).

▷***1955 SERVO INNER & OUTER PISTON NOTE:** Arrangement of servo pistons (double & single piston units) vary with the different transmission models. See Overhaul data below for removal & installation procedures for the different types.*

TORQUE CONVERTER: *CAUTION—Torque Converter (and Direct Drive Clutch) serviced as an assembly and cannot be disassembled for parts replacement.*

TRANSMISSION DISASSEMBLY: Install transmission in Transmission Holding Fixture J-5484, and proceed as follows:

▷*TRANSMISSION DISASSEMBLY NOTE—Transmission sub-assemblies that can be removed and re-installed without removing complete transmission from car are indicated below.*

Front Pump & Collector Ring Removal: Place Ring gear Retaining Clip J-4668-3 on main shaft and secure it in place with a rubber band (clip prevents movement of gear and eliminates possibility of dislocating thrust washers in the gear train). Remove capscrews in the front pump flange, and tap front pump housing loose from transmission case and slide assembly forward off main shaft. Remove front ring gear front thrust washer from rear face of front pump-and-collector ring assembly.

Extension Case Removal: Remove universal joint flange, lock washer and tongued washer. Punch mark one spline of main shaft and corresponding groove of the flange to insure correct reassembly. Using Companion Flange Puller J-2046, remove flange. Shift selector control lever out of "Park" position. Place an oil drain pan under extension case and remove the six capscrews holding extension housing to transmission case, and slide extension housing rearward, being careful not to drop gears and spacers that may slide off main shaft during case removal.

▷*CAUTION—Do not allow main shaft to move toward the rear which would cause dislocation of thrust washers in the gear train.*

Removal (With Transmission in Car)—Disconnect universal joint, drain oil, control arms and wiring, then proceed as above.

Valve Block Removal: Remove capscrews attaching oil pan to transmission case and remove oil pan and gasket. Remove the seven screws attaching valve block to transmission. Remove the valve block base plate rear gasket.

▷*CAUTION—Care must be taken to see that selector valve is not moved out of its normal operating range.*

Removal (With Transmission in Car)—Drain oil from transmission case, then proceed as above.

Main Shaft Removal (Studebaker): Remove flange spacer, governor drive gear, parking brake gear, from main shaft, then remove main shaft rear bearing lock ring. Using Bearing Puller Plate J-1298 with Adapter Rings J-1298-3 and Universal Puller HM-925, remove rear bearing. Install J-2204-4 spacer and J-2204-3 sleeve on rear end of main shaft, and secure it in place with the universal joint companion flange, flat washer and nut. Make sure the Ring Gear Retainer Clip J-4668-3 is securely in place on front end of main shaft. Pull assembly forward, being careful not to disengage ends of bands from struts or dislodge bands from guide at top of transmission case. Any cocking of the bands will hinder removal of the assembly. Then remove assembly from case.

Main Shaft Removal (Hudson): Remove transmission companion flange spacer, governor drive gear. parking brake gear, and governor drive gear spacer from main shaft. Grasp mainshaft and front ring gear shaft and while holding the mainshaft assembly compressed, move the main shaft assembly towards front of case. The main shaft rear bearing should be removed with the main shaft assembly to assist in holding the main shaft together as an assembly. If bearing sticks in case bore, use a piece of pipe with a 1.195" I.D. and 1.500" O.D., 7" long. Drive against inner race of bearing to move bearing and main shaft forward and out of case bore. (*CAUTION*—Make sure Ring Gear Retainer Clip J-4668-3 is still in place on front end of main shaft). Pull main shaft forward and out of case, being careful not to disengage the ends of the bands from guide at top of transmission case, as any cocking of bands will restrict removal of main shaft assembly.

▷*REAR BEARING REMOVAL NOTE—Rear bearing may be removed with transmission in car by first removing extension case. See "Extension Case Removal" above.*

Brake Band Removal: Remove brake anchor side strut from forward brake band by pulling the band shoe away from adjustment screw, disengaging pin from notch in strut, and then removing strut from end of the adjustment screw. Disengage other end of band from piston strut, and lift band out of band guide. Move band to rear of transmission case. Disengage low band in same manner as forward band and move it to rear of case. Disengage the re-

CONTINUED ON NEXT PAGE

STUDEBAKER AUTOMATIC TRANSMISSION (C nt.)

verse band shoe from anchor side strut and remove strut from screw. Disengage reverse band shoe from piston strut, turn the band 90°, spread it slightly, and slip end of band out of case and over flange, then roll top of band forward out of case. **Do not distort band during removal.** Remove low and forward brake bands in same manner as reverse band.

Brake Band Strut Removal: All three brake band struts are removed in the same manner. Loosen band adjustment screw locknut. Hold shoes of band together, being careful not to disengage band from piston strut, and back off adjustment screw until strut can be slipped off screw and past brake band shoe.

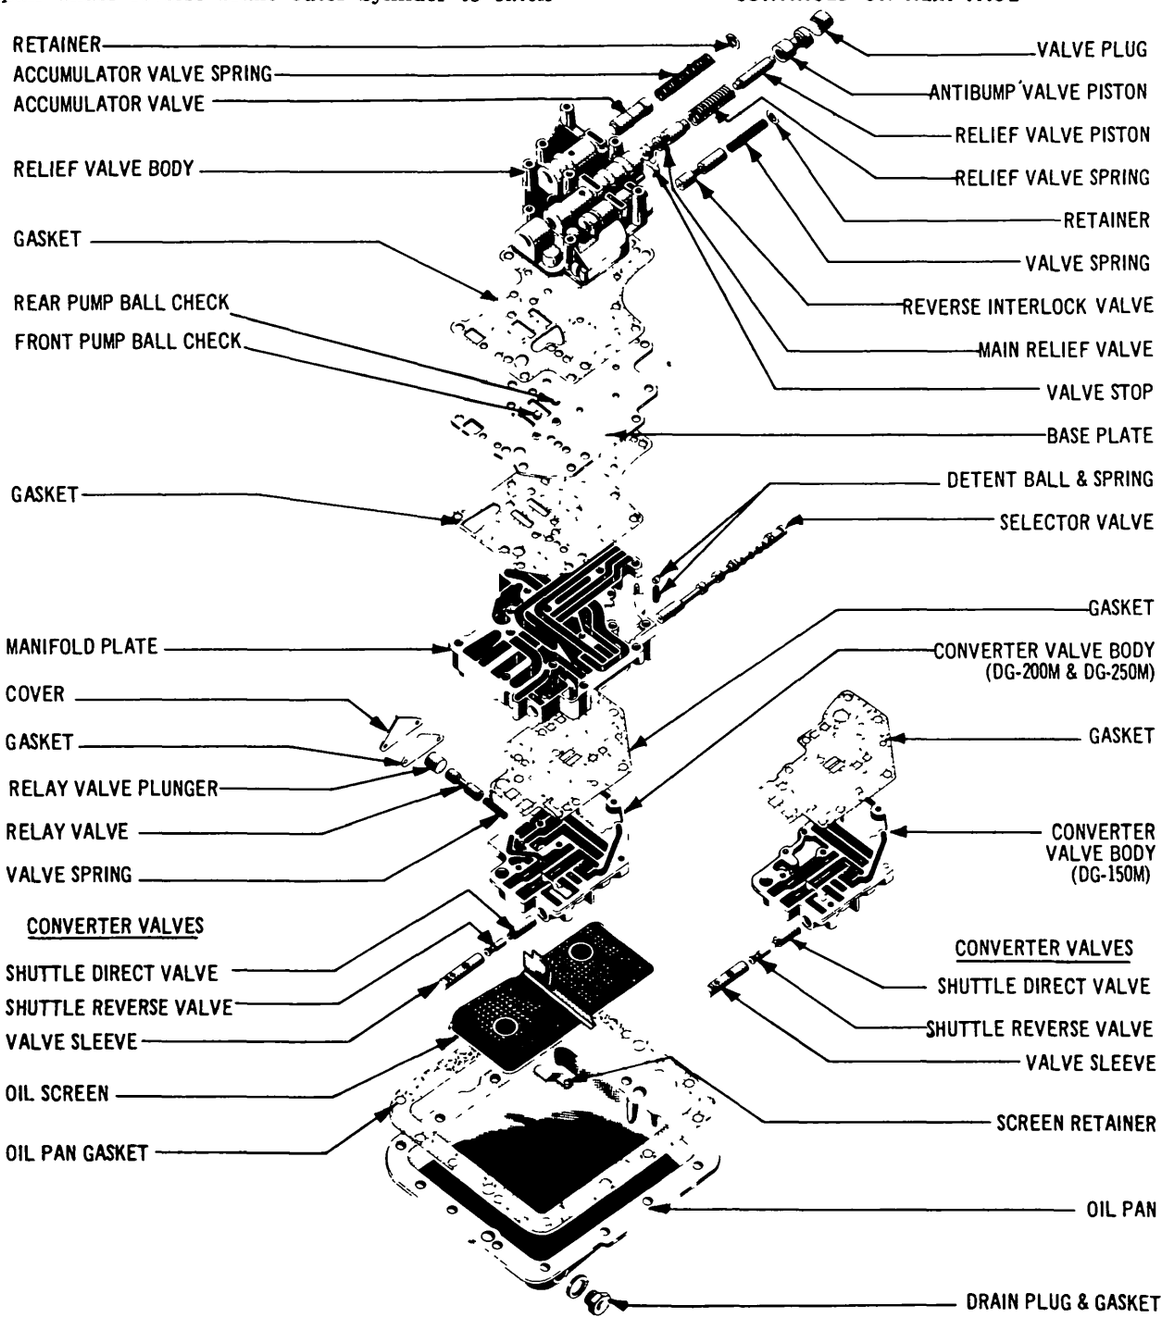
Removal (With Transmission in Car)—Drain oil from transmission unit only, remove oil pan, and remove valve block assembly, then proceed as above.

REVERSE SERVO UNIT: Located on left side of transmission and consists of inner and outer piston assemblies, remove as follows:

►*1953 OUTER CYLINDER PRODUCTION CHANGE:* Two types of cylinders used. First type has two plugs (square head pipe plug in upper hole, and an Allen type pipe plug in lower hole). Later type has one plug (square head) located in bottom side of lower casting boss. Both types of cylinders are interchangeable, and service procedures are the same. When draining converter or checking converter pressure on the later type, remove plug in bottom of lower casting boss. On earlier type, remove upper plug.

Outer Cylinder Removal: Hold low brake band adjustment screw and remove the adjustment screw locknut. Place a clean pan under the cylinder, and remove the seven capscrews holding unit to transmission case. Remove the low brake band outer cylinder from case, being careful not to damage threads of low band adjustment screw. Remove cylinder inner gasket from transmission case.

►***CAUTION—Do not allow the inner brake piston to come out of the inner cylinder and drop into transmission case.***



Removal (With Transmission in Car)—Clean off side of case thoroughly. Disconnect accelerator-to-transmission rod at governor lever. Disconnect bellcrank-to-transmission rod at selector control shaft lever. Remove clevis pin holding hand control tube-to-bellcrank rod to the bellcrank and then remove the bolts holding bellcrank to cross-member and remove bell crank. Complete the removal as indicated above. ***(CAUTION—If inner brake piston drops into transmission case, it will be necessary to remove oil pan and valve block to recover piston).***

Reverse Brake Inner Piston Removal: Place thumb against piston spring retainer, and the fingers on top of piston to prevent dropping the assembly as it is removed. Then, with the thumb, push the assembly outward, disengaging the strut from brake band shoe, and remove piston assembly from transmission case. Lift piston seal out of groove in piston, then bring it over top of piston and pull it the rest of the way out of groove. Discard seal.

Removal (With Transmission in Car)—Drain fluid from transmission unit only, remove oil pan and gasket. Remove valve block assembly, and remove reverse brake outer cylinder assembly, then proceed as above.

Reverse Shuttle Valve Removal (Exc. 1954-55 Champion)—(With Transmission in Car): Place a clean pan under reverse brake outer cylinder to catch fluid as valve is removed. Remove three capscrews attaching shuttle valve to reverse brake cylinder and remove shuttle valve assembly and gasket. Re-

CONTINUED ON NEXT PAGE

AUTOMATIC TRANSMISSION CONTROL VALVE ASSEMBLY (DG-150M, DG-200M, DG-250M)

STUDEBAKER AUTOMATIC TRANSMISSION (Cont.)

move valve cover plug with an Allen wrench, then remove valve and spring.

LOW & FORWARD SERVO UNIT: Located on right side of transmission case.

Low Brake Outer Cylinder Removal (Exc. 1950-54 Champion): Hold reverse band adjusting screw, then loosen and remove locknut. Remove nine capscrews attaching unit to transmission case and remove the unit, being careful not to damage threads of reverse band adjusting screw. Remove cylinder plate gasket.

Removal (With Transmission in Car)—Clean side of transmission case thoroughly. Drain transmission unit only, then proceed as above.

▷*CAUTION—Do not allow forward brake piston or low brake inner piston to come out of the case. If this occurs, it will be necessary to remove oil pan and valve block assembly.*

Low & Forward Inner Pistons Removal: To remove low brake piston (1950-54 Champion) or low brake inner piston (other models), place thumb against piston spring retainer and the fingers over top of piston to prevent dropping the assembly as it is removed. Then with thumb, push assembly outward, disengaging strut from brake band shoe and remove assembly from case. Remove forward brake piston assembly in the same manner. Remove seals from both pistons by lifting seals from groove, then over top of piston. Discard seals.

Removal (With Transmission in Car)—Drain fluid from transmission, remove oil pan and valve block assembly. On 1950-54 Champion, remove low & forward brake cylinder cover. Complete removal as indicated above.

Selector Control Shaft & Lever Removal: Remove nut, washer, and flat washer which hold selector control shaft inner lever to selector control shaft. Pull shaft outward and slip control shaft inner lever off shaft, then pull shaft assembly out of case. Remove the "O" ring seal from groove in selector shaft and then remove flat washer from shaft.

Removal (With Transmission in Car)—Drain fluid from transmission only, and remove oil pan. Disconnect hand control bellcrank-to-transmission rod from selector control shaft outer lever, then complete removal as indicated above.

Parking Brake Actuating Rod Removal: Remove snap ring from toggle shaft sleeve, slip toggle shaft sleeve out of case, then remove complete assembly.

Removal (With Transmission in Car)—Remove main shaft assembly. Disconnect control shaft inner lever from control shaft. Disengage forward brake band from the struts and move it forward. Complete removal as indicated above.

TRANSMISSION REASSEMBLY: Clean case thoroughly and blow out all oil passages with air, making sure they are open.

Parking Brake Actuating Rod Installation: Install with Selector Control Shaft & Lever (below):

Installation (with Transmission in Car)—Insert toggle shaft sleeve in case, align flats of selector control shaft and inner lever, and install inner lever on shaft. Make certain that inner lever is in slot of selector valve. Install flat washer, lock washer, and nut and tighten nut securely. Install snap ring on toggle shaft sleeve. Install forward brake band in position in struts and band guide. Install main shaft assembly.

Selector Control Shaft & Lever and Parking Brake Actuating Rod Removal: Round off sharp corner of selector shaft bore at base of counterbore to prevent scuffing of "O" ring oil seal during installation. Clean selector shaft bore and lubricate with automatic transmission fluid, then install a new cork packing. Install the flat washer on selector control shaft, lubricate shaft and new "O" ring with automatic transmission fluid and install seal in groove of selector control shaft. Apply coat of fibre grease to shaft between "O" ring seal and outer lever. With a twisting motion, install selector control shaft outer lever so that it points toward top of transmission. Align flats of selector shaft and selector control shaft inner lever and install lever on shaft. Install flat washer, lock washer, and nut and tighten nut securely.

Installation (with Transmission in Car)—Proceed as above, then connect hand control bellcrank-to-transmission rod to selector control shaft outer lever. Install oil pan, with new gaskets, and tighten capscrews to 10-13 ft. lbs.

Low & Forward Servo Unit Installation: (Low & Forward Inner Pistons)—Install both pistons in same manner. Hold piston so offset notch of strut is to front and insert assembly in bore of case. Push assembly into bore, being careful not to turn seal over or damage lip of seal.

Installation (with Transmission in Car)—Proceed as above, except that notch in strut must be aligned with pin in brake band shoe before piston assembly pushed into bore.

Low Brake Band Outer Cylinder Installation (Exc. 1950-54 Champion): Apply thin coat of petroleum jelly to transmission case and place a new brake cylinder plate gasket in position on case, making certain that holes in gasket are aligned with holes in case. Slip the low band cylinder assembly over reverse band adjusting screw, position it on case and install retaining capscrews. Tighten capscrews to 15-18 ft. lbs. Install reverse band adjusting capscrew locknut.

Low & Forward Brake Cylinder Cover Installation (1950-54 Champion): Install in same manner as plate for other models (above).

Reverse Servo Unit Installation: (Reverse Brake Inner Piston)—Install inner piston in same manner that Low & Forward Inner Pistons installed.

Reverse Brake Outer Cylinder Installation: Apply thin coat of petroleum jelly to transmission case and place a new cylinder plate gasket in position on case. Slip reverse brake outer cylinder assembly over low band adjusting screw. Position it in case and install retaining cap screws. Tighten the 5/16" x2¼" and 5/16"x1" capscrews to 15-18 ft. lbs. torque, and the 3" screws to 10-13 ft. lbs. torque. Install low band adjusting screw locknut.

Installation (with Transmission in Car)—Proceed as above, then check adjustment of band and adjust if necessary. Retorque reverse cylinder retaining capscrews. Install bell crank on cross member and connect hand control tube-to-bell crank rod.

Brake Band Strut Installation: All three struts are installed in the same manner. Slip strut over end of adjustment screw, with adjustment screw backed off.

Installation (with Transmission in Car)—Hold ends of band together and slip struts over end of adjustment screws. Screw in adjustment nut and make sure that all struts are properly seated in ends of band.

Brake Band Installations: *(NOTE—Low & Forward bands are lighter than the reverse band and are interchangeable. DO NOT INTERCHANGE REVERSE BAND WITH LOW OR FORWARD BAND.)* To install bands, select one of the lighter bands and slip one end over flange of transmission case as during removal. Then turn band so that end of band which has the offset pin is toward the low & forward piston side of case. Move band to rear of case. Install the other light band in same manner and move it to rear of case. Install the reverse band in the same manner except that band must be turned so end of band having offset pin is toward reverse piston side of case. Place all three bands in position as follows: Set band into band guide strap at top of case. Engage band on piston side of case with the piston strut, making sure pin is in notch of strut. Pull shoes of band together, without disengaging piston strut and slip anchor side strut on end of adjustment screw. Then release band and allow shoe to engage anchor side strut. Make sure that all pins of the brake band shoes properly engage notches of their respective struts, and that guides are properly positioned in guide straps.

Main Shaft Installation (Studebaker): With Retaining Clip J-4668-3 in position on front end of main shaft, and that Spacer J-2204-4, and Sleeve J-2204-3, flat washer, and nut are securely in position on rear end of main shaft. Support main shaft assembly with one hand under low drum, insert the assembly in transmission case, thread it through brake bands, and seat bearing in bore of rear face of case. *(CAUTION—*Make sure brake bands and anchor struts have not been moved out of position). Remove Sleeve & Spacer Tools from end of main shaft. Make sure rear bearing spacer is in position on main shaft. Install rear bearing using J-2204-A Pusher Assembly, sleeve and spacer. (Do not remove the pusher at this time.) Install rear bearing snap ring, then push against rear face of case. Remove pusher tool. Install Extension Case (see instructions following).

Main Shaft Installation (Hudson): With Retaining Clip J-4668-3 in position on front end of main shaft and main shaft rear bearing in position on rear of main shaft, insert main shaft assembly into transmission case, threading it through bands and seating the rear bearing in bore of rear face of case. Install main shaft rear bearing lock ring, then push mainshaft forward until lock ring seats against transmission case. Install Extension Case. (See instructions following.)

▷NEW MAIN SHAFT ASSEMBLY INSTALLATION CAUTION—With a new main shaft assembly, it will be necessary to check endplay and determine thickness of the front ring thrust washer. With main shaft installed in case, install universal joint companion flange and tighten nut to 60-80 ft. lbs. torque. Move mainshaft toward rear as far as possible, and install Endplay Gauge J-4668 over the main shaft and ring gear shaft and fit gauge to

CONTINUED ON NEXT PAGE

STUDEBAKER AUTOMATIC TRANSMISSION (Cont.)

front of transmission case. Use three of the front pump retaining capscrews to hold gauge to face of case. Turn hub of gauge so indicator is over the start step. Rotate hub counterclockwise while pushing hub inward, maintaining a steady pressure on hub. The step, over which the indicator is stopped by the next higher step, represents the thrust washer to be used. Code number and thickness in thousandths, of thrust washer, is stamped on face of ring opposite the step. ***(CAUTION—If indicator stops over either the high "no-go" step, or the low "no-go" step, the mainshaft assembly cannot be used in that particular transmission case, and another mainshaft assembly must be tried.***

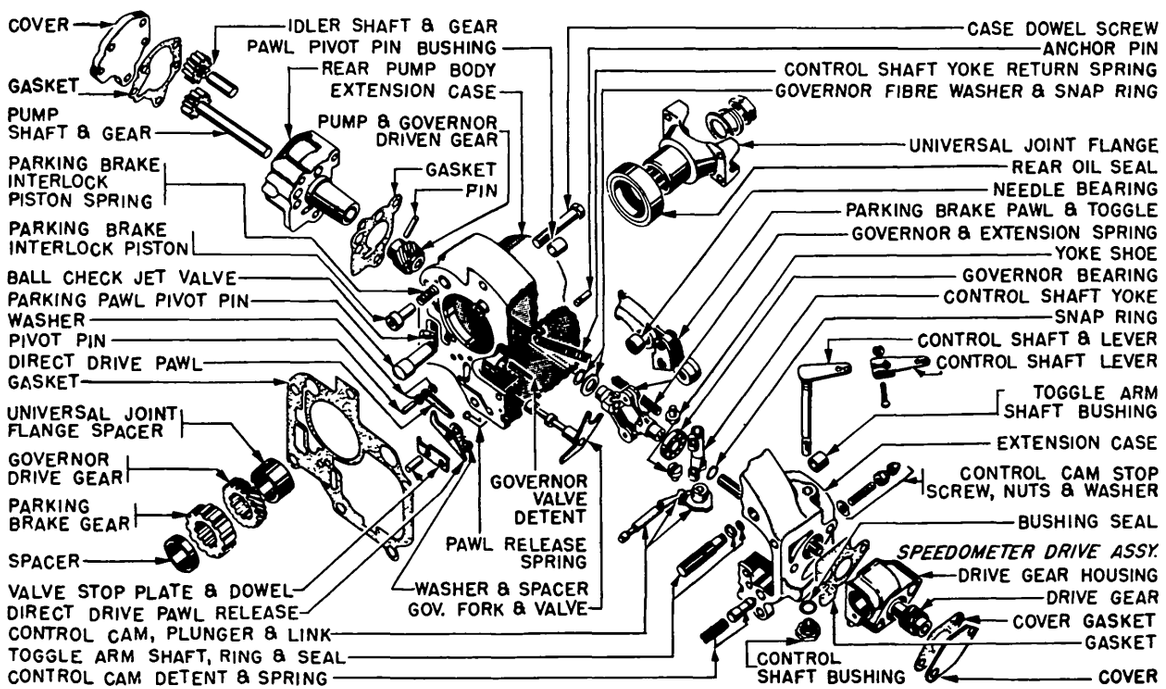
►*NOTE*—If indicator stops over the high "no-go" step, measure distance from end of ring gear shaft to end of main shaft. If measurement less than 3/16" check ring gear thrust washer to see if it has slipped out of place.

Extension Case Installation: Before installing extension case, check the following points and make the necessary corrections.

1) Ball check valve on machined surface of extension case, below main shaft bore, must be free and seating properly. NOTE—This valve will not be found on all extension cases.

2) Check both end brackets of governor assembly for free operation on governor shaft.

3) On models with direct drive pawl, check operation by positioning pawl so it locks governor. With a spring scale, check amount of pull required to release governor valve. If more than 9 ozs. pull required, make necessary corrections.



4) Check governor fork endplay in groove of governor end bracket. If clearance greater than .030", replace governor assembly.

►***NOTE*—If new extension case being installed, see below.** To install extension case, apply a thin coating of petroleum jelly to machined face of transmission case and install a new gasket, making sure holes in gasket are aligned with holes in case. Shift selector control shaft lever on transmission to LOW position by pulling lever as far rearward as possible, then moving it forward one detent. Install governor drive gear spacer, parking brake gear, governor drive gear, and universal joint spacer flange, **in that order,** on main shaft ***CAUTION—beveled side of parking brake gear must be toward rear.*** Lubricate all parts with automatic transmission fluid type A, then turn toggle splined shaft so that its wide spline is to the left. ***(CAUTION*—On cars with direct drive pawl, position pawl against governor valve fork, holding governor valve in direct drive position. Be careful not to dislocate pawl during installation of extension housing). Lift extension case into position on shaft and engage splines of toggle arm shaft sleeve splines (move selector lever slightly to aid the engagement), and push case forward against transmission case. Install capscrews and tighten finger tight (so case can be centered with companion flange), and then push selector control shaft lever on transmission forward to PARK position. Align punch marks of universal join flange and main shaft and install flange. Install tongued washer, lock washer, and nut and tighten to 60-80 ft. lbs. torque. ***(CAUTION*—Correct torqueing is very important since endplay is controlled by companion flange). Tighten extension case-to-transmission case capscrews to 28-33 ft. lbs. torque.

►***NEW EXTENSION CASE INSTALLATION NOTE*—If** extension case being replaced, remove parking brake interlock piston and spring from case being replaced and install them in new case. Insert spring in bore and slip stem of piston into spring and push piston into bore of case. Check fit of piston in bore to make sure it moves freely. Also, remove governor control detent spring and detent and install in new case with tapered end first, and place the spring in bore on top of detent.

►**Centering New Extension Case Caution**—A special capscrew is furnished with each new extension case, which must be installed in TOP HOLE of new case to insure proper centering.

Front Pump & Collector Ring Installation: Apply thin film of petroleum jelly to collector ring flange and install a new gasket. Align all holes and oil passages. Coat hub of collector ring and place front ring thrust washer on rear face of assembly, fully engaging tongues of washer in slots. **Steel face of washer must be toward hub of assembly.** Inspect the three seal rings on mainshaft and replace if broken or damaged. Install a 1½" long starting stud in top hole of transmission case, then hold pump so elongated oil inlet hole and round oil outlet hole in flange are at bottom. Check to see that all oil passages are properly indexed with corresponding holes in case, then slip assembly on main shaft. Using the starting stud, position assembly on case and install retaining capscrews. Replace starting stud with capscrew and tighten all screws to 15-18 ft. lbs. torque. Remove ring gear retaining clip from main shaft, and make sure that main shaft assembly turns freely in both directions while holding ring gear shaft.

TYPICAL EXTENSION CASE ASSEMBLY

SUB-ASSEMBLY OVERHAUL

EXTENSION CASE DISASSEMBLY:

Governor Removal: Remove the two speedometer gear housing cover screws, cover and gasket (NOTE—The extension case may be equipped with either a one piece speedometer drive gear and governor shaft assembly, or the speedometer drive gear and governor shaft may be separate pieces with the gear splined to shaft). If equipped with the one piece assembly, pull gear housing away from extension case and withdraw governor shaft and gear assembly from governor assembly, then remove shaft and gear assembly from speedometer gear housing. If equipped with separate gear and shaft, slip gear off shaft and remove speedometer gear housing. Then remove shaft from governor assembly. Disengage governor end bracket from governor valve fork. Slide governor bearing out of governor control shaft yoke shoes and remove governor from case. Remove yoke shoes and governor spring.

Inspection—Inspect governor shaft and make sure it is free of burrs and that splines are not scored. (NOTE—Burrs on shaft can be caused by governor spring not seating properly in governor end brackets). Check governor valve for free operation within valve sleeve. Make sure that hydraulic

C NTINUED N NEXT PAGE

STUDEBAKER AUTOMATIC TRANSMISSION (Cont.)

detent piston is in place in governor valve sleeve (NOTE—If detent is the stepped type, the step end should be inserted in cylinder first, and the long plain end out) Check length of governor spring to make sure the proper spring is used, as follows

▷*LATE 1954-55 GOVERNOR SPRING CAUTION (Cars with "Low Speed Start" Except Early 1955 Champion)* Two governor springs are used and it is very important to use the correct governor tension and booster springs to maintain the proper shift speeds Booster and Tension springs must be in matched sets as indicated in Governor Spring Specification Table (below)

Governor Spring Specifications

Trans.	Booster Spring Part No.	Booster Spring Free Lgth.	Tension Spring Part No.	Tension Spring Free Lgth.
DG-150①			529969	3 1/32"

①—1950-Early 1954 Before Transmission Serial No SCH-60,000 (With second gear start)
②—Early 1954 Champion After Transmission Serial No SCH-60,000 and before Serial No SCH-66,199 (with first gear start)
③—Late 1954-55 Champion (with first gear start)
④—1950 Commander
⑤—1951-Early 1955 Commander (with second gear start)
⑥—1954 Hudson (with second gear start)
⑦—Late 1955 Commander, First Series (with first speed start)
⑧—1955 President & Late 1955 Commander, Second Series, (with first speed start)
⑨—Hudson Part No

▷*CAUTION—Under no circumstances cut or stretch a spring to obtain desired length.*

Governor Control Shaft & Lever Removal: Unhook governor return spring from governor adjusting yoke. Hold shaft in position using Wrench J-5482, loosen set screw, and withdraw shaft from the assembly. Remove governor control shaft yoke and governor control detent cam and plunger assembly (if so equipped), from case If equipped with direct drive lockup, remove governor control detent cam and plunger assembly, swing cam and link toward governor return spring anchor pin, push plunger into case, and remove assembly

Governor Control Direct Drive Lockup Mechanism Removal: To remove pawl, remove cotter pin and flat washer and slip pawl and spacer washer off pivot pin Remove rocker arm spring by slipping the end out of hole in rocker arm and then removing other end from hole in case To remove rocker arm remove retaining plate screw, retainer plate and spacer washer, then remove flat washer and rocker arm from pin To remove plunger, follow procedure outlined under "Governor Control Shaft And Lever" above

Governor Valve & Detent Piston Removal: Turn governor fork so end of fork is out of notch of direct drive rocker arm retaining plate and slide valve out of sleeve Remove hydraulic detent piston If detent piston is stuck in bore, position governor fork so that it contacts the stop on retainer plate Cover the valve body-to-governor passage and the multiple disc clutch passage with fingers, then using compressed air, blow into direct drive passage This will force piston out of bore against fork of governor valve.

Parking Brake Pawl & Toggle Removal: Using a small drift, loosen pivot pin and toggle shaft by tapping pin and shaft forward Remove pawl & toggle assembly from case (NOTE—On some transmissions, pivot pin and toggle shaft do not extend through case Pivot pin is internally threaded and can be removed by inserting a screw, and pulling pin from case) Toggle shaft can be removed with a pair of pliers). *(CAUTION—On some extension cases, a steel or fibre washer is used on toggle shaft back of the toggle lever. Do not interchange washers, use only the same type washer at reassembly.)* Remove the "O" rings from toggle shaft and pivot pin ("O" rings are used to prevent leakage where pin and shaft holes extend through case.)

Extension Case Rear Oil Seal Removal: Drive rear oil seal rearward out of case using a brass drift Do not damage rear pump drive gear or bore of extension case.

Rear Oil Pump Removal: *(CAUTION—Rear oil pump can be removed from extension case without removing case from transmission, if extension case is equipped with one-piece governor shaft and speedometer drive gear assembly. If equipped with the two-piece type, extension case must be removed. To distinguish between the two types, remove speedometer gear housing cover and check position of shaft. If shaft is flush with outer end of gear when gear is held in operating position in housing, it is a two-piece type. If shaft is ½" to ¾" short of being flush, it is one-piece assembly.)* Remove the three screws (two at top, and one at bottom) attaching pump to case, and slip pump out of case. (If two-piece speedometer drive gear and shaft assembly used, hold shaft to prevent removing it with pump)

Rear Oil Pump Gasket Replacement—Rear oil pump is serviced only as an assembly. If leak occurs between pump body and cover, the gasket can be replaced Gaskets are available in five thicknesses. The three thinner gaskets are identified by color only. 002" (red), 003" (green or clear), .005" (blue). Sizes 006" & .009" are black and the size is stamped on face of gasket. There is also an extra ⅛" hole in long ear of the .009" gasket.

▷*CAUTION—Always use a gasket of the same thickness as the one replaced.*

EXTENSION CASE REASSEMBLY:

Rear Oil Pump Installation: Apply a thin film of petroleum jelly to machined face of extension case and position a new gasket on case Make sure gasket does not obstruct governor drain hole. Insert end of pump through opening in case, and install pump retaining screws. Tighten screws to 15-18 ft. lbs .torque.

Installation (With Transmission on Car)—Proceed as above, except that when pump is installed on case, hold face of pump parallel to face of case, push pump into case and engage splines of pump gear and governor shaft. It may be necessary to turn pump slightly to engage splines. If equipped with two-piece speedometer drive gear and shaft assembly, hold shaft to prevent moving governor assembly and yoke out of position.

Extension Case Rear Oil Seal Installation: Coat outer surface of seal with suitable sealer, and place seal in counterbore driver J-2038 (used with Handle J-270-1), with the felt part of seal (lettered side) toward driver. Using an arbor press, start seal into case making sure that seal is not cocked, and enters bore squarely. Remove handle and install it on other side for driver and press the seal in until it is flush with case.

Parking Brake Pawl & Toggle Installation: If "O" rings used, apply automatic transmission fluid to them and install on pivot pin and toggle shaft Position pawl & toggle assembly in case with dog of pawl pointing downward. Align pivot pin hole of pawl with hole in case and install pivot pin Swing end of pawl & toggle assembly into position in case, align wide splines of toggle shaft and toggle lever, and install toggle shaft If equipped with a spacer washer between pawl & toggle assembly and rear of case, be sure this washer is installed and positioned correctly.

▷*CAUTION—If necessary to replace the washer, use only same type washer as used originally. DO NOT INTERCHANGE STEEL AND FIBRE WASHERS.*

Governor Valve & Detent Piston Installation: *(CAUTION—Two types of pistons used; stepped type and straight type. It is very important that stepped piston is installed with the step end inserted in cylinder first.)* Apply automatic transmission fluid to governor valve and hydraulic detent and carefully insert valve and detent in sleeve and place end of the fork in position in notch of direct drive rocker arm retaining plate.

Governor Control Direct Drive Lockup Mechanism Installation: Install plunger by following procedure outlined under "Governor Control Shaft and Lever Installation " Place flat washer on rocker arm pivot pin and install rocker arm on pin Place retainer plate on rocker arm over the pin, slip spacer washer between plate and case, align spacer washer and install retaining screw Install rocker arm spring, making sure upper end of spring is in hole of rocker arm Place flat washer on pawl pivot pin and install the pawl and another flat washer on pin and secure with a cotter pin Check pawl to see that it will drop of its own weight

Governor Control Shaft & Lever Installation: If extension case equipped for direct drive lockup, insert the plunger in hole in case (from inside case) slipping the rocker arm out of way to allow plunger to come through case Make sure that key is properly installed in governor control shaft and insert end of shaft in case Hold governor control shaft yoke in position and slip the shaft onto yoke Align key in shaft with keyway in cam, and insert shaft in cam Fully seat shaft in cam and tighten set screw securely Hook governor return spring to governor control shaft.

Governor Installation: Insert one end of governor spring in governor, compress spring and install the other end *(CAUTION—correct governor spring must be installed. See "Governor Spring Specifications" in "DISASSEMBLY" above.)* Install governor shaft yoke shoes Align slots of shoes and slide governor bearing into position in shoes, then engage groove of governor inner bracket with governor

CONTINUED ON NEXT PAGE

STUDEBAKER AUTOMATIC TRANSMISSION (Cont.)

fork. Apply a thin coating of petroleum jelly to machined surface on side of extension case and install a new speedometer housing gasket. If equipped with one-piece shaft, insert governor shaft and speedometer drive gear assembly into gear housing. Align the shaft and governor end bracket and insert shaft in governor. With the shaft through governor assembly, hold governor inner end bracket in on governor fork and engage shaft in splines of rear oil pump gear. If equipped with a two-piece assembly, insert the shaft in governor end brackets and insert shaft in rear oil pump gear. Install speedometer drive gear and housing. Align mounting holes of gear housing with holes in case. Position a new housing cover gasket, making certain that cover and gasket are aligned with housing. (The center opening in gasket is offset and improper installation will damage gasket). Install retaining screws and tighten to 10-13 ft. lbs. torque.

►**New Governor Installation Note**—If installing a new governor, check clearance **between** governor end brackets when governor valve is in its full open position and the governor control lever is in its full forward position. Clearance should be approximately .010". If clearance is not correct, remove acorn nut located on rear of extension case, loosen the locknut and turn screw (clockwise) until proper clearance is obtained.

►*CAUTION*—If after road testing car, and kickdown upshift speed is too high, turn screw (clockwise) a little at a time until proper kickdown upshift speed is obtained *(See "Transmission Shift Speeds" above).*

FRONT PUMP & COLLECTOR RING DISASSEMBLY: Remove the five capscrews attaching front pump to collector ring and remove front pump. Lift pump gear from housing and check them for wear or damage. If gears or casting are found to be worn, replace pump body and gears. Drive the oil seal out of housing using a drift punch. Be careful not to damage pump bushing.

FRONT PUMP & COLLECTOR RING REASSEMBLY: Clean oil seal bore of pump to remove all of the old sealer, then apply a thin coat of suitable sealer to oil seal and, using an arbor press, install seal in housing, with lettered side of seal toward outside. After making sure that interior of pump is clean, place the inner gear in position ,with the side of the gear having drive lugs toward outside. Lubricate gears with automatic transmission fluid Type A. Clean collector ring face and align front pump with collector ring. Install retaining capscrews and tighten to 10-12 ft.lbs. (¼"-20); 15-18 ft.lbs. (5/16"-18).

►*1955 SLOW REVERSE ENGAGEMENT CORRECTION (When shifting from either "D" or "L" range to "R" range):* There are two possible causes for the condition, one being insufficient diameter of the selector valve bleed hole, and the other being overtravel of the selector valve in the reverse position. Both causes result in slow bleed of low and forward servos. *NOTE*—The larger bleed hole entered production with Transmission Serial Nos. SP-24369 (DG-250M Trans.), SCH-3805 (DG-150M Trans.), ST-1547 (DG-250TM Trans.). It is suggested that both corrections be made when valve removed.

1) Remove valve block assembly and remove selector valve (be sure selector valve is turned so that detent ball does not stick in valve lever slot). Enlarge the present 7/64" bleed hole in selector valve housing to 5/32". Coat drill with petroleum jelly to trap aluminum chips.

2) Grind the detent flats (four) on selector valve down to the detent root diameter. The flats must be ground in the same plane as the previous flats and the selector lever milled slot. *CAUTION—Do not nick lands on the valve or touch them with the grinding wheel. Do not overheat valve while grinding.*

VALVE BLOCK DISASSEMBLY: (1) Remove the two capscrews holding relief valve body to valve block assembly and remove relief valve body and gasket. Remove rear pump relief valve screen, then remove valve block oil screen retainer and screen, and the three shroud-to-block capscrews, which permit removal of shroud reinforcing plate and shroud. Remove oil screen shroud gasket.

2) Turn valve block assembly over and remove capscrew holding control valve body to valve block, and very carefully lift converter valve body from base plate. *(CAUTION—Hold valve body level while removing converter valve body to avoid losing converter ball check and rear pump ball check).* Remove the two ball checks and converter valve body gasket from base plate. Separate base plate from valve block manifold and remove valve manifold plate gasket and front pump ball check. Remove the front pump relief valve sleeve retainer from valve manifold, then slip front pump relief valve piston sleeve and valve piston-and-spring assembly out of manifold.

3) Using the spring compressor of Valve Spring Unloader J-4547, compress rear pump relief valve springs, then position spring retainer tool of J-4547 between spring and spring retainer. Remove spring compressor and slip spring retainer out of manifold body. Install spring compressor again to remove retainer tool, then remove compressor and the two valve springs, and piston.

4) Remove converter valve cover plate screws and remove converter cover plate and gasket. Remove compensating piston, springs, stop plate, and valve piston. Using Valve Spring Unloader J-4547 in the same manner as outlined for removal of rear pump relief valve spring retainer, remove reverse interlock valve spring retainer, then remove reverse interlock valve spring and valve piston.

5) Turn selector valve (in valve block manifold) so the milled slot is away from selector valve detent ball and spring housing. Push selector valve into valve block manifold past the detent ball and spring *(CAUTION—Hold hand over opening in manifold so that detent ball which is spring loaded, will not be lost),* and remove ball and spring. Remove selector valve from either end of valve block manifold.

Inspection: Inspect all valve bores and valves in their respective valve bodies for scratches or scoring and for free movement. Small scratches may be polished out to provide free operation. If scoring or scratching is excessive, replace the valve body. Make sure passages in valve block manifold have no obstructions and are not porous. Front and rear pump ball check seats must be tight in manifold and plate. Clean rear pump relief valve intake screen.

VALVE BLOCK REASSEMBLY: Before reassembly, clean all parts of valve block in solvent and dry with air. Take all precautions to keep valve block clean during reassembly.

1) Install front pump relief valve piston and spring assembly, and sleeve in relief valve manifold. Install piston sleeve retainer, and retain it in position with petroleum jelly. Install rear pump relief valve piston and springs in manifold. Using the spring compressor of Valve Spring Unloader J-4547, compress the spring. Slip spring retainer tool in position, withdraw spring compressor, and install the spring retainer. Insert spring compressor, remove retainer tool, then remove compressor.

2) Install reverse interlock valve piston in converter valve body. Use Valve Spring Unloader J-4547 and install reverse interlock valve spring retainer in the same manner as for rear pump relief valve spring retainer. Install converter valve piston, stop plate, springs and the compensating piston. Place a new gasket in position and install cover plate and retaining screws.

3) Install selector valve in valve block manifold, with the milled slot at the detent housing, and with valve slot away from detent housing. Position valve so that end of valve clears opening in detent housing, then install spring and detent ball. With a small screw driver, force ball down into opening, and carefully move selector valve over ball, pushing screw driver off ball. Move valve out until detent ball locks up in first groove of valve. Turn selector valve so that milled slot is toward valve block manifold .

4) Install front pump ball check in valve manifold (check ball check seat to make sure that it is tight). Place manifold plate gasket in position, making sure all holes are aligned, then carefully place the base plate over gasket.

5) Place converter control valve body in position on base plate ,and install converter ball check, and rear pump ball check in the proper holes (converter ball check is the larger of the two). Carefully place converter control valve body over the ball checks and position converter body on base plate. Install a capscrew in hole near valve-end of reverse interlock valve piston housing, and tighten finger tight (converter control valve body is also held to valve block by shroud retaining capscrews and relief body capscrews). It may be necessary when installing other parts of the assembly to shift converter valve body for alignment.

6) Turn valve block over and place relief valve gasket in position. Insert rear pump relief valve screen in passage, making sure that screen is fully seated and is flush with, or below surface of body. Place relief valve body on valve body and align mounting holes. Install two retaining capscrews (in holes toward inside of valve block), and shift relief valve body as far as possible away from end of selector valve housing, to side opposite selector valve housing. Tighten capscrews finger tight.

7) Place oil screen shroud gasket on valve block manifold, making sure all openings are aligned. Install shroud and shroud reinforcing plate, and the three 1¼" retaining capscrews, finger tight.

8) After making certain that all parts are properly positioned by inserting the valve block-to-transmission case screws in holes of valve body, tighten all capscrews to 6-8 ft. lbs. torque.

MAIN SHAFT DISASSEMBLY: *(NOTE*—To provide a means of holding main shaft assembly for overhaul, drill a 2½" hole in a piece of wood 2"x4"x24"

CONTINUED ON NEXT PAGE

STUDEBAKER AUTOMATIC TRANSMISSION (Cont.)

and secure this to work bench with a large "C" clamp. The main shaft assembly can then be placed upright with end of main shaft through hole).

1) Slide front ring gear forward, disengaging it from front planetary carrier pinions ,and remove it from the shaft. Remove front ring gear thrust washer from planetary carrier.

▷*RING GEAR OIL SEAL CAUTION—It is not necessary to remove ring gear oil seals unless they are to be replaced. If only one of the rings are broken, all rings ahead of the broken ring MUST BE REPLACED.*

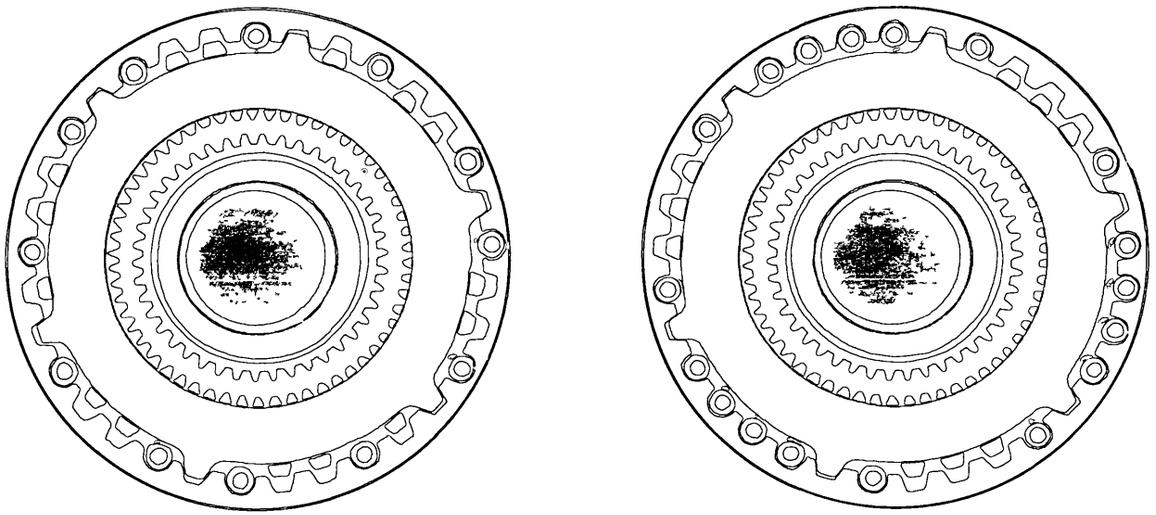
2) To remove ring gear oil seal rings, turn ring so that split is at top, then hold ring tight in groove at one side and press against lower part of ring at other side, causing ring to raise, with end separated. Spread ring just enough to permit removal from groove.

▷Front Ring Gear Needle Bearings & Bushings Note—Needle bearings and bushings are not serviced separately, but are available only as part of the ring gear assembly.

3) Remove reverse drum-and-front planetary carrier by sliding it forward off mainshaft. Remove front sun gear thrust washer from within front sun gear or from hub of front planetary carrier.

4) If necessary to remove planetary carrier from reverse drum, first remove the snap ring by inserting a small screw driver in the slot provided, lifting end of ring out of groove, and then pulling ring completely out of groove. Support drum on arbor press and press carrier out of drum.

▷Planetary Carrier & Pinion Note—Serviced as an assembly only. Separate parts not available.



5) Remove sleeve and spacer of Tool J-2204 (installed for removal from transmission case), and remove rear bearing spacer. Slip the forward speed brake drum assembly rearward and remove from shaft. Using a small screw driver, remove the forward speed free wheel unit spacer snap ring, and remove spacer plate from drum. Remove spacer dowel, and the free wheel unit snap ring, then remove the forward speed free wheel unit from drum.

▷Forward Speed Brake Drum Bushing Note—Bushing not serviced separately. Available only as part of forward speed drum assembly.

6) Remove rear sun gear rear spacer washer retainer, and thrust washer from main shaft. Move the low brake drum plate snap ring so that end of ring is above one of the plate slots. Using a small screw driver, lift end of ring and remove it from groove, then pick the two dowels out of plate slots. Remove plate assembly and rear sun gear as an assembly. Slip rear sun gear out of reverse free wheel unit. Remove free wheel unit snap ring and lift free wheel unit out of plate.

▷Bushing Note—Rear sun gear bushing and low brake drum plate bushing not serviced separately.

7) Pull main shaft rearward and remove main shaft and rear planetary carrier as an assembly from the low brake drum assembly. Remove rear planetary carrier front thrust washer, and carrier oil seal retainer snap ring. The rear planetary carrier is not pressed on splines of main shaft, but is held in position by planetary carrier oil seal ring retainer and snap ring. Place the assembly in an arbor press and press shaft out of seal retainer and carrier. Remove seal retainer, rear planetary carrier, and rear sun gear front thrust washer from main shaft.

12 SPRING TYPE — 18 SPRING TYPE

MULTIPLE DISC CLUTCH RETRACTOR SPRING ASSEMBLY

▷*REAR PLANETARY CARRIER CAUTION*—Two types used; one counter-bored at the thrust washer position, and the other not counter-bored. *If carrier is counter-bored type, a steel spacer must be used in addition to thrust washer.*

▷Planetary Carrier Oil Seal Ring Note—Same type as used on main shaft, and are removed in same manner.

8) Slide rear ring gear out of low brake drum, and with a sharp pointed tool, pick the inner "O" ring seal out of retainer and remove it from inside bore of ring gear. Pick outer "O" ring seal out of hub and slip it off hub of ring gear. If necessary, remove oil seal ring and planetary carrier snap ring.

9) Place the low brake drum assembly in an arbor press and place Multiple Disc Clutch Fixture J-5478 on multiple disc clutch retractor spring retainer. Place steel plate on fixture and then apply sufficient pressure to retainer to relieve pressure of retainer against snap ring. Remove snap ring with a small screw driver, then slowly release arbor press to gradually relieve retractor spring pressure. Remove retractor spring retainer, and retractor springs. Remove clutch disc plates, and discs, and retractor spring plate out of drum.

10) To facilitate removal of clutch piston, insert Piston Installing Pins J-5487 in grooves of drum, equally spacing the pins about five grooves apart. Pins will permit seal to slip past circular grooves inside drum. (CAUTION—To prevent damage to multiple disc clutch piston inner bore during removal of piston, place two layers of masking tape over teeth of front sun gear). Lift piston out of drum. To remove piston inner seal, squeeze seal to one side and pull it completely out of groove.

▷*CLUTCH PISTON REPLACEMENT CAUTION—Champion clutch piston has rubber outer seal, while Commander models have a cast iron seal. If clutch piston having rubber seal is to be replaced, use CAST IRON RING SEAL KIT for repalcement.*

▷*LOW BRAKE DRUM REPLACEMENT (1950-51 MODELS)*—Service replacement low brake drums have a centrifugal check (bleed) valve installed in back wall of multiple disc clutch cylinder in the low brake drum. Valve is adaptable for service replacement only when new low brake drum assembly installed.

▷Low Brake Drum Bushing Note—Bushing is not serviced separately. Available only as part of low brake drum assembly.

Inspection: Inspect all carriers, pinion ring gear, and sun gear teeth, oil seal rings, and free wheel unit sprags for wear or damage. Check thrust washers for wear or scoring. Inspect the lining of multiple disc clutch friction discs, and check the clutch disc plates for "dishing." Place a plate on a flat surface, and using a feeler gauge, check clearance at inner diameter of disc plate. If dish is more than .010", plate must be replaced. Inspect brake drums for scoring, and make sure that check valve in multiple disc clutch cylinder is free. Test the tightness of lubrication valve in end of main shaft with Test Rod J-5481.

MAIN SHAFT REASSEMBLY: (1) Lubricate new clutch piston inner seal with Automatic Transmission Fluid Type A, and hold seal so that lip of seal is toward drum. Stretch seal just enough to slip it over sun gear and place it in groove.

2) Two different seals used on clutch piston, requiring different installation procedures. Coat inside of low brake drum and piston seal with Automatic Transmission Fluid Type A, then proceed as follows:

Cast Iron Piston Seal—Install seal in ring groove of piston, and place Piston Installing Pins J-5487 in grooves of drum as during piston removal. Compress clutch piston ring and slip piston into cylinder.

CONTINUED ON NEXT PAGE

STUDEBAKER AUTOMATIC TRANSMISSION (Cont.)

Rubber Piston Seal—Use a piece of .002"x3"x18" steel shim stock (hone all edges to prevent cutting rubber seal). Coat shim stock with transmission fluid and place shim stock around inside bore of multiple disc clutch cylinder (make sure that shim stock is down to bottom of clutch cylinder), then slip piston and seal assembly into sleeve formed by shim stock, and push piston down into position. Make sure piston is to bottom of cylinder, and remove shim stock.

►*1950-55 MULTIPLE DISC CLUTCH SERVICE REPLACEMENT CAUTION & 1955 PRODUCTION CHANGE:* Sintered friction discs and flat separator plates are used in 1955 production and for service replacement on all 1950-55 models. Previously the separator plates were slightly "dished." The early type friction discs were thicker, therefore when installing the new type discs in early transmissions it is necessary that Spacer Plate, Part No. 537720 be used. When it is necessary to replace either a disc or a disc plate, all discs and plates should be replaced in complete sets.

3) Slip multiple disc clutch retractor spring plate into drum with spring recesses upward. Lubricate clutch friction discs and plate with transmission fluid, and starting with a disc, place plates and discs alternately in the drum *(CAUTION*—Disc plates are dished, and can be installed with the dish to either front or rear, but **all disc plates must have dish in same direction).** Since lugs on disc plates are not evenly spaced, make sure that lugs are in the same grooves with master lugs of retractor spring plate. *(CAUTION—Studebaker Commander and Hudson Model transmissions multiple disc clutch has FIVE disc plates, and FOUR friction discs. Studebaker Champion has FOUR disc plates, and THREE friction discs).*

4) Center friction discs around sun gear and align teeth of the friction discs. *(CAUTION*—If centrifugal check valve in multiple disc clutch cylinder, **12 retractor springs are used.** If centrifugal check valve NOT used, **18 retractor springs are used.** SEE ILLUSTRATION FOR CORRECT PLACEMENT OF RETRACTOR SPRINGS.) Place retractor springs in groove as indicated in illustration, then place retractor spring retainer over the springs. Using an arbor press as used during disassembly, compress springs so retainer is just below snap ring groove in drum. Install snap ring making sure it is fully seated in groove, and remove assembly from arbor press.

►*RETRACTOR SPRING RETAINER CAUTION—A thinner retainer is used on Commander models than the retainer used on Champion models.*

5) Lubricate rear ring gear inner and outer "O" ring seals with automatic transmission fluid and install the seals *(CAUTION*—Do not stretch outer seal any more than is necessary to slip seal over ring gear shaft). If ring gear oil seal ring and the front planetary carrier snap ring were removed, use a pair of snap ring pliers and install parts on ring gear shaft. Coat oil seal ring and outer "O" ring seal with petroleum jelly and install rear ring gear in the low brake drum.

6) Place rear planetary sun gear front thrust washer on main shaft with the steel face of washer to front of shaft and engage washer with splines of shaft. If carrier is counter-bored, install carrier spacer washer in same manner *(spacer washer not used if carrier NOT counter-bored).* Slip rear planetary carrier on front end of main shaft, engage splines, and seat carrier against shoulder on splines. Install planetary carrier oil seal ring in the retainer and slip retainer on main shaft. Place assembly in an arbor press and press shaft into seal retainer just enough to install snap ring. *(CAUTION*—Care must be taken to press on the inner portion of retainer to prevent damage to seal lands, and binding of ring). Make sure ring is free in groove, and install retainer snap ring. If there is clearance between retainer and snap ring, press retainer back against snap ring.

7) Place rear planetary carrier front thrust washer over shaft and on rear planetary carrier with steel face of washer against carrier. Apply a light coat of petroleum jelly to hold it in place. Install main shaft-and-rear carrier assembly in rear ring gear and low brake drum assembly. Install reverse free-wheel unit in low brake drum plate, making sure side of unit which has the ARROWS is upward. Install unit snap ring in groove. Lubricate rear sun gear bushings and outside of rear sun gear with automatic transmission fluid and install sun gear on shaft.

8) Place low brake drum assembly over end of sun gear with flat side of plate toward drum. Tilt assembly slightly and slip the free-wheel sprags down over edge of sun gear on one side. With a small screw driver, move each sprag outward, slipping it over edge of gear and at the same time holding free-wheeling unit against sun gear. Seat low brake drum plate in drum. Align slots of plate and drum and place the dowels in position in openings. Install snap ring making sure it is seated securely in groove. Place the forward free-wheel unit in forward brake drum, making sure that the side with ARROWS is downward, and install snap ring in groove.

9) Place forward brake drum assembly over rear sun gear. Tilt assembly slightly and slip free-wheel sprags down over edge of sun gear at one side. With a small screw driver, move each sprag outward, slipping it over edge of gear and at the same time holding free-wheel unit against sun gear. After all the sprags are outside edge of gear, rotate the unit clockwise and slide assembly down on sun gear. Slip the rear sun gear rear thrust washer on the shaft with bronze face of washer toward sun gear and place it on rear face of gear. Install spacer washer.

10) Insert the free-wheel unit spacer dowel in hub of forward brake drum and position the spacer within drum, then install spacer snap ring securely in groove of hub. Install rear bearing spacer on main shaft. Install Tools J-2204-4 (spacer), & J-2204-3 (sleeve), companion flange, flat washer and nut on rear end of main shaft and tighten securely.

11) Align splines of front planetary carrier and reverse brake drum. Using an arbor press, press the carrier into drum. Install snap ring, being careful not to distort snap ring. Coat front sun gear thrust washer with petroleum jelly and install the washer within front planetary carrier hub with the tangs in slots, and with steel face against hub.

12) Install reverse drum-and-front planetary carrier assembly. After engaging carrier splines with rear ring gear splines, it may be necessary to turn the assembly to engage the clutch friction disc teeth. **Do not force the assembly into position as this may result in damage to teeth of discs.** Apply petroleum jelly to front planetary carrier thrust washer and place it in position on rear ring gear shaft splines with steel face of washer against front planetary carrier.

13) If front ring gear or main shaft oil seal rings have been removed, install new rings. Spread the rings just enough to permit slipping it over shaft, and install it in groove. Then hold ring tight in groove at one side and press against lower part of ring at other side. This will cause end of ring to lift, then slide finger toward end of ring and lock ends of ring together. Coat main shaft oil seal rings with petroleum jelly and install the front ring gear. Install Retaining Clip J-4668-3 on front end of main shaft to hold assembly in position.

REVERSE SERVO OUTER CYLINDER DISASSEMBLY: Separate reverse brake cylinder plate from cylinder, lift plate off piston rod and remove it from cylinder. Remove reverse brake outer cylinder from gasket. Grasp reverse brake outer piston rod and pull piston out of cylinder. Use a pointed tool and pick the "O" ring seal out of groove in plate and discard seal. Lift piston seal out of groove on one side, then bring it over top of piston and pull it out of groove. Discard the seal.

Inspection: Clean all parts and check gasket surface of cylinder for warpage. Check cylinder plate for warpage, and bore of cylinder for pits or scoring.

REVERSE SERVO OUTER CYLINDER REASSEMBLY: Lubricate a new piston seal with Automatic Transmission Fluid Type A and slip edge of seal into groove of piston at one point, making sure that lip of seal is toward outer face of piston, away from piston rod. Work progressively around piston and seat seal in groove. *(CAUTION*—Avoid stretching seal any more than is necessary to install it on piston.) Lubricate a new "O" ring seal with automatic transmission fluid, and install seal in groove of cylinder plate. Holding piston at an angle, insert it in cylinder, being careful not to damage lip of seal. After top edge of piston is below bottom edge of cylinder, straighten piston and push it into cylinder. Apply a thin coat of petroleum jelly to machined surface of cylinder and place a new outer gasket in position on cylinder, making sure that holes of gasket and cylinder are aligned. Carefully slip cylinder plate over rod of outer piston and position plate on cylinder.

LOW SERVO OUTER CYLINDER DISASSEMBLY & REASSEMBLY: Commander models have two low servo pistons instead of the single piston used on Champion models. Disassembly and reassembly procedure is the same as for Reverse Outer Piston (above).

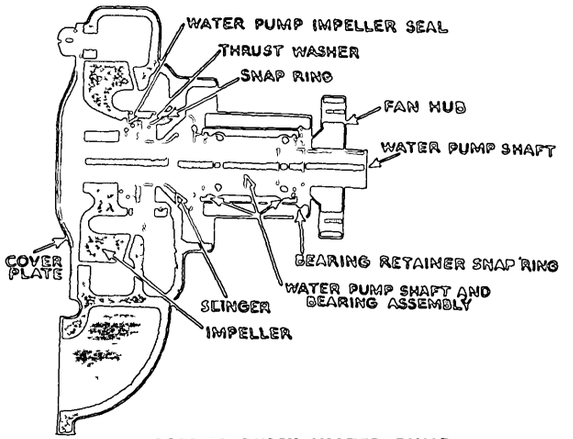
1939-48 BUICK



All Series (1939 to 1947)

①All Series except Dynaflow (EARLY 1948)

①—Pump body casting no. 1330139 (on left front face).

REPLACEMENT PUMP NOTE: Replacement parts not furnished for this pump. Latest type pump can be installed as a complete assembly.

TYPE: Ball bearing, packless type. Seal consists of spring-loaded rubber seal and carbon block assembled in impeller hub and retained by snap ring. Bearing consists of a double row ball bearing permanently assembled on shaft (shaft serves as inner race and cannot be removed), factory lubricated and sealed (requires no attention in service). Bearing and shaft assembly retained in pump body by snap ring at forward end of bearing hub.

1939-48 BUICK WATER PUMP

OVERHAUL: Disassembly. Remove fan and fan pulley use special puller to remove fan hub, take out rear cover screws and remove cover, remove bearing snap ring at forward end of pump body. Support pump in arbor press, press shaft out of impeller, lift impeller out, press shaft and bearing assembly out of pump body toward front.

Seal Assembly. Manufacturer recommends that seal not be disassembled (seal and impeller serviced as assembly). Carbon disc is ground convex on one surface and assembled with this face toward body.

Assembly. See that face of pump which contacts carbon seal is smooth (replace pump body if rough or burred). Use arbor press to install bearing and shaft assembly supporting pump body on press and applying pressure to bearing outer race only (do not press on shaft or bearing seal), install bearing snap ring. Press fan hub on shaft (support impeller end of shaft allowing pump to float on shaft so that bearings will not be damaged) until shaft projects beyond front face of hub exactly 3/8" (Series 40 '39-40, 50 '40), 3/16" (60,80,90 '39-40, 70 '40), 13/64" (All 1941-48). Apply cup grease lightly on the impeller end of shaft, face of pump body and face of carbon disc, press impeller on shaft so that it is flush with end of shaft (support shaft at fan hub end allowing pump to float on shaft while installing impeller).

1948-53 BUICK (EXC. V8)

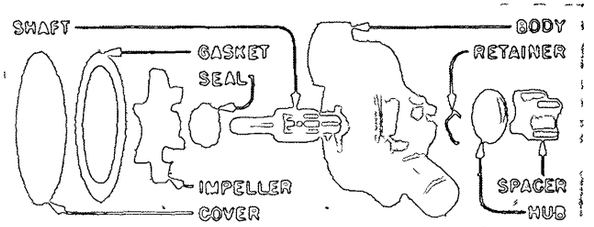
①All Roadmaster Dynaflow Series 70 (1948)

①All Series with Synchro-Mesh Trans. (LATE 1948)

All Series (1949-52)

Series 40 (1953)

①—Pump casting no. 1336756 (on left front face).



TYPE: Similar to preceeding type except seal assembly:

Seal Assembly. Consists of brass sleeve, helical spring, rubber bellows, and carbon washer. Sleeve is pressed in hub of pump body with spring pressing end of bellows against sleeve (at front) and opposite end of bellows and carbon washer against impeller hub. Inner diameter of sleeve notched which engage similar notches on carbon washer to hold washer stationary.

REPLACEMENT PUMP: This type pump furnished for replacement of other types used on earlier cars.

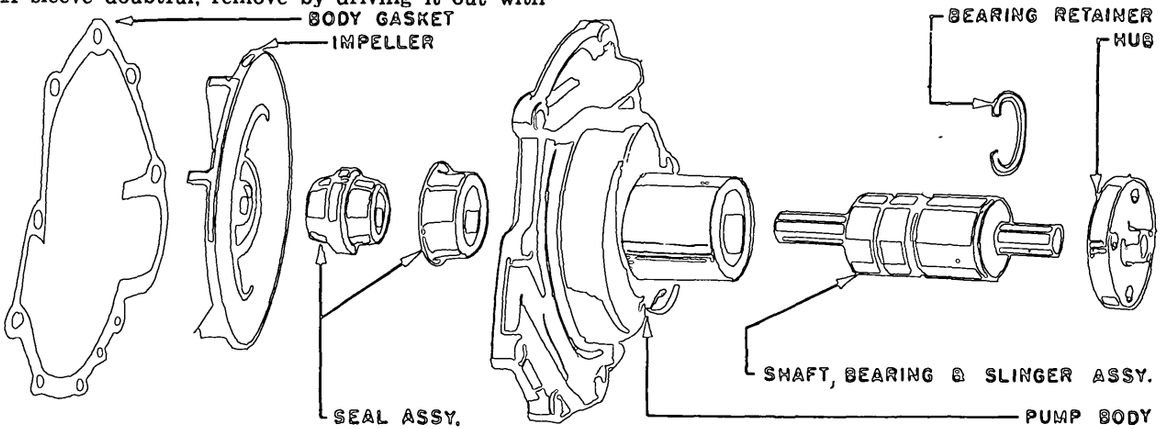
DISASSEMBLY: For Renewing Seal. Take pump off engine. Remove fan blade and pulley from pump shaft hub. Take off pump cover. Pull impeller off shaft using 2 hook or 3 hook puller with puller screw contacting end of pump shaft. Take out carbon washer, spring, and bellows from brass sleeve (NOTE—If sleeve in good condition, do not remove sleeve). Sleeve can be removed by driving sharp punch through bottom and prying out. Clean pump body (*CAUTION—Pump should not be soaked in gasoline—may destroy lubricant in sealed bearing*).

REASSEMBLY: Installing New Seal. Install sleeve as an assembly using a thick walled tube to press on flange of sleeve. If old sleeve not removed, soak new seal assembly in hot water to separate parts. Install bellows, spring, and carbon washer (low shouldered side to outside). Two notches in washer must engage dents in sleeve. Coat face of washer and impeller hub with rust preventive (or Seco Oil). Press impeller on end of shaft until rear face flush with end of shaft (support pump on fan end of shaft). Use new cover gasket and install pump cover. Install pump on engine.

1948-53 BUICK WATER PUMP

1953-55 BUICK V8

Series 50 & 70 (1953)



Series 40, 50, 60 & 70 (1954-55)

TYPE: Ball bearing, packless type. Non-adjustable seal consists of a rubber bellows and spring which bears against a sleeve in pump body. Bearing consists of a double row ball bearing held on shaft by a bearing retainer. Bearing is factory lubricated and sealed so that no lubrication required in service.

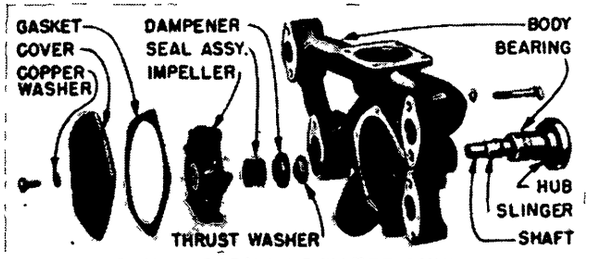
OVERHAUL: Disassembly—Remove pump cover assembly and gasket from timing chain cover. Remove impeller from pump shaft, using suitable puller (*NOTE*—Puller with two hooks preferred, one with three hooks may be used). Remove carbon washer, rubber bellows and spring from brass sleeve that is pressed into pump housing. It is not necessary to remove brass sleeve if in good condition. If sleeve doubtful, remove by driving it out with punch inserted through vent hole in pump body. Thoroughly clean pump cover to remove rust, old gasket, etc. ***Do not soak in cleaning solvent as this may leak into pump shaft bearing and destroy lubricant.*** Check pump shaft bearing for endplay, or roughness in operation. If bearing not serviceable, press fan hub off shaft, remove bearing retainer, then press bearing out toward FRONT of pump cover.

Reassembly: If old pump shaft bearing removed, press new bearing in against shoulder in pump cover, long end first, then install bearing retainer. Use care to start fan hub squarely on front end of bearing shaft and press it into position 13/64" from end of shaft. If brass seal sleeve removed from pump body, carefully press sleeve of new seal into place

CONTINUED ON NEXT PAGE

1953-55 BUICK V8 WATER PUMP

1953-55 BUICK V8 (C nt.)



with thick-walled tube that bears fully against sleeve flange. *(NOTE*—External spring seal used alternately in production or service). If old sleeve not removed, separate new seal sleeve from seal bellows by soaking in hot water to soften cement used to hold seal parts together for ease of handling. Install carbon washer, bellows and spring assembly in old sleeve in pump body, being careful to engage the two notches in washer with driving dents in brass sleeve. Coat face of carbon washer and impeller hub with rust preventative or Seco oil, then support pump on fan end of shaft, press impeller on shaft until rear face of impeller is flush with end of shaft. Install pump cover with new gasket. Tighten pump cover bolts with lockwashers uniformly.

1949-55 CADILLAC

Cadillac V8, All Series (1949-55)

►*WATER PUMP REPLACEMENT NOTE:* Use water pump assembly Part No. 3630518 as replacement for all 1949-55 cars. Also use for replacement of 1949-54 water pump bodies. This water pump will improve cooling of older models. It may be identified by figures "C55" on upper left hand leg of pump body. Use nipple Part No. 1462815 for heater hose take-off on 1954 cars, plus Tee Part No. 1455348 in right hand heater hose between pump and Ranco valve for left hand Ranco valve hose.

DESCRIPTION: Ball bearing packless type with plastic impeller.

1949-55 CADILLAC WATER PUMP

OVERHAUL: Disassembly. Remove fan blades and pulley. Take off pump cover and remove plastic pump impeller, using tool J-3211A. (Early type pump bearing retainer ring must be removed and shaft and bearing assembly removed from pump housing before impeller is taken off shaft). Remove seal assembly, and inspect housing seal seat for wear. Do not remove shaft assembly from housing unless inspection indicates roughness or end play.

Reassembly. If new shaft and bearing assembly is to be installed, replace by pressing into pump housing with tool J-3249. Install seal thrust washer, dampener and neoprene shaft seal over driving lugs of shaft slinger. Press impeller on shaft until outer face is .005 to .010 inches below back face of pump. Press new fan hub on shaft, using tool J-3249, until tool bottoms on shaft. Cement gasket and install cover. Spin pump shaft to be sure impeller has clearance. (Install bearing retainer snap ring on early 1949 pump).

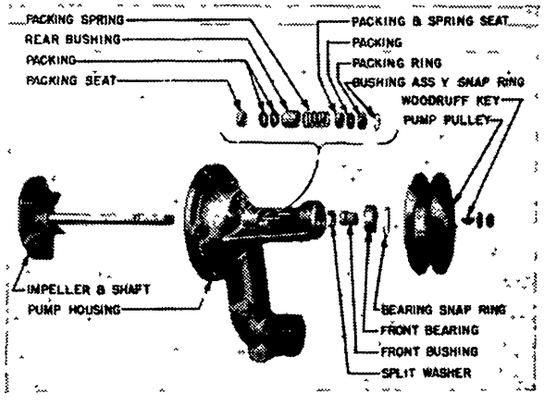
CAUTION—Support end of shaft so that press load will not be exerted on bearing.

1939-48 CADILLAC

Cadillac V8, All Series (1939-48)

TYPE: Self-adjusting type (no packing adjustment required in service). Packing rings installed at each end of rear bushing with packing spring located between bushing and front packing ring. Shaft mounted on bushing at rear and sealed type ball bearing at front end.

Lubrication. Grease fitting provided for rear bushing and packing assembly. Should be filled with water pump grease (G-13) every 1000 miles (front bearing requires no attention).



OVERHAUL: Disassembly. Remove nut and lockwasher on front of pump pulley, remove pulley and woodruff key in shaft. Remove bearing snap ring in front end of housing, push impeller to rear to expose split washer in back of front bearing, remove washer. Remove snap ring at forward end of rear bushing assembly, withdraw impeller and shaft through rear end of housing. Remove rear bushing assembly toward front noting location of spring, spring seats, bushing and packing rings to insure correct reassembly. If necessary, press front bearing out of housing toward front, press bushing out of bearing.

Bushing & Packing Assembly. To assemble packings on shaft, install special pilot, No. J-831, on end of shaft, insert shaft in pump housing, wind washer groove on shaft with string to avoid damage to packing rings. Coat packing rings with water pump grease, install packing, spring, and bushing parts in same order as removed from pump (make certain that bushing installed with grooved side toward rear packing rings).

Packing Spring—Spring free length should be 1¼" and spring should show no set when compressed so that coils touch.

Pump Assembly. Reverse disassembly directions given above. Make certain that split washer and snap rings correctly installed and that fan pulley key is in place in shaft before tightening pulley nut.

Clearances—Shaft clearance in bushing should be .0010-.0025" (new), .0035" (worn limit). Impeller clearance in pump body should be .050-.092".

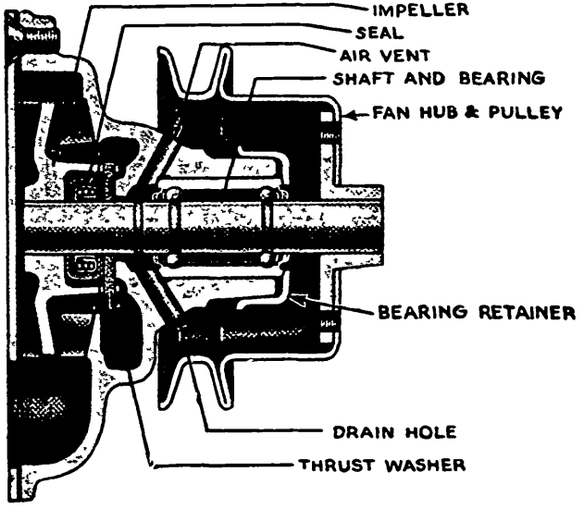
1939-48 CADILLAC WATER PUMP

1946-54 CHEVROLET

Chevrolet, All Models (1946-54)

TYPE: Ball bearing, packless type. Seal consists of a spring-loaded rubber seal and thrust washer assembled in impeller hub (spring and spring cups are integral part of rubber seal). Bearing consists of a double row ball bearing permanently assembled on shaft (shaft serves as inner race and cannot be moved), factory lubricated and sealed. Assembly retained in housing by cap press fit on forward end of housing. The pump has two outlets (water is discharged along both sides of cylinders.

►*1953 & LATER NOTE:* These pumps have a by-pass to provide circulation even though the thermostat is closed.



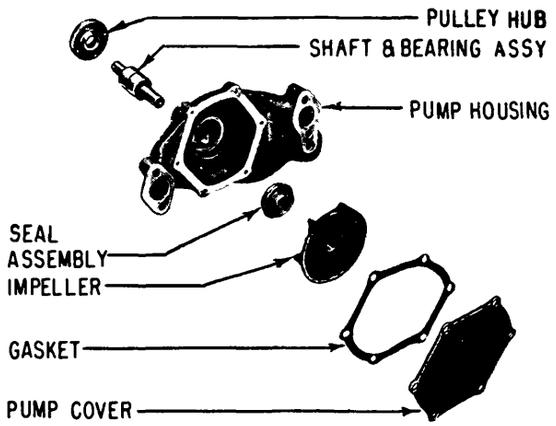
OVERHAUL: Disassembly—Remove screws and rear cover plate. Use puller to remove fan pulley from shaft, remove bearing retainer cap. Support pump housing in arbor press, press bearing and shaft assembly out of impeller and housing toward forward end, lift off impeller and remove thrust washer and rubber seal from impeller recess. Do not attempt to remove bearing from shaft.

NOTE—Puller tool J-1226 used for removal of fan hub and pulley.

Seal Assembly—Install rubber seal in impeller hub (spring is integral part f seal), place thrust washer on seal with lugs on washer engaging slots in impeller so that washer bears against ground face of pump housing when impeller installed.

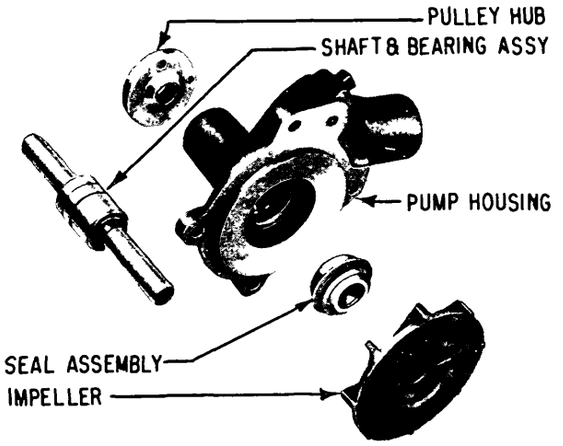
Assembly—Reverse removal procedures.

NOTE—When installing impeller, pump to impeller clearance should be .010-.035".



CHEVROLET PACKLESS BALL-BEARIN PUMP

1955 CHEVROLET



Chevrolet, 6 Cyl. & V8 Models (1955)

►*WATER PUMP & FAN PULLEY REINFORCEMENT (6 Cyl. Cars):* Part No. 3720 616 has been released for installation on engines where greater pulley durability is required. On early type pumps, when this reinforcement is installed, a slight fan belt misalignment will result. In all cases, clearance between pulley and pump body should not be less than .065".

1955 CHEVROLET V8 WATER PUMP

TYPE: Ball bearing, centrifugal vane impeller type. Keep air vent (top) and drain (bottom) holes open at times. Drive shaft and bearing are integral, prelubricated at time of assembly. Pump shaft seal, a combination of rubber and plastic is retained in housing by a metal seal housing pressed into pump body. 6 Cyl. and V8 pumps are basically similar.

1955 CHEVROLET 6 CYL. WATER PUMP

►*CAUTION:* On 6 Cyl. models, pull pump straight out of cylinder block to avoid damage to impeller or shaft.

OVERHAUL: Disassembly - V8 Models - Remove back plate screws, plate, and gasket.

All Models - Support fan hub in arbor press and press pump shaft out of hub. Support pump in arbor press on the face that attaches to cylinder block. Press shaft and impeller assembly out of pump, applying pressure on outer race of shaft bearing only *(CAUTION* - pressure on shaft will cause damage to bearing). Support impeller on seal surface, using press plate J-5855, Generator Bearing Remover and Installer, in an arbor press, and press shaft out of impeller. Discard seal.

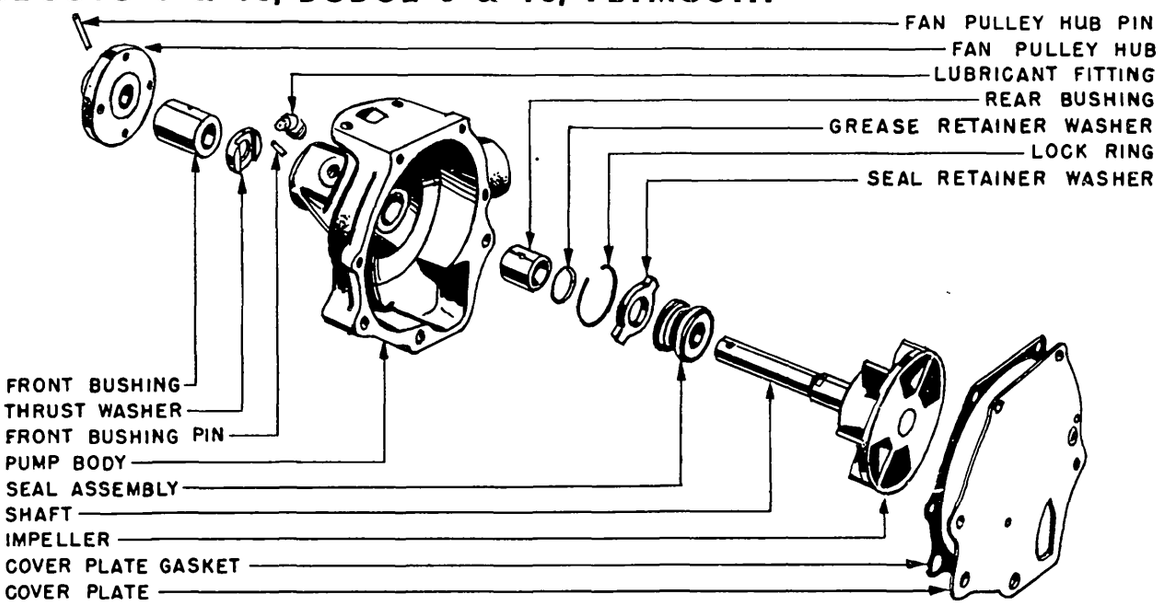
►*CAUTION:* Do not wash permanently sealed and lubricated pump shaft bearing in cleaning solvent.

Assembly - Press on bearing outer race only to install shaft and bearing in pump housing until flush with front of pump body. Press new seal into place (with sealing compound on outer diameter only) until it bottoms with outer flange against pump body. Press on fan hub. Install fauge J-5775 in one of bolt holes from rear of pump. Place a straight edge on front face of hub with head of gauge held firmly against body, straight edge should lightly contact **short** step on gauge for **6 Cyl. models** and **end** of gauge for **V8 models.** A tolerance of ± .005" is permitted. Support pump on front or hub end of shaft and press on impeller, to obtain .010" - .035" clearance between impeller vanes and pump body. *NOTE* - On V8 models it will be necessary to put bend about ½" from end of feeler gauge to measure clearance.

CHRYSLER 6, DE SOTO 6 & V8, DODGE 6 & V8, PLYMOUTH

Chrysler 6, DeSoto 6, Dodge 6, Plymouth 6 (1939-55).
DeSoto V8 (1953, 1954 early).
Dodge V8 (1953-55 early).
Plymouth V8 (1955 early).

TYPE: Packless type. Shaft mounted on two bushings in front of impeller.



1942 & Later Seal Thrust Spring Note—Spring is installed with large end in toward impeller (reversed from 1941 and previous types).

Chrysler C38 and DeSoto S11 Seal Change— Bellows type seal (similar to 1946 Chrysler 8) used after engine no. C38-26622 and S11-29106. Separate seal thrust spring and seal retainer are not used with this new seal.

SERVICING: Lubrication—Single grease fitting provided on lower left side of pump body. Keep reservoir filled with water pump grease (lubricate at 2000 mile intervals).

OVERHAUL: Disassembly—Drive out fan pulley hub pin, pull hub (use puller C-412), remove capscrews on rear cover plate and remove cover, pull impeller and shaft assembly out of pump. Drive out pin holding impeller on shaft, remove impeller and dismantle seal assembly. To remove bushings, drive front bushing pin into shaft hole to free bushing in housing, use puller C-373 (6 Cyl.), C-3208 (V8) and pull bushings and thrust washer out at forward end.

CONTINUED ON NEXT PAGE

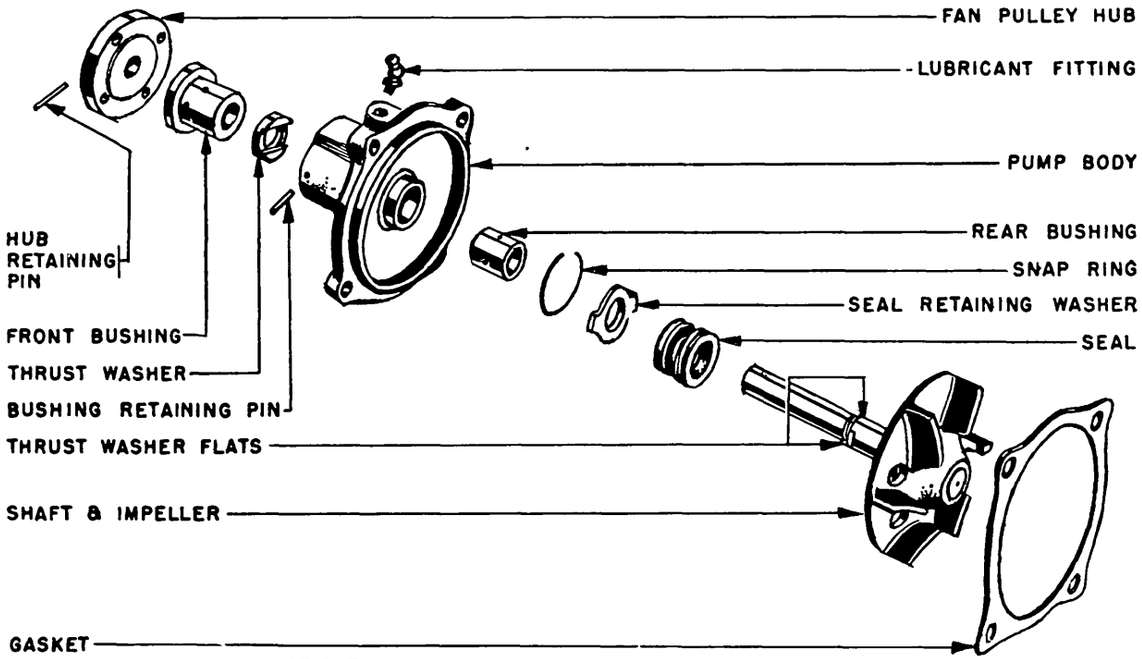
CHRYSLER 6, DE SOTO 6, DODGE 6, PLYMOUTH PUMP
(IMPELLERS ARE 2- OR 6-BLADED)

CHRYSLER 6, DE SOTO 6 & V8, DODGE 6 & V8, PLYMOUTH (Continued)

Servicing—If new bushings installed, use special tool C-373 (same puller used when removing bushings) to press bushings in place. See that thrust washer installed between bushings with slotted side or large diameter hole toward rear of pump. Install locking pin in hole in pump body and make certain that pin engages hole in front bushing to prevent bushing turning in service. Burnish bushings and reface pump body with special tool C-384. Insert tool through rear end of pump, turn tool evenly in clockwise direction until cut has been taken on rear face of pump body, withdraw tool while it is still being turned (this is important to prevent tool leaving ridge on housing).

Tool C-373 Note—When using this tool to install new pump bushings, clamp puller screw upright in vise, install special tool bushing No. 3 with the large diameter against the small hexagonal nut on the puller screw, start rear bushing in pump body, assemble the complete body on the puller screw, install pump thrust washer on puller screw with flat side up (toward front of pump), assemble pump front bushing, install tool thrust bearing and large hexagonal nut on puller screw, tighten the nut to draw pump bushings into place until top face of nut lines up with lower edge of groove in puller screw which will give required 3/32" clearance between face of seal thrust washer and snap ring when pump is assembled (see Assembly directions below for directions on checking this clearance).

No Tool Note—When special tool C-373 not available, press rear bushing into bore .130-.150" beyond seal seat surface (6 Cyl. & V8), press front bushing (6 Cyl.) in until distance from outer surface of bushing to rear seat of pump housing face is 2.782-2.787", (V8) in until bushing shoulder contacts housing, using suitable washer to prevent damage to front face of bushing.



Bushing Pin Drill Note—Use No. 13 drill (.185") to drill front bushing for pin using hole in body as guide for drill. Remove drill burr from inside of bushing and install pin so that outer end is flush with pump body.

Seal Assembly—Install seal parts on shaft within impeller hub in following order: Thrust Spring with small end in toward impeller ('41 and previous car models), large end toward impeller ('42 & later car models), seal retainer (not used with bellows type seal), seal using tool C-528 to install seal on shaft, seal retainer washer (with ears on washer engaging notches in impeller hub), and locking ring. Place grease retainer washer against rear bushing and install impeller assembly in pump housing.

Seal Note—When installing seal retainer (not used with bellows type seal), solid end of retainer should be toward spring and cupped end toward seal.

Assembly—Press impeller on shaft so that back of impeller is flush with end of shaft but do not install pin (assembly must be checked in housing first). Install seal assembly (see data above), slide impeller and shaft assembly into place in pump body, aligning the shaft and washer. Push shaft assembly into pump body firmly so as to compress seal and spring. Sight through water inlet and note clearance between face of seal retainer washer and lock ring in impeller hub. If clearance less than 3/32", remove assembly and press impeller further on shaft, recheck clearance. When correct clearance of not less than 3/32" secured, drill shaft and install impeller pin. Install impeller and shaft assembly. When installing new fan hub (below), press hub on shaft, leaving .0005-.005" (.003" preferred) clearance between front bushing and hub for shaft end play.

Fan Hub Installation—New fan hub must always be used when pump overhauled (old hub will not have satisfactory tight fit on shaft after having been removed. Mark location of old fan hub pin hole on end of shaft before installing new hub, drill new pin hole at right angles to old hole through both hub and shaft, install new pin (pin should not project from hub at either end). Use No. 22 drill.

DE SOTO 8, DODGE 8 & PLYMOUTH 8 WATER PUMP

1946-50 CHRYSLER EIGHT

Chrysler 8 (1946-50)

TYPE: Packless type with ball bearing shaft. Bearings are new type (two individual ball bearings) which can be removed from shaft and serviced separately. Seal is bellows type. Pumps fitted with lubricant fitting (for seal lubrication), grease fitting (for bearing lubrication).

SERVICING: Lubrication—Two lubricant fittings provided (rear fitting for seal lubrication, front fitting for bearing lubrication). **Lubricate with Water Pump Grease at 1000 mile or 30 day intervals.**

OVERHAUL: With pump removed from engine (spacer or back cover remains on engine block), disassemble and service pump as follows:

Disassembly: Drive out fan pulley hub pin, pull hub using special puller C-412. Remove bearing snap ring (in groove in housing ahead of front bearing) with special pliers C-760. Remove impeller and shaft assembly through rear of pump housing. Remove seal washer lock ring from groove in impeller hub, remove seal parts from impeller. Drive out impeller pin, press impeller off shaft. Withdraw ball bearing assemblies and bearing spacer from pump housing.

CAUTION—Fan pulley hub and impeller must not be re-used after having been removed from shaft.

Reassembly: Reface seal seat in pump body with cutter tool C-551 (use pilot DD-811 to insure cutter forming a perfectly flat seal bearing surface). Install bearings in pump body with spacer between bearings, install front bearing snap ring. Press new impeller on shaft (if old impeller removed), install impeller lock pin. Install seal parts in impeller hub, install seal lock ring. Insert impeller and shaft assembly in pump. Press new fan pulley hub on forward end of shaft, install hub lock pin. Check pump assembly for free rotation by spinning shaft.

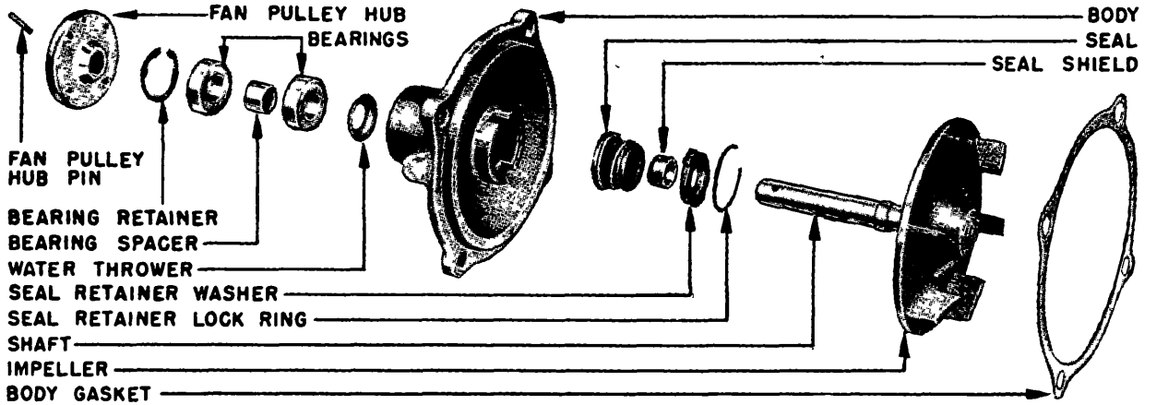
CAUTION—Lubricate pump seal and bearing fittings while spinning shaft.

1951-54 CHRYSLER V8 & LATE 1954-55 DE SOTO V8

Chrysler V8 (1951-54)
DeSoto (Late 1954-55)

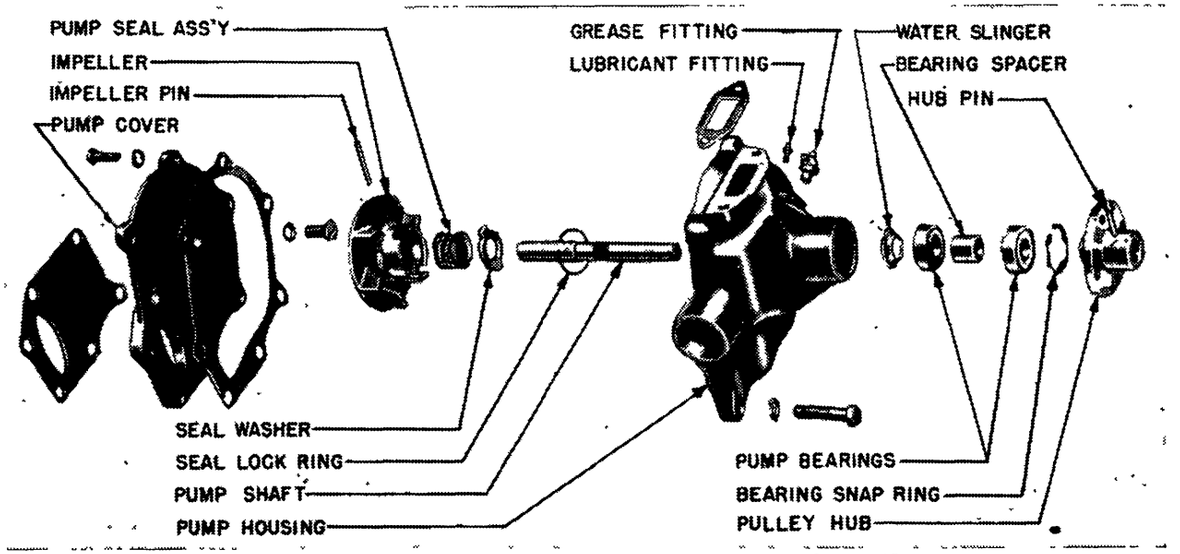
►*1951 IMPELLER NOTE:* Use 8-bladed impeller when replacing 6-bladed impeller used in 1951 pumps.

TYPE: Packless, Ball bearing type. Bearings can be removed from shaft and serviced. Seal is bellows type.



LUBRICATION: Pump is lubricated through a grease fitting in housing, using water pump lubricant.

OVERHAUL: With pump removed from engine, disassemble and overhaul pump as follows:



Disassembly: Drive out the fan hub pin and remove fan hub using Tool C-412. Remove bearing retainer with snap ring pliers and remove the impeller and shaft assembly through rear of body. Remove seal retainer washer lock ring, seal retainer washer and seal. Withdraw the outer shaft bearing, spacer, inner shaft bearing and water thrower.

Checking Pump Seal—Distance between shoulder on shaft & impeller hub face should be 1⅛-1 3/16". If not within these measurements, or if impeller seal face is scored or damaged, replace impeller.

Reassembly: Install seal, retainer, and lock ring. Install impeller shaft. Install water thrower, inner bearing, spacer, outer bearing and bearing retainer. Drill hole through fan hub and shaft and insert new pin. (If the old shaft has been used, drill a new hole at right angles to the old hole.) Remove all traces of old gasket and install a new one. Lubricate with water pump lubricant and check pump shaft for free rotation.

1951-54 CHRYSLER V8 & LATE 1954 DESOTO V8 TYPE PUMP

CHRYSLER 8 (1946-50) PACKLESS, BALL-BEARING TYPE PUMP

1955 CHRYSLER, DODGE & PLYMOUTH V8

Chrysler V8 (1955)
Dodge V8 (Late 1955)
Plymouth V8 (Late 1955)

TYPE: Packless type. Double row ball bearing and pump shaft serviced as a unit.

NOTE—Replace shaft with bearing when overhauling as shaft removal operation usually damages bearing.

SERVICING: **Disassembly**—Remove bearing lock spring, cover plate screws, plate and gasket. Press pump shaft and bearing (down) out through impeller and housing, using arbor press to support housing with impeller side up. ***CAUTION—To press shaft and bearing out in opposite direction will cause damage to housing.*** Lift out impeller, remove seal retaining washer lock ring, washer and seal assembly.

Assembly—*NOTE*—Always replace seal and seal washer, pump shaft and bearing, whenever disassembling water pump. Install fan pulley hub on new pump shaft (Hub must be tight fit), install water thrower. Install seal assembly in impeller with lock ring, place impeller in housing. Support housing (impeller side down) on press and press shaft and bearing into impeller with tool C-3468. Install cover using new gasket. Special sealing washers are used on cover plate.

1952-55 FORD 6 CYLINDER

Ford, 6 Cylinder (1952-55)

TYPE: Packless type with sealed double row ball-bearing shaft.

OVERHAUL: Disassembly—Press shaft out of hub, remove snap ring retaining bearing in housing. Press shaft out of impeller and pump body. Press out pump seal.

Reassembly: Clean off any gasket material on mounting face of pump. Install a new seal in pump housing. Coat seal with light coating of waterproof sealer. Use the seal installing tool marked 8501-DD-17 (for seal Part No. 7RA-8564-B). Coat bearing outer diameter lightly with grease and press shaft and bearing into pump housing, applying pressure to outer shell of bearing. Check impeller thickness at hub. If thickness is 1.252-1.257", shim up impeller adapter ring with three equally spaced .020" shims between the ring and counter-bored tool base. Do not allow shim stock to protrude into space where impeller is to be placed. If impeller thickness is 1.232-1.237", no shims are required. Coat seal rubbing face of impeller lightly with grease. Press shaft into impeller. *(CAUTION*—Press shaft into impeller just far enough so pump housing lightly touches face of insert ring. If excessive pressure exerted on shaft after rear face of housing contacts insert ring, pump bearing will be damaged). Impeller to pump body clearance should be .020-.030" after pressing on impeller. Tighten set screw in bottom of fixture plate until screw touches end of shaft. Do not lift pump body off fixture plate. Install snap ring in housing. Press water pump hub on shaft until dimension from inner hub face to machined surface of pump housing is 4.24" (1952-54), 4.36" (1955).

1941-47 FORD 4 & 6 CYL.

FORD NO. 9N-8501

Ford 4 Cyl., Comm'l & Truck (1941-42)

FORD NO. 2GA-8501

Ford 6 Cyl. "G", All Models (1941-42)

FORD No. 5GA-8501

Ford 6 Cyl. "G", All Models (1946-47)

TYPE: Ball bearing, packless type with non-adjustable seal assembled on shaft within impeller hub. Pump on 4 Cylinder models is same design in 1941 and 1942. 6 Cylinder pump design is different in 1941 than on 1942 and later models (1942 and 1946 types similar except for pump pulley and hub). These pumps have following features:

4 Cyl. Pump—Pump is ball bearing type (similar to '79' type) and is mounted on front end of engine block with a back cover plate mounted on the pump body by capscrews. Fan is bolted on shaft in front of water pump pulley. This pump serviced in same manner as '79' type except that screws must be taken out and cover removed for access to impeller.

1941 6 Cyl. Pump—Pump same design as '78' type used on V8 Engines with shaft mounted on porous bronze bushing and seal assembled in impeller hub recess. This pump not lubricated from engine oiling system and reservoir in pump body should be kept filled with oil.

1942-47 6 Cyl. Pump—Bearing is integral with shaft and furnished as an assembly. Pulley hub is retained on shaft by snap ring on forward end of shaft with pulley and fan blades bolted to hub by four capscrews. Seal is similar to type used on Ford V8 models.

SERVICING: Lubrication (6 Cyl. Pump only)—Keep oil reservoir in pump body filled with engine oil through oiler on top of body behind pulley.

OVERHAUL: Disassembly (6 Cyl.)—Take out capscrews and remove fan blades and pulley from pulley hub, remove snap ring on forward end of pump housing, press impeller off shaft, press shaft and bearing assembly out of housing. Remove bearing snap ring from shaft, press shaft and bearing assembly out of pulley hub. Remove snap ring from impeller hub, withdraw seal parts.

CAUTION—Do not attempt to remove bearing from shaft. These parts are furnished as an assembly.

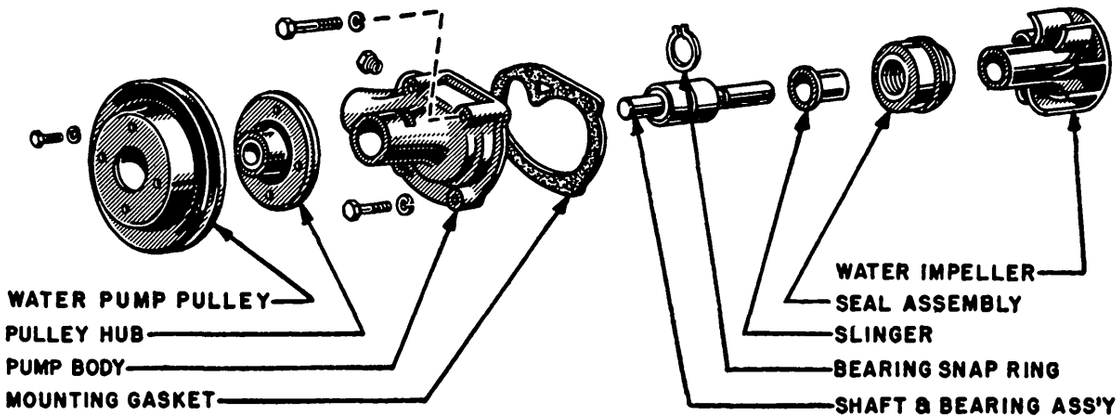
Seal Assembly—Install seal parts in impeller hub in following order: Seal Spring (large end out toward spring guide), Seal Clamp Ring, Spring Guide (tangs out toward seal), Seal (smaller end in and lugs engaged in slots in impeller hub), Seal Washer (lugs engaging slots in impeller hub), install snap ring to retain seal assembly.

Pump Assembly—Press shaft and bearing assembly into housing. Assemble seal in impeller hub (see above), press impeller on shaft until it is flush with end of shaft. Place bearing snap ring on pulley hub, press pulley hub on shaft until groove in shaft is flush with end of hub. Install bearing snap ring on end of shaft, install snap ring in housing.

Pump Installation—Use new gasket when installing pump back cover (4 Cyl.), use new gasket when installing pump on engine (all models).

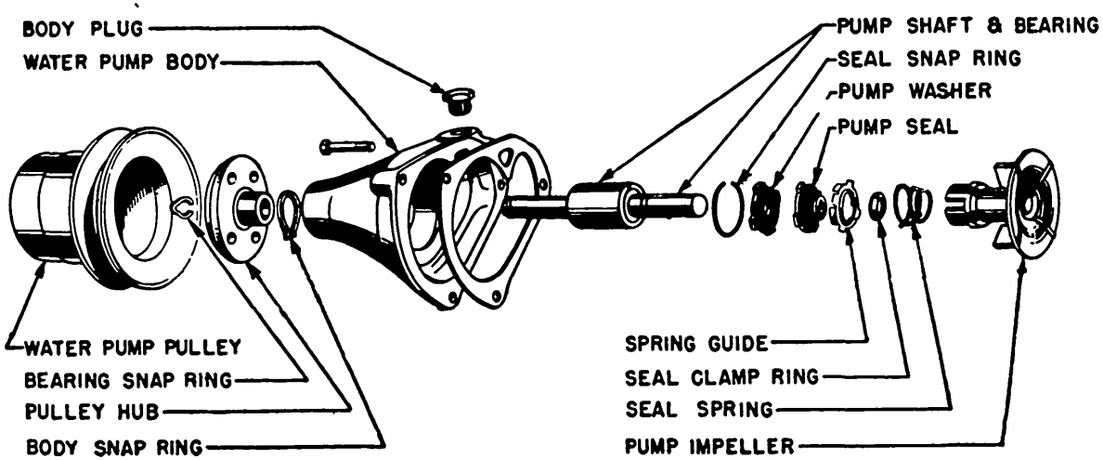
1947-51 FORD 6 CYLINDER

Ford, 6 Cyl. Pass. Cars & Trucks (1947-51)



TYPE: Packless type with sealed double row ball-bearing shaft (shaft serves as inner race for bearing).

Model	Replacement Pump	Ford Part No.
1947 Pass. Cars, 1947-53 Trucks		7HA-8501
1948-51 Pass. Cars		OHA-8501-B



►*CAUTION*—Impeller-to-pump body clearances are different See Reassembly following.

OVERHAUL: Disassembly. Take off fan blades and pulley from hub. Pull hub with puller off front end of shaft. Take out bearing snap ring from slot in pump body. Press shaft and bearing assembly out through rear of pump body. Use care when pressing shaft and bearing out, if assembly not being replaced. Press shaft out of impeller exposing seal assembly.

Reassembly: Carefully press new seal assembly (with slinger) in pump body. Press shaft and bearing into pump body from front until groove in bearing aligned with slot in pump body, and insert bearing snap ring. Press pulley hub on front end of shaft until flush with end of shaft. Press impeller on rear end of shaft to the proper position (clearance between impeller and body face) as follows: .020-.044" (7HA-8501), .024-.034" (OHA-8501).

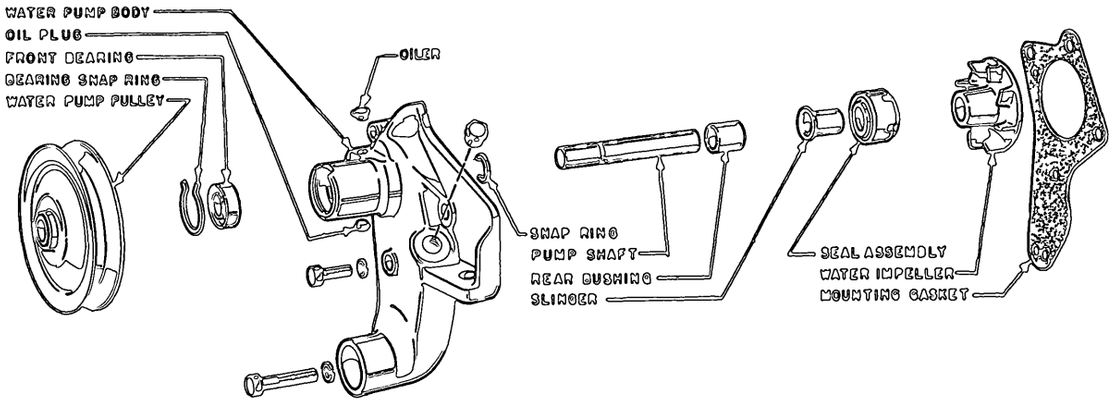
FORD SIX CYLINDER PUMP (LATE 1947-51 TYPE)

F RD 6 CYLINDER PUMP (1942-47 TYPE)

1948-53 FORD V8 & MERCURY (WITH OIL CUP)

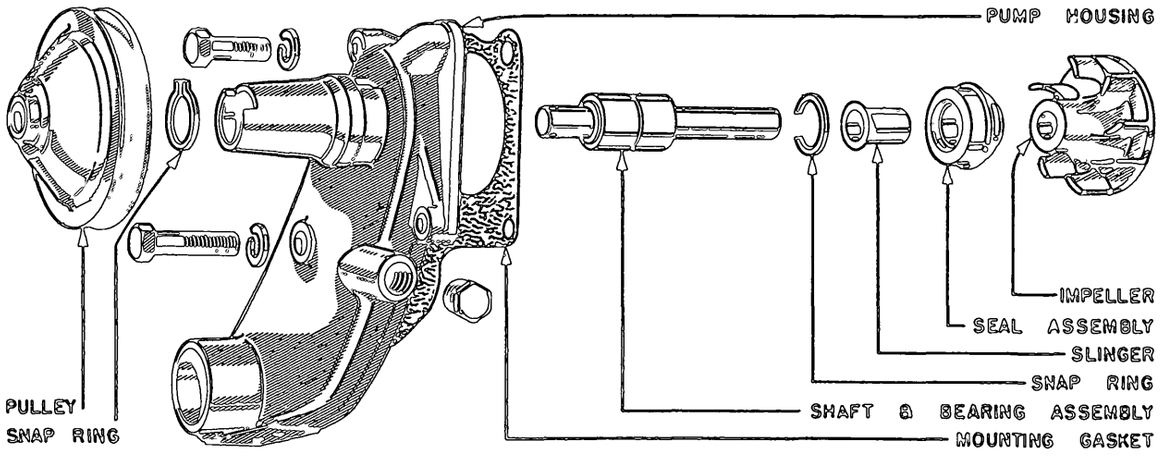
No. 8RT-8501-A (R.H.), 8RT-8502-A (L.H.)
Ford Trucks, F-1, 2, 3, 4, 5, 6 (1948-50)
No. 8BA-8501-B (R.H.), 8BA-8502-B (L.H.)
Ford Passenger Cars, 8BA (Early 1949)
No. 8CM-8501-B (R.H.), 8CM-8502-B (L.H.)
Mercury, 9CM (Early 1949)

NOTE—Replacement for above pumps are without oil cup. *See 1948-53 Ford V8 & Mercury following.*



TYPE: Packless type with sealed single row ball-bearing in forward end of pump body with bronze bushing pressed in body next to seal. Front bearing retained by snap ring in groove in shaft on rear side, and by snap ring installed in front end of pump body on front side. Bushing lubricated by means of oil reservoir in pump body with oil cup at top. Seal seats in recess in pump body.

LUBRICATION: *CAUTION—When installing new pump on engine, fill oil reservoir with SAE #20 engine oil. Use a piece of wire inserted in oil cup to allow air trapped in reservoir by wicking to escape.*
Regular Lubrication—Fill oil reservoir through oil cup at top of pump (SAE 20 oil every 1000 miles).



OVERHAUL: Disassembly. Remove pulley from shaft (use Puller Tool No. 8505-N). Remove bearing snap ring from front of pump body. Remove impeller from shaft (use Puller Tool No. 8505-N). Press shaft and bearing out through front of pump body, and press bushing and seal out through rear of pump If required, press ball-bearing off shaft.

▷*CAUTION—Use new impeller, seal, shaft, and bearing whenever water pump disassembled.*

Reassembly: Press new bushing in pump body with .5925" arbor (inside diameter of bushing installed should be .5920-.5925"). Press new seal in pump body with Tool No. 8564-P. Insert bearing snap ring on shaft and install bearing. Use Tool No. 8530 and press shaft and bearing into pump body (must press on outer race of bearing to avoid damaging bearing). Insert bearing snap ring in front of pump body. Support rear end of shaft and press pulley on front end until it bottoms against inner race of ball-bearing. Press impeller on rear end of shaft (clearance between impeller blades and pump body must be .030-.040"). Fill oil reservoir with #20 engine oil.

MERCURY PUMP WITH OIL CUP (FORD V8 SIMILAR)

FORD V8 PUMP WITHOUT OIL CUP (MERCURY SIMILAR)

NOTE—Above pumps replacement for pumps with oil cup.

▷*TEMPERATURE GAUGE FALSE READING CORRECTION (1954 8 Cyl. Engines):* In cases where heat indicator shows a reading higher than actual water temperature, check water temperature gauge bulb on engine to see that it is not contacting a casting flash inside cylinder head. Remove flashing with a rat tail file.

▷*RESTRICTED WATER BY-PASS CAUTION (1954 8 Cyl. Engines):* A restricted or blocked passage caused by casting flash will decrease flow of water in engine when thermostat is closed. Check for this condition by listening for gurgling sound when engine is stopped after short period of operation. If noise is heard, remove water by-pass tube and inspect for restricted opening in water pump housing. If necessary remove pump and drill opening with a 19/32" drill.

▷*1952 COOLING SYSTEM CHANGE FOR IMPROVED COOLING—See "Cooling" on 1952 Car Model Pages.*

DESCRIPTION: Pre-packed, double row ball bearing type requiring no additional lubrication. Shaft and bearing assembly is held in position with snap rings at front and rear of housing. Seal assembly is a unit containing graphite seal washer and neoprene shaft seal and spring. (Seal assembly cannot be disassembled and must be replaced each time pump is disassembled). A slinger is also provided to further protect the bearing assembly.

OVERHAUL: Disassembly. Remove pulley from shaft using tool 8505N or suitable puller. Remove bearing retainer snap ring from pump housing and press the shaft and bearing assembly out through the rear of the pump housing. Press shaft from impeller. Examine shaft and bearing assembly for roughness or excessive end play. Replace if necessary.
Assembly. Press new seal assembly into pump housing, using tool 8564P to prevent damaging seal. Press shaft and bearing assembly into front end of housing, positioning bearing so groove in bearing lines up with groove in housing and then install snap ring. Press shaft into impeller to give .030-.040" clearance between impeller and pump housing. Press hub onto shaft to give 4.480" (Ford), 3.9375" (Mercury), between outer face of hub and inner machined surface of housing.

HENRY J 4 CYL. WATER PUMP

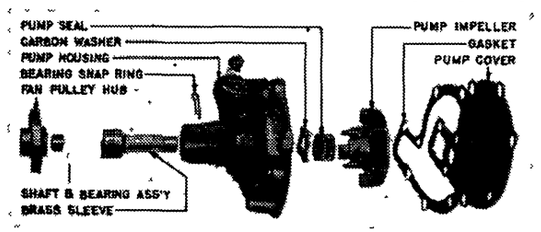
HENRY J 4 CYLINDER

All 4 Cylinder Series (1951-54)

DESCRIPTION: Packless type with double row ball bearing integral with pump shaft.

OVERHAUL: Disassembly—Remove fan from pulley and hub. Remove bearing retainer snap ring. Remove pump impeller with Puller W-116. If pump body properly supported, an arbor press can be used to press pump shaft out of both impeller and pump body. Remove seal and carbon washer. Remove drive shaft assembly from pump body by driving or pressing with arbor. Remove pulley and hub from drive shaft with Puller W-115.

Seal Seat Refacing: Reface as required.



Reassembly: Press pump drive shaft assembly into pump body just far enough to insert snap ring. Insert snap ring. Apply oil or fine graphite to carbon washer and to its seat on pump body, then install carbon washer and seal onto shaft. Press impeller onto shaft until flush with end of shaft. Make sure "ears" of carbon washer are properly entered into impeller hub slots. Check impeller position to assure clearance with pump body. Press pulley and hub assembly onto shaft until center of pulley V-grove is 3 9/32" from mounting face of pump body. Install fan to pulley and hub assembly.

1947-51 FRAZER & KAISER

Frazer (1947-51)
Kaiser (1947-50)

TYPE: Packless type with special double row ball bearing shaft (shaft serves as inner race, bearing is sealed type and packed with lubricant at assembly).

OVERHAUL: Disassembly. Take off fan blades and pulley. Remove pump cover and gasket. Take out bearing snap ring from slot in top of pump body.

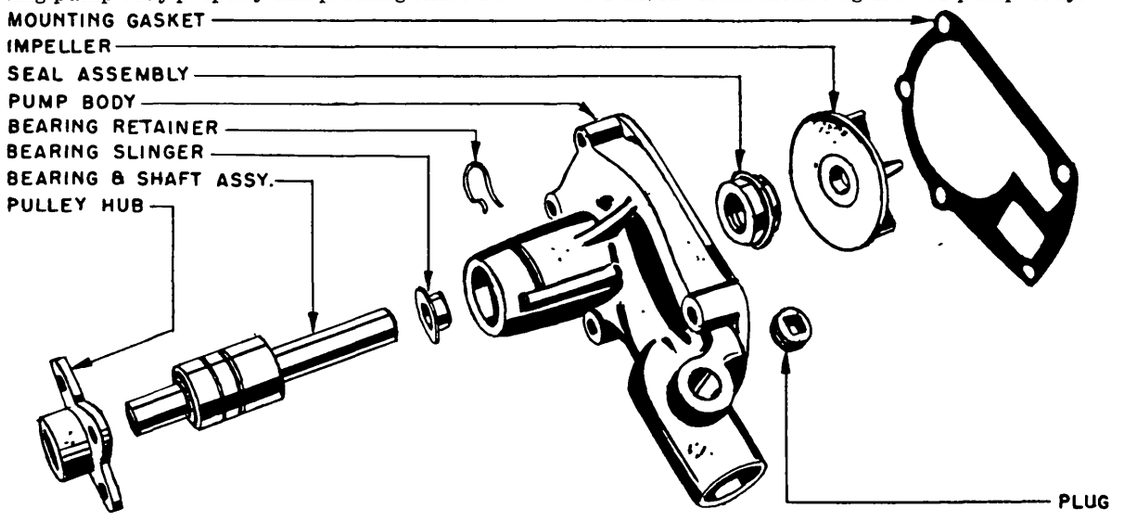
FRAZER & KAISER PUMP

If brass impeller blades used, drill two ¼" holes in hub next to shaft, spread hub and remove with puller (if necessary use torch and separate blades from impeller and then pull impeller hub off shaft). If cast-iron impeller used, press shaft out of impeller. Then take out pump seal and washer. Drive out shaft and bearing assembly.

Seal Seat Refacing: Reface as required.

Reassembly: If new shaft, bearing and sleeve assembly being installed, use new fan hub and press on shaft until hub 5/64" beyond end of shaft. Apply cup grease on shaft, sleeve, carbon washer, and seal surface in pump body. Install shaft assembly in pump body and lock in place with bearing snap ring. Place washer and seal on shaft, press impeller on flush with end of shaft. Impeller to pump body clearance should be 1/16". Install cover with new gasket.

HENRY J 6 CYLINDER



All 6 Cylinder Series (1951-54)

DESCRIPTION: Similar to 4 cylinder type except for seal assembly as follows:

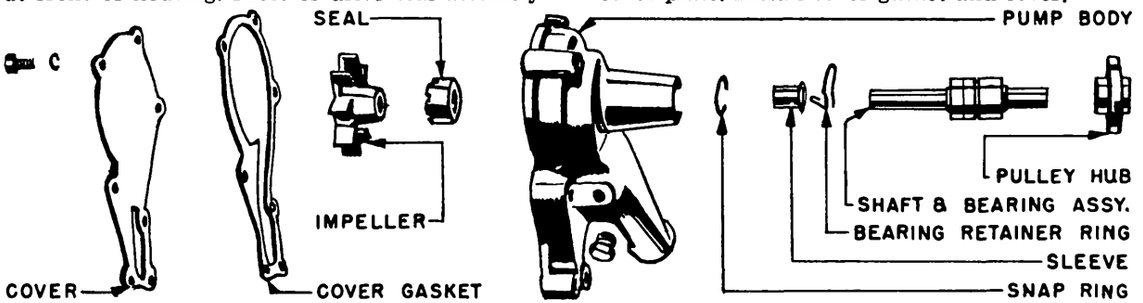
Seal Assembly—Consists of sleeve seated in recess in pump body with a rubber seal ('U' section with spring within 'U') and seal washer between seal impeller. Slinger is used on shaft

OVERHAUL: Disassembly—Remove fan and pulley from hub. Remove bearing retainer snap ring. Remove shaft from impeller and pump body by supporting pump body properly and pressing shaft free from both impeller and pump body. Remove hub from shaft with Puller W-115. Press or drive seal assembly out front end of pump body.

Reassembly: Carefully seat new seal assembly in pump body. Press shaft assembly into pump until front face of bearing aligned with front end of pump. See that seal washer in place and press impeller on rear end of shaft until flush with end of shaft. Install bearing snap ring in pump body (align groove in bearing with slot in pump body). Press hub onto shaft until center of pulley V-groove is 2 11/32" from mounting face of pump body.

HENRY J 6 CYL. WATER PUMP

1951-55 KAISER & 1954-55 WILLYS



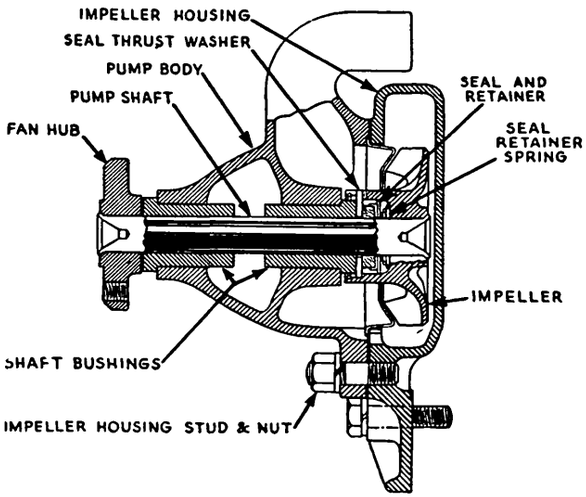
Kaiser (1951-55), Willys, 6 "226" (1954-55)

DESCRIPTION: Packless type with double row ball bearing. Pump shaft and bearing assembly are integral and cannot be disassembled. Seal assembly is a self contained unit pressed into pump body.

OVERHAUL: Disassembly—Remove fan and pulley from pulley hub. Remove pump cover and gasket. With Puller KF-29 and adapter, KF-113, remove impeller from pump shaft. Remove bearing retainer ring from slot in housing and press shaft assembly out front of housing. Press or drive seal assembly from pump body.

Reassembly: Press seal assembly carefully into pump housing. Apply oil or graphite to face of carbon seal washer. Press pump shaft and bearing assembly into pump housing just far enough to insert retaining ring, insert ring. Press impeller on until flush with shaft end. Check impeller position to be sure it clears cover.

Pulley Hub Installation—Press hub on shaft so fan mounting face is 5 7/32" from rear face of rear cover plate. Install cover gasket and cover.



1951-55 KAISER & 1954-55 WILLYS PUMP

1939-47 HUDSON

Hudson 6 & 8, All Models (1939-47)

TYPE: Packless type. Requires no adjustment in service. **Pumps with By-Pass—Pumps on cars with by-pass (for water re-circulation during warm-up) have a** 2nd water inlet with hose to cylinder head outlet.

SERVICING: Lubrication—Water pump grease fitting is special type with spring-loaded plunger which cuts off grease inlet when reservoir is filled to prevent overfilling. Lubricate at 1000 mile intervals using only an aluminum soap base grease.

HUDSON PUMP

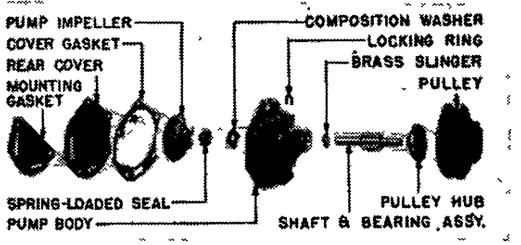
OVERHAUL: Disassembly—Remove fan, pulley, impeller housing screws and housing. Clamp pump **upright in vise (grip fan hub in vise jaws), mount tool set body on pump, assemble cutter and thumbscrew and cut burr off shaft at impeller end (turn cutter with wrench while applying pressure with thumbscrew). Install driver and press shaft through impeller, remove shaft from forward end. Lift off impeller and baffle plate, pull old bushings (rear bushing toward rear, front bushing toward front). Take out seal lock ring, remove seal.**

Bushing Installation—New bushings have inside diameter of .6205-.6206" which is reduced to .6185-.6190" when bushing pressed in place. Bushings cannot be reamed and special bushing pilot must be used to press bushings in (driving bushings with hammer cause bushings to collapse). Shaft clearance .0015-.0025" if bushings properly installed.

NOTE—Thrust face of rear bushing must be burnished smooth and flat to prevent thrust washer wear (Tool J-733A-8).

Assembly—Press new bushings into place. Assemble seal in following order: compression spring, seal retainer, seal, thrust washer, locking ring (see that it engages groove in impeller hub). Install shaft assembly, place baffle and new impeller assembly on shaft, peen impeller end of shaft (use ball peen hammer) until endplay as measured between pulley flange and front bushing face is .005-.009" (first type impeller), .010-.014" (1939 and later type impeller). Assemble impeller housing on pump body, fill reservoir with aluminum soap base grease.

1948-55 HUDSON



Hudson, All Models Exc. V8 (1948-55)
Hudson Jet & Super Jet (1953-54)

►*WATER PUMP LUBRICATION CHANGE:* Starting with 1955 engine number H-57911, the Rambler water pump lubrication fitting was eliminated and prelubricated water pump seal cartridge was used.

TYPE: Packless type with special double-row sealed ball-bearing shaft held by locking ring in housing. Bearing and shaft must be replaced as an assembly.

OVERHAUL: Disassembly. Remove locking ring from slot in housing, pump rear cover and gasket. Place pump assembly in "Water Pump Holding Fixture J-2778," and using shaft driver, press out pump shaft and bearing assembly with pulley hub attached. Check pump body bore with an inside micrometer. If this dimension greater than 1.1015", replace water pump body. Also check pump body and if impeller has been scraping body, it indicates excessive end thrust (replace complete pump).

Reassembly: Assemble the shaft and bearing in pump

HUDSON 6 & 8 PUMP

body. Bearing should be slight press fit into pump body, and assembled so that the groove on outer race is aligned with locking ring slot in pump body bore. When pressing bearing and shaft in housing, press against face of outer race, not against shaft. Install fan pulley hub. Proper pulley spacing should be. (Hudson Line 8) 4 27/32"; (Hudson 6) 5 5/32" (less Pwr. Strg.), 5 5/16" (Pwr. Strg.); Jet 5 1/64", from front face of **HUB** to cover face on rear of pump body. Assemble seal, combination washer and brass slinger in impeller and install impeller. **Impeller must extend out .007-.017" beyond cover face of pump body.** Install bearing locking ring, new cover gasket and install pump cover.

1955 HUDSON, NASH & PACKARD

Hudson, Nash & Packard V8 (1955)

TYPE: Centrifugal type, with non-adjustable packless type seal. Shaft and sealed double row ball bearing are integral assembly, prelubricated in assembly.

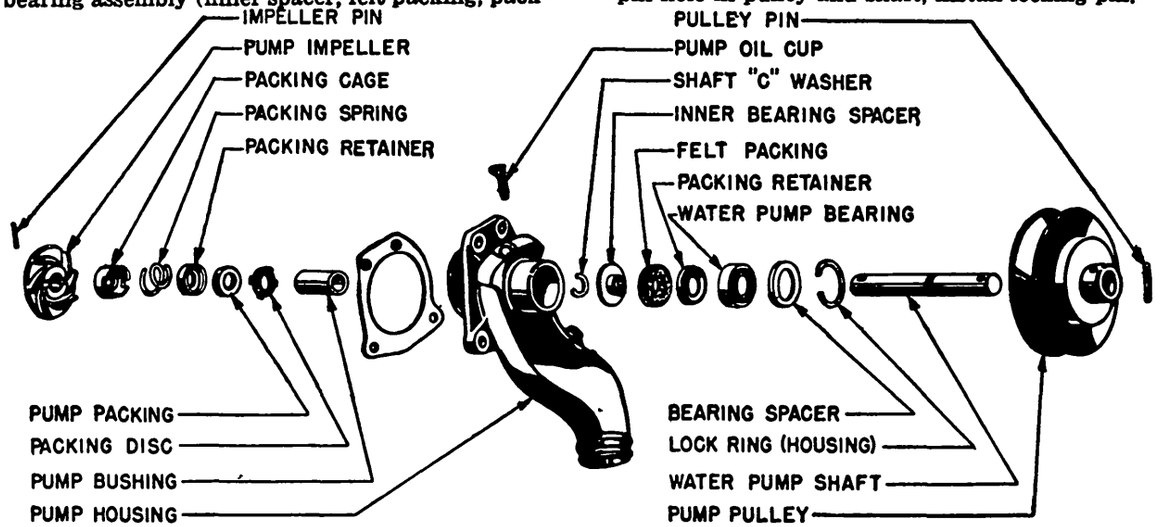
OVERHAUL: Disassembly—Remove bearing lock ring, press hub, shaft and bearing assembly out of impeller and cover. Press shaft and bearing assembly out of hub. Remove seal assembly.

Assembly—Install new seal assembly, new hub on shaft flush with end of shaft. Install shaft and bearing assembly in housing and install lock ring. Press impeller on shaft until flush with end of shaft. Clearance between impeller and cover must not exceed .090".

1940-48 LINCOLN

Lincoln, Zephyr & Cont'l 06H (Early 1940)
Lincoln, All Models (1941 to 1948)
(R.H.)—Right hand pump. (L.H.) Left hand pump.

TYPE: Packless type. Shaft mounted on ball bearing (front) and bronze bushing (rear).



SERVICING: Lubrication—Oiler provided for rear bushing. Lubricate with engine oil each 1000 miles.

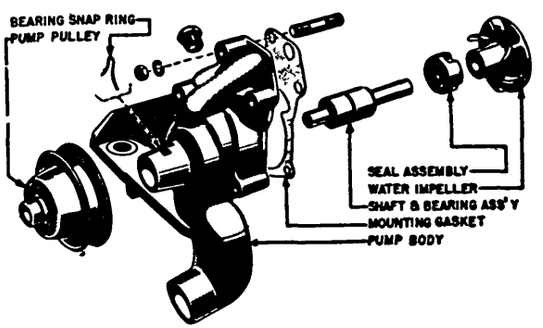
OVERHAUL: With pumps removed from engine, disassemble and service both pumps as follows:

Disassembly: Press out pin in impeller hub, press impeller off pump shaft, remove seal cage and seal parts (spring, packing retainer, packing, packing disc) from shaft. Press locking pin out of pump pulley, press pulley off shaft. Press shaft and bushing out at rear of housing ("C" washer in shaft groove will push bushing out). Remove bearing retainer snap ring from within forward end of housing, press bearing assembly (inner spacer, felt packing, packing retainer, bearing, and bearing spacer out at forward end of housing.

Seal Assembly—Seal is assembled in cage which fits on shaft in front of impeller. To assemble seal, install parts in cage in following order: Packing Spring (large end seated in cage), Packing Retainer Washer or cup (cupped end out to receive packing), Seal Packing (fits in cupped end of retainer), Disc or thrust washer.

Reassembly: Install inner bearing spacer, felt packing, and packing retainer in bearing recess in housing, press bearing and bearing spacer in housing, install bearing snap ring. Install "C" washer in groove on shaft, press shaft and bushing in pump housing. Install seal assembly on shaft (see seal data above), press impeller on shaft until locking pin hole in impeller and shaft are aligned, install locking pin. Press pulley on shaft and align locking pin hole in pulley and shaft, install locking pin.

LINCOLN 1940-48 PUMP (EARLIER ZEPHYR PUMP SIMILAR)



1949-51 LINCOLN

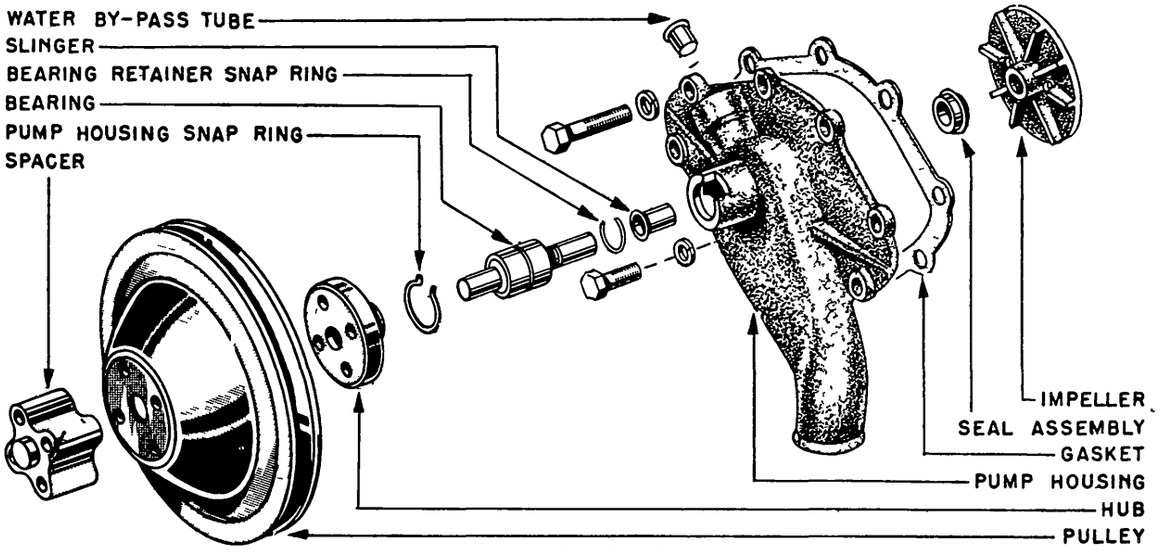
Lincoln & Cosmopolitan (1949-51)

TYPE: Packless type with sealed double row ball-bearing shaft (shaft serves as inner race for bearing). Bearing and shaft furnished as an assembly and cannot be dismantled.

OVERHAUL: Disassembly—Remove pulley from shaft (use Puller Tool No. 8505-N). Remove bearing snap ring from slot in pump body. Press shaft and bearing out through rear of pump body (use Tool No. 8564-N). Press impeller off shaft and take off seal assembly.

Reassembly: Carefully press new seal assembly in pump body (use Tool No. 8564-P). Press shaft and bearing into pump body from front (use Tool No. 8564-N) until groove in bearing aligned with slot in pump body, insert bearing snap ring. Press pulley on front end of shaft until pulley flush with end of shaft. Press impeller on rear end of shaft, impeller must be flush to .010" under pump body rear face.

1949-51 LINCOLN V8 PUMP



1952-55 LINCOLN

Lincoln, All Models (1952-55)

TYPE: Packless type with sealed double row ball-bearing shaft (shaft serves as inner race for bearing). Bearings are permanently lubricated and require no additional attention in service. Shaft retained by locking ring in slot in pump body.

OVERHAUL: Disassembly—Remove snap ring from groove in front of pump housing, directly behind pulley (NOTE—If pump has pressed steel pulley, remove pulley first, then remove snap ring). Using arbor press, piece of bar stock having smaller diameter than pump shaft, and Tool 8501-DD-21 with three pins installed in tool, press shaft and bearing assembly and pulley from impeller. Remove impeller. Press shaft and bearing assembly and pulley from housing. Using Tool 8501-DD-16 and piece of bar stock, press shaft and bearing assembly from pulley. With Tool 8501-DD-19 press seal and sleeve assembly from pump housing. NOTE—It is not necessary to remove snap ring in center of pump housing.

Reassembly: Coat all surfaces of pump lightly with cup grease. Install shaft and bearing assembly in pump housing using Tool 8501-DD-19. *(CAUTION—* When pressing shaft into housing, stop applying pressure when resistance is felt or the snap ring inside housing will be broken). Install snap ring at front of housing to retain shaft and bearing assembly. Using Tool 8501-DD-17 or DD-18, depending on type of seal and sleeve assembly used, and Tool 8501-DD-16, install seal and sleeve assembly into housing. Remove pins from Tool 8501-DD-21, and turn tool upside down. Place Tool 8501-DD-22 in center of Tool 8501-DD-21 and place both tools on arbor press. Lower adjusting screw in center of tool by turning counter-clockwise. Install impeller on shaft assembly and set pump on tool so impeller is on tool recess. Press downward until pump body makes light contact with tool. This automatically sets impeller-to-housing clearance. Turn screw in Tool 8501-DD-21 clockwise until it contacts the shaft assembly. Using Tool 8501-DD-19, install water pump pulley hub. NOTE—It is necessary that the distance from the lower surface of the pump pulley to the machined surface of the housing be maintained as near to 3 15/16" as possible. This will assure correct pulley alignment.

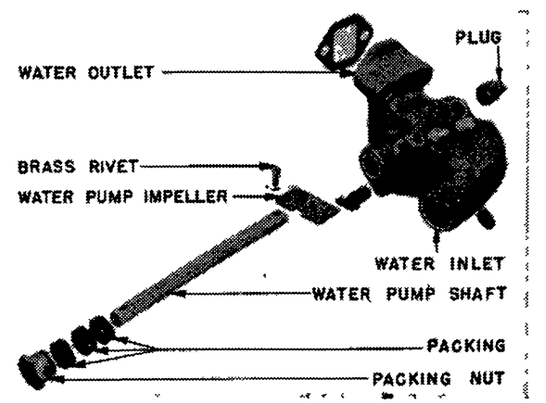
1952-55 LINCOLN PUMP

1939-49 NASH

Nash Six, All Models (1939-48), "600" (1949)

Nash Eight, All Models (1939-42)

NOTE: Pumps on all models are similar design but **have slight differences in construction (cover plate at rear n some models, at front on shaft on others). All models serviced in same manner.**



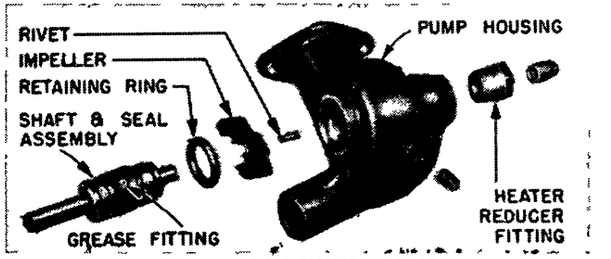
TYPE: Adjustable packing type with 'floating impeller'. **Pump is mounted on side of engine block and driven by flexible coupling from generator armature shaft. Packing adjusting nut provided on** shaft on forward end of pump. Shaft operates in bronze bushing pressed in pump body.

SERVICING: Packing Adjustment. Adjusted in usual **manner by turning up packing adjusting nut. Make adjustment with engine running and turn up nut only enough to stop leaks.**

Lubricati n. Pressure fittings on housing at rear of packing nut. Lubricate with water pump grease at 2000 mile intervals (1942 and earlier cars), 3000 mile intervals (1946-47-48 cars). CAUTION—Lubricate sparingly—do not use high pressure grease gun.

OVERHAUL: Disassembly. Remove impeller by taking out plug in pump and drive out brass rivet while supporting shaft through water outlet. Remove packing nut and withdraw shaft. If bushing removal required, use Water Pump Bushing Remover and Replacer Tool J-1419.

Reassembly: If new bushing being installed, use Replacer Tool J-1419 and ream bushing with Bushing Reamer KMO-314. Install shaft in pump, place impeller on shaft with rivet holes aligned, peen rivet (supporting shaft through water outlet). Install packing rings (3 total) one at a time and draw each one down with packing nut (do not set packing nut tight until pump on engine and allowed to run in).



1939-49 NASH WATER PUMP

1949-55 NASH

Nash, All Models Exc. 1949 "600" & 1955 V8

DESCRIPTION: Centrifugal blade type, with a sealed-in shaft sealing assembly. This is of the cartridge

1949-55 NASH WATER PUMP

in shaft sealing assembly (cartridge type, factory sealed and lubricated. Cannot be dismantled). Held in pump body by flexible rubber ring.

OVERHAUL: Disassembly. Remove plug in pump body and drill or drive out rivet holding impeller to shaft. Support shaft through water outlet hole during this operation. Seal and shaft assembly can then be removed from pump body.

Assembly. Insert new rubber retainer in pump body, then apply a small amount of soapy water to the inner part of the rubber ring. Install new shaft and seal assembly. Install impeller using a new rivet to fasten impeller to shaft. Lubricate with chassis lubricant.

1939-54 OLDSMOBILE & PONTIAC

Oldsmobile 6 (1939-50)
Oldsmobile 8 (1939-49)
Pontiac 6 & 8, All Models (1939-54)

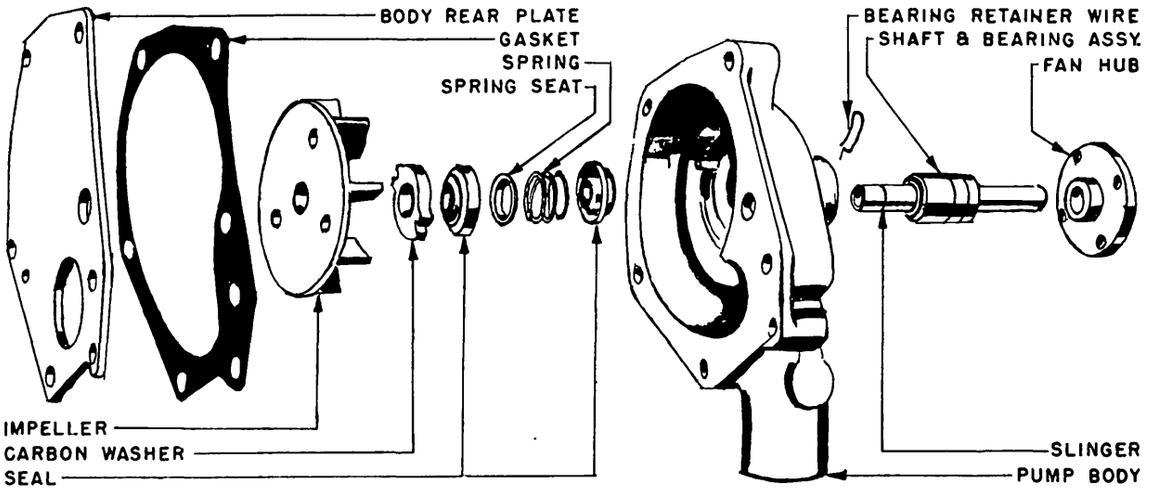
►*LATE 1951 PONTIAC PRODUCTION CHANGE*—Pump provided with seal lubrication. Drain hole has been eliminated so oil will be retained in seal cavity. Fill through upper vent hole.

►*LUBRICATING WATER PUMPS ON EARLIER CARS*—If pump has a drain hole, plug hole with a bottle cork and then fill through upper vent hole.

SPECIAL SERVICE NOTES: 1941 Pontiac Pump Shaft & Bearing Assemblies—1941 pumps serviced by 1942 type shaft and bearing assembly which is furnished with brass moisture slinger (as used in 1942 pumps) installed on shaft. When installing this type shaft in 1941 pump, remove brass moisture slinger from shaft (use pliers) and install neoprene bearing shield (included separately in all service packages) in pump instead. CAUTION—1941 pumps not counter-bored for brass slinger clearance and slinger must not be used in these pumps.

TYPE: Packless type with special factory-lubricated ball bearing shaft. No adjustment or lubrication required. *See NOTE above.*

1940-50 Oldsmobile—New type Brass Moisture Slinger used instead of Neoprene bearing shield. See special Moisture Slinger service data below. Fan pulley hub is ⅛" shorter than type used on 1939 cars and earlier type cannot be used on these cars. NOTE—By-pass to cylinder head is not used on 1942 Eight Cylinder models (by-pass on all 1942 models is similar to type used on 1941 and previous Six Cylinder Models). See Installation Note below for new type gaskets required for 1942 Eights.



1940-41 Pontiac—All models have same type Neoprene bearing shield as used on late 1939 pumps. See Bearing Shield service data below.

1942 Pontiac—Neoprene bearing shield is not used and new type brass moisture slinger is installed on all 1942 Pontiac Pumps (similar to type used on Oldsmobile). All service shaft and bearing assemblies are furnished with brass moisture slinger installed. Refer to Special Service Note above for removal of slinger when using 1942 type shafts for replacement on 1941 Pontiac Pumps.

1946-53 Pontiac—Brass moisture slinger on shaft (see 1942 data above) is longer and extends through the seal and carbon washer to protect surface of shaft from corrosion. Service shaft and bearing assemblies are furnished with the moisture slinger installed.

OVERHAUL: Disassembly. Remove fan and pulley and cover plate on rear of pump housing. Take out shaft retainer wire (bearing lock ring) in slot at top center of bearing hub on housing. Support front face of pump housing in arbor press, press shaft and bearing assembly out of impeller and housing toward front end. Remove seal assembly from housing (On Oldsmobile models, first take out locking ring in seal recess at rear of housing). If shaft and bearing assembly being replaced, press fan hub off old shaft and install on new shaft.

Servicing—If bearing retainer wire worn (indicating that bearing rotates and has excessive end thrust), or if impeller scrapes on housing due to excessive end thrust, pump assembly should be replaced. If bearing is rough or bearing seals loose in outer race so that they can be turned by hand, replace bearing and shaft assembly. Carbon washer, rubber seal, and spring are furnished as a package unit.

1939-54 OLDSMOBILE & PONTIAC WATER PUMP

Neoprene Bearing Shield (1939 Oldsmobile, 1939-40-41 Pontiac)—Install shield in bearing bore in pump housing with smaller diameter end toward impeller and larger diameter end toward bearing before installing shaft and bearing assembly in housing.

Brass Moisture Slinger (1942-53) Pontiac—Service shaft and bearing assemblies are furnished with this slinger installed and there should be no occasion to remove slinger unless shaft is being used for replacement on 1941 Pumps (refer to Special Service note above). **NOTE**—Slinger on 1946-50 pumps is longer type and extends through washer and seal.

Brass Moisture Slinger (1940-50) Oldsmobile. Install slinger on shaft before shaft and bearing assembly installed in pump housing. Start slinger on shaft with flared end toward bearing, stand shaft and bearing assembly in arbor press with slinger end up, use special tool J-1446 to press slinger down on shaft until slight drag felt on .025" feeler placed between end of bearing and slinger, then install assembly in pump housing. CAUTION—This .025" clearance between slinger and bearing necessary for proper protection of bearing without danger of slinger dragging on bearing which will cause noise.

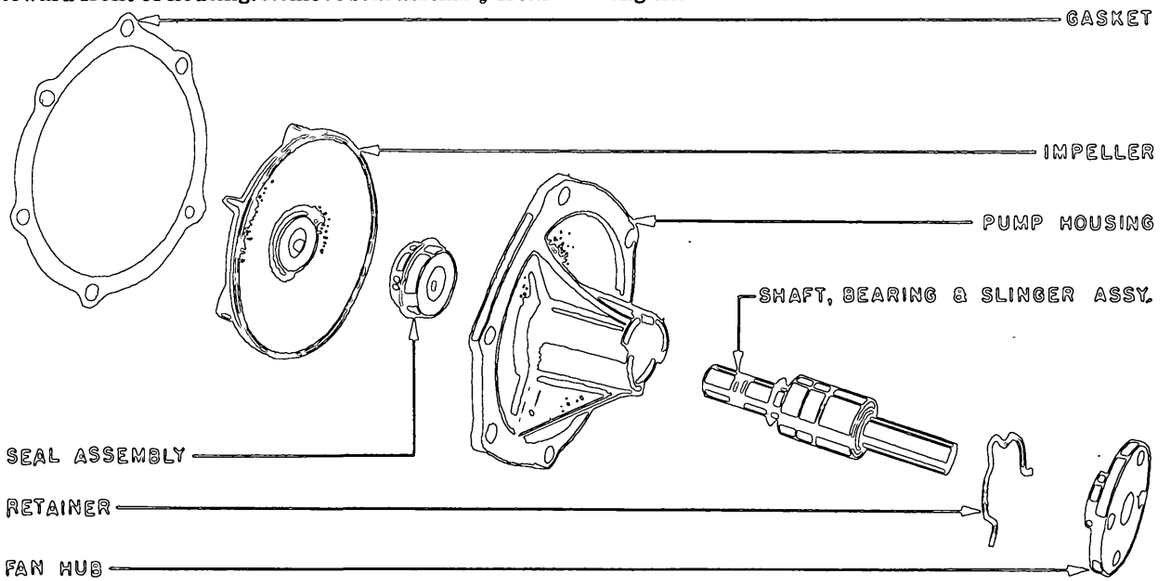
Seal Assembly—Machined seal seat in pump housing must be smooth and clean to insure good seating of seal. Clean seat with thinner to remove all dirt and gum and wipe dry (seal seat inthe pump body can be cleaned by using special Pump Body Cleaning Reamer No. J-1455). Install seal assembly in pump housing in following order: Inner Spring Cup (cupped side out), Spring, Outer Spring Cup (flanged end out toward seal), Rubber Seal (smaller diameter out—make certain that flared portion of inner spring cup enters seal so that it is retained in housing when installed), Graphite Seal Washer (polished side toward impeller). On Oldsmobile models, install locking ring in groove in housing to retain seal parts. Make certain that all seal parts are properly seated and do not hang up on sides of casting. On Pontiac, make certain that ears on graphite washer engage slots in body (1939-42), or that notches in ears of graphite washer engage the pins in body (1946-53).

NOTE—On Oldsmobile models, tool #J-1456 should be used to install seal. Installation will be facilitated by wetting housing with soap solution.

Pump Assembly—Insert shaft and bearing from front, lining up retainer grooove with slot in housing (if bearing is press fit in housing, remove fan hub install bearing in arbor press applying pressure on outer race only, re-install fan hub applying pressure to impeller end of shaft and allowing housing to float on bearing so that no pressure exerted on bearing or races). Press impeller on shaft (support assembly on fan end of shaft) until clearance between rear face of impeller and face of cover plate flange on housing is 1/32" (Oldsmobile), 3/64" (Pontiac). Install shaft retainer wire through slot in housing, use new gasket when installing pump rear cover plate.

Installation (Oldsmobile only)—Use new rubber grommet between water pump and by-pass port in cylinder head to prevent leaks at this point when pump installed on engine. NOTE—This bypass not used on 1939-42 Six Cylinder or 1942 Eight Cylinder Models. Refer to following note for 1942 Eight Cylinder Gasket data.

Oldsmobile 1942 Pump Note—New type by-pass on 8 cylinder models consists of hole in rear cover plate opening into hole in front face of block. Requires new type gaskets as follows:
Pump Cover Gasket (1942 6 & 8).....No. 416432①
Pump-to-Block Gasket (1942 6 & 8).....No. 416433②
①—May be used on all 1939-40-41-42 6 & 8 cylinder models. Previous type gasket No. 411045 may be used on 1942 8 cyl. cars by punching hole for by-pass.
②—May be used on all 1939-40-41-42 6 & 8 cylinder models. Previous type gasket No. 411046 may be used on 1942 6 cyl. cars but cannot be used on 1942 8 cyl. cars.



1949-55 OLDSMOBILE & 1955 PONTIAC

Oldsmobile V8, (1949-55)
Pontiac V8, (1955)

DESCRIPTION: Permanent seal, permanently packed double row ball bearing type. The permanent seal consists of a graphite washer (against which the impeller turns) backed with a neoprene seal and spring assembled in a sealed housing. This seal cannot be disassembled and must be replaced each time the pump is disassembled.

OVERHAUL: Disassembly. Remove fan and two fan pulleys. Remove six water pump attaching bolts and take pump from engine. Remove bearing housing from front of pump and remove snap ring bearing retainer. Support bearing housing in arbor press and press shaft through impeller and housing with a ½" x 2½" drift, pressing on impeller end of shaft toward front of housing. Remove seal assembly from housing by driving against inside of seal with a drift punch. Clean housing and impeller seal seat.

Assembly: Press bearing shaft, (end with two small grooves toward impeller) slinger and shaft assembly into bearing housing, using tool BT-16. (In the event that new shaft and bearing assembly is used, it will be necessary to assemble slinger and hub to shaft before pressing into housing). Install seal in housing, pressing into place with tool BT-16, until shoulder of seal is in positive contact with housing. Support impeller (Bt-15) and press bearing shaft through impeller until bottom edge of vanes are 13/16" from machined face at edge of housing. Install bearing retainer snap ring. Install new gasket using cement on one side and mount bearing housing on pump housing. Four mounting bolts should be dipped in CP-9 Sealer. Install pump on engine.

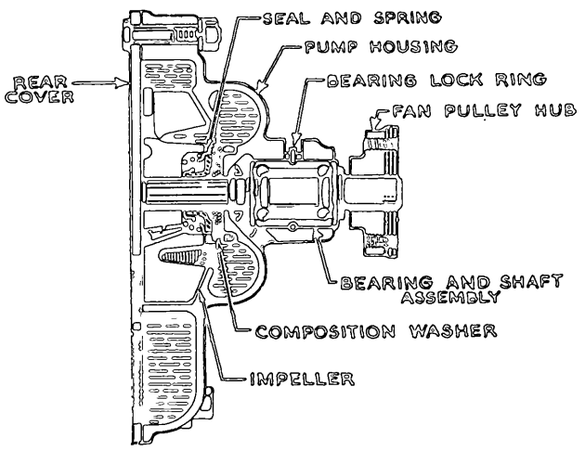
1949-55 OLDSMOBILE & 1955 PONTIAC WATER PUMP

1951-54 PACKARD

TYPE: Packless type with ball-bearing shaft. No lubrication required in service.

OVERHAUL: Disassembly—Using screwdriver, pry out bearing retainer lock. Remove pump rear cover plate and gasket by taking out screws and bolts. Support the pump body securely and press shaft out of impeller (NOTE—Shaft and bearing assembly consists of shaft, bearing and brass bushing which is pressed on long end of shaft). Press seal assembly out of water pump body. Press fan hub off shaft.

Reassembly: Press fan hub on shaft and bearing assembly. Install this assembly into pump body with groove in center of bearing and shaft assembly lined up with slotted opening in water pump body. Insert bearing lock through this opening and spring end of bearing lock over pump body hub. Support pump body and press seal into bore until it bottoms against shoulder in pump body. Support pump body and press impeller onto shaft, leaving a clearance of .030" plus or minus .010" between face of impeller and pump body. Coat cover gasket with Perfect Seal Grade A paste or its equivalent, install gasket on body. Assemble pump cover plate with the attaching screws and tighten. Coat smaller gasket (water pump assembly gasket) with Perfect Seal Grade A paste or its equivalent, then position it on body. Install pump cover attaching bolts and nuts and torque tighten to 15-18 ft. lbs.



1939-50 PACKARD

Packard 6 & 8, All Models (1939-50)

TYPE: Packless type with ball-bearing shaft. No lubrication required in service.

OVERHAUL: Note—Rebuilt pumps available from factory on 'exchange' basis. To service pumps proceed as follows:

Disassembly—Remove fan and pulley, take out bearing locking ring in slot in bearing hub on housing. Support pump housing in arbor press, press impeller off shaft, remove shaft and bearing assembly through front of housing. To remove seal, take out locking ring in impeller hub, withdraw composition thrust washer, rubber seal, spring cup and spring. NOTE—Do not remove fan pulley hub or attempt to remove bearing from shaft. Shaft, bearing, and pulley hub serviced as an assembly.

PACKARD PACKLESS, BALL-BEARING PUMP

Seal Assembly—When installing seal in impeller, make certain that small end of spring in toward impeller, coat inner surface of seal with glycerine and install with larger flanged face out toward composition washer, install composition thrust washer with smooth (convex) face out toward pump housing, install locking ring.

NOTE—Machined face of pump body on which seal washer bears must be smooth and flat. If this surface rough or scored, resurface face or replace pump body.

Assembly—Install shaft and bearing assembly in pump housing making certain that locking ring groove in bearing lines up with slot in pump housing. Coat impeller end of shaft with glycerine (to prevent damage to seal when impeller pressed on. Heat impeller in water just under boiling point for 1½ minutes, press impeller on shaft until clearance between impeller vanes and housing is .012-.074". Coat pump cover gaskets with Perfect Seal Grade A gasket paste when installing cover. Make certain that bearing locking ring installed in pump housing slot.

1939-55 STUDEBAKER (PACKLESS TYPE)

Champion, All Models (1939-55)
Commander, All Models (1947-50)
President, (1941-42)

TYPE: Packless type with spring loaded rubber seal and fiber thrust washer assembled within recess in impeller. Shaft mounted on special sealed double row ball bearing which is an integral assembly with the shaft (bearing cannot be removed and assembly serviced as a unit). Pump requires no lubrication in service.

Champion 1947-53. New seal used, consisting of a rubber bellows with a spring installed on the outer circumference and bearing on the ends of the seal to maintain seal contact on impeller and thrust washer faces.

President 1941-42. This pump new packless type with ball-bearing shaft. Similar to design used on Champion except that impeller located within pump housing. Serviced in same manner as Champion pump except that rear cover plate must be removed from housing before pump can be disassembled. Use new gasket when replacing cover plate.

Commander 1947-50. Seal is shown in illustration below. Pump has rear cover (adapter plate).

OVERHAUL: Disassembly. Remove bearing lock ring from slot in housing hub at center of bearing. Support housing in arbor press, press shaft and bearing assembly out of impeller and housing toward front end, lift off impeller and remove seal and thrust washer from impeller recess. Support fan hub in arbor press and press shaft out of hub (new hub must be used when reassembling pump—old hubs will not be sufficiently tight fit on shaft).

Servicing—Impeller assembly must be replaced as a unit. If seal thrust washer bearing surface in pump body is rough or scored, resurface with special Pump Facing Tool J-1501.

Seal Assembly (1939-40)—Spring and cups are located within rubber seal. Install rubber seal in impeller hub and place fiber thrust washer on rubber seal so that ears engage slots in impeller and washer contacts face of water pump housing when impeller installed.

Seal Assembly (1941-42)—Install seal parts in impeller hub in same order as removed. See that ears on spring plate, seal, and thrust washer engage slots in impeller hub, install locking ring in hub and see that ring properly seated in grooves.

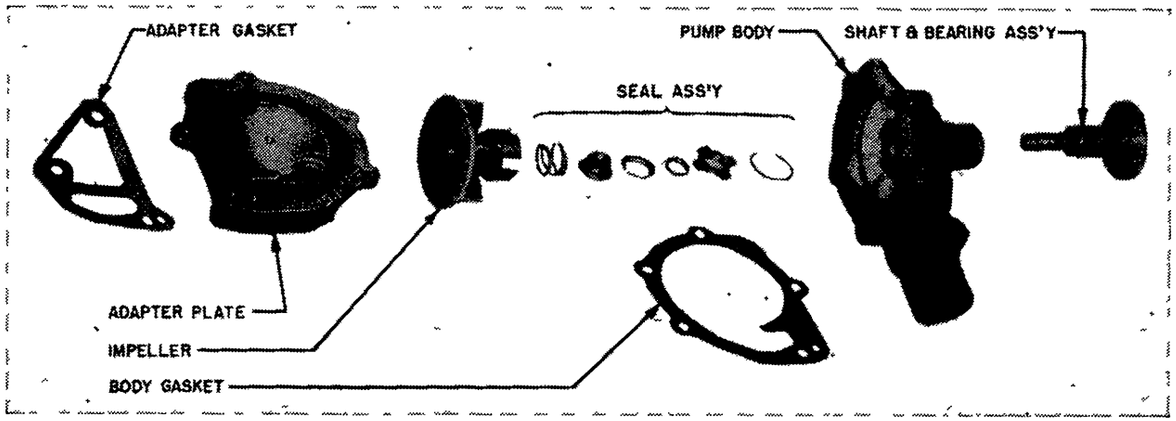
Seal Assembly (1946-53)—See that spring properly installed on seal, install seal and thrust washer within impeller hub making certain that thrust washer ears engage slots in hub, install locking ring to retain seal assembly in hub.

Pump Assembly—Press new fan hub on shaft so front face is flush with end of shaft, install shaft and bearing assembly in pump housing so that groove in bearing lines up with locking ring notch in housing, install locking ring. Press impeller on shaft until clearance between edge of impeller vanes and the pump body is .015-.031". On the Commander & President models, use new gasket when installing pump rear cover plate (no cover used on Champion).

STUDEBAKER (ADJUSTABLE PACKING TYPE)

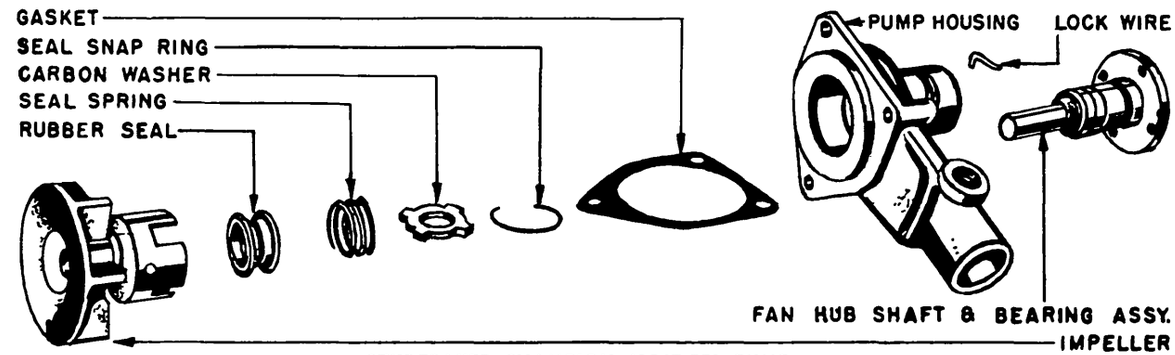
Commander, All Models (1939-42)

TYPE: Adjustable packing type. Packing located under adjusting nut at forward end of rear bushing. Shaft mounted on two bushings in pump housing (front bushing within fan pulley).



ADJUSTMENT: Adjust packing by turning up adjusting nut (insert screwdriver between pulley and pump housing). Packing is grapho-metal ring type and requires more pressure than ordinary packing. To renew packing, thoroughly clean out old packing, install four new packing rings, one at a time, tightening adjusting nut down on each ring as it is installed. This special ring packing prevents shaft scoring (with more than ordinary adjusting nut pressure) and gives longer service.

OVERHAUL: Disassembly. Remove fan and pulley (on models where these are mounted directly on water pump shaft), take off rear cover plate on pump housing, drive out pin on the fan hub (Dictator 1936-37), press fan hub or coupling off shaft. Withdraw impeller and shaft through rear of pump housing (impeller pinned to shaft). Remove packing nut and packing, press rear bushing out to rear (see Note), front bushing out toward front end.
NOTE—On President 1936-37 models, rear bushing is inserted in blind hole in pump rear cover behind impeller.



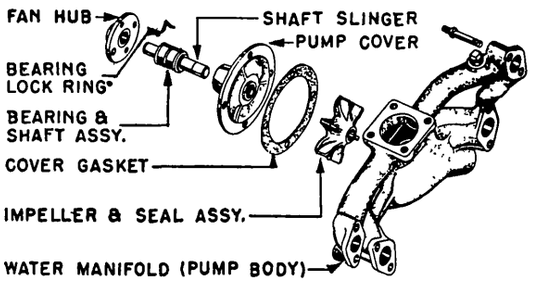
Bushing Installation—Press new bushings in and check clearance on shaft. Should be .001-.003" (bushings need not be reamed if clearance is correct).

Assembly—Reverse disassembly directions. Make certain that thrust washer installed on shaft next to impeller before installing in pump housing. When pressing fan hub on shaft, see that clearance between hub and flange on forward bushing is .003-.005" for correct endplay. See Packing renewal instructions under Adjustment above.

Fan Hub Servicing—New fan hub should be installed whenever hub removed from water pump shaft. Hub must be tight fit on serrated end of shaft and will be loosened by removal so that tight fit cannot be secured if hub re-installed.

STUDEBAKER COMMANDER (1947-50) PUMP

STUDEBAKER CHAMPION (1947-55) PUMP



1951-55 STUDEBAKER COMMANDER V8

Commander, All Models (1951-53)
Commander & President, All Models (1954-55)

TYPE: Pump has ball-bearing shaft. Bearings are pre-lubricated and pump packings are non-adjustable.

OVERHAUL: Disassembly—Remove four capscrews which retain cover to pump housing. Remove cover and impeller assembly from pump. Remove bearing lock ring. Place assembly in arbor press and press hub, shaft, and bearing assembly out of impeller and cover. Press shaft and bearing assembly out of hub. Remove four capscrews which retain water outlet to pump housing. Remove outlet, gasket, and thermostat.

Reassembly: Press a **new** fan hub on shaft so that it is flush with end of shaft. Insert shaft in housing, install bearing lock ring. Then install **new** seal assembly in impeller and press impeller on shaft so that impeller is flush with end of shaft. Clearance between impeller and cover must **not** exceed .090". Position assembly on pump housing, aligning holes of cover and housing. Place **new** copper gaskets on cover retaining screws and install screws securely.

1951-55 STUDEBAKER V8 PUMP

WILLYS 6 CYLINDER

Willys, All Models (1948-55)
Willys, 6 "226" Eng. See 1951-55 Kaiser

TYPE: Similar to 4 cylinder type except for seal assembly (See 6 Cyl. Note under Willys 4 Cyl).

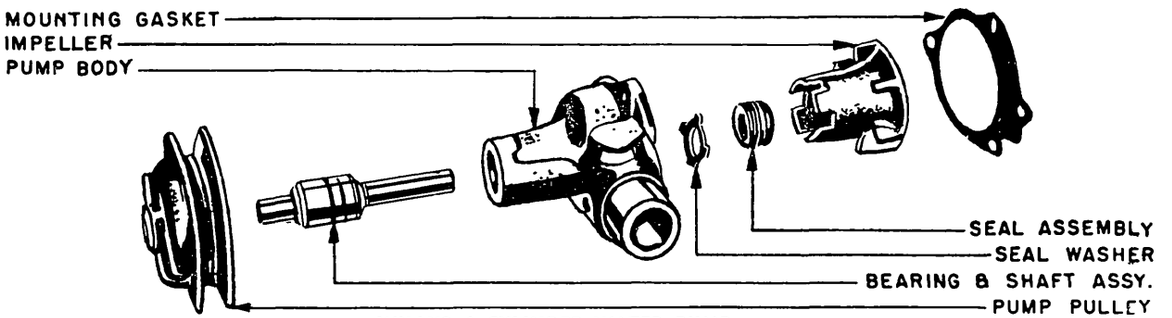
OVERHAUL: Disassembly. Take out bearing snap ring from hole or slot in pump body (pulley may have to be removed for access to snap ring). Pull impeller off shaft. Take out seal washer. Press shaft and bearing assembly out through forward end of pump.

Reassembly: Carefully seat new seal assembly in pump body. Press shaft assembly into pump until front face of bearing aligned with front end of pump. See that seal washer in place and press impeller on rear end of shaft until flush with end of shaft. Install bearing snap ring in pump body (align groove in bearing with slot in pump body). Press pulley on front end of shaft if removed.

WILLYS 4 CYLINDER

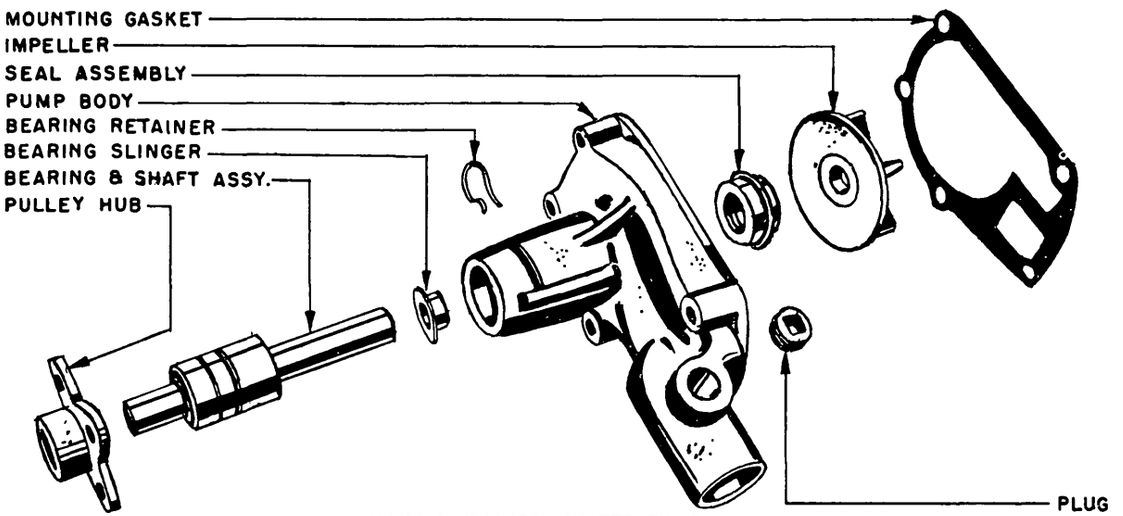
Willys, All 4 Cyl. Models (1940-55). See 4 Cyl. Note below.

TYPE: Packless type with special double row ball bearing shaft (shaft serves as inner race, bearing is **sealed type and packed with lubricant at assembly). Shaft and bearing cannot be dismantled and serviced as an assembly. No lubrication required in service.** Various type seals used (See Notes below).



4 Cylinder Seal Note—Seal is one of two types, either "U" shaped with spring within seal or bellows type with spring assembled on outer circumference of seal.

6 Cylinder Seal Note—Seal assembly consists of sleeve seated in recess in pump body with a rubber seal ("U" Section with spring within "U") and seal washer between seal and impeller. A slinger is used on shaft just behind bearing.



OVERHAUL: Disassembly—Use special W-116 puller **and pull impeller off shaft, lift out bakelite seal washer. Remove bearing lock ring from slot in bearing hub on pump housing, support pump housing in arbor press, press shaft and bearing assembly out of pump housing toward forward end. To remove fan pulley from shaft, use any regular puller (special W-115 puller furnished for this purpose) to pull pulley off shaft. Do not attempt to remove bearing from shaft (shaft and bearing serviced as assembly).**

Servicing—If rear face of pump housing is not smooth and flat, resurface with special Tool C-551 or install new pump body.

Pump Reassembly: Install shaft and bearing assembly in pump housing (long end of shaft to rear) so that outer end of bearing is flush with front end of housing. Install seal assembly in impeller (dip seal parts in brake fluid before installing), press impeller on shaft until end of shaft is flush with face of impeller hub. Press fan pulley on forward end of shaft until end of shaft is flush with face of pulley. Check location of locking ring groove in bearing with respect to slot in housing, align groove and slot, install bearing locking wire.

1953-54 CHRYSLER, DESOTO, DODGE AIRTEMP

Chrysler, DeSoto, Dodge (1953-54)

DESCRIPTION

Compression process cycle type, using Freon as refrigerant. System consists of basic groups of elements as follows:

Refrigerating: Compressor—4 cylinder, V-type piston compressor, located at right front corner and above engine. Operated by wedge belt from pulley on water pump through idler pulley which provides for belt tension adjustment. Operation causes and maintains necessary high pressure in system needed to increase Freon vapor temperature.

Condenser—Split type. Upper section of condenser located in front of radiator, lower section fills entire space between bottom edge of radiator and front stone shield. Condenses and cools refrigerant vapor discharged from compressor, through action of fast moving air over metal surfaces of condenser.

By-Pass Valve—Automatic. Between the compressor and evaporator. By-passes hot refrigerant gas directly from compressor to evaporator when temperature falls to preselected minimum. By-passed hot gases raise temperature of evaporator coils and car cooling air; also prevents ice forming on coils when blowers stopped, and maintains sufficiently rapid circulation of refrigerant to carry entrained oil back to compressor. A thermal bulb, located in return air stream on right side of car, is the valve's sensing element through reaction to changing temperatures within car.

Receiver—Located at outside edge of car frame below right front door. Stores liquid refrigerant, more than that needed for normal operation, and assures an uninterrupted supply of liquid refrigerant to expansion valve.

Sight Glass—In evaporator-blower in trunk of car between receiver and strainer-dryer. Provides means for determining adequacy of refrigerant charge.

Strainer-Dryer—In evaporator-blower housing in trunk of car between sight glass and expansion valve. Filters and dehydrates Freon as it passes through system.

Expansion Valve—In evaporator-blower housing in trunk of car. Supplies liquid to evaporator coils at same rate that refrigerant is removed from it in a vaporous state.

Evaporator—In evaporator-blower housing in trunk of car. Container for refrigerant which readily absorbs heat from surrounding area when temperature of refrigerant liquid is reduced. In cooling coils of the evaporator refrigerant is changed from liquid to vapor.

Air Circulating: Blowers—In evaporator-blower housing in trunk of car. Consists of two centrifugal blowers driven by a single electric motor mounted between them. Force air from refrigerated area in evaporator-blower housing to interior of car.

Air Circuits—Warm air from inside car is drawn into evaporator-blower housing through grilles on either side of rear seat shelf, cooled air is delivered into car through a center outlet. Fresh air is drawn in from each side of car through 3 holes. All inlets and outlets are connected to evaporator-blower housing through ducts. Fresh air ducts are fitted with dampers to seal them off during cold weather.

Control: Single instrument panel control is switch located at extreme left below car light switch. Switch has four positions "OFF," "LOW," "MED.," and "HIGH." Its various positions regulate blower speed and hence rate at which cooling air is circulated through car. The automatic by-pass valve (see above) provides additional control of minimum interior temperatures.

OPERATION

With Air Conditioner Control Switch in any of the three "ON" positions and engine and compressor operating, heat laden, low pressure Freon is compressed by the compressor and discharged into condenser where it is cooled to remove the "sensible" heat of compression. The Freon is forced into the receiver under pressure when by-pass valve is closed. After passing through sight glass and strainer-dryer Freon enters the expansion valve. At orifice in expansion valve high pressure liquid Freon changes to low pressure liquid, then enters evaporator coils through distributor tubes. The "boiling" Freon, while in the evaporator coils, absorbs heat from the surrounding air and vaporizes. The vapor is drawn through the low pressure line to compressor where cycle is repeated.

PRECAUTIONS, LEAK TESTING & TROUBLE SHOOTING

See "Air Conditioning Service Cautions," "Trouble Shooting" and "Leak Tests."

ADJUSTMENTS

DRIVE PULLEY BELT: Two type belts used, single and double. Adjust as follows:

Single Type Belt: A deflection of ¼" should result when a load of 6 to 8 lbs. is applied at center of longest belt span (compressor to fan, or generator to fan).

Double Type Belt: A deflection of ¼" should result when a load of 9 to 11 lbs. is applied to each individual belt at the center of longest span (fan to idler).

TEMPERATURE: Temperature range can be varied 10 degrees either way by means of adjusting screw on automatic by-pass valve. Each full turn changes range 2½°.

FAST IDLE (If So Equipped): *See "Adjustments" under 1955 Chrysler, DeSoto, Dodge "Airtemp."*

DISCHARGING THE SYSTEM

1) Install Gauge Set Manifold C-3354. Fully backseat both discharge and suction service valves (counter-clockwise). Connect 6-foot test hose to manifold center fitting. Insert free end of hose into exhaust suction system and turn exhaust system blower on. *NOTE*—Although Freon is non-toxic unless released in or near an open flame, expelling Freon gas into the exhaust system is recommended as a safety precaution.

2) Open discharge and suction service valves ½ turn. Then, crack manifold gauge set discharge hand valve a fraction of a turn counter-clockwise to allow gas to escape. *CAUTION*—Opening manifold discharge hand valve too much in order to more quickly discharge system will draw compressor lubricant off with the Freon.

3) As pressure on manifold discharge gauge drops near zero, open manifold suction hand valve. *NOTE*—If brazing or some similar repair is to be made on system, leave system open to atmospheric pressure. After service work has been completed, the system must be evacuated, partially charged and leak tested before final charge.

EVACUATING & CHARGING THE SYSTEM

See 1955 Chrysler, DeSoto, Dodge "Airtemp" and note the following:

1) FREON-22 is used in the 1953-54 systems.

2) Freon-22 capacity of 1953-54 systems is 5 lbs.

3) Do not permit suction pressure to EXCEED 90 lbs. when controlling Freon-22 entry into system with Freon-22 tank valve.

CHECKING & LUBRICATION

See 1955 Chrysler, DeSoto, Dodge "Airtemp" and note the following:

1) Correct oil level should be 1⅛-1½" on 1953-54 systems.

REMOVAL & INSTALLATION TO WORK IN ENGINE COMPARTMENT

COMPRESSOR: Removal—Start engine and operate at fast idle until compressor is warm. Shut off engine. Remove valve stem protective caps from both discharge and suction service valves. Close off both valves by rotating valve stems clockwise with Tool C-3361 until they are fully seated. Loosen port caps on both discharge and suction service valves two turns to gradually release Freon gas pressure from the compressor. Loosen oil filler plug on side of compressor to release gas pressure from compressor crankcase. (*NOTE*—It is not necessary to remove oil filler plug. Loosen about one full turn. This precaution will prevent dirt from entering crankcase). Remove compressor drive belt or belts. Clean dirt away from both discharge and suction service valves with a suitable solvent and blow dry with compressed air. Remove discharge and suction service valve attaching bolts. Gently move valves and tubes away from compressor. Cover ports in valves and compressor openings with masking tape. Tighten port caps and oil filler plug. Replace service valve protective caps to prevent air, moisture or dirt from entering system. (*CAUTION*—Care must be taken not to force valves and tubes out of alignment too far or the vibration eliminator may be damaged). Remove compressor-to-mounting bracket bolts and nuts. Lift compressor from engine and set it on bench with pulley hanging over side of bench. *CAUTION*—Never rest weight of compressor on pulley, otherwise shaft seal may become damaged.

Installation: Reverse removal procedure using new valve gaskets coated with Mopar Air Conditioning Compressor Oil. Torque all bolts evenly to 20 ft. lbs. Purge air from compressor as follows: Loosen oil filler plug one or two turns. Loosen discharge service valve port cap ½ turn, slightly open suction service valve with Tool C-3361 by turning stem counter-clockwise. Let gas drift slowly through

CONTINUED ON NEXT PAGE

AIR CONDITIONING SERVICE CAUTIONS

HANDLING FREON: Though considered the safest and best refrigerant for use in Air Conditioning systems, the following precautions must be observed to avoid serious accidents or damage to the system

Drum: 1) Do not leave drum uncapped (metal cap furnished with drum is for protection of valve and safety plug) It should be replaced after each use of drum
2) Do not carry drum in passenger compartment of car Place drum in luggage compartment or, if in an open truck, cover drum to protect it from radiant sun heat If precaution not taken, resultant increase in pressure may cause safety plug to release or drum to burst
3) When charging system, do not subject drum to high heat Use water no warmer than 125°F (Hot rags will suffice) *Never place drum on radiator, stove, or use torches for heating during charging.* Keep drums upright
4) Never permit a drum to be dropped or strike another drum violently
5) Do not fill drum completely (when filling one drum from another) Leave space above liquid for expansion

Personal: 1) Do not discharge Freon into room with exposed flame because concentrations of this gas in contact with open flame will produce a toxic gas
2) Do not expose eyes to liquid, *USE GLASSES OR GOGGLES Liquid Freon will freeze anything with which it comes in contact* If Freon should strike eyeballs, splash water to area of eye to gradually get temperature above freezing point, apply a few drops of sterile mineral oil to eyes as an irrigator If irritation continues wash eyes with a weak solution of boric acid *DO NOT RUB EYES See an eye specialist at once*
3) Do not inhale large quantities of Freon vapor as it will act an an anesthetic
4) If Freon comes in contact with skin, injury should be treated for frostbite

HANDLING REFRIGERANT LINES: 1) Keep refrigerant lines dry and clean Whenever a connection or joint is broken, clean all dirt from joint or connection
2) Parts from stock are capped and dehydrated Caps should only be removed just prior to installation Lines removed from system to be used again, should be capped immediately, to prevent dirt and moisture from entering lines
3) Lines should be free of kinks, and should be carefully stored to avoid crushing or bending
4) Proper size wrenches should be used when tightening fittings Always use two wrenches to prevent twisting copper tubing
5) Tubing that is left free to vibrate will harden and crystallize the area of the tubing at flare sections so that it may become brittle and break
6) When using paint drying lamps, ovens, steam cleaners, or other heat producing devices, avoid heating any part of system If sufficient heat applied, pressure will increase to a point where some part of system will rupture
7) When undercoating, use care to see that undercoating does not plug evaporator drain Do not coat air conditioning joints and connections
8) Keep gauge set and lines free of moisture
9) Compressor lubricant container must not be left open longer than necessary as the special oil is moisture free and will absorb moisture from air if left uncapped

AIR CONDITIONING LEAK TESTS

LEAK TESTING CONFINED AREAS: For leak testing confined areas, such as sections of evaporator and condenser, a torch or flame type detector must be used Two types are available One type uses anhydrous methyl alcohol, under pressure for producing the testing flame The cylinder is refillable and must be preheated to pressurize cylinder The other type uses propane gas, under pressure, to produce the testing flame The cylinder is replaceable and comes already pressurized, making it unnecessary to pre-heat cylinder in order to produce testing flame Instructions for use of the detectors are furnished with the detector

Leak Testing: With flame adjusted, explore for leaks by moving end of hose or sampling tube around all points where a leak may be Especially check around bottom of connections, since Freon is heavier than air and will be more apparent at bottom of fitting Color of flame will turn to a yellow-green when a small leak is detected Large leaks will be indicated by a change in color to bright or brilliant blue or purple When hose or tube is moved away from leak, flame will clear to an almost colorless pale-blue or green *CAUTION*—Do not use lighted detector in any place where combustible or explosive gases, dust or vapors may be present Do not breathe fumes and black smoke that are produced if leak is a big one Before leak testing be sure car is thoroughly aired (particularly if Freon tank used or if system opened for any reason) and moved to a Freon-free area in order that false readings may be prevented

PIN-POINTING LEAKS: There are a number of fittings and places throughout the air conditioning unit where a leak detector solution or detergent may be used to pin-point leaks Apply solution to suspected area with with swab that is attached to bottle cap Bubbles will will form, within seconds if there is a leak

AIR CONDITIONING TROUBLE SHOOTING

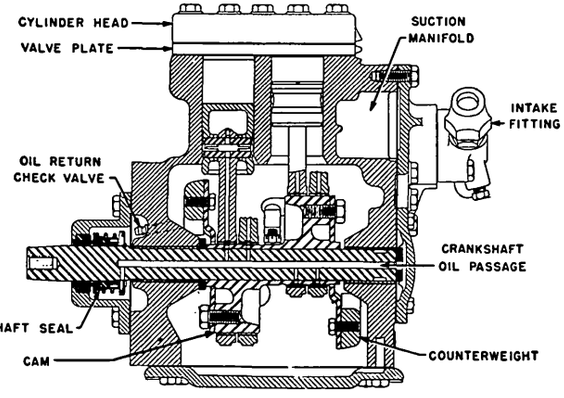
►*CAUTION· Do not disconnect refrigerant lines, replace parts, or attempt adjustments without complete instructions. See "Air Conditioning Service Cautions".*

POOR COOLING: 1) Blowers Not Operating—Fuse blown or faulty circuit breaker, switch in "Off" position, defective switch, switch resistors or blower rheostats inoperative, broken wire or loose connections, blower motor defective, blower fans or motor improperly installed
2) Restricted Air Flow—Filters clogged, dirt or other obstructions in air ducts, evaporator fins or coils clogged or restricted with frost or ice
3) Refrigerant Flow to Cooling Coils or Fins Incorrect—Expansion valve improperly adjusted or defective, power element or temperature bulb does not contact pressure line properly, restriction in liquid line between receiver and cooling coils or fins, power element or temperature bulb discharged, insufficient refrigerant, by-pass valve, thermostatic switch or solenoid (if so equipped) not properly set or inoperative, modulator valve (if so equipped) defective, break in any part of closed refrigeration system
4) Refrigerant Not Condensing Properly—Air flow through condenser, restricted, high engine operating temperatures, air or excess refrigerant in system, restriction in high pressure side of compressor and condenser
5) Clutch (If So Equipped) Does Not Engage—Defective coil or relay, clutch plate lining worn or saturated with oil causing slippage, air conditioning "On" switch defective, thermostat inoperative, clutch adjustment incorrect
6) Compr ssor—Belts not adjusted properly, worn, or broken, operating above normal pressures, disconnect pulley bolts not in place, valves faulty, service valves not fully open
7) El ctrical—Loose connections or broken wires between electrical units, blown fuses or faulty circuit breakers

TOO COLD: 1) Clutch (If So Equipped) Do s N t Disengage—Thermostat inoperative, relay stuck closed, air conditioning "On" switch inoperative
2) Blower Speed Cannot be Reduced—Defective blower switch

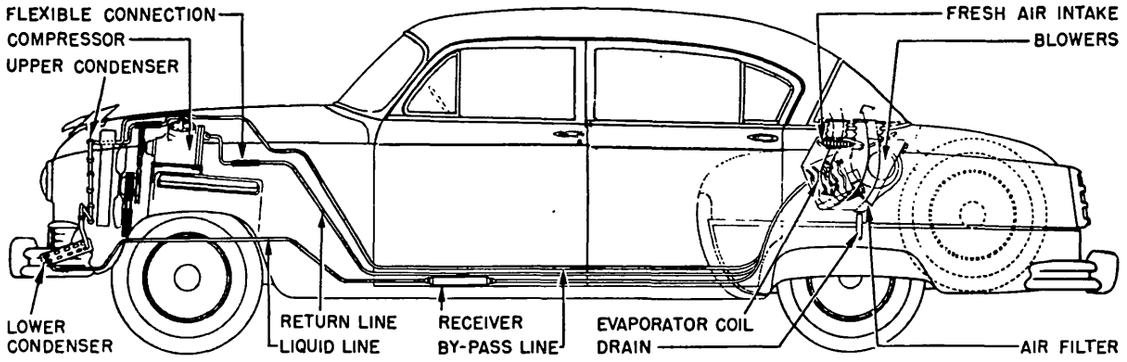
VIBRATION—NOISE: 1) Blow rs—Loose on shaft, striking housing, foreign material, motor bearings or mounts loose or worn
2) Compressor—Mounting brackets loose, loose internal parts, insufficient oil, too much refrigerant
3) Air Flow—Foreign material in air system, small slits or openings in ducts

INCORRECT OPERATING PRESSURE: 1) Exc ssiv Pressure on High Pressure Sid—Air or excess refrigerant in system, air flow through condenser core restricted, kinks or restrictions in line on high pressure side, high engine temperature, shut-off valve on high pressure side of compressor not fully open, insufficient air flow through cooling coil, defective expansion valve or incorrect adjustment
2) Insufficient Pressure on High Pressure Side—Shortage of refrigerant, defective expansion valve or incorrect adjustment, leaky or broken compressor valves
3) Excessive Pressure on L w Pressure Sid—Power element or temperature bulb not making correct contact with pressure line, expansion valve needle stuck open or leaking
4) Insufficient Pressure on L w Pressur Sid—Restriction in lines, shortage of refrigerant, expansion valve needle stuck shut, expansion valve not open far enough, plugged, or defective, dehydrator-filter (strainer-drier) plugged, power element or temperature bulb charge lost or line plugged, compressor valves faulty, blower fans inoperative, temperature control thermostat does not cut out, moisture or freeze-up



1953-54 AIRTEMP (C nt.)

compressor for about ten seconds. Tighten port cap and oil filler plug. Open both discharge and suction service valves all the way by turning stems counterclockwise until fully back-seated. Replace protective caps on discharge and suction service valves. Install compressor drive belts and adjust.



UPPER CONDENSER: Discharge system. Using flare nut wrench disconnect upper and lower flared fittings on upper condenser. ***(CAUTION—Use two wrenches on fitting when loosening to prevent damage to tubing.)*** Remove four upper condenser to radiator yoke screws and lockwashers, remove condenser. To install, reverse removal procedure. Charge system, test for leaks.

LOWER CONDENSER: Discharge system. Using flare nut wrenches, disconnect lower condenser inlet manifold tube flare nut located between upper and lower condensers, disconnect lower condenser outlet manifold tube connector on tubing located between lower condenser and receiver. Remove four front sway eliminator nuts, lockwashers and screws, move sway eliminator out of way. ***(CAUTION—Lower condenser mounting brackets held in position by sway eliminator mounting bolts.)*** Remove condenser. To install, reverse removal procedure. Charge system, test for leaks.

DRIVE PULLEY: Loosen drive belt idler pulley adjusting screws, remove belt from compressor pulley. Remove compressor pulley shaft screw and washer. Using Tool C-3351, remove pulley from crankshaft. NOTE—Pulley keyed to crankshaft by Woodruff key. Inspect keyway in crankshaft and pulley for wear. To install, place compressor pulley key into position in crankshaft. Align keyway in pulley with key in crankshaft, install pulley on shaft. Install compressor pulley shaft washer and screw, tighten to 20 ft. lbs. torque.

COMPRESSOR SECTIONAL VIEW

CHRYSLER, DE SOTO & DODGE AIRTEMP SYSTEM

►***CAUTION: The compressor oil seal and thrust bearings are made partly from a carbon-like material which is subject to damage from impact. Consequently, a hammer should never be used to loosen or remove the seal from the shaft as this shock may crack or shatter the carbon bearings. Always use a puller to remove the pulley from the shaft.***

CRANKSHAFT OIL SEAL: Remove compressor, and pulley from compressor (see above). Remove eight seal housing bolts, then seal housing from compressor. Press seal floating seat out of housing from pulley end of seal housing. Remove neoprene seal ring and bellows assembly. Assembly is held tightly to shaft by neoprene sleeve of seal. Pry it off in such a manner so as not to scratch shaft. Wash seal housing with solvent. Dry and coat counterbore with film of refrigerant oil. To install seal, coat sealing surfaces and neoprene rings with refrigerant oil. Start seal seat into counterbore of housing. Using thumbs only, press seal seat and ring to bottom of housing counterbore. Wipe shaft clean and apply coat of refrigerant oil, dip new shaft seal into refrigerant oil and press on shaft. Dip housing cover gasket in refrigerant oil, align its holes with compressor housing holes and smooth out any wrinkles. Hold seal housing with left hand, put right forefinger through opening in seal housing and against end of shaft. Using forefinger as guide, carefully slide seal housing into place without letting end of shaft touch capped surface. Install two bolts, center clearance between housing and shaft, tighten bolts to bring housing to compressor. Install remaining bolts and tighten finger tight. Check and align clearance between housing and shaft with feeler gauge or piece of paper to obtain equal clearance at all points. Tighten all housing bolts to 20 ft. lbs. Replace compressor pulley, check and add oil as required (compressor on bench) to bring level to 1⅛-1½" when measured with dipstick and compressor in normal operating position. Install compressor (see above).

RECEIVER FUSIBLE PLUG: *See "Parts Replacement" under 1955 Chrysler, DeSoto, Dodge "Airtemp."*

VALVE PLATE ASSEMBLY: Run engine a few minutes to warm compressor. Stop engine, remove caps from compressor discharge and suction service valves, close both valves by turning clockwise as far as they will go. ***(CAUTION—Do not run engine with valves closed.)*** Carefully loosen cap on service port fitting of discharge valve approximately ¼ turn to gradually relieve pressure in compressor, remove dirt from around cylinder heads. Remove ten cylinder head screws, carefully lift cylinder head from compressor, remove cylinder head gasket. Lift valve plate assembly from compressor, remove valve plate gasket. ***(CAUTION—Valve plate assembly is dowelled on compressor by four small pins. Pins also retain reed valves in position. Make sure reed valves do not fall into cylinders when valve plate assembly removed.)*** Clean gasket mating surfaces, make sure they are free from dirt, nicks, and burrs. NOTE—Valve plate serviced as assembly only. If any part damaged, entire valve plate assembly must be replaced. To install, reverse removal procedure. Tighten cylinder head screws to 15-20 ft. lbs.. Purge air from system (see above). Open both service valves by turning stems clockwise as far as they will go. Start engine and run for few minutes to warm compressor. Check Freon charge, then oil level (see above). Replace caps on discharge and suction service valves. Test for leaks (see above).

1955 CHRYSLER, DESOTO, DODGE AIRTEMP

Chrysler, Imperial, DeSoto, Dodge (1955)

►CHANGES & CORRECTIONS

►*1955 COMPRESSOR SHAFT SEAL PRODUCTION CHANGE:* Replacement of new type seal for old type seal includes seal and bearing end plate. Replacement of new type seal with seal of same type requires seal only.

DESCRIPTION & OPERATION

Similar in design and operation to 1953-54 Airtemp Air Conditioning system. 1955 changes over previous models are as follows:

Refrigerant: Freon-12 replaces Freon-22 as refrigerant.

Compressor: A 2-cylinder reciprocating compressor replaces V-type, 4-cylinder compressor.

Condenser: A single unit condenser replaces two-unit condenser used previously.

Receiver & Strainer-Drier: Strainer-drier has been combined with receiver. Unit is located near bottom of condenser.

Control Units: A magnetic clutch has been added on some models, permitting pulley to free-wheel when system is not in operation. Some models also incorporate a fast idle device which operates when transmission control lever is in neutral. A temperature control switch connected in series with a thermal switch (attached to suction pressure line at evaporator outlet manifold) and the solenoid by-pass winding, regulates temperature of air delivered to passenger compartment.

PRECAUTIONS, TROUBLE SHOOTING & LEAK TESTING

See "Air Conditioning Service Cautions", "Trouble Shooting" and "Leak Tests".

ADJUSTMENT

ADJUSTMENTS: Compressor Belt–Adjust tension of each compressor belt so that a pull of 9-12 lbs. at center of longest span will provide a ¼" deflection at that point.

Fast Idle Device (If so Equipped): Back off round adjusting nut on diaphragm shaft away from pawl. Start engine, attach tachometer, and with transmission control lever in "Neutral" position and engine at operating temperature, adjust engine idle to 475-500 RPM. Turn blower control switch to first position, and temperature control switch to second position. Adjust round adjusting nut on fast idle diaphragm shaft to increase engine RPM to 700-800 RPM. With hand brake on, move transmission control lever to "Drive" range and then back to neutral. Readjust fast idle if necessary. Lock round nut with hex nut.

Expansion Valve: No adjustment. Replace as necessary.

Magnetic Clutch (If so Equipped): Measure air gap between drive plate electromagnet and drive plate. Air gap should measure .025"-.035". To adjust,turn screws located in center of three hexagon headed nuts on front face of drive plate. Adjust all three screws to obtain evenly spaced air gap, Measure air gap with long feeler that will reach into gap at hub.

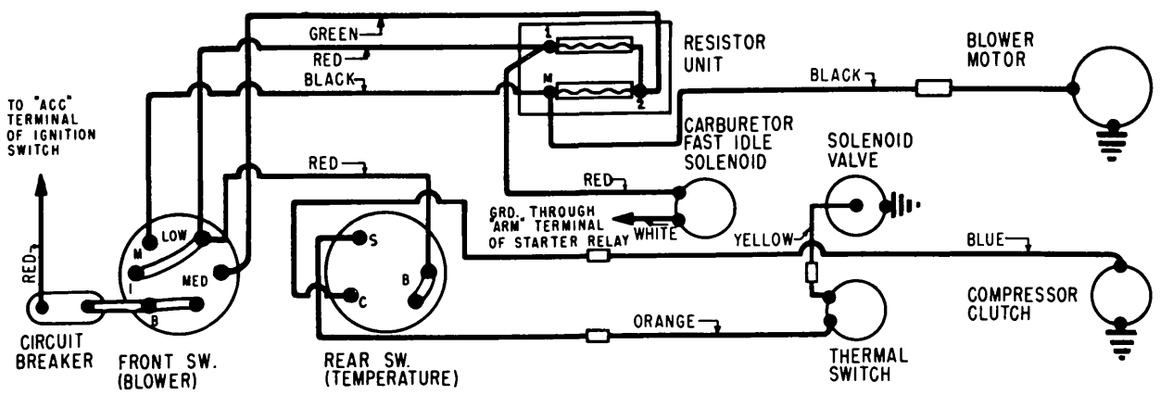
DISCHARGING THE SYSTEM

See 1953-54 Chrysler, DeSoto, Dodge "Airtemp".

EVACUATING & SWEEPING THE SYSTEM

Before evacuating the system, sweep system in order to remove as much moisture as possible. Proceed as follows:

SWEEPING THE SYSTEM: Charge discharged system with one lb. of Freon-12 (Freon-22 used in 1953-54 systems); or until a pressure of 100 lbs. registers on discharge gauge. Operate system for 5 minutes and again discharge.



EVACUATING THE SYSTEM: Connect Gauge Manifold Set C-3354 to compressor. Discharge system if not previously discharged, sweep the system (see above). *(CAUTION*–Be sure pressure has dropped to zero before attaching hose to vacuum pump). Connect 6-foot test hose to center fitting of gauge set and to connection on vacuum pump(Tool C-3372). Open both discharge and suction service valves about one turn, rotating both valve stems clockwise. Open both gauge manifold set hand valves (counter-clockwise). Start vacuum pump and observe compound gauge. Operate pump until gauge registers 26 to 28 inches of vacuum. for five minutes. *(NOTE*–Failure to obtain 26 to 28 inches of vacuum would indicate a leak in system. Close both gauge set manifold hand valves by turning clockwise. Turn off vacuum pump and remove long test hose from pump. Charge system with one lb. of Freon (see below). Start engine and adjust speed to 1200 RPM. Turn blower control to high and temperature control to cold. Operate in this manner for five minutes and test for leaks. Discharge system which will sweep out any remaining moisture). Again evacuate system at 26 to 28 inches of vacuum for 30 full minutes. Recharge system.

CHARGING THE SYSTEM

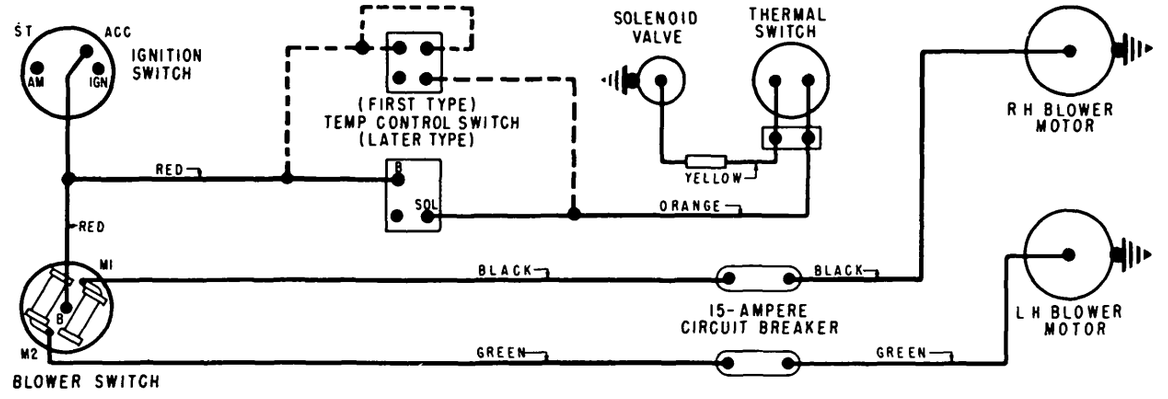
►*NOTE:* If only a partial charge of refrigerant is required, the following "Adding Partial Charge of Freon-12 (Using Gauge Set Manifold Tool C-3354)" method can be used providing unit is equipped with a sight glass. If not so equipped the entire system will have to be discharged, swept, evacuated and recharged with a full charge following directions given under "Adding Complete Charge of Freon-12 (Using Gauge Set Manifold Tool C-3354)". **The above is applicable to 1953-54 units except that Freon-22 is used, Freon-22 capacity is 5 lbs., and allowable pressure when controlling Freon-22 entry into system with Freon-22 tank valve is 90 lbs. instead of 60 lbs. Since there is no temperature control switch on 1953-54 units blowers are operated on "High" when operating engine during the adding of a partial charge of Freon-22.**

ADDING PARTIAL CHARGE OF FREON-12 (Using Gauge Set Manifold Tool C-3354): Remove protective caps from compressor discharge and suction service valves. Using Tool C-3361, make sure both valves are completely back-seated (counter-clockwise). Remove protective caps from discharge and suction service ports. Install 4-foot test hose from 600 lb. gauge fitting on gauge manifold to discharge service port fitting. Install other 4-foot test hose from 300 lb. gauge fitting on gauge manifold to suction service port fitting. Turn both valve handles on gauge manifold clockwise as far as they will go. Connect 6-foot test hose to center fitting of gauge manifold and to connection on Freon-12 tank. Be sure both gauge manifold valves are fully closed (clockwise). Open valve on Freon-12 tank slightly and loosen 6-foot test hose at gauge manifold for about one second to purge air from hose. Close Freon-12 tank valve. Start engine and operate at 1200 RPM. Turn blower control to "Low" position and temperature switch to "Cold". Rotate both suction and discharge service valve stems one turn (clockwise). *(NOTE*–If discharge gauge hand fluctuates whenengine and compressor are running, close discharge valve

CONTINUED ON NEXT PAGE

CHRYSLER, DESOTO DELUXE, DODGE AIR CONDITIONING CONTROL DIAGRAM
(CARBURETOR FAST IDLE SOLENOID NOT USED ON DODGE)

1955 AIRTEMP (C nt.)



slowly (counter-clockwise) until gauge hand steadies). Open Freon tank valve ½ turn. Open suction valve on gauge manifold slightly (counter-clockwise). Control Freon entering system with this valve. *DO NOT ALLOW SUCTION PRESSURE TO EXCEED 60 LBS.* Carefully watch sight glass. The moment sight glass is clear of bubbles, **close** gauge manifold suction valve (clockwise). *(CAUTION*–Stopping flow of Freon into system as soon as sight glass is clear (free of bubbles) is important. Too much Freon in system can cause damage). Operate system for 5 minutes and again observe sight glass for presence of bubbles. If bubbles still evident carefully continue to charge until sight glass is clear, repeat 5 minute run. Where no bubbles are present after 5 minutes of operation, charge system with additional Freon for 10 seconds. Close Freon tank valve. Loosen hose connection at tank to gradually release Freon from hose. Disconnect hose after Freon has escaped. Back-seat suction and discharge service valves (counter-clockwise). Remove gauge manifold and install service valve and port protective caps

►*ADDING COMPLETE CHARGE OF FREON (Using Gauge Set Manifold Tool C-3354): (NOTE*–When completely charging system on 1953-54 units do not operate blowers during operation, on 1955 units operate blowers on "Low" and set temperature switch to "Cold"). Follow preliminary steps for adding partial charge of refrigerant. Place Freon drum in pail of warm water (temperature not to exceed 125°F). Then set pail and Freon tank on accurate scale (bath scales not accurate below 100 lbs.) and weigh assembly. Open Freon tank valve ½ turn, and suction valve on gauge manifold slightly (counter-clockwise). Control Freon entering system with this valve. DO NOT allow suction pressure to exceed 60 PSI (1955 Freon-12), 90 PSI (1953-54 Freon-22). Be sure both suction and discharge valves are open about one turn clockwise. Carefully watch scale and shut Freon tank valve off when system has absorbed 4 lbs. of Freon-12 (1955), 5 lbs. of Freon-22 (1953-54). Close suction valve on gauge manifold (clockwise). To disconnect Freon tank, loosen six-foot test hose and allow Freon in hose to escape slowly, then remove hose from tank.

CHECKING & LUBRICATION

►*NOTE:* There is no temperature control switch nor thermal switch on 1953-54 units.

CHECKING: Bubbles in Sight Glass–Connect a tachometer to engine, start and adjust engine speed to 1200 RPM. Turn blower control to full speed and temperature control to maximum cold. Open car windows and allow engine to operate at 1200 RPM to clear sight glass. Observe sight glass. Sight glass should be perfectly clear (no bubbles) within 3-5 minutes after system started operation (system not by-passing). If not, thermal switch and by-pass valve should be tested, and if found satisfactory, system should be partially charged to remove bubbles (see below). *NOTE*–A system that is low on Freon-12 should be tested for leaks, leaks corrected, and system charged.

DE SOTO (STD.) AIR CONDITIONING CONTROL DIAGRAM

►*NOTE:* Correct oil level for 1953-54 units is 1 1/8-1½" and capacity is 32 ozs. of 300 Saybolt refrigerant (1¾" on dipstick).

Compressor Oil Level & Adding Oil: *(NOTE*–An oil sight glass is provided in compressor crankcase so that oil splash may be observed while compressor is in operation. If a splash is observed while compressor is operating, it indicates **only** that there is oil in the compressor, and **not how much**). To check for proper oil level, start engine and run at moderate speed (air conditioning turned on) until compressor is warm. Stop engine, remove protective caps from compressor discharge and suction valves, close both valves by turning valve stems clockwise until they seat firmly. *(CAUTION*–Never start engine with discharge valve closed, drive belts connected to engine when magnetic clutch is engaged). Clean dirt away from compressor oil filler plug with solvent and blow dry with compressed air. Carefully loosen cap on service port of discharge valve approximately ¼ turn and gradually release gas pressure from compressor. When gas pressure in head decreases, loosen, but do not remove oil filler plug on side of compressor. This will allow pressure in compressor crankcase to drop. *(NOTE*–If oil level is checked immediately after a trip–driven at high speeds–level will be slightly higher than normal). Remove oil filler plug and, using a dry, clean plunger type rod (1/8" welding rod), measure oil level. Correct level is ¾" to 1". After oil level has been checked, siphon off excess oil or add Mopar Air Conditioning Compressor Oil (300 Saybolt at 100°F), replace filler plug **but do not tighten at this time.** To purge air out of compressor cylinder and crankcase, make sure cap on discharge valve service port is loosened approximately ½ turn, and oil filler plug on side of compressor a full turn. Slightly open suction service valve by turning valve stem counter-clockwise. Let gas drift slowly through compressor for about 10 seconds. First tighten filler plug and then cap on discharge service port. Backseat both discharge and suction service valves by turning counter-clockwise, replace protective caps.

►*REPLACEMENT COMPRESSOR OIL LEVEL CAUTION:* New compressors are fully equipped with exception of drive pulley and magnetic clutch assembly. Compressors are charged with treated dry air to prevent moisture or dirt from entering, and contains 12 ozs. of 300 Saybolt refrigerant (oil level at center of sight glass, compressor horizontal on bench). When compressor replac- for any reason, oil level in compressor must be corrected to proper amount. Even though compressor had no oil when removed, some oil may still remain in system. When old compressor is found to have no oil, or where oil level is very low or is too high, oil must be siphoned off to the minimum lever of ¾". After installation completed, system should be operated for 10 minutes, engine stopped, and oil level rechecked and adjusted to ¾-1", if required. Use suction gun if oil level too high. Repeat procedure several times until level remains at ¾-1".

REMOVAL & INSTALLATION TO WORK IN ENGINE COMPARTMENT

COMPRESSOR REMOVAL (To Work on Engin): *(NOTE*–On DeSoto, split muffler bracket with hacksaw). Start engine, operate at fast idle until compressor is warm. Remove valve stem protective caps from discharge and suction service valves. Close both valves (clockwise) with Tool C-3361. Loosen port caps on both service valves about two turns to gradually release Freon gas, pressure from compressor. Loosen oil filler plug a few turns. Remove drive belts and belt tension adjusting strap from compressor. Disconnect magnetic clutch electrical lead (if so equipped). Disconnect discharge tube flared connection at discharge (lower) muffler and cap tube nut and male connector. Remove Allen screws from suction service valve. Remove upper muffler bracket-to-compressor attaching bolt and gently lay the suction valve, muffler and tube assembly to one side. Do not bend vibration eliminator excessively or it may become damaged. Cover suction port in compressor and suction valve with masking tape. Remove compressor-to-mounting bracket and support bracket bolts, remove compressor.

COMPRESSOR INSTALLATION: 1) Place compressor on mounting bracket and start bolts, tightening them finger

CONTINUED ON NEXT PAGE

1955 AIRTEMP (C nt.)

tight Remove masking tape from suction service valve and compressor port, being sure surfaces are clean Coat a new suction service valve gasket with refrigerant oil and place over valve port Install suction service valve and tighten Allen screws to 15-20 ft lbs Install muffler bracket bolt (DeSoto) and tighten to 15-20 ft lbs Tighten compressor mounting bracket-to-compressor and support bracket attaching bolts to 20-25 ft lbs

2) Remove caps from discharge tube nut and muffler connector Insert new copper washer and connect flared connection, tightening securely Install compressor rive belts and belt tension adjusting strap Adjust belts (see ADJUSTMENTS above) Install magnetic clutch electrical lead (if so equipped)

3) Install manifold gauge set (Tool C-3354) First remove valve stem protective caps from compressor discharge and suction service valves Using Tool C-3361, make sure both valves are completely back-seated (counter-clockwise) Remove protective caps from discharge and suction service port caps Install 4-ft test hose from 600 lb gauge fitting to discharge service valve port fitting Install other 4-ft test hose from 300 lb gauge fitting to suction service valve port fitting Turn both handles of manifold gauge clockwise as far as they will go Crack suction service valve open (counter-clockwise) and tighten oil filler plug Crack suction gauge hand valve **for an instant** to purge air from compressor and suction tube Close suction gauge hand valve and open discharge service valve (counter-clockwise) slightly Crack discharge gauge hand valve **for an instant** to purge air from discharge side of compressor Rotate both gauge set hand valves (clockwise) until they are fully seated Rotate both discharge and suction service valve stems until they are fully back-seated

4) Start engine and turn blower and temperature controls to "High" and "Cold" Operate engine for 5 minutes, stop engine, and test for leaks Test system for operation If satisfactory, remove gauge set and replace protective caps

CONDENSER REMOVAL & INSTALLATION: Discharge system (see above) Disconnect discharge and by-pass tubes from discharge valve and liquid line to receive and cap tubes Remove hood lock plate and support bracket Remove four bolts that attach condenser brackets to radiator support and lift condenser from car To install reverse removal procedure Partially charge system, test for leaks correct leaks evacuate and charge system

RECEIVER STRAINER-DRIER REMOVAL & INSTALLATION: Discharge system (see above) Lift car with hoist Disconnect receiver flare connections at both ends of receiver (*CAUTION*–Wear goggles) Cap ends of receiver if unit to be used again Leave caps on connections until ready to make connections To install reverse removal procedure Partially charge system, check for leaks and correct as necessary evacuate and charge system

PARTS REPLACEMENT

RECEIVER FUSIBLE PLUG: A fusible plug is installed in receiver as a safety device This plug has a standard pipe plug thread and contains a core of material which will blow at approximately 210°F If the refrigeration unit is damaged or some component fails to function properly and a temperature is built up in the receiver sufficiently high to blow the fusible plug, the Freon charge will escape (*NOTE*–Occasionally a fusible plug might blow if the system is subject to extreme conditions such as prolonged idling of motor or in very hot weather) Whenever plugs blow following steps should be taken to put system in operation.

1) Locate and repair damage or improperly functioning part causing fusible plug to blow Replace fusible plug in receiver *NOTE*–A pipe joint sealer should always be used when replacing fusible plugs Torque to 20 ft lbs

2) Discharge and recharge system, check for leaks and for sufficient oil supply in compressor

3) Inspect condensers for cleanliness and plugged passages

COMPRESSOR SHAFT SEAL: (*NOTE*–Two types used Replacement of new type seal for old type seal includes bearing end plate Replacement of new type seal with seal of same type requires seal only) Start engine and operate at fast idle with temperature control switch at "Cold" and blower switch set to "High" speed until compressor is warm Shut off engine Remore valve stem protective caps from both discharge and suction service valves Close both valves by rotating valve stems clockwise (Tool C-3361) until they are fully seated Gradually loosen oil filler plug a few turns to release pressure from compressor Remove upper right-hand radiator fan shroud Remove self-locking bolt and washer from compressor shaft at front center of magnetic clutch While supporting pulley and clutch assembly with one hand, tap pulley with a soft hammer to jar hub from tapered shaft and remove assembly from compressor *Be careful not to damage brushes when removing pulley and clutch assembly* Remove brush holder assembly

Neoprene Type Seal Removal: Push seal ring towards compressor and remove snap ring with snap ring pliers, Then pull seal assembly from shaft It may be neces sary to pry bellows from front bearing end plate with a screwdriver

Metal Bellows Type Seal Removal: Remove compressor front bearing end plate screws Install special puller C-3473 Screw in on alignment screws until inner steps on puller contact bellows evenly Hold compressor shaft from rotating by placing screwdriver in shaft keyway slot and allow it to rest against puller leg while turning puller screw When bellows have compressed far enough to clear the snap ring retainer, remove snap ring with snap ring pliers Change puller screw in center of puller Turn in on center screw and remove compressor front bearing end plate and seal assembly Remove puller from end plate Remove carbon seal and "O" ring from bearing end plate

Metal Bellows Type Seal Installation: 1) Coat new bearing end plate and large "O" ring with refrigerant oil Install "O" ring in front bearing end plate Install gasket, end plate and two long screws at opposite sides of end plate *Be sure that oil pocket is up* Start end plate squarely, and tighten screws evenly finger tight Install puller While holding compressor shaft with a screwdriver, turn puller screw to pull bearing end plate into compressor housing Remove puller and install end plate screws Tighten screws evenly to 15-20 ft lbs

2) Coat carbon seal with refrigerant oil and place over shaft, positioning tangs on carbon in recesses in bearing end plate Lubricate "O" ring in bellows with refrigerant oil and place bellows and snap ring over compressor shaft Install puller Compress bellows with puller and, at same time, rotate bellows assembly to insure proper alignment This will prevent pinching "O" ring which would result in a leaky seal Install snap ring retainer when bellows clear groove in shaft Remove puller Check snap ring to be sure that it is securely seated in shaft groove Otherwise it may slip out and result in a leaky seal Install brush holder assembly, pulley, and magnetic clutch assembly, lining up key and keyway Push assembly over shaft and install washer and self-locking nut Tighten bolt to 15-20 ft lbs Backseat both service valves and bleed air from compressor Tighten oil filler plug Install protective caps, check for leaks *NOTE*–Leaks are more noticeable when new seals are first installed than after system has been in operation for a while and parts are worn in

MAGNETIC CLUTCH: Service is limited to drive plate, pulley and electromagnet assembly snap rings bearing and brush holder assembly

Clutch Assembly Removal: See "COMPRESSOR SHAFT SEAL" above

Drive Plate Removal & Installation: Remove drive plate retaining snap ring hub with Tool C-3301 Place suitable sleeve against hub and remove drive plate by tapping against sleeve with a hammer Inspect springs for loss of tension and cracks Inspect lining on face of plate Replace drive plate if liner is worn, springs are weak or broken, or if drive plate is warped (*NOTE*–A sintered iron liner impregnated with fibrous material is bonded to the drive plate If this liner is worn through, replace drive plate) Start drive plate hub squarely into inner bearing race Place a brass drift against drive plate inner hub and tap plate hub into bearing by tapping on brass drift with a hammer Install snap ring on drive plate hub Adjust (see Adjustments)

Brush Assembly Replacement: Remove ground brush lead screw from compressor Disconnect insulated lead from Wade connector Remove screws attaching brush holder to compressor and remove brush holder assembly Clean collector rings in clutch assembly with carbon tetrachloride and wipe surplus grease from around clutch bearing Install new brush holder assembly *Use care not to break brushes If brushes ar allowed to snap to the end of their travel, they may break*

►*ELECTROMAGNETIC COIL CAUTION:* Do not attempt to remove electromagnet coil from pulley assembly The coil is held in place by a special adhesive material Once this bond is broken coil cannot be reattached

1953 FRIGIDAIRE

Buick, Cadillac, Oldsmobile, Packard (1953)

▷CHANGES, CAUTIONS, CORRECTIONS

▷*CADILLAC AIR CONDITIONER CAP SCREW REPLACEMENT:* Cars factory equipped with Air Conditioners prior to Engine No. 29000 and field installation kits prior to March 12, 1953 have twelve-sided cap screws which should be replaced by hexagonal cap screws, Part No. 5915222. To replace, close high and low pressure shut-off valves tightly (use Tool No. J-5427). ***(CAUTION—Do not operate compressor with high pressure line closed).*** Replace cap screws, one at a time (momentary release of vapor normal). Open shut-off valves, then leak test. If leaks at shut-off valve replace valve "O" ring, Part No. 5887997 and flange gasket, Part No. 5888680 by first closing shut-off valve and removing valve attaching screws. Apply Frigidaire Oil to "O" ring before installing fitting into bore.

▷*SOLENOID BY-PASS VALVE REWORK (For Improper Seating due to Presence of Foreign Particles):* See "Solenoid Valve" under CHECKING for proper corrective procedures. NOTE—Solenoid valves with screens installed are marked with stamped "S" or a daub of red paint on housing. When screen is installed daub of red paint should be placed on housing.

▷*SOLENOID BY-PASS VALVE DIAPHRAGM POOR SEATING CORRECTION (Causing Poor Cooling):* To correct, install new tube and bonnet assembly, Part No. 566259, which has a shoulder to maintain proper diaphragm alignment. At same time install new by-pass valve screen, Part No. 5915508, if not already in place. In some cases it may also be necessary to install a new diaphragm, Part No. 5883746.

DESCRIPTION

Compression process cycle type, using Freon as refrigerant. System consists of following elements:

Refrigerating: Compressor—Located directly above generator on right side of engine. Operation causes and maintains necessary high pressure in system needed to increase Freon vapor temperature.

Condenser—Located in front of radiator. Condenses refrigerant vapor discharged from compressor, through action of fast moving air over metal surfaces of condenser.

By-pass Solenoid—In engine compartment between condenser and receiver. When cooling system is in "Off" position valve operated by solenoid is open, thereby removing restriction between high and low pressure sides of system, and preventing compressor from reducing pressure in cooling coil necessary to permit vaporization of Freon.

Check Valve—Located between condenser and receiver. Prevents liquid refrigerant from entering by-pass and low pressure lines when solenoid valve is open. Protects compressor against possible damage caused by liquid entering compressor.

Receiver—Located in front of radiator and beneath condenser. Stores liquid refrigerant and maintains supply more than that needed normally.

Sight Glass—Located in engine compartment between receiver and dehydrator-filter (under car). Provides means for determining adequacy of refrigerant charge.

Dehydrator-Filter—Located under car to right rear. Filters and dehydrates circulating Freon.

Expansion Valve—Part of evaporator assembly located in trunk of car. Supplies liquid to cooling coils at same rate that refrigerant is removed from it in a vaporous state.

Cooling Coils—Part of evaporator assembly located in trunk of car. Container for refrigerant which readily absorbs heat from surrounding area when temperature of refrigerant liquid is reduced. In cooling coils refrigerant is changed to vapor.

Air Circulating: Blowers—Located in evaporator assembly in trunk of car. These squirrel cage type fans, two in number, on each side of car, force air from refrigerated area in evaporator assembly to ducts leading to car interior.

Discharge Air Ducts—Connected to grille located at each end of package shelf. Entry point of refrigerated air to interior of car.

Return Air Duct—Located near center of package shelf. Air is filtered through this duct and returned from interior of car to refrigerating area in evaporator assembly.

Outside Air Ducts—Located to rear on each side of car. Manually controlled damper controls amount of air admitted from outside to refrigerating area in evaporator assembly.

Control: Various methods used to control degree of coldness are as follows:

Buick & Oldsmobile—Two knobs control fan speed and coldness. Left hand knob controls fan speed and right hand knob degree of coldness. Turning knob all the way to right gives maximum coldness.

Cadillac—Control panel consists of 3-way toggle switch and control lever. Three-way toggle switch has positions marked "Vent" (for normal ventilation, blowers operating), "On" which causes Air Conditioner to operate, and "Off" which makes blowers and Air Conditioner inoperative. Lever controls degree of coolness when Air Conditioner is "On," position farthest to right providing maximum coolness.

Packard—Control panel consists of three knobs. Center knob controls degree of coldness. By turning knob all the way to right maximum coldness is obtained. The two outer knobs regulate speed of right and left blower fans independently.

All Cars—Mercury Thermostat & Control Relay—With Air Conditioner "On" and temperature control lever all the way to right, full line voltage is directed to heating element of thermostat. Resulting heat keeps mercury at higher position than at other positions of lever when heat on mercury column is less. Relay that energizes by-pass solenoid is grounded through mercury thermostat. If mercury column is below upper contact, relay coil cannot be grounded and solenoid by-pass valve cannot be energized. This means there is no refrigeration unless temperature at thermostat increases sufficiently to provide current to the relay. The amount of heat applied to the thermostat determines length of time current is supplied to the relay and consequently time Air Conditioner is operative. The heat supplied the thermostat may be the temperature within the car itself or that artifically supplied to the heater element of the thermostat.

OPERATION

With Air Conditioner Control Switch "On" and engine and compressor operating, heat laden, low pressure Freon is compressed by compressor and discharged into condenser where it is cooled to remove the "sensible" heat of compression. The Freon is forced into receiver under pressure when by-pass solenoid is energized and closed. After passing through sight glass and dehydrator-filter, Freon enters expansion valve in evaporator assembly. At orifice in expansion valve, high pressure liquid Freon changes to low pressure liquid, then enters cooling coils through distributor tubes. The "boiling" Freon, while in the cooling coils, absorbs heat from the surrounding air and vaporizes. The vapor is drawn through the low pressure line to compressor.

PRECAUTIONS, LEAK TESTING & TROUBLE SHOOTING

See "Air Conditioning Service Cautions," "Trouble Shooting" and "Leak Tests."

MAINTENANCE & INSPECTION

SEASONAL OPERATION: Winter—On Buick and Cadillac, remove longer compressor drive belts, install standard generator belt. On Oldsmobile and Packard remove compressor belts.

Summer—To start Air Conditioner after the winter season, reinstall compressor drive belts, open outside intake ducts, then proceed as directed under Preliminary Check (see above). Check unit outlet air differential with temperature outside car.

FILTER RECONDITIONING: Filter should be cleaned regularly during season of operation. This should be every two months or 2,000 miles, and more frequently in extremely dusty areas. To clean filter, wash in warm water, shake out excess moisture. *CAUTION—Do not use air hose*

FUSES: 15 ampere (Buick), 20 ampere (Cadillac, Oldsmobile), 30 ampere (Packard), in lead near ignition switch. 3 ampere (Packard), 2 ampere (Others) in line from thermo gauge to solenoid valve.

ADJUSTMENT

BELT ADJUSTMENT: Buick—Adjust belt by moving generator so that there is a ⅜" deflection between the fan and compressor pulleys.

Cadillac—Loosen generator mounting bolts three or four turns, loosen generator adjusting strap screw. Place Fan Belt Adjusting Tool, No. J-3046 over head of front mounting bolt and rotate tool until arm on tool contacts edge of generator drive end plate. Place ⅞" socket over tool, place 50 ft. lb. torque wrench in socket. Pull outward on torque wrench until 24 pounds torque is indicated on scale. Tighten generator adjusting strap screw. Remove tool and tighten mounting bolts to 15-18 ft. lbs.

Oldsmobile—Loosen compressor bracket adjusting bolt. Using Tool J-5394 and a torque wrench, torque tighten belts to 50 ft. lbs.

Packard—Loosen compressor bracket adjusting bolt. Using Tool J-5577 and a torque wrench, torque tighten belts to 58 ft. lbs.

EXPANSION VALVE: Remove access plate located centrally on evaporator housing. Using 1" socket, while supporting mating parts (to prevent distortion), remove cap nut from expansion valve. Using 3/16" valve key, Tool J-5426, on adjusting stem of expansion valve, first CLOSE valve completely, then OPEN (counter-clockwise) 5-6 complete turns. If the above does not correct ineffective cooling, proceed with alternate adjustment below:

Alternate Adjustment—Connect high and low pressure gauge set to compressor, remove spare tire, and cover plate from high and low pressure lines at cooling unit. Attach thermometer to low pressure line

CONTINUED ON NEXT PAGE

1953 FRIGIDAIRE (C nt.)

with mercury bulb in contact with tubing. Tape securely, pack insulation around tubing and thermometer bulb (extremely important since air currents or poor contact affect thermometer reading). Start engine, operate at 1300 RPM for 15 minutes. Sight glass should contain no bubbles. Read low pressure gauge and low pressure line temperature at cooling unit simultaneously. For any given low pressure, line temperature should be within following limits:

Low Pressure Line

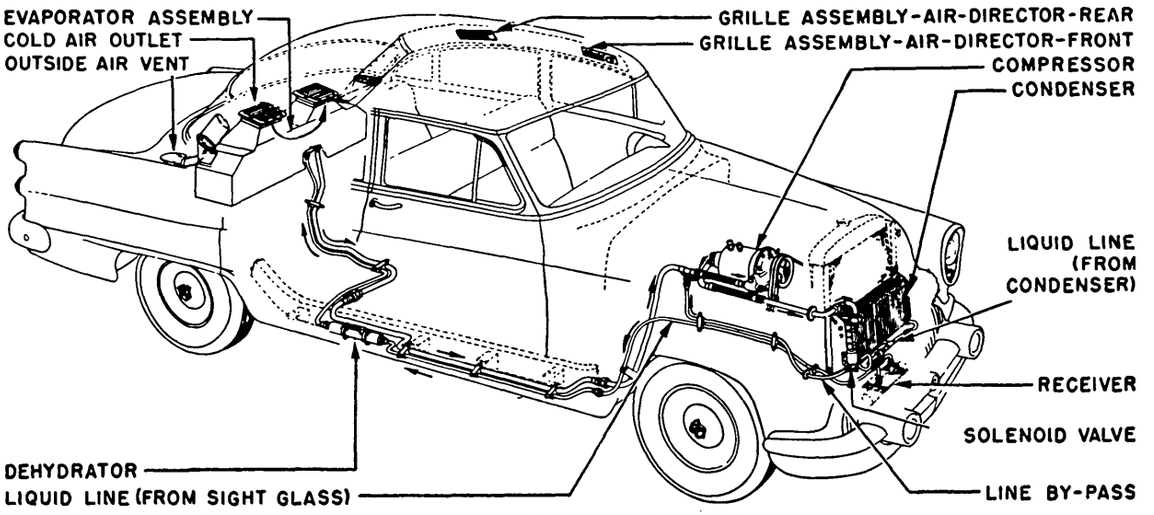
Pressure	Line Temp.
5 lbs. per sq. in.	2°-17° F.
10 lbs. per sq. in.	15°-30° F.
15 lbs. per sq. in.	25°-40° F.
20 lbs. per sq. in.	34°-49° F.
25 lbs. per sq. in.	41°-56° F.
30 lbs. per sq. in.	48°-60° F.

If low pressure line temperature below limits at cooling unit, expansion valve must be closed ½ turn at a time until both temperature and pressure readings agree with above table. If above limits at cooling unit, expansion valve must be opened ½ turn at a time until readings agree with table above. Sufficient time (20 minutes) must be allowed between adjustments for temperatures and pressures to stabilize. High and low pressures, indicated on gauge set at compressor should be within limits shown in following table according to outside air temperature at time test is being performed.

Temp of Surrounding Air	Low Pressure Lbs. per Sq. In.	High Pressure Lbs. per Sq. In.
65° F.	1-8	100-110
70° F.	2-11	105-125
75° F.	4-13	115-140
80° F.	6-16	125-155
85° F.	8-18	135-175
90° F.	10-21	140-190
95° F.	12-23	150-205
100° F.	14-26	155-220

IDLE SPEED-UP CONTROL (Cadillac): Start engine, allow to warm up, then turn Air Conditioner "ON." With transmission shift lever in neutral position, adjust serrated nut on rod to maintain idle speed at 750-800 RPM.

CHECKING



BUBBLES IN SIGHT GLASS: Appearance of bubbles in sight glass when engine idling or when solenoid valve is open is not unusual, and does not indicate a shortage of refrigerant. To check, operate engine at 1300 RPM for 15 minutes with Air Conditioner switch "ON", blowers operating, and jumper wire connected between battery and solenoid wire to close solenoid valve. If bubbles are still present after above tests, proceed to check as follows:

Solenoid Valve—Check for leaks by feeling the pipes on both sides of the valve. If there is any difference in temperature between the two pipes, the solenoid coil is burned out, solenoid plunger is sticking open and not seating on valve stem, refrigerant is leaking past valve seat. Check in following sequence:

Coil—Disconnect solenoid valve lead-in wire at junction, connect one end of jumper wire to valve lead-in wire. Touch other end of jumper wire to positive post of battery. If coil operating, a "thump" will be heard as neoprene end of valve plunger contacts valve stem. When jumper wire is removed from battery post, a "click" is heard as valve plunger rises under spring pressure. If movement of valve plunger cannot be heard, replace coil. To replace coil, disconnect ground wire at bottom of solenoid, remove self locking nut from top of solenoid. Remove tube cup, coil housing, sleeve, and spring washer. Remove and replace coil, reassemble. After replacing coil, check operation of valve plunger as described above. If plunger travel still cannot be heard, cause is not in coil.

NOTE—In some cases plunger can be freed up by opening and closing the circuit at the battery a few times. If plunger still inoperative, disassembly of the solenoid valve is necessary. For Removal and Installation of Solenoid Valve see REMOVAL & INSTALLATION TO WORK IN ENGINE COMPARTMENT following.

►**SOLENOID BY-PASS VALVE REWORK:** Remove two Allen head screws from base of valve body, remove base. Remove neoprene valve seat from body. Mark with a pencil the location of the four staking points, then clamp valve body lightly in a bench vise on flat faces near center of casting. *(CAUTION —Extreme care must be used to prevent scratches or nicks on flange face of body or surface of ring seat in center of casting, as any damage to these surfaces could result in refrigerant leaks after assembly).* Inspect valve body for evidence of foreign material. Similarly inspect inlet pipe. If no evidence found, solenoid valve assembly must be replaced. If foreign material found, clean valve body with Frigidaire oil. Install new screen, Part No. (G.M.) 5915508, in valve body with dished face on top side and flanged edge down. Hold staking tool (Can be made from standard 5/32" pin punch) at pencil scribe marks in a vertical position, with ground surface of shank toward center of valve. (NOTE—Round side of pin should be against wall of casting). With a ½ lb. ballpeen hammer, strike a light blow at each of the four staking points. This will prevent screen from shifting position or becoming dislodged. Assemble valve and replace in car. Note—Place daub of red paint on valve body next to name plate to indicate screen has been installed.

FRIGIDAIRE AIR CONDITIONING SYSTEM (TYPICAL)

Lines—Check for kinks in liquid line between sight glass and receiver, and also high pressure line from compressor to condenser and from condenser to receiver. Replace any kinked or damaged lines. Leak test system. If **no** leaks are found, **do not** add refrigerant.

Expansion Valve—Check expansion valve power element for full contact with low pressure line. Be sure bulb does not contact the liquid line or cover. Add insulating material where required. Adjust expansion valve to 5-6 turns open *(a change over previously recommended 10 turns).*

Receiver—If bubbles remain after adjustment of expansion valve, it is an indication that there is a restriction or a mispositioned pick-up tube in receiver. Replace receiver.

PUMPING DOWN THE SYSTEM

To replace many components of the system refrigerant must be pumped into receiver in order to save as much refrigerant as possible. To Pump Down the System proceed as follows:

►*CAUTION—When attempting to remove or replace flare fittings or any component, extreme care should be taken to give support to mating member to avoid distortion.*

1) Connect lines of gauge set to high and low pressure connections on compressor.
2) Remove cap from shut-off valve at receiver.
3) With ¼" valve key (Tool J-5427), close liquid line shut-off valve at receiver.
4) Remove caps from high and low pressure shut-off valves on compressor. *NOTE—Purpose of this step is to facilitate closing off lines quickly if necessary.*
5) Energize solenoid (close valve) by disconnecting solenoid wire at connector and connecting it to battery with jumper wire.
6) Remove plug from center fitting on gauge set.
7) Purge air from gauge lines by slightly cracking low and high pressure valves on gauge set, then close valves.
8) Turn ignition on, operate engine at low idle

CONTINUED ON NEXT PAGE

1953 FRIGIDAIRE (C nt.)

speed, then turn air conditioning control switch to "ON" position.

►*CAUTION*—Since receiver will not hold entire charge of refrigerant, it may be necessary to discharge some during the operation. **If pressure reaches 275 lbs.** turn off ignition, then discharge refrigerant by opening valve on high pressure side of gauge set to atmosphere.

9) Allow compressor to operate until low pressure gauge reads "O", stop engine, remove ignition key. With valve key (Tool J-5427) close high pressure shut-off valve at compressor.

10) Low pressure gauge shows more than "O" lbs. Purge remaining refrigerant from low pressure side by opening valve on that side. Allow 1 or 2 lbs. pressure to remain.

11) Shut low pressure gauge valve for 5 minutes. If pressure builds up above 5 lbs. repeat 10) above. With valve key (Tool J-5427) close low pressure shut-off valve on compressor.

EVACUATING THE SYSTEM

Evacuation of the System is required when system is opened for any reason. For this operation use Vacuum Pump, Tool J-5428. Proceed as follows:

1) Connect lines of gauge set to high and low pressure connections on compressor.

2) Install gauge line from center connection of gauge set to tee connector (Tool J-5462-2).

3) Install female connector (Tool J-5462-7) at inlet side of vacuum pump.

4) Insert flare seat (Tool J-5462-8) in connector (Tool J-5462-7) at vacuum pump.

5) Install hand shut-off valve (Tool J-5462-1) to connector at vacuum pump.

6) Install gauge line from one side of tee connector to valve at vacuum pump. Valve should be closed.

7) Install connectors (Tools J-5462-4, 6) on one end of a gauge line (J-5418).

8) Insert lead washer (Tool J-5462-3) in large end of drum connector (Tool J-5462-4).

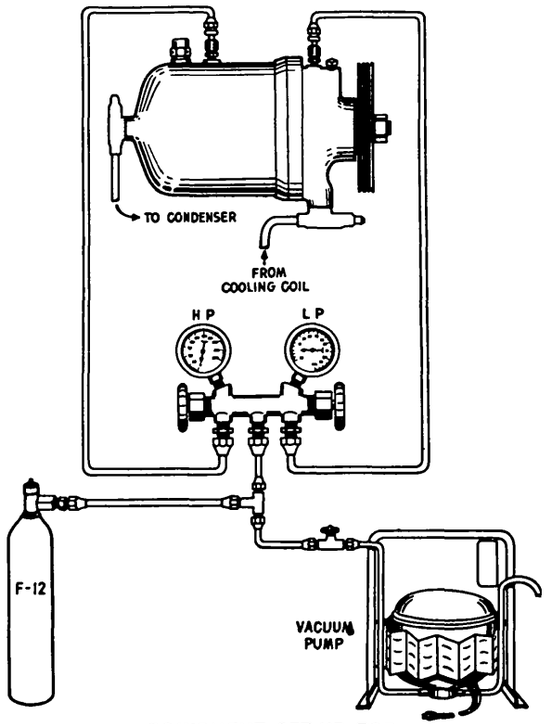
9) Insert a gauge line from remaining tee connection to drum of Freon.

NOTE—Whenever gauge lines installed for purpose of adding refrigerant or checking pressure AIR MUST BE REMOVED BY PURGING (allowing refrigerant pressure to force air out to atmosphere). This is accomplished by slightly opening and closing valves on gauge set.

Evacuating Low Pressure Side of System:

1) Open low pressure valve at compressor, close liquid shut-off valve at receiver and high pressure valve at compressor.

2) Open low pressure valve at gauge set (high pressure valve remains closed).



3) Connect and start vacuum pump.

4) Slowly open two-way shut-off valve at vacuum pump to avoid forcing oil out of pump.

5) Operate pump to obtain 28" vacuum for 10 minutes. Close shut-off valve at pump, stop pump. Check gauge to see if vacuum holds. NOTE—If vacuum of 28" cannot be obtained proceed with 6) following for leak test.

6) Open Freon drum valve, allow system to come to drum pressure. Close drum valve. Leak test complete low side of system, including gauge fittings, with Leak Detector J-5419. If leak cannot be found vacuum pump may be faulty.

►*NOTE*—If oil blown out of vacuum pump, refill to proper level with Frigidaire 75 viscosity oil.

EQUIPMENT SET-UP FOR EVACUATION OF SYSTEM

7) If leak found, fix leak and operate pump to obtain vacuum as in step 5). Watch gauge to see if vacuum will hold 3-5 minutes. If not, repeat 6).

8) With all leaks eliminated, open Freon drum and bring system to drum pressure again. Both gauges should equalize. Close drum valve.

9) Repeat evacuation procedures to pick up any air or moisure remaining in system.

10) System is now ready for **partial** charge of refrigerant.

Evacuating Entire System:

1) Make certain low pressure shut-off valve at compressor is open. The liquid shut-off valve at receiver and high pressure shut-off valve at compressor must also be open.

2) Open low and high pressure gauge valves on gauge set.

3) Perform operations outlined in steps 3) through 9) in "Evacuating Low Pressure Side of System" above.

4) System is now ready for **complete** charge of refrigerant.

ADDING REFRIGERANT

►***CAUTION—Never add refrigerant until system has been leak tested and properly evacuated. Refrigerant is always added to low pressure side of compressor*** **in a vaporous state.**

Preparation of Freon for Charging: Place drum in bucket of hot water. Temperature of water should not exceed 125°. Since temperature of water and drum will decrease as vapor leaves drum, drum pressure may decrease to point where it will be necessary to replenish or reheat water. Place Freon-12 drum and bucket of hot water on scales so it can be determined when complete charge of 7 lbs. of refrigerant has been added to system.

►*CHARGING CAUTIONS*—Whenever compressor is in operation during charging observe the following:

1) Wear goggles when handling Freon or breaking line connections.

2) High pressure **should not exceed 275 lbs.**

3) Close low pressure hand shut-off valve on gauge set completely at frequent intervals in order to maintain pressure on low side of compressor **above 12 lbs.** NOTE—When valve closed, pressure on low side of compressor is indicated; when open, drum pressure is indicated.

)4 Drum pressure minimum should be 12 lbs., maximum 90 lbs.

5) Close solenoid by connecting jumper wire from battery to solenoid wire at connector.

Adding Partial Charge: Evacuate low pressure side of system. ***See Evacuating The System above.*** Then proceed as follows:

1) Open high pressure valve at compressor (low pressure valve at compressor and valve at receiver must also be open).

2) Operate engine and compressor at slow idle speed.

3) Open low pressure valve on gauge set (high pressure valve on set must be closed).

4) Open drum valve slightly (90 lbs. max.), watch sight glass until solid column of liquid appears.

5) Note scales and allow compressor to operate until 1 additional lb. of Freon-12 has been charged into system.

6) Close drum valve, then close low pressure hand shut-off valve on gauge set.

7) Make certain compressor valves open, then operate engine at speed corresponding to 35-40 MPH. Observe gauges, sight glass, and entire system for proper performance.

8) After 5 minutes operation, should bubbles appear, add 1 more lb. of refrigerant.

9) When satisfied with operation, remove gauge connections on compressor, disconnect Freon drum, then cap gauge connections on compressor with flare nuts.

Adding Complete Charge: Evacuate complete system. ***See Evacuating The System above.*** Then proceed as follows:

1) Open both hand shut-off valves on compressor and low pressure valve on gauge set.

2) Freon-12 vapor will flow into system **without** operating compressor. **Amount should not exceed 7 lbs. by weight.**

►*NOTE*—If not possible to charge total of 7 lbs. by this method, it is permissible, after 1½-2 lbs. have been forced into system, to operate compressor and engine at slow idle speed. Hand shut-off valve on high pressure side of gauge set should be closed. Continue to operate engine and compressor at slow idle until 7 lbs. total is charged into system.

3) Close drum valve, then close low pressure valve on gauge set.

4) Operate engine and compressor at speed corresponding to 35-40 MPH. Observe high and low pressure gauges, sight glass, and general performance of system.

CONTINUED ON NEXT PAGE

1953 FRIGIDAIRE (Cont.)

5) When satisfied with operation, stop engine, remove gauge line connections at compressor and cap with flare nuts. Remove drum from water.

CHECKING & ADDING OIL

Checking Oil Level: From point in front of grille of car direct flow of air from a 12" or 15" fan at condenser (to keep engine temperature down and provide for more efficient functioning of condensing unit), operate engine at fast idle or speed corresponding to 35-40 MPH for 10 minutes with cooling control switch "ON" and blowers operating at High Speed. Stop engine. Remove flare nut and deadhead from Schrader valve on underside of compresser housing. Depress Schrader valve core, allowing first surge of oil to escape. If oil continues to escape with the Freon vapor, oil level is to be considered satisfactory. Add oil if oil does not continue to escape with Freon vapor.

Adding Oil (Minor Loss): Use 525 viscosity Frigidaire Oil. Proceed as follows:

1) Shut high and low pressure hand shut-off valves at compressor, depress Schrader valve core on high pressure test connection to purge Freon until low audible hiss is heard. Allow to stand a few minutes, then repeat purging. Remove high pressure relief valve.

2) From graduated bottle, pour 4 ozs. of oil into high pressure relief valve opening. Replace high pressure relief valve using new copper gasket.

3) Open high pressure hand shut-off valve, purge air from compressor by depressing Schrader valve core on high side gauge connection of compressor.

4) Recheck oil level. Shut-off valves at compressor must be open. *See "Checking Oil Level" above.*

5) If oil still low, continue to add 4 ozs. at a time until satisfactory level reached, following steps outlined above.

6) Make sure high and low pressure shut-off valves are completely open, replace protective caps over valve stems. Replace flare nuts and deadhead on both oil test fitting and high pressure gauge fitting connections. Leak test all connections that have been disturbed.

Adding Oil (Major Loss): Use 525 viscosity Frigidaire Oil. Proceed as follows:

1) Close both high and low pressure hand shut-off valves at compressor, depress Schrader core on high pressure gauge connection of compressor. Purge pressure until only slight audible hiss is heard. Repeat, if necessary, to be sure pressure is at a minimum.

2) Remove valve flange mounting screw and hand shut-off valves from bore of compressor. Remove belts and compressor from mounting brackets, place compressor on work bench. Remove high pressure relief valve.

3) Invert compressor, drain oil into clean container.

▷*NOTE*—Examine oil for foreign material, such as metal chips, water and sludge. This oil should be discarded. If excessive amount of water found, install new liquid dehydrator-filter in high pressure liquid line. *See "Replacing Dehydrator-Filter" following.*

4) From graduated bottle, pour 16 ozs. of oil into high pressure relief valve opening in compressor. Replace high pressure relief valve using new copper gasket.

5) Reinstall compressor on mounting brackets, connect high and low pressure hand shut-off valves using new "O" rings and gaskets. Reinstall belts.

6) Open high pressure hand shut-off valve and, by depressing Schrader core on high pressure gauge connection, purge air from compressor. Open low side hand shut-off valve.

7) Leak test all connections that have been disturbed.

PURGING AIR FROM SYSTEM

To determine presence of, and remove air and excess refrigerant from system proceed as follows:
1) Connect high side of gauge set to high pressure gauge connection on compressor. With compressor not operating, open high pressure valve on gauge set slightly, allow vapor and air mixture to exhaust SLOWLY through center connection of gauge set to atmosphere, then close valve.

▷*NOTE*—To determine if all air exhausted, place small flame (cigar lighter or match) at point of discharge. Freon vapor will put out flame. Air will cause flame to move but not put it out.

2) Clip ⅝" thermo-well (Tool J-5422) on inlet tube of condenser. Fill well cavity with water and insert 0-225° F. thermometer (Tool J-5421) in cavity.

3) Operate engine and compressor at fast idle or speed approximately 35-40 MPH for 5 minutes.

▷*CAUTION—Do not allow high pressure to exceed 275 lbs. See Pumping Down The System above.*

4) Stop engine, allow system to attain room temperature, observing high pressure gauge and thermometer.

▷*NOTE*—If high pressure gauge reading reduces as condenser cools and conforms to pressure-temperature relationship of Freon 12 (See Chart below), difficulty was due to overcharge of refrigerant and not air. If pressure does not reduce as condenser cools in conformity with pressure-temperature relationship of Freon 12 there is air in system. In either case high pressure side of system must be purged.

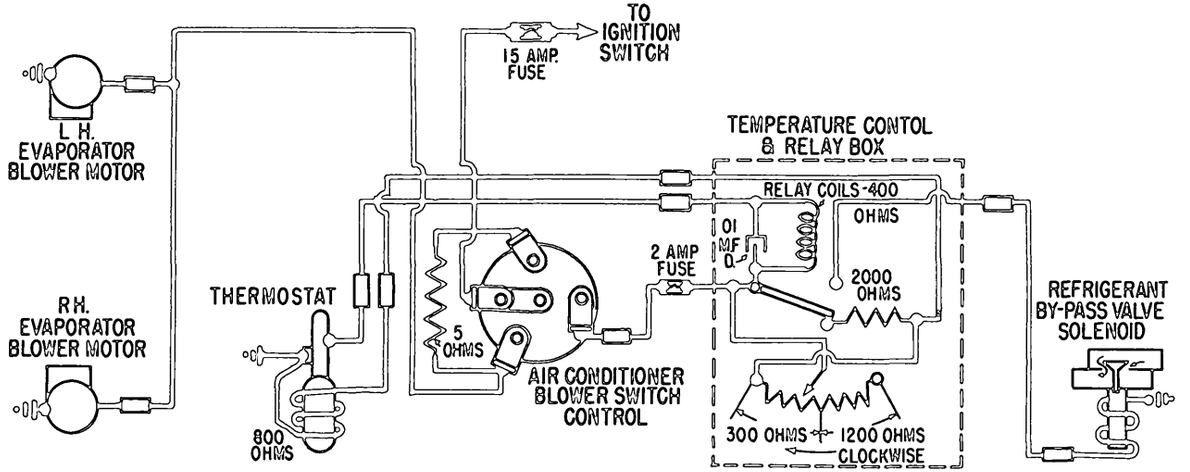
Pressure-Temperature Relationship—Freon 12

°F.	Lbs. Press.	°F.	Lbs. Press.	°F.	Lbs. Press
0	9.2	40	37.0	80	84.1
10	14.6	50	47.0	90	99.6
20	21.0	60	58.0	100	117.0
30	28.5	70	70.0	110	136.0

5) Open high pressure valve on gauge set SLOWLY, allow vapor to exhaust at center connection on gauge set.

▷*CAUTION—Cover connection with cloth to prevent oil and refrigerant from contacting persons or objects.*

6) Repeat 5) at frequent intervals, observing pressure gauge and thermometer, until both correspond to temperature-pressure relationship of Freon 12.



▷*NOTE*—If cause of difficulty was overcharge of refrigerant, it is necessary to purge excessive Freon to point where high side pressure does not build up rapidly when engine operating.

7) Open low side hand shut-off valve on compressor and valve on receiver, operate engine at fast idle or speed corresponding to 35-40 MPH for about 5 minutes. Check operating pressures and sight glass. When satisfied with operation of system, disconnect gauge set, replace flare nuts, tighten all fittings.

REMOVAL & INSTALLATION TO WORK IN ENGINE COMPARTMENT

▷*CAUTION—Refrigerant in the system is under high pressure at all times. Loosening any fitting in the system will release Freon under pressure. ALTHOUGH FREON IS NOT HARMFUL AS A VAPOR, IT COULD CAUSE SERIOUS DAMAGE IF IT REACHED THE EYES IN LIQUID FORM. CONNECTIONS SHOULD NOT BE LOOSENED UNTIL PRESSURES HAVE BEEN REDUCED, AND PROTECTIVE GOGGLES PLACED OVER THE EYES.*

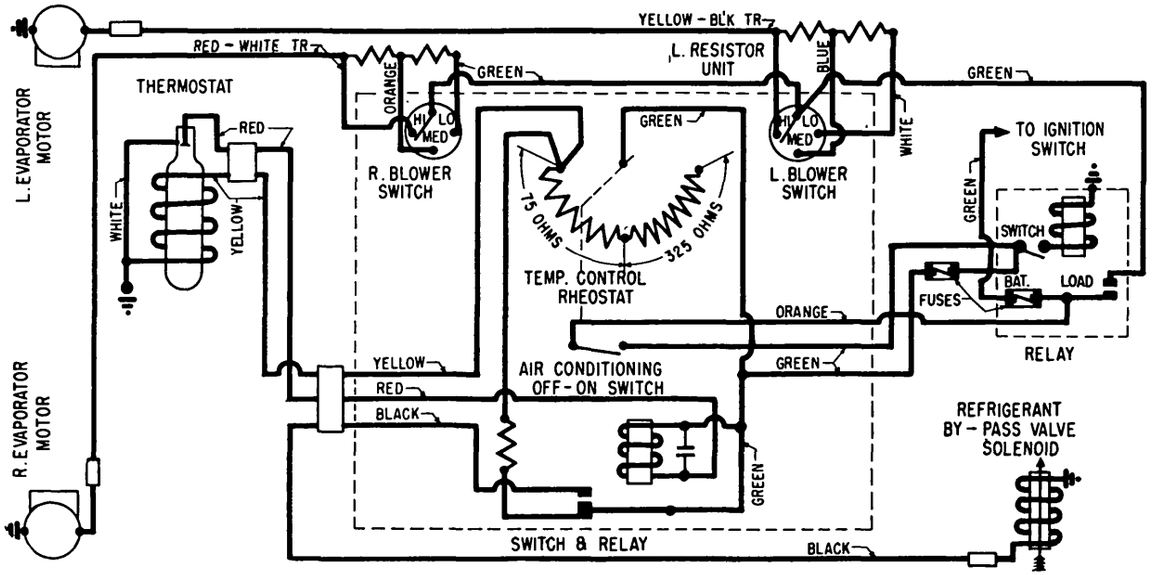
COMPRESSOR: Located directly above generator on right side of engine, is driven by two "V" belts from crankshaft pulley. Two lines connect refrigerating system to compressor. High pressure line connects at rear of compressor body, and low pressure line at front. Each line contains a shut-off valve at point where line attaches to compressor. Valves are operated with a ¼" key (Tool J-5427) after hexagonal

CONTROL SYSTEM WIRING (BUICK—TYPICAL OF CADILLAC & OLDSMOBILE)

CONTINUED ON NEXT PAGE

1953 FRIGIDAIRE (C nt.)

caps are removed from valves. Closing these valves shuts off system from compressor.



►*CAUTION—Compressor should not be operated with high pressure line valve closed.*
In addition to manual valves there are Schrader type valves in compressor at points of line attachment. Valves automatically close, sealing compressor when lines are removed from compressor body. On top of compressor body are high and low gauge line fittings. Fittings are capped and contain Schrader type valves which seal compressor from outside air.

Removal—Remove covers from high and low line valves at compressor. Using ¼" key or square socket, close valves tightly by turning clockwise. Remove protective covers from high and low pressure gauge fittings (on top of compressor). NOTE—Hold fitting with wrench to prevent its turning.

►*CAUTION—Wear protective goggles as some fluid may escape under pressure left in compressor.*
Drape clean wiping cloth over a small brass rod and depress Schrader valve in high pressure gauge line fitting. Allow pressure to escape until there is no audible hissing sound (caused by escaping pressure). Repeat this bleeding procedure on low pressure gauge fitting. *NOTE—Cloth will deflect gas. Be sure face is not in path of escaping gas.* Remove high and low pressure lines by removing two bolts attaching each fitting to compressor. Cover compressor and pressure line openings with masking tape. Remove compressor adjusting bracket bolt, then belt from compressor pulley. Remove compressor from bracket by removing two attaching bolts and nuts.

Installation—Reinstall compressor to bracket, assemble and tighten belts (See Belt Adjustment under Maintenance and Inspection). Install new "O" ring seals on high and low pressure line fittings. Carefully insert high and low line fittings into their respective bores in compressor, being careful not to damage "O" ring seals. Tighten lines evenly to compressor body. Crack open high pressure line valve (rear valve) with valve key. Depress Schrader valve in low pressure gauge line fitting for a few seconds to allow pressure to escape (purges any air from compressor). Open high and low pressure line valves all the way by turning counterclockwise. NOTE—Valves must come against their seats in open position as they seat against a seal. Replace protective covers on line valves and gauge fittings. Test for leaks at compressor fittings, using Leak Detector J-5419 in accordance with instructions furnished with detector.

SOLENOID VALVE: Removal—Close hand shut-off valve at receiver. Discharge high and low sides of system. NOTE—If compressor already removed discharge system through hand shut-off valves at point of connection to compressor. If compressor not removed discharge through gauge set connections on top of compressor. *Use cloth to deflect escaping Freon.* (The closed shut-off valve and check valve at receiver will prevent Freon present in receiver from escaping). Disconnect wiring leads, remove solenoid valve from line by disconnecting flare nuts at valve.

PACKARD CONTROL SYSTEM WIRING

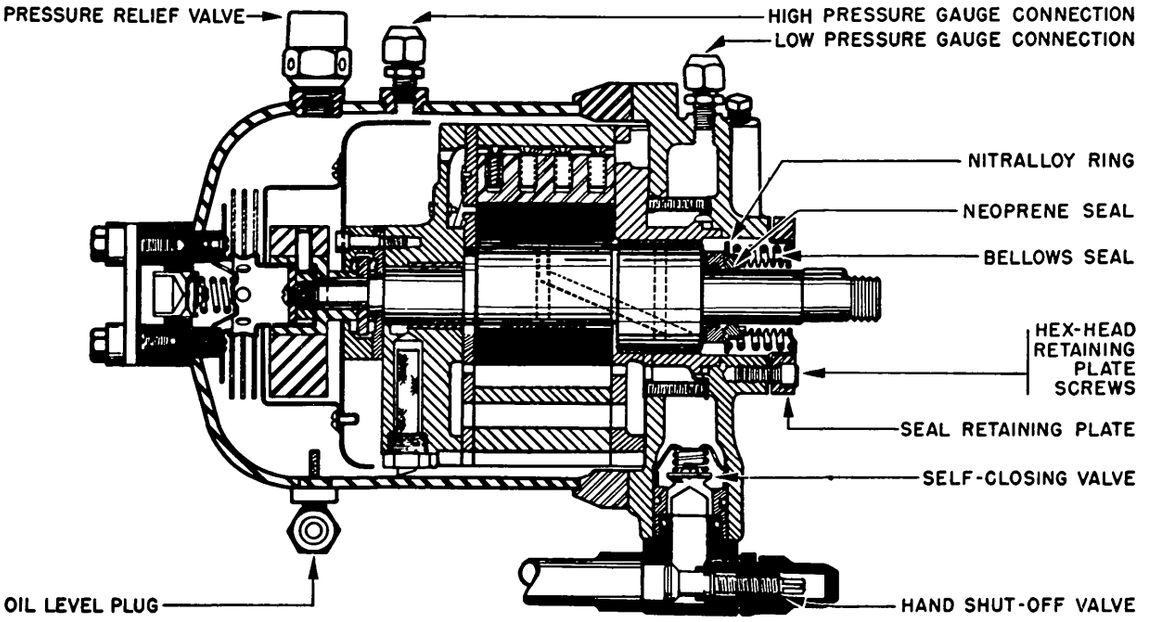
Installation—If no parts other than compressor and solenoid removed reinstall solenoid valve (and compressor—See Compressor Installation above) making sure refrigerant flow is in direction of arrow on valve, toward rear of car. Reconnect wiring to valve. Open hand shut-off valve at receiver and make sure hand shut-off valves at compressor are open. Allow system to build up pressure to between 35-40 lbs. Close valve and test for leaks. If no leaks found, leave receiver valve closed and evacuate system after attaching gauge set. Open hand shut-off valve at receiver and recharge system with refrigerant *(See Adding Refrigerant above).*

ENGINE COMPARTMENT ASSEMBLY: In order to work on engine and units around radiator it may be necessary to remove the compressor, solenoid valve, condenser and receiver assembly. Proceed as follows:

Removal—Discharge complete system through Schrader valves at test fittings on compressor. *Use cloth to deflect escaping Freon.* Remove hood lock plate and baffle. Disconnect high pressure line (flared connection at condenser inlet), outlet lines at flared connection alongside condenser and at inlet elbow on receiver. Remove condenser mouting bolts, remove condenser. Disconnect high pressure inlet flare at receiver and high pressure outlet line from shut-off valve at receiver. Remove receiver mounting bolts, then receiver. Remove brackets holding connecting tubing. Remove Compressor and Solenoid Valve, if necessary *(See Compressor & Solenoid Valve Removal above).*

Installation—Reverse removal procedures above. Evacuate entire system and recharge with refrigerant. Test for leaks (Tool J-5419).

PARTS REPLACEMENT



COMPRESSOR: Connect gauge set to high and low gauge connections on compressor. Close high pressure hand shut-off valves at compressor and receiver. Energize solenoid, closing valve by connecing jumper wire to battery. Discharge low pressure side of system through gauge set. Close low pressure hand shut-off valve at compressor. Disconnect dehydrator-filter in liquid line (See Dehydrator-Filter Replacement following). Disconnect gauge set, high and low pressure valves from compressor, remove compressor from mountings. Open hand shut-off valve at receiver, allow refrigerant in high side to escape at open dehydrator-filter connection (Catch Freon with rags or container). NOTE—If system completely discharged due to compressor failure, flush with Freon-12 from drum. Proceed as follows: Remove Schrader core from self-closing valve in header inlet of condenser. Install charging line to this connection and Freon drum containing no more than 5 lbs. of Freon-12. Invert drum and with valve open wide allow liquid Freon to flush through condenser, receiver, and line to dehydrator-filter open connection. *(CAUTION—Use goggles).* Close drum valve, disconnect charging line from drum and condenser, replace core in Schrader valve. Install new dehydrator-filter in liquid line. Remove cone screen from liquid inlet of expansion valve, install new screen cone. Install new compressor in mounting, install and tighten belts. Install hand shut-off valves at compressor, using new "O" rings and gaskets. De-energize solenoid by removing jumper wire to battery. Install gauge set, open hand shut-off valves on compressor. Evacuate system, test for leaks, and recharge system with refrigerant.

COMPRESSOR SHAFT SEAL: With ignition off, close high and low pressure shut off valves at compressor,

CONTINUED ON NEXT PAGE

1953 FRIGIDAIRE (C nt.)

relieve remaining pressure in compressor by depressing Schrader valve cores in gauge connections on compressor to 2-5 lbs. Remove shut-off valve fittings from compressor. *Wear goggles.* Loosen compressor pulley lock-nut (Tool J-5454). Loosen generator belt adjusting strap, remove compressor belts, then compressor. Remove pulley from shaft (Do not hammer off). Remove seal retaining plate, Nitralloy ring (Tool J-5425). Install new ring (Tool J-5425) making sure neoprene seal rests evenly and firmly against shaft shoulder (Keep fingers off polished ring seat which makes contact with bellows seat). Apply clean Frigidaire oil to ring and seat and first three turns of bellows seal. With Tool J-5425 install seal and gasket. Install retainer plate, tighten bolts alternately to insure even pressure against seal. Do not remove tool until all bolts tight. Add oil as required (See Adding Oil above). Install compressor, pulley and belts. Tighten belts. Install low and high pressure valves in compressor, using new "O" ring seals and gaskets. Open high pressure shut-off valve at compressor, purge air from compressor by depressing Schrader core in high pressure gauge connections for few seconds. Open low pressure shut-off valve on compressor, start engine and allow it to operate for several minutes, repeat purging to remove air that has entered during seal replacement. Recap high pressure gauge connection. Leak test compressor shaft seal and connections that were disturbed.

FRIGIDAIRE COMPRESSOR SECTIONAL VIEW

1954-55 FRIGIDAIRE & HARRISON AIR CONDITIONING

Buick (1954-55)
Cadillac (1954-55)
Chevr l t V8 (1955)
Oldsmobile (1954-55)
Packard (1954-55)
P ntiac (Lat r 1955) ①

①—For first 800 cars in 1955 see "1954-Early 1955 Pontiac" Air Conditioning.

►CHANGES, CAUTIONS, CORRECTIONS

►*1954 BUICK CLUTCH BEARING INSTALLATION CAUTION:* Compressor clutch bearings installed on compressors prior to Compressor No. 64MB060 were slip fit. Clutch bearings installed on later compressors were pressed on, due to increase in diameter of shaft to give a press fit of .002-.0005". It will be necessary to use a suitable puller to remove pulley from compressor.

►*1954-55 CLUTCH LUBRICATION CAUTION:* When assembling compressor clutch it has been found advisable to lubricate between outer bearing and pulley, between inner bearing and shaft, and between hub and spline. Use high pressure grease, preferably one with a melting point above 250°F. Apply grease sparingly to prevent transfer of grease to clutch plates, due to centrifugal force. It is suggested that lubricant be applied by first spreading it in a transparent film on a clean, flat surface, such as a piece of glass or paper. Then, wipe a brush over the film to pick up the lubricant and apply it to clutch parts. Be sure to wipe brush longitudinally on splines as any crosswise motion would deposit an excessive amount of lubricant.

►*1955 CHEVROLET THERMOSTATIC SWITCH ADJUSTMENT (To Provide Full Temperature Control):* An adjustment of the thermostatic switch is now included in adjustment procedures to correct frosting or icing condition in evaporator (results in poor or no cooling). See "Thermostatic Switch Adjustment (Chevrolet)" under ADJUSTMENTS below.

►*1954 EXPANSION VALVE PRODUCTION CHANGE:* Approximately June 1, 1954 a new smaller thermostatic expansion valve was incorporated in evaporator assemblies on air conditioning units in production. Evaporator assemblies beginning with Serial No. 511B852 will have new expansion valve. Part No. 5440860 will continue to be released for service until stock is exhausted, at which time new valve will be released for service replacement on both 1953 and 1954 models. The factory setting of the *new smaller expansion valve is approximately 5 turns counter-clockwise from fully closed position. Factory setting on early type is approximately ten turns from fully closed position.*

►*1954 CADILLAC FAN SHROUD VIBRATION CORRECTION:* A roaring noise may be noted on some early production air-conditioned cars (18-20 M.P.H. in second gear, 35 M.P.H. in third gear, or 50 M.P.H. in fourth gear) due to vibration of fan shroud. To correct, reposition fan shroud-to-radiator support bracer so that long, flat portion of spacer is below attaching screws, parallel to ground.

►*1954 CLUTCH SOLENOID GROUNDING CAUTION:* Clutch solenoid used on some early cars equipped with Air Conditioner has, in some instances, become inoperative due to inadequate grounding. To correct, install kit, Part No. 3630558, containing ground wire and lock nut.

►*1955 MAGNETIC CLUTCH PRODUCTION CHANGE:* Effective with Compressor, Serial No. 16XB275, tear drop depression on both clutch plates has been changed, and clutch activating coil has been redesigned (new plates identified by letter "O" stamped on inner face of each clutch plate, new coil by an orange ground lead). When necessary to replace either of two old type clutch plates, replace **both** old plates with new type and new coil (*NOTE*—New coil should always be used with new plates).

Part	New Part N .
Coil	5912343
Plate & Counterweight	5912346
Plate & Armature	5912345

►*1955 CLUTCH PLATE ACTUATING BALL REPLACEMENT CAUTION:* When replacing actuating balls in 1955 Compressors, be sure to use **nylon** type, Part No. 5917481 (1954 type was steel).

►*1955 CLUTCH ACTUATING COIL RETAINER PRODUCTION CHANGE (To Correct Compressor Noise & Failure of Clutch to Disengage):* Effective with Compressor, Serial No. 44XB653, a more positive means of retaining coil has been incorporated in production. Kit,

CONTINUED ON NEXT PAGE

1954-55 FRIGIDAIRE & HARRISON (Continued)

Part No. 5876681, contains parts necessary for service replacement on all 1955 compressors. To install kit, remove compressor, then compressor pulley. Remove and discard coil retainer and outer insulating gasket. Disconnect leads and remove coil, then discard inner insulating gasket. Drill three holes (No. 24 drill) in seal housing 9/64" down from outer face of housing. One hole must be diametrically opposite coil lead part, others at 120° intervals along diameter of housing. Place new inner gasket (one with holes) in bottom of seal housing. Replace actuating coil, connect leads, then place new outer gasket and retainer ring over coil. With two 3" C-clamps and two ½" lengths of 5/16" round rod as dowels (placed on outer edge of retainer ring) force coil and retainer ring snugly into seal housing applying pressure evenly on both C-clamps. While coil is held by C-clamps, insert the three self-tapping screws in holes drilled previously and tighten until heads snug against housing. Remove clamps and rods. Blow chips from tapped holes with compressed air. *CAUTION*–No portion of screw heads should extend beyond face of seal housing.

►*1955 COMPRESSOR DUST CAP (ON END OF COMPRESSOR SHAFT) PRODUCTION CHANGE:* Effective with Compressor, Serial No. 31XB936, compressor dust cap has been replaced by a washer assembly, Part No. 5912455. Torque for tightening bolt holding washer assembly is 5-7 ft. lbs. (previously 10-15 ft. lbs.).

►*1955 COMPRESSOR FREON OR OIL LEAK CAUTION:* Leaks between compressor head and shell flange **can t** be corrected by tightening mounting bolts. Replace compressor.

►*1955 CLUTCH COIL INSULATOR INSTALLATION CAUTION:* Insulators, used on each side of clutch coil, should be located with glazed surface **away** from coil.

►*1955 CLUTCH SNAP RING INSTALLATION CAUTION:* Snap ring must be installed so radius on inner diameter of one side of ring faces compressor pulley to insure that it will not slip out of groove.

►*CAR UNDERCOATING CAUTION:* Make certain that undercoating does not plug evaporator drain.

►*1955 CADILLAC COMPRESSOR VIBRATION CORRECTION (Due to Incorrect Pulley Installation):* Splined end has one spline cut down to mate with corresponding spline in compressor pulley. Unless installed in this **one** position, it will throw compressor out of balance, resulting in vibration when compressor is operating.

►*1955 CADILLAC ROOF DUCT AIR NOZZLE BIND CORRECTION:* To correct, remove retaining spring and file off sharp edges.

►*1955 PONTIAC RECEIVER & DEHYDRATOR-FILTER PROD. CHANGE:* Combination unit (after first 800 cars in 1955) replaces two units used previously. Combination type has no shut-off valve. Freon capacity of system with combination type is 3¾ lbs. instead of 5¼ lbs. with early type unit with separate receiver.

►*1955 PONTIAC AUTOMATIC FAST IDLE CHANGE:* Automatic fast idle, which was actuated by placing selector lever in neutral, is not used in 1955.

►*1955 PONTIAC AIR RECIRCULATION PROD.CHANGE:* An air recirculation system has been included to increase cooling capacity or eliminate outside odors when necessary. Exclusive use of outside air or recirculation of air within car may be selected by movement of one push-pull control. When pulled out, air in the car and system is recirculated, with a small amount of outside air still being admitted to pressurize the inside of the car. Pressure prevents warm air from entering any openings in body. With control button pushed in, only outside air passes through system into car. Positions between full out and in will give mixed outside and recirculated air. Fan must be on full speed (switch fully down) when recirculation is used. Recirculation should only be used after car has started to cool.

►*1955 PONTIAC COMPRESSOR BELT MISALIGNMENT CORRECTION:* To correct, elongate the two front inner insulator bracket (Part No. 521086) bolt holes by ¼" back toward compressor mounting flange, then place a 1/16" thick flat washer at each of the two insulator bolts to space bracket out from rubber insulator. Bend outer end of front outer insulator bracket back and in towards compressor 1/8". Condition has in later production.

DESCRIPTION & OPERATION

Similar in design and operation to 1953 Frigidaire (G.M.) unit with changes over previous models as noted below:

1954 Cadillac: Temperature control lever, solenoid bypass valve, relay, shut-off valve at receiver, check valve, and by-pass line were eliminated. Blower switch rheostats were changed to provide slower blower speeds. Temperature control is maintained by varying blower speed. A magnetic clutch is used in conjunction with the compressor.

1955 Cadillac: Same changes as in 1954 except that temperature control lever and a new type temperature control thermostat and compressor are used.

1954 Buick, Oldsmobile, Packard: Shut-off valve at receiver and check valve were eliminated. Magnetic clutch is used in conjunction with compressor.

1955 Buick, Oldsmobile, Packard: New type temperature control thermostat and compressor used. On Oldsmobile, all elements of system are located on dash and in engine compartment.

1955 Chevrolet: Shut-off valve at receiver, solenoid valve, and check valve not used. Temperature control is maintained through a temperature control lever and magnetic switch. Magnetic clutch is used in conjunction with compressor. All elements of system are located on dash and in engine compartment.

1955 Pontiac (After First 800 Cars): Similar in design and operation to 1954 Air Conditioning unit. Shut-off valve at receiver and fast idle diaphragm and solenoid have been eliminated.

PRECAUTIONS, TROUBLE SHOOTING & LEAK TESTING

See "Air Conditioning Service Cautions", "Trouble Shooting" and "Leak Tests".

MAINTENANCE & INSPECTION

MAINTENANCE & INSPECTION: Preliminary Check– High and low pressure shut-off valves at compressor must be fully open. Drive belts must be properly installed to prevent slippage. Make certain clutch is engaging and disengaging. Using leak detector, test entire system for leaks. If there is evidence of oil leaks, check oil level. Check operation of blower fans at all control positions. Check operation of temperature control lever or knob, relay, and thermostat.

Seasonal Operation: Winter– Close outside air intake ducts. *NOTE*–It is advisable to operate compressor for a few minutes each month during winter season.

Summer– Leak test entire system. If leaks found, check oil level. Check belts for proper tension. See that clutch engages and disengages. Make certain clutch is not slipping by observing dust cover or washer assembly bolt at center of pulley. Bolt should be turning at same speed as pulley. Operate system, with control set at maximum cooling, for 10 minutes at fast idle. Check sight glass for absence of bubbles which would indicate system has sufficient Freon charge. Open outside air intake ducts. Check blower fans for variable speeds.

2000 Mile Inspection: Check unit for evidence of leaks. If there is evidence of oil leakage, check compressor for proper oil level. Tighten compressor mounting brackets, check belt tension. Check sight glass for absence of bubbles indicating proper Freon charge (after running engine at fast idle for 10 minutes with Air Conditioning "ON" and compressor clutch engaged).

Filters: Air filters should be cleaned regularly during season of operation. This should be every two months, or 2000 miles, or more frequently in those areas which are extremely dusty. To clean filter, use solvent or soapy solution made with household detergent. After filter has been cleaned, rinse and blow dry with compressed air, then spray a light coating of SAE 30 detergent free, non-odorous, engine oil or RP filter coat on entire filter surface.

ADJUSTMENTS

COMPRESSOR BELTS: Adjust as follows:

Buick: Adjust drive belts to ½" deflection midway between fan and compressor pulleys.

Cadillac: Loosen generator pivot bolts and adjust strap screw, pull generator out until belt is just tight enough to drive generator and compressor without slip.

Chevrolet V8: Loosen compressor brace bolt and bracket pivot bolt. Check to see that lower brace bolt and compressor bracket-to-engine mounting bolts are drawn up tight. Assemble belt tensioning tool J-6212 to torque wrench J-4435 or similar 0-50 ft. lb. torque wrench. Position tool on seal and coil housing with lug on tool facing toward rear of car and inserted into unused hole

CONTINUED ON NEXT PAGE

1954-55 FRIGIDAIRE & HARRISON (Continued)

in compressor mounting flange on battery side of electrical connector (*NOTE*–It may be necessary to shift connector in clip slightly to obtain clearance for proper engagement of tool). Apply 30-40 ft. lbs. torque to compressor, tighten brace and bracket pivot bolts.

Oldsmobile: Loosen generator bolts, place tool J-4170 against generator between bracket and generator housing. Attach torque wrench to tool and apply a torque of 20 ft. lbs. Tighten attaching bolts while holding tension on belt.

Packard: Using tool J-5577 and a torque wrench, tighten belts to 58 ft. lbs. Tighten compressor-to-mounting bracket bolts while maintaining this 58 ft. lbs. torque.

P ntiac: Loosen three bolts retaining idler pulley to mounting bracket (pump support bracket on power steering equipped cars). (*NOTE*–Heads of bolts are behind pulley). Insert torque wrench in square hole at end of bracket and apply 60 ft. lbs. torque to tighten belt. While holding 60 ft. lbs. torque, tighten retaining bolts securely.

CLUTCH LEVER ADJUSTMENT (1954): Turn cooling switch "ON" to energize clutch solenoid. Loosen clutch lever adjusting nut jam nut, and adjust to obtain .015-.020" (.015-.025" on Buick) clearance between clutch lever and pin. Tighten jam nut. Start engine and check to be sure clutch drives compressor when solenoid is energized (switch on), and that clutch is fully released (pulley free-wheeling) when clutch is de-energized.

MAGNETIC CLUTCH (1955): Energize clutch coil from battery, check clearance between clutch plate armature (not rear pulley cover ring) and coil housing at three different positions. The clearance should be .025-.035". If clearance not correct, it will be necessary to remove pulley and add or remove shims accordingly. Shims are available in following sizes: .015", .020", .025". By proper selection of shims, .005" variance in clearance can be obtained.

VALVE ADJUSTMENTS: Proceed as follows:

Expansi n Valv (Except Chevrolet & Pontiac): Remove cap nut from expansion valve making certain that expansion valve is supported by a second wrench to prevent damage to line and fittings. Use tool J-5426 (3/16" Valve Key), first close valve completely, then open counter-clockwise approximately 5 complete turns (4½-4¾ turns on Oldsmobile). If this does not eliminate ineffective cooling condition, replace expansion valve, assuming that remainder of system is in good operating condition.

Expansi n Valve (Ch vrolet & Pontiac): If refrigerant flooding through valve in abnormal quantity (heavy sweating or frosting may occur), close valve adjusting stem ½ turn clockwise. If insufficient refrigerant being supplied to cooling coils, open valve ½ turn counter clockwise. If necessary, repeat above operation by turning valve in ½ turn increments at a time (should not exceed one full turn).

Automatic By-Pass Valve (1955 Oldsm bil & P ntiac): Turn screw clockwise to increase pressure, counter-clockwise to decrease pressure (*NOTE*–By-pass valve should not open until low pressure or suction reading is below 15 PSI. and ambient (surrounding air) temperature is below approximately 85°F.).

THERMOSTATIC SWITCH (Chevrolet): If icing or frosting conditions exist in evaporator (results in poor or no cooling) thermostatic switch is probably set too cold. To adjust, remove fiber cover from end of switch assembly and turn adjusting screw one turn clockwise (raises temperature 3°F). Test operation of unit and check for icing, repeating adjustment as required. Reinstall fiber cover.

CONTROLS: Adjust as follows:

Chevrolet: Fast Idle–Adjust hand throttle wire guide stop to limit engine speed to 900 RPM with control pulled out and transmission in neutral. Check to see that fast idle control linkage does not interfere with normal operation of carburetor linkage when fast idle is not in operation.

Outside-Inside Air–Adjust cable so that door is open with control set at "Outside Air" or closed with control set at "Inside Air".

By-Pass (Air Duct): Adjust controls for maximum nozzle flow by pulling by-pass control to full out position and securing cable to door control rod with rod positioned at end of travel nearest driver's side of car.

Thermostatic Switch: If icing or frosting condition exists in evaporator (results in poor or no cooling) thermostatic switch is probably set too cold. To adjust, remove fiber cover from end of switch assembly and turn adjusting screw one turn clockwise (raises temperature 3°F). Test operation of unit and check for icing, repeating adjustment as required. Reinstall fiber cover.

Pontiac: Air Valve Control Cable - First move air conditioning control lever to "OFF" position. Loosen air valve control cable at hood hinge attaching screw. Clamp must be loose enough to allow cable housing to slide freely. Hold cable and housing so that cable cannot move inside housing and slide cable assembly through clamp toward center of car until valve is tightly closed. While holding cable in this position, tighten clamp.

Air Temperature Valve Control Cable–Move air conditioning control lever all the way to "COLD" position. Loosen air temperature valve control cable clamp on side of evaporator housing. Hold cable and housing assembly so cable cannot move inside housing and slide cable assembly toward rear of car to close valve against sealing lip. While holding in this position, tighten cable clamp. *NOTE*–Excessive tightening can force valve past its sealing lip.

Air Recirculation Valve Control Cable: Push recirculation knob all the way in to close recirculation valve, then pull out 1/8". Remove right kick pad to gain access to cable clamp. Loosen cable clamp. Hold cable and housing so that cable cannot move inside housing and move cable assembly down through clamp to tightly close valve (Recirculation is closed off when valve is vertical). While holding cable assembly in this position, tighten cable clamp.

CHECKING

BUBBLES IN SIGHT GLASS: Appearance of bubbles in sight glass when engine idling or by-passing (if equipped with by-pass valve) is not unusual and does not indicate a shortage of refrigerant. Operate engine at fast idle for at least five minutes with air conditioning "ON", blowers operating. If bubbles still appear, check lines for kinks and leaks. If no leaks found, **do not** add refrigerant. Check expansion valve power element for full contact with low pressure line. Be sure bulb does not contact liquid line or cover. Add insulating material when required. Adjust expansion valve. If bubbles remain after adjustment of expansion valve, it is an indication that there is a restriction or a mis-positioned pick-up tube in receiver. Replace receiver- dehydrator.

OPERATION OF COMPRESSOR DISCHARGE VALVE REEDS: Connect gauge set to compressor (see Installation of Gauge Set to "Check Operation of System" below). Connect jumper wire from positive battery post to magnetic clutch coil. Operate engine and compressor at slow idle for five minutes. Slowly close low side valve on compressor until low side gauge reads between 5-10 lbs. pressure. Stop engine and immediately close low side valve on compressor. Allow system to remain idle for approximately five minutes. At the end of this time, low side gauge should not show any rapid rise of pressure, nor should the low pressure gauge have equalized to the high side pressure. If this has occurred, it is evident that the discharge valve reeds are leaking and the compressor should be replaced. If the low side pressure did not show a rapid rise, the compressor can be considered satisfactory as the discharge reeds were holding properly. Open low side valve on compressor, remove gauge set from compressor.

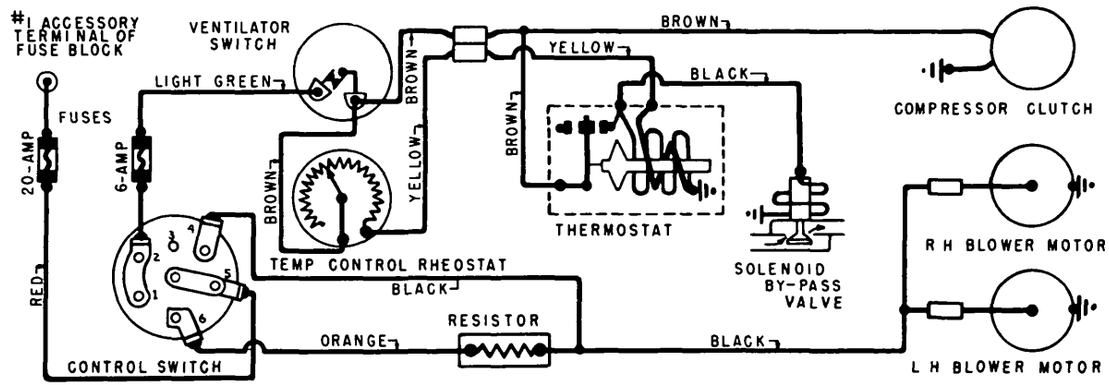
GAUGE SET INSTALLATION

TO CHECK OPERATION OF SYSTEM: With gauge set valves closed, connect gauge line to high pressure Schrader type gauge fitting at compressor. (*NOTE*–Make certain center connection of gauge set is plugged). Open both valves on gauge set ¼ turn counter-clockwise, purging Freon and air from lines and, at same time, install low pressure gauge line to gauge fitting at compressor. Close gauge valves. Leak test all gauge connections. If no leaks are found proceed as follows: Position temperature control to extreme "Cold" position to energize clutch. Turn Air Conditioner switch "ON" and operate blowers at full speed. A check of the system pressures can now be made. After completing check, remove gauge lines and replace caps.

TO PURGE THE SYSTEM: Remove caps from high and low pressure gauge connection fittings at compressor. Connect gauge lines. Make certain gauge valves are closed tightly. Connect gauge line to center connection of gauge set, removing plug from end of line.

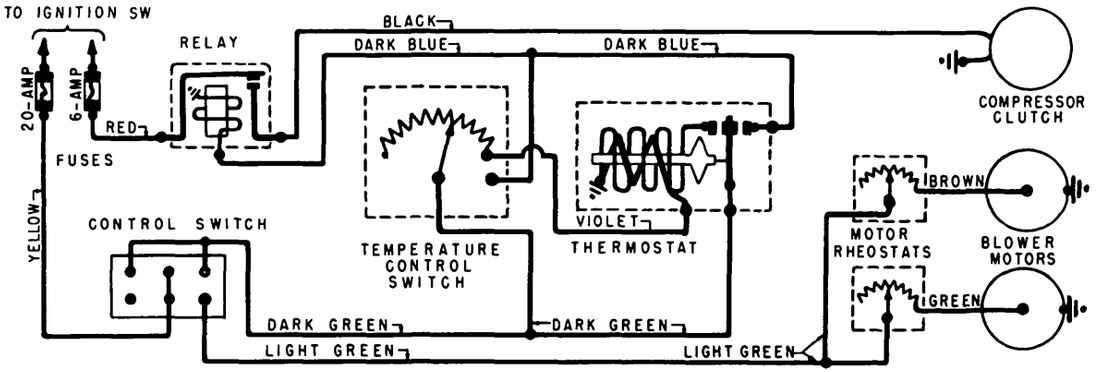
TO EVACUATE & CHARGE THE SYSTEM: Remove caps from high and low pressure gauge fittings at compressor. Connect gauge lines to fittings. Make certain gauge set valves and shut-off valve at vacuum pump are closed tightly. Remove valve caps from compressor hand shut-off valves and make certain valves are fully open.

CONTINUED ON NEXT PAGE



1954-55 FRIGIDAIRE & HARRISON (Continued)

PURGING THE SYSTEM



In replacing any of the air conditioning components (except compressor) the system must be completely drained of refrigerant. The purpose is to lower the pressure inside the system so that a component part can be removed safely. To purge system, connect gauge set to compressor (See "To Purge the System" above). Purge refrigerant from system through center connection of gauge set by first opening high pressure valve on gauge set. (*NOTE*–Do not open valve wide until pressure in system has been lowered, as refrigerant under pressure will force oil out of compressor). Close valve on gauge set from time to time for the purpose of allowing 1-2 lbs. of refrigerant pressure to remain in system, then close both valves on gauge set. (*NOTE*–Allowing 1-2 lbs. of refrigerant pressure to remain in the system will prevent air and dirt from entering system when a part is replaced). Leave gauge set connected in preparation for evacuating and recharging.

EVACUATING THE SYSTEM USING VACUUM PUMP

Whenever system is opened for any reason, it should not be put into operation again until it has been evacuated. For this operation use Vacuum Pump. Tool J-5428, to remove air and moisture which may have entered the system when it was opened to replace a part. Make sure dust cap on discharge side of vacuum pump has been removed. Check fluid level. This should be between the high and low screws in the side of the pump. Add Frigidaire viscosity 75 oil to bring to proper level (*NOTE*–Change oil in pump every 250 hours of operation by removing top and laying pump on side with discharge oil trap up. Hold rotor firmly in position to prevent its coming out while draining oil. A small amount of oil may be drawn into pump occasionally to insure protection of internal parts during periods of disuse). If pump should fail to start; check capacitor, relay, or remove the top and turn rotor by hand to relieve a temporary stuck condition. (*CAUTION*–Do not use vacuum pump as an air compressor as it will not receive proper lubrication under such usage. Keep suction and discharge fittings capped when not in use). Connect gauge lines (See "To Evacuate & Charge The System" above) if not installed previously. Open high and low pressure valves on gauge set. Connect and start vacuum pump. Slowly open the shut-off valve at the vacuum pump to avoid forcing oil out of pump. This will permit drawing of a vacuum on both the high and low pressure sides of system at same time. Operate to obtain approximately 28" of vacuum for ten minutes. If sufficient vacuum cannot be obtained, vacuum pump or gauge may be faulty. Close shutoff valve at pump and then stop pump. Check gauge to see if vacuum holds for at least three minutes. If not, open Freon drum valve and allow system to reach drum pressure. Close drum valve. Leak test complete system, including gauge fittings, with leak detector, Tool J-5419; if leak cannot be found, the vacuum pump or gauge may be faulty. (*NOTE*–If oil is blown out of vacuum pump, it should be filled to proper level with Frigidaire 75 oil). Correct all leaks, then operate pump to obtain vacuum of 28". Watch gauge and see if vacuum will hold for ten minutes. With all leaks eliminated, open Freon drum and bring system to drum pressure. Close drum valve. Evacuate the system again as previously described for purpose of picking up any air or moisture that may have remained in the system. Close gauge valves. System is now ready for a complete charge of refrigerant.

BUICK AIR CONDITIONING CONTROL DIAGRAM

CADILLAC AIR CONDITIONING CONTROL DIAGRAM

ADDING REFRIGERANT

Refrigerant should always be added to low pressure side of the compressor in a vaporous state and the amount added, under any condition, should not exceed that prescribed. Do not add a complete charge of refrigerant until system has been leak tested and properly evacuated. In order to charge refrigerant in a vaporous state, Freon-12 drum should be heated by placing drum in a container of hot water. The temperature of the hot water should not exceed 125°F. Since temperature of water and drum will decrease as the vapor leaves the drum, drum pressure may be reduced to a point where it will be necessary to replenish or reheat the water. Both Freon drum and container of hot water should be placed on suitable scales, with drum in upright position. Note scale reading before opening valve on drum so that it can be determined when a complete charge of refrigerant has been added to the system.

►*CAUTION: Always wear goggl s wh n ver handling Freon-12, and when breaking lin conn ctions. Th high pressure should not xc d 275 lbs. Drum pr s- sure should not exceed 90 lbs.*

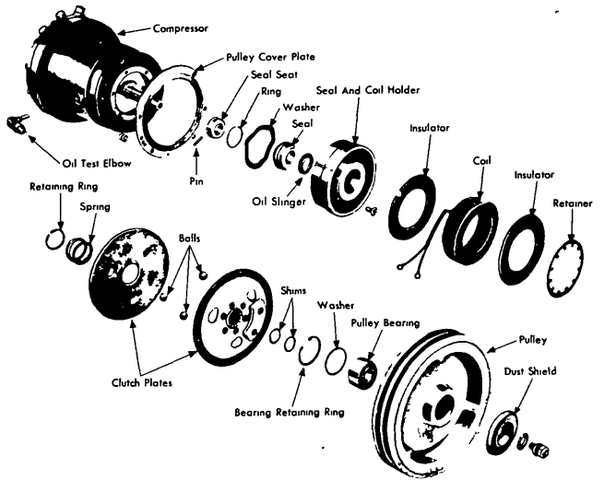
ADDING COMPLETE CHARGE: Evacuate complete system (see above). With gauge set connected as when evacuating system, open low pressure valve on gauge set. Open drum valve to obtain maximum pressure of 90 lbs. Freon vapor under pressure will flow into system without operating compressor. This amount should not exceed 2½ lbs. (Chevrolet), 3¾ lbs. (Oldsmobile & Pontiac), 5 lbs. (Others). (*NOTE*–If it is not possible to charge system with the total by the mothod just described, it is permissible after about 1 lb. has been forced into the system, to operate the engine and compressor at slow idle. Hand shut-off valve on

CONTINUED ON NEXT PAGE

1954-55 FRIGIDAIRE & HARRISON (Continued)

high pressure side of gauge set should be **closed.** Continue to operate engine and compressor at slow idle until total has been charged into the system). Close drum valve and low pressure shut-off valve on gauge set. Operate engine at 1500 RPM with compressor clutch engaged to observe high and low pressure gauges as well as sight glass and general performance of system. Stop engine and remove gauge set.

►*NOTE:* Jumper wire between battery positive terminal and clutch coil will insure continuous operation of compressor during period engine and system are operating at maximum output (system stabilizing).



ADDING PARTIAL CHARGE OF REFRIGERANT: Remove caps from compressor suction and discharge valve gauge fittings and valve stems. Attach gauge set J-5725 to gauge fittings. Attach flexible hose from center fitting of gauge set loosely to Freon drum. Crack compressor suction and discharge valve stems slightly to purge gauge lines of air. Tighten fittings on Freon drum when all air has been removed from gauge lines. Close both hand shut-off valves of gauge set. Start engine, set controls to "COLD" and turn blower on high speed. Operate engine for 10 minutes at 1200 RPM to stabilize system. Open compressor suction valve gauge fitting by turning valve stem 1½ turns clockwise. Turn compressor discharge valve ¼ turn clockwise so high pressure gauge can be observed. Place Freon drum on scales, note weight, and open low pressure valve only on gauge set. With compressor operating, allow Freon to flow into system until liquid indicator clears and **immediately** shut off valve on Freon drum. Check weight of Freon drum and pail of water. Then open valve on Freon drum and add Freon-12 as follows: (Chevrolet) ½ lb., (Oldsmobile & Pontiac) ½ lb. if room temperature is below 85°F., or 1 lb. if room temperature is above 85°F., (Others) 1 lb. Note total amount of freon added. Close drum valve. Close low pressure valve on gauge set. Operate engine at fast idle, compressor clutch engaged (controls set for maximum cold or jumper wire attached to clutch coil from battery). Observe gauges, sight glass, and entire system for performance. After 5 minutes, should bubbles reappear at sight glass (system not by-passing), add same amount of Freon added above. If bubbles still appear, check operation of system. Adequate cooling may be obtained even when a few bubbles are evident. Remove gauge set, install gauge fitting caps. Remove jumper wire from clutch coil if installed above. *CAUTION*–Do not charge more than 2½ lbs. (Chevrolet), 3¾ lbs. (Oldsmobile & Pontiac), 5 lbs. (Others) into system at any time.

CHECKING & ADDING OIL

CHECKING & ADDING OIL (1954): *See "1953 Frigidair "*

CHECKING OIL LEVEL (1955): Operate the air conditioning system for 10 minutes at fast idle, then turn off engine. Remove nut and "dead head" assembly from oil test elbow on bottom of compressor. Depress Schrader valve core in oil test elbow for several seconds and allow Freon and oil to escape. Oil will invariably appear the first time valve is depressed, regardless of oil level. Again depress Schrader valve core. If oil continues to be ejected with Freon second time valve is depressed, oil level in compressor is satisfactory. (*NOTE*–A positive check for oil in vapor can be made by allowing vapor to come in contact with a clean white rag). If no oil escapes second time valve is depressed, oil level is low and oil will have to be added.

►*NOTE:* Compressors with Serial Nos. between 12XB756 and 14XB771 do not have a standpipe to permit oil level checking as above. In order to check oil level on these compressors, it will be necessary to remove compressor and follow procedure outlined for "Adding Oil–Major or Minor Loss (Without Gauge Set)" below.

FRIGIDAIRE COMPRESSOR ASSEMBLY

ADDING OIL (1955)-Major or Minor Loss (Without Gauge Set): Remove compressor (see below). Purge pressure from compressor by depressing Schrader valve at gauge fittings on compressor until low audible hiss is heard. Remove oil test elbow from compressor. Invert compressor and drain oil into clean container. (*NOTE*–Examine condition of oil to determine whether or not it is contaminated with any foreign material. If so, this oil should be discarded and new oil used. If excessive amount of water found, install a new liquid dehydrator-receiver assembly in high pressure liquid line). Pour nine ozs. of 525 viscosity Frigidaire oil into compressor at oil fitting opening (*NOTE*–Do not add oil at relief valve opening). Install oil test elbow. Install compressor, using new "O" ring seals at hand shut-off valves.

ADDING OIL (1955)–Minor Loss (Using Gauge Set J-5725):

►*EARLY 1955 PONTIAC ACCESS HOLE NOTE:* If compressor mounting bracket does not have access hole for oil test elbow, it will be necessary to cut a hole. Drill a 7/8" hole 3/16" in from engine side of bracket with centerline of hole in same plane as perpendicular line through center of oil test elbow. Drill another 7/8" hole 1/16" from the first (in same plane and on fender side of first hole). Cut web from between holes to form a slot-shaped hole.

1) Connect high pressure line from gauge set to high pressure fitting on compressor. Cap center connection on gauge manifold with gauge fitting cap from compressor discharge valve. Attach adapter J-5420 to low pressure line and start adapter on oil test elbow (*NOTE*–Do not screw on far enough to depress valve stem).

2) Crack open high pressure valve on gauge manifold and discharge valve on compressor. Slowly open low pressure valve on gauge manifold (This will purge air from low side line). While Freon is escaping from low side line, tighten gauge adapter J-5420 on compressor oil test elbow.

3) Close high and low pressure valves on gauge manifold. Close low pressure valve on compressor (turn until seated).

4) Attach ¼" oil charging tube to center connection on gauge manifold (*NOTE*–Oil charging line can be made from piece of clean, dry ¼" tubing by flaring one end and installing a flare nut (flared end of piece of brake line can be used together with a flare nut). Pipe should be long enough to reach bottom of oil bottle). Secure a **graduated** bottle of Frigidaire 525 viscosity oil. Leave capped until needed.

5) Crack open high pressure valve at gauge manifold to purge air from oil charging line. While vapor is still slowly escaping from oil charging line, insert tube to bottom of oil bottle and allow vapor to bubble slowly through oil. Close high pressure valve at gauge manifold. Leak test all connections that have been made. Position gauge manifold and oil charging line, while still inserted in bottom of bottle, so that they will not be disturbed during following procedure.

6) Operate engine at slow idle, observe low side gauge until approximately 10" vacuum is obtained. Stop engine and observe gauge to see if vacuum will still hold. There should not be any fast rise of pressure.

7) Open low pressure valve on gauge set about 1½ turns. Vacuum in compressor should now draw oil from bottle. Allow level of oil in bottle to reduce so that 2 ozs. are drawn into compressor. Close low pressure valve on gauge manifold, remove oil charging line from center connection on gauge manifold and replace cap (Loosen oil charging line while still in bottle so that oil from line will drain back into bottle).

8) Open high pressure shut-off valve on gauge manifold. Open low pressure shut-off valve slowly to allow high side pressure to force oil remaining in gauge manifold and low pressure gauge line into compressor. Also allow pressure to break the vacuum and pressurize compressor to approximately 5 lbs. Close both high and low pressure valves on gauge manifold. Remove gauge adapter connection from oil test elbow.

9) Recheck oil level. Continue to add oil in 2 oz. quantities until a satisfactory level is obtained. Open high and low pressure valves (fully counter-clockwise), remove high pressure gauge line, replace high pressure

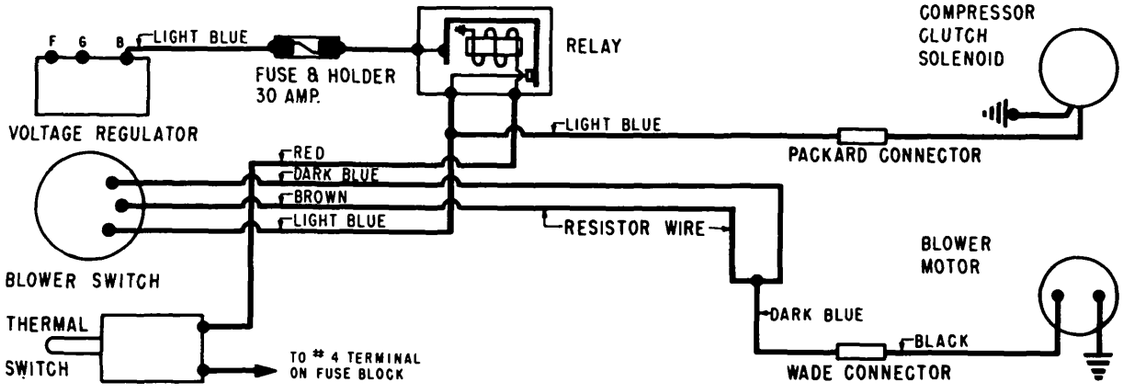
CONTINUED ON NEXT PAGE

1954-55 FRIGIDAIRE & HARRISON (Continued)

gauge fitting cap, valve stem cap, and oil test elbow nut and "dead head".

REMOVAL & INSTALLATION TO WORK IN ENGINE COMPARTMENT

►*NOTE:* If it is necessary to remove parts other than the compressor (involving the breaking of refrigerant lines), it will be necessary to purge, evacuate, and completely recharge the system (see above).



1954 BUICK, CADILLAC, OLDSMOBILE, PACKARD

COMPRESSOR REMOVAL & INSTALLATION: Same as "1955 Buick, Cadillac, Packard" below except high and low pressure valve fittings are held to compressor by two screws. Each pair of screws should be loosened about 7 turns and the valve fitting backed firmly against the head of the screws to permit automatic shut-off valve in compressor to close quickly.

1955 BUICK, CADILLAC, PACKARD

COMPRESSOR REMOVAL: Remove shut-off valve caps from ends of both pressure lines. Using Tool J-5427, close both hand shut-off valves at compressor. *(CAUTION–Do not operate compressor with shut-off valves closed. REMOVE IGNITION KEY).* Remove high and low pressure valve fitting center bolt, remove fitting from compressor. *(NOTE–*A momentary release of vapor can be expected as fitting leaves bore. If vapor continues to escape, the spring-loaded automatic valve in compressor is not seating properly. If this is the case, purge Freon vapor pressure by depressing Schrader core in the high pressure gauge connection until a low audible hiss is heard. Any air in compressor must be forced out when unit is reinstalled). Cover pressure openings in both compressor and compressor line fitting with masking tape to keep out dirt. Disconnect clutch coil wires and drive belts. Remove compressor from mounting bracket.

COMPRESSOR INSTALLATION: Check clutch adjustment (see ADJUSTMENTS above). Install compressor on bracket. Place belt on pulley and adjust tension (see ADJUSTMENTS above). Connect clutch coil wires. Install new "O" rings and flange gaskets on high and low pressure line valve fittings. Apply a slight amount of Frigidaire oil to *"O" ring* before installing fitting into bore. Insert pressure line fitting into bore in compressor and tighten securely. Use care to see that "O" ring seals are not damaged. Using ¼" key, Tool J-5247, open both high and low pressure line valves all the way (counter-clockwise). *(NOTE–*These valves open against a seal type seat, and must be turned open all the way against stops to prevent leaks). Depress Schrader valves to purge air from low and high sides of compressor. Test for leaks at all connections on compressor (Tool J-5419 or J-6084). If leaks are indicated, connection must be removed and "O" rings and gaskets replaced. *(CAUTION–*It is very important that all leaks be repaired. Under no conditions should compressor be run when a leak exists, as a complete loss of refrigerant would damage compressor). Connect gauge set and check clutch operation and general performance of system. Remove gauge set and install caps on fittings.

PONTIAC AIR CONDITIONING CONTROL DIAGRAM

1955 CHEVROLET, OLDSMOBILE, PONTIAC

COMPRESSOR REMOVAL (OLDSMOBILE & PONTIAC):

Intake Manifold Not Removed: Remove power steering pump and bracket assembly with lines attached and lay it aside. Remove compressor from its mounting bracket, with lines attached, and lay it aside. Remove generator from mounting bracket and lower it onto upper control arm. Mounting bracket can then be removed from engine.

COMPRESSOR REMOVAL (CHEVROLET, OLDSMOBILE & PONTIAC):

Intake Manifold to be Removed: Operate air conditioning system for 10 minutes at 1200 RPM to stabilize system. Return engine to normal idle speed, then close compressor suction valve (all the way in) with compressor operating. **Immediately** disconnect clutch wire to stop compressor. Connect and disconnect clutch wire at 5 second intervals four times to pump all Freon out of compressor. *(CAUTION–*Be careful wire does not touch metal while disconnected since it is still energized). Close compressor discharge valve (turn all the way in) and shut off engine. Remove compressor belt. Very slowly loosen screw retaining valve body to compressor. As screw is loosened, work valve body back and forth to break seal and bleed off pressure. *(CAUTION–*High pressure will still exist at discharge valve. If pressure released too rapidly there will be a considerable discharge of Freon and oil). When all pressure has been relieved, remove screw and remove valve body and "O" ring seals. Immediately cover compressor openings. Remove compressor from mounting bracket.

COMPRESSOR INSTALLATION (Valve Body with Lines Not Removed): Reverse removal procedures given for "Removal (To Work on Engine–Intake Manifold Not Removed)" above.

COMPRESSOR INSTALLATION (Valve Body with Lines Removed): Attach compressor to mounting bracket. *(NOTE–*Rear insulator and insulator-to-compressor bracket, and front outer insulator should be in place on mounting bracket. Front inner insulator and front outer insulator bracket should be attached to compressor). Attach ground strap under front outer insulator bracket-to-insulator attaching screw. Remove cover over compressor openings very slowly to bleed off pressure *(CAUTION–*New compressors are charged with a mixture of nitrogen and Freon and 9 ozs. of Frigidaire 525 viscosity oil. If cover removed too rapidly, oil will be blown out violently). Attach valve body to compressor using new "O" ring seals and new 3/8" plain lockwasher on screw (tighten attaching screw to 10-12 ft. lbs.). *(NOTE–*3/8" lockwasher was not used in early production, but should always be used when valve body is re-attached). Install and adjust compressor belt (see ADJUSTMENTS above). Connect compressor clutch wire. Evacuate compressor as follows:

Compressor Evacuation (Using Gauge Set J-5725): With compressor still sealed from system (suction and discharge valve stems turned all the way in) proceed as follows: Remove high pressure relief valve and connect tube and rubber hose in place of relief valve so that oil that pumps out of compressor during evacuation can be collected. Place clean, dry container under end of hose to collect oil *(NOTE–*Tube to be inserted into compressor can be made from a 3/8"-24 bolt by cutting head off and drilling a hole through it). Connect low pressure line of gauge set to gauge fitting on suction valve, Run compressor until gauge shows 28" vacuum, then continue to run for 5 minutes. At end of 5 minutes, with compressor still operating, replace and tighten relief valve. Purge air from compressor head by backing compressor suction valve out (counter-clockwise) and loosening pressure relief valve for approximately 15 seconds. Completely back-seat both compressor suction and discharge valves (back valve stems out). Make Operational Test (see below), add oil and Freon as required.

Compressor Evacuation (Gauge Set Not Available): Turn suction valve stem completely counter-clockwise to open suction hose to compressor and replace cap. Loosen pressure relief valve for approximately 30 seconds to purge air from compressor, then tighten

CONTINUED ON NEXT PAGE

1954-55 FRIGIDAIRE & HARRISON (Continued)

relief valve. (*CAUTION*–If air is not bled out of compressor, performance of system will be affected and excessive head pressure may result). Turn compressor discharge valve completely counter-clockwise and replace cap. Install compressor belt and adjust (see ADJUSTMENTS above). Connect compressor clutch wire. Clip clutch and blower wires to compressor bracket.

PARTS REPLACEMENT

DAMAGED COMPRESSOR (1954): Remove compressor (see REMOVAL & INSTALLATION above), remove pulley-clutch assembly and reinstall on replacement compressor.

Pulley-Clutch Removal & Installation: (*CAUTION*–Use only a clean, dry cloth to wipe off clutch parts. Do not use any type of solvent. Do not clean pulley bearing with any type of solvent as it will wash grease out of bearing (factory lubricated and requires no further lubrication). Prevent fingers, dirt, grease, oil, or any foreign matter from coming in contact with ball bearings, frictional or mating surfaces of clutch plates. Do not attempt to dress off frictional lining material on clutch plates). Disconnect and remove clutch actuating arm at compressor and solenoid. Remove clutch cover plate screws, then plate. Pull out two clutch plates, being careful not to lose the three actuating steel balls. Using Truarc pliers No. J-4880, remove snap ring retaining pulley housing on shaft. Remove pulley from compressor shaft. If pulley housing requires replacement, remove Truarc snap ring, using Tool J-4245. Remove bearing from pulley housing. To install, clean all clutch parts. Using a socket or short length pipe, carefully press new bearing into pulley hub and install snap ring with beveled side out. Install pulley and bearing assembly in position on shaft. Install pulley housing snap ring on compressor shaft with concave side of ring out. With compressor upright, install counterweight clutch plate on splined shaft, frictional lining toward compressor. To do this, position the one blind spline of shaft with open spline of inner clutch plate hub. Place three steel balls in tear drop depressions of counterweight plate. Insert teaser spring in bore of compressor shaft. With frictional lining outward, place actuator plate on top of steel balls, making certain balls are located in tear drop depression of both plates. Plates and steel balls can be installed as an assembly if compressor is not removed. Install clutch cover plate, being sure that the two small holes in cover plate line up with the two locating dowel pins in pulley. Install cover plate-to-pulley lockwashers and screws and tighten to 12-14 ft. lbs. (*NOTE*–Make sure all lockwashers are in place to assure proper balance). Install clutch actuating arm bracket to compressor. Install compressor on car. Adjust clutch (see ADJUSTMENTS).

COMPRESSOR SEAL REPLACEMENT (1954): Remove compressor (see REMOVAL & INSTALLATION). Relieve pressure in compressor through two gauge connections to 2 to 5 lbs. or until a low audible hiss is evident. Remove clutch and pulley assembly from compressor (see above). Remove seal retaining plate and bellows seal. Remove nitralloy ring from shaft using Tool J-5425. Check shaft to see that it is polished and free of paint, corrosion, nicks, burrs, tooling marks, and the like. Flush seal cavity with Frigidaire oil. Wet a cleaning tissue with a good grade of lighter fluid and allow tissue to dry. Then remove any trace of oil or lint. Shaft and shoulder, also, must be clean and dry. Insert nitralloy ring in Seal Centering Tool J-5425 so that synthetic rubber is visible. (*CAUTION*–Do not handle surfaces of nitralloy ring with fingers). Using cleaning tissue wetted with lighter fluid, wipe entire rubber surface, including inner diameter and radius of seal, until all protective oil coating is removed and the rubber is completely clean and dry. Install nitralloy ring on shaft, making certain that neoprene rests evenly and firmly against shaft shoulder (*NOTE*–This can be done by reversing tool so that small tubular end is pressed firmly by hand against inner ring of synthetic rubber). Apply clean Frigidaire oil to nitralloy ring, seat bronze seal that contacts nitralloy ring, and first three turns of bellows seals. Using Seal Centering Tool J-5425, install new bellows seal and gasket. Install retainer plate and screws, tightening screws alternately to insure even pressure against seat. Do not remove centering tool until all screws are tightened. If a major loss of oil has occurred, add oil (see CHECKING & ADDING OIL above). Reinstall compressor, after assembling and installing clutch on compressor. Purge air from compressor by depressing valve stem in high pressure gauge connection for a few seconds. Start engine and, after several minutes, repeat purging operation.

DAMAGED COMPRESSOR (1955): (*NOTE*–If damaged compressor is replaced, replacement compressor name plate must be stamped with numeral 1/8" high indicating Freon capacity of system and is required by law in some states). Remove shut-off valve caps from ends of both pressure lines. Using Tool J-5427, close both hand shut-off valves at the compressor (*CAUTION*–Do not operate compressor with shut-off valves closed. REMOVE IGNITION KEY). Remove high and low pressure valve fitting center bolt and remove fitting from compressor. (*NOTE*–A momentary release of vapor should be expected as the fitting leaves its bore in the compressor. If vapor continues to escape, the spring loaded automatic valve in the compressor is not seating properly. If this is the case, purge Freon vapor pressure by depressing Schrader core in high pressure gauge connection until a low audible hiss is heard (1 or 2 lbs. pressure). Any air in the compressor must be forced out when the unit is reinstalled). Cover pressure openings in both compressor and compressor line fitting with masking tape to keep out dirt. Disconnect clutch coil wires and drive belts. Remove compressor from mounting brackets. (*NOTE*–Gauge Set J-5725 may be used for this operation. If used, purge vapor from compressor until 1 or 2 lbs. remain, allow to stand for about five minutes, observing gauges for any pressure build-up. If build-up occurs, repeat purging operation until there is no longer a build-up). Remove clutch and pulley assembly and clutch coil, reinstall on new compressor.

▷*CAUTION:* If there is any possibility that broken parts from the compressor got into the discharge line, condenser should be cleaned and a new dehydrator, filter and receiver assembly should be installed. If condenser cleaned or a new dehydrator, filter and receiver assembly was installed it will be necessary to purge, evacuate, and completely recharge system.

Pulley-Clutch Assembly Removal & Installation: Remove compressor and follow steps outlined under "Compressor Seal Replacement" below.

Clutch Parts or Coil Replacement: Remove compressor and follow steps outlined under "Compressor Seal Replacement" below.

Compressor Seal Replacement: Remove compressor, then proceed as follows:

1) Remove pulley screw, lockwasher and dust cover from end of shaft. Remove pulley from shaft, using a puller such as harmonic balancer puller, J-2582-A (Install retaining screw in shaft so that end of large puller screw will bear against head of pulley retaining screw. *CAUTION*–Make certain the puller does not damage the internal threads of the shaft or the inner race of the bearing).

▷*NOTE:* Three types of dust covers have been used at the front of the pulley. First type is a metal cap retained by pulley retaining screw. Second type is a rubber cap held in place by a retaining ring. Third type is a felt and steel washer which seats in the counterbore of the pulley and is held in place by the pulley retaining screw and washer.

2) Remove clutch actuating coil retainer.

▷*NOTE:* Two types of coil retainers used. On early compressors (prior to 44XB653), remove clutch coil retainer by bending retainer teeth forward with a small screwdriver. The retainer should be discarded and replaced by same type retainer used on later compressors. On later compressors, back out alternately the three retaining screws until threaded end of screws are flush with inside face of coil housing. Remove coil retainer ring.

3) Remove and discard outer gasket from front of coil. Disconnect coil leads and remove coil from cavity. Remove and discard inner gasket from coil cavity.

▷*NOTE:* On early compressors, prior to compressor 44XB653, drill three holes in seal and coil housing. First hole should be diametrically opposite the coil lead port; the two remaining holes should be located one on either side approximately 120° from the first. Holes should be accurately located 9/64" from front face of housing. Use a No. 24 drill.

4) Remove the 6 Phillips head screws that were behind inner gasket and pull seal and coil holder from the compressor (loosen screws by tapping with punch). Press defective seal assembly from holder cavity. Thoroughly clean seal cavity and replace internal "O" ring with a new one coated with clean Frigidaire oil. Press new seal assembly into cavity using Seal Installer J-5922. Replace large external "O" ring seal with a new one coated with clean Frigidaire oil.

5) Force retainer from groove to the rear area of rotating seal seat ring, using small screwdriver. Exercise care not to mar oil pump cover. Remove drive pin from seal seat groove using needle nose pliers. Pull seal seat from shaft and wipe shaft clean with tissue furnished in seal package.

CONTINUED ON NEXT PAGE

1954-55 FRIGIDAIRE & HARRISON (Con.inued)

6) Check shaft spline for burrs or sharp edges. Remove burrs or sharp edges using India Stone No. FT-134 and then clean shaft to remove all stoning or metal dust.

7) Install new "0" ring seal inside the new seal seat and place the seat face down on a piece of oil soaked wiping tissue so as to protect polished face. Force retainer down over seal seat to forward area (Use 1¼" socket to push ring on). Install new seal seat after coating the internal "0" ring gasket with clean Frigidaire oil. *(CAUTION–*Use extreme care not to damage "0" ring when starting seal seat over splined end of shaft. Also keep fingers off seal surface). Align hole in seal seat with one in shaft and insert drive pin. Force retainer into groove.

8) Examine oil pump cover plate to make certain small dowel pin is in proper place, and flush with outer cover. Make certain wave washer is in place.

9) Install housing for seal and coil holder, using care not to damage large "0" ring. Replace 6 Phillips head retaining screws. *(NOTE–*If heads of screws become burred or damaged in removal, install new screws to prevent damage to coil). Install oil slinger with flange outward leaving approximately .010" clearance between seal and slinger. Use Tool J-6086-A to positively position slinger .010" from seal.

10) Place a new inner gasket (neoprene cork with holes) in bottom of seal and coil housing. Install actuating coil and connect leads. Place new outer gasket (fish paper without holes) over coil.

11) Discard clutch coil retainer if removed from early type compressor and procure later type retainer used on compressors after No. 44XB653. Position this retainer over outer gasket. Use two ½" lengths of 5/16" round rod and two 3" "C" clamps to force coil and retainer ring snugly into coil housing. Apply pressure evenly on both "C" clamps. *(CAUTION–*No portion of coil housing-to-compressor screw heads should extend beyond inner face of coil housing). While coil and retainer are being held in place by the "C" clamps and 5/16" round rods (used as dowels), insert the three No. 8 self-tapping screws removed from later production compressors (or furnished in service package) into holes in housing. Tighten screws until heads are snug against side of seal housing. In this position the threaded end of each screw will press on the tapered portion of the coil retainer ring and secure parts in their proper position. Remove "C" clamps and 5/16" rods. Blow out tapping chips with compressed air. Fill coil lead wire port with caulking compound to seal against entry of dirt, grease, oil vapors, and the like.

12) Remove clutch ring by removing the 6 screws and lockwashers. Examine frictional surface for dirt, scoring or other damage. Replace if necessary.

13) Remove clutch assembly from pulley *(NOTE–*Spacer shims will be found between clutch assembly and pulley. These should be inspected and placed aside for later reassembly).

14) Disassemble clutch plate using Tool J-4880 (No.2 Truarc pliers) to remove retaining ring. Inspect all parts of assembly for wear and replace if necessary. Inspect pulley bearing for wear or tightness. Replace if necessary.

15) Reassemble clutch. To install retaining ring, place ring on spring, expand ring with Tool J-4880 and force downward on ring and spring until ring engages groove. Place clutch ring over coil and seal holder with ground surface facing pulley end of shaft.

16) Install clutch plate assembly on splined shaft locating pin in hub spline in cut-off spline on shaft, and with clutch spring toward seal cavity. Install spacer shims on shaft using the original shims removed during disassembly.

17) Install pulley. Exert pressure on inner race of bearing only, when pressing pulley on shaft. Install dust cover and retaining screw with lockwasher. Torque screw to 5-8 ft. lbs. Install clutch ring to pulley using 6 screws and lockwashers.

18) Adjust clutch. See ADJUSTMENTS above.

FORD "SELECTAIRE" AIR CONDITIONING

Ford V8 (1955)

►CHANGES, CAUTIONS, CORRECTIONS

►*1955 FORD SOLENOID BY-PASS VALVE CAUTION:* When air conditioner is serviced, the four Allen head screws at base of solenoid by-pass valve should be checked for tightness. Screws must be snug to insure proper sealing. Do not overtighten.

►*1955 OIL BAFFLE INSTALLATION (To Facilitate Checking Compressor Oil Level):* Oil baffle is available for installation on all 1955 Air Conditioning units. *See "Checking Compressor Oil Level" below.*

►*1955 COMPRESSOR PULLEY-TO-SHAFT LOCKING CORRECTION (Early Cars):* Some early production compressor units were not provided with a positive lock between compressor pulley and shaft. Compressors should be checked and, if necessary, modified as follows: Secure large flat washer (Part No. EAA-6278-B) to face of pulley and pulley shaft by screwing bolt 20348-S8, with lockwasher 34807-S8 in place, into tapped hole in end of compressor shaft. Torque to 23-28 ft. lbs.

►*1955 FORD SOLENOID BY-PASS VALVE INTERFERENCE WITH HOOD CORRECTION:* If condition encountered it can be corrected, in some instances, by adjustment of rubber bumpers on either side at front of hood. If hood bumper adjustment does not provide needed clearance, and less than 1/8" is needed, remove nut on top of by-pass valve and grind off some of bolt and bottom of nut. If adjustment of hood bumpers interferes with satisfactory hood-to-fender line, or if grinding nut and bolt will not provide clearance needed, it will be necessary to remove condenser assembly and elongate holes in mounting brackets to obtain proper clearance.

DESCRIPTION

Compression process cycle type, using Freon-12 as refrigerant. The evaporator assembly and allied parts are mounted on the dash. A solenoid valve functions automatically and is controlled by the setting of a thermostatic switch. *For functioning of the various components of the system listed below (except controls, solenoid by-pass and check valves) see "1953-55 Lincoln & Mercury" Air Conditioning.*

Refrigerating: Consists of compressor, condenser, solenoid by-pass valve, check valve, receiver, dehydrator, sight glass, expansion valve and evaporator unit.

Solenoid By-Pass Valve–By-pass valve is located in line between condenser and compressor inlet line. When solenoid is energized (air conditioning "ON"), valve is closed, and compressor will develop maximum pressure difference between high and low sides of compressor, and maximum cooling at the particular compressor speed will be provided. Valve is held in closed position, giving full possible refrigeration, until a car speed of approximately 40 MPH is reached, then the by-pass valve begins to control the cooling, depending on the surrounding temperature and humidity. With valve open (solenoid de-energized) pressure on both sides of the compressor will be approximately equal, no refrigerant will flow through the system, and no cooling will result.

Check Valve–Check valve is located in high pressure line connecting condenser outlet to receiver inlet. Prevents reverse surges of liquid Freon-12 from receiver into condenser, due to opening and closing of by-pass valve. It also maintains high pressure at expansion valve when by-pass opens, to prevent too great an unbalance in system pressures.

Air Circulating: Consists of blowers and discharge, return and outside air ducts.

Control: Consists of control panel (air conditioning and heater controls combined), compressor clutch, thermostatic and control cut-out switches to control cooling.

OPERATION

See "1953-55 Lincoln & Mercury" Air Conditioning. Solenoid valve performs same functions as the modulator valve on Lincoln & Mercury cars.

PRECAUTIONS, TROUBLE SHOOTING & LEAK TESTING

See "Air Conditioning Servic Cautions", "Troubl Shooting", and "Leak Tests".

CHECKING & ADJUSTMENT

SEASONAL OPERATION: Cooling system may be permanently shut down by removing two compressor disconnect pulley bolts. This allows pulley to rotate on

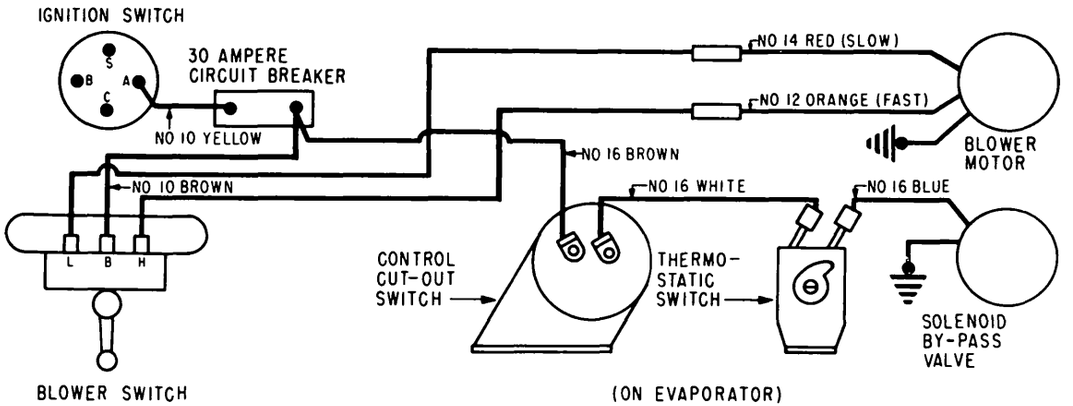
CONTINUED ON NEXT PAGE

FORD "SELECTAIRE" (Cont.)

an integral ball bearing in the pulley, and the compressor will not operate.

ADJUSTMENTS: Compress r Belt—Adjust compressor belt (and generator belt) by loosening generator-to-bracket bolt and pulling out on generator so there is approximately ¼" deflection at point midway between water pump and compressor pulley with normal thumb pressure.

Control Cabl Adjustments (Ford): Air Duct Valve—Set temperature control lever at its extreme left position. With lever in this position, adjust cable leading to right air duct valve so that valve is in the completely closed position (maximum counter-clockwise).



Louvre—Adjust evaporator louvre cable so that the louvres are completely closed when the temperature control lever is in center position (directly under the dot). If evaporator unit has been removed, it will be easier to adjust cable at the evaporator end before installing the evaporator. Only a slight adjustment of the louvre cable is possible at the control unit.

H ater Th rm stat—With temperature control lever at the center position, adjust heater thermostat cable until heater thermostat is in the closed position (thermostat lever all the way to right).

Evap rat r Th rm static Switch Adjustment: Proceed as follows: *(NOTE*—Adjusted at time of installation and generally requires no further adjustment. However, in very dry climates such as the Death Valley area, the switch can be set to its very lowest temperature position. In higher humidity areas, set switch at index lines to prevent evaporator from icing and clogging air passages. Factory setting of control is at scribe mark on control, representing a temperature setting of 28°F. Control may be adjusted to maintain an evaporator temperature of 24-45°F. The thermostatic switch operating differential is 6°F. at any one setting). To adjust control, remove glove box to gain access to the adjusting screw. Turn thermostatic switch adjusting screw clockwise to lower temperature and counter-clockwise to raise it.

CHECKING: Bubbles in Sight Glass—Appearance of bubbles in sight glass when engine idling or by-passing is not unusual and does not indicate a shortage of refrigerant. Remove cover from sight glass. Run engine and compressor for 5-10 minutes, with engine at fast idle, temperature control at maximum cold, then observe sight glass for one minute. If no bubbles appear in sight glass (system not by-passing) it may be assumed that there is sufficient Freon-12 in the system, providing cooling system is in working order. If bubbles appear, add Freon-12 to system until bubbles disappear, then add one lb. additional as a safety factor. See "Adding Partial Charge of Refrigerant" following.

Compr ssor Oil Level & Adding Oil (With ut Oil S parator): *(CAUTION*—Under no circumstances should oil filler plug on compressor be removed to check oil level **as a maint nanc pr c dur** . Should any portion of system be removed and reinstalled or replaced, oil level should be checked **nly** at time of reinstallation

FORD AIR CONDITIONING CONTROL DIAGRAM

or replacement). To check oil level and add oil, operate system for 30-35 minutes. Turn off engine, and turn both service valves clockwise until seated. Loosen high pressure service valve gauge port cap slightly to to let compressor gas pressure reduce to air pressure (observe "Service Precautions"). Remove oil filler plug, insert a 1/8" diameter rod (do not use coated welding rod) in the oil filler plug hole until it bottoms **holding rod vertically. Rod should show ¾". Add Suniso 4-G Refrigerant Oil as required. Replace oil filler plug, then evacuate and purge compressor (see below).**

Compressor Oil Level & Adding Oil (With Oil Separator): Make sure compressor pulley disconnect bolts are in place. Run engine at approximately 1500 RPM, full air conditioning, for 15 minutes in 60°F. ambient (surrounding air) temperature or above. Check evaporator sight glass for bubbles (see above) to determine if Freon-12 charge is sufficient (save for future reference). Shut engine off and isolate compressor by turning both service valve stems fully clockwise until seated. Loosen high pressure service valve gauge port cap slightly to **let compressor pressure bleed off. Next, remove the** cap from drain hose fitting in compressor. Insert a clean 1/8" diameter rod (flat on one side for approximately 3" at bottom end—do not use coated welding rod) into compressor crankcase through fitting until it bottoms (approximately 8" will be required to reach bottom). *(NOTE*—Compressor crankshaft may have stopped with counterweights in position to prevent rod from bottoming on compressor base. If so, remove rod and tap starter to rotate compressor slightly. Try dipstick rod again. Repeat, if necessary, until rod bottoms, being careful never to rotate compressor with rod inserted). Oil level, measured from bottom of dipstick **rod, should be 2-2¼".**

(NOTE—This represents 8-12 ozs, of oil). Add oil, as necessary, to bring oil level to maximum amount specified (Suniso 4-G). If level above normal, foaming of oil may be causing a false reading. Allow open compressor to set for 15 minutes and recheck. If still high, remove enough oil to bring oil level to maximum amount **specified. Replace cap on drain hose fitting in compressor, using new ¼" gasket under cap. Evacuate and purge compressor (see below).**

Evacuating & Purging Compressor—*(NOTE*—Since only Freon vapor is present in the compressor, very little Freon is lost when checking and adding oil, or when compressor only is removed and reinstalled to work on engine. Normally, it will be necessary to purge air and moisture from the compressor and hoses but not evacuate and add Freon-12 (partial charge) unless there is evidence of a low charge of Freon, as shown by checking liquid sight glass for bubbles (see CHECKING above). If additional charge of Freon required, see "Evacuating Compressor & Adding Partial Charge of Refrigerant" below). To purge compressor of air and moisture loosen cap on service port of high pressure valve, open low pressure valve slightly and allow Freon to purge suction hose, compressor, and discharge hose. Tighten service port cap. Open both service valves fully. Run engine at fast idle for at least five minutes (air conditioning fully on) and make "Bubbles in Sight Glass" check (see CHECKING above). If Freon charge low follow procedures under "Evacuating Compressor & Adding Partial Charge of Refrigerant" (see below).

MANIFOLD GAUGE SET INSTALLATION

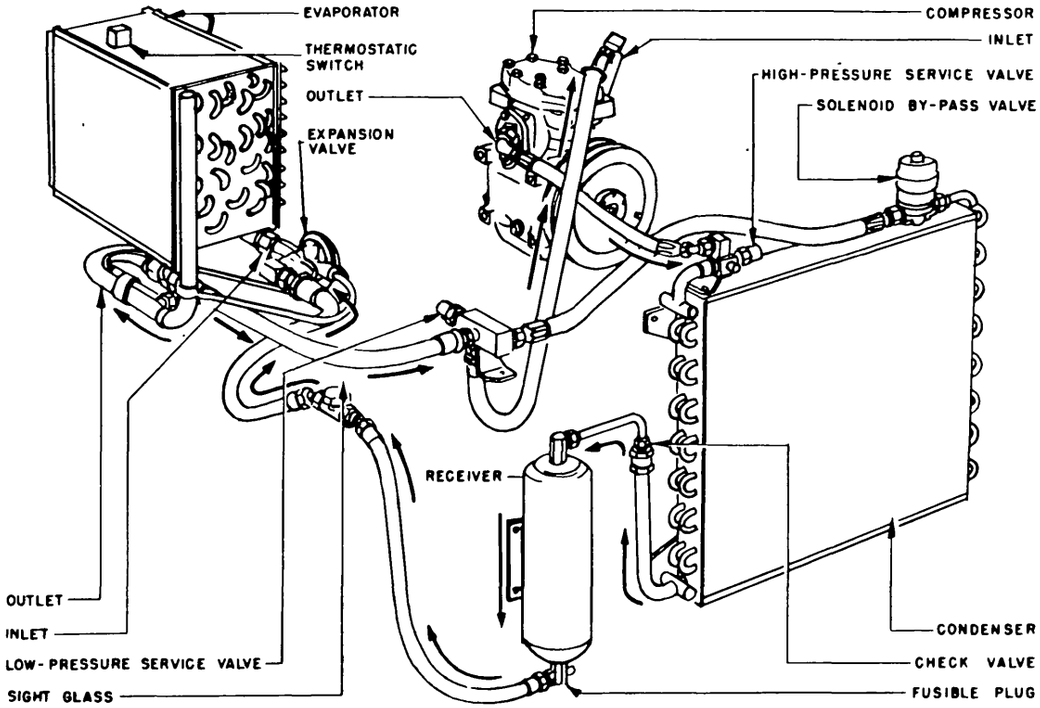
Attach Gauge Manifold to hood lock support panel mounting bracket. Remove service valve stem covers and make sure both service valves are at the maximum counter-clockwise position. Remove service valve gauge port covers, and attach the flexible hoses to the gauge ports and to a tank of Freon-12. Turn both Manifold Gauge valves to the maximum clockwise position. *NOTE*—**The manifold valves are so arranged that when they are in the maximum or closed position, the center manifold connection is shut off from the gauges.**

TESTING THE SYSTEM

TESTING SYSTEM PRESSURES: Attach manifold gauge set. It will not be necessary to attach the Freon-12 tank unless refrigerant is to be added to the system. Set both gauges valves at the maximum clockwise, or

CONTINUED ON NEXT PAGE

FORD "SELECTAIRE" (C nt.)



closed, position. Set both service valves at the center position. Run engine at 1500 RPM. Set temperature control lever at the maximum cooling position and turn blower to the "High" position. The actual pressures indicated on the gauge will depend on the temperature of the surrounding air. Higher air temperatures will give higher system pressures. The figures given are for an ambient (surrounding air) temperature of 75°F. For every 10°F increase in ambient air temperature, the pressures will increase approximately 17 lbs. The low pressure gauge should indicate a pressure of 16-25 lbs. at 75°F. The high pressure gauge should indicate a pressure of from 100-165 lbs. at 75°F.

TESTING COMPRESSOR PRESSURES: Attach manifold gauge set as indicated for checking system pressures above, but turn low pressure service valve to maximum clockwise position. Run engine at 1500 RPM for a short time. Observe both high and low pressure gauges. Low pressure gauge should indicate a vacuum of 24" minimum. Stop engine and continue to observe gauge pressures. The gauge should hold for several minutes. If the pressures equalize rapidly, the compressor discharge valves are defective. If both gauges hold their indication but values indicated are not normal (vacuum of 24" minimum and high pressure of 60-100 lbs.), the compressor intake screen is probably clogged. If no further work is to be done on the system after making the pressure check, close both service valves by setting them at the maximum counter-clockwise position. Remove manifold gauge set, and replace the service valve gauge port and valve stem caps.

TESTING SYSTEM TEMPERATURES: Place temperature control lever at maximum cooling position. Open one of the instrument panel outlet air valves by pushing on the valve control knob. Place the stem of a thermometer through the right outlet air vent door as far as it will go. Run engine at 1500 RPM. Turn blower switch to "High" position. The thermometer should indicate a temperature of approximately 40°F. with a room temperature of 75°F. and a relative humidity of 50%. The outlet air temperature should be about 35°F. below the surrounding air temperature with 50% relative humidity. In case the humidity is higher than 50%, the temperature differential will be somewhat less. If the humidity is less than 50%, the air outlet temperature will approach closer to the evaporator temperature setting of 32°F.

DISCHARGING THE SYSTEM

Discharge refrigerant from system before replacing any part of the system except compressor or its two connecting hoses. To discharge the system, connect manifold gauge set to system. **Do n t c nnect manif ld c nt r c nn ction hos t Freon tank.** Place open end of this hose in a garage exhaust outlet. Set high pressure gauge valve at maximum counter-clockwise or open position. Open the high pressure service valve a slight amount, and allow the refrigerant to discharge from the system. *CAUTION–Do not allow refrigerant to rush out, as the oil in the compressor will be forced out along with it.*

FORD AIR CONDITIONING SYSTEM

EVACUATING THE SYSTEM

Attach manifold gauge set, a tank of Freon-12, and a vacuum pump to the system. Set both service valves to the mid-position. Open both manifold valves. Run vacuum pump until low pressure gauge reads at least 25", and as close to 30" of vacuum as possible. Continue vacuum pump operation 15 minutes to boil any moisture out of system. Close pump valve, turn off pump.

EVACUATING COMPRESSOR & ADDING PARTIAL CHARGE OF REFRIGERANT (After Checking & Adding Oil or After Re-installation of Compressor): Attach manifold gauge set, tank of Freon-12, and a vacuum pump to the system as follows: Remove service valve stem covers and make sure that both service valves are at maximum counter-clockwise position. Remove service port gauge port covers, and attach flexible hoses of gauge set to gauge ports and to a tank of Freon-12 (center line). Turn both manifold gauge valves to the maximum clockwise position. Attach vacuum pump to center connection of gauge manifold. Place both service valves at maximum clockwise position, and both gauge valves at maximum counter-clockwise position. Run vacuum pump until low pressure gauge indicates as close to 30" of vacuum as possible. Close pump valve, turn off pump. Open Freon-12 tank valve, then check all compressor connections for leaks. Shut Freon tank valve. Turn both service valves to maximum counter-clockwise position. Check quantity of Freon-12 in system (see "Bubbles in Sight Glass" under CHECKING above). Add partial charge of refrigerant as follows:

Adding Partial Charge of R frigerant: With manifold gauge set attached, open Freon-12 tank valve. Purge air from high pressure hose by loosening high pressure hose at service valve. Tighten connections and set high pressure gauge valve at maximum clockwise position. Set low pressure gauge valve at maximum counter-clockwise position. Loosen low pressure gauge hose slightly at low pressure service valve to purge air from hose. Tighten connection. Set both service valves at center position. Run engine at 1500 RPM with temperature control knob at maximum cold position. Charge system until liquid sight glass shows no bubbles. Continue to charge system until one additional lb. of Freon-12 has been removed from tank. It may be necessary to place Freon-12 tank in a container of hot water (not to exceed 125°F.) to force gas from tank. *(CAUTION–Never heat Freon-12 tank with torch. A dangerous explosion may result).* Set both service valves at maximum counter-clockwise position. Remove gauge set, cap service valve gauge ports and valve stems.

►*CAUTION:* If system is low on Freon and cannot be recharged, disconnector bolts should be removed from

CONTINUED ON NEXT PAGE

FORD "SELECTAIRE" (C nt.)

pulley so that system cannot be operated until proper amount of Freon-12 has been added. *Do not disconn ct lines, except as described above, without complete instructions.* Should any part of system become damaged, Freon and lubricating oil will escape. Seal any openings caused by damage with masking tape to prevent entrance of dirt and moisture. Do not steam clean any portion of car adjacent to refrigeration units or lines. Abnormal heat will cause Freon to "boil" resulting in excessive pressure.

ADDING COMPLETE CHARGE OF REFRIGERANT

Evacuate the system. Leave both service valves at the mid-position. Leave low pressure gauge valve at the maximum counter-clockwise or open position. Set high pressure gauge valve at the maximum clockwise or closed position. Set temperature control lever to maximum cold position. Open Freon-12 tank valve. Run engine at 1500 RPM. Weigh 4½ lbs. of Freon-12 into the system. During the charging, the high pressure may build up to an excessive value. This can be caused by an overcharge of refrigerant, an overheated engine or air in system. Never allow the high pressure to exceed 240 lbs. Stop engine, determine cause, and correct it. When the proper charge has entered the system, no bubbles will be seen in the sight glass. The bubbles will begin to disappear when approximately 3½ lbs. of refrigerant are in the system. After the proper charge has been made, close the Freon-12 tank valve, and check the system pressures for proper operation. Set both service valves at the maximum counter-clockwise position. Remove the gauge set, and cap the service valve gauge ports and valve stems.

BLEEDING AIR FROM SYSTEM

Air trapped in the system will cause high pressure to build up excessively. To bleed air from system, attach manifold gauge set to system, set both service valves at center position. Run engine at 1500 RPM with temperature control lever at maximum cold position. If air is trapped in the system, the high pressure may exceed 150-200 lbs., depending on the surrounding air temperature and the amount of air in the system. Turn engine off. Let system stand for 10 or 15 minutes to allow air to collect at the high pressure service valve. Loosen high pressure gauge hose at high pressure service valve slightly, and allow the gas and air to escape for 5-10 seconds. Tighten the connection, start the car, and check the pressure again. Repeat procedure if necessary. After bleeding, check the liquid sight glass to make certain that too much refrigerant was not removed. Put partial charge of Freon-12 in system if necessary (See "Adding Partial Charge of Refrigerant" above).

REMOVAL & INSTALLATION TO WORK IN ENGINE COMPARTMENT

COMPRESSOR REMOVAL (To W rk n Engin): Isolate compressor by turning both high and low pressure service valves to extreme clockwise position, then loosen cap on high pressure service valve gauge port, and allow gas to escape until compressor and attaching hoses are relieved of refrigerant pressure. *(CAUTION–* Loosen cap a small amount only, and do not remove it until pressure is completely relieved). Raise car on hoist or jacks and remove splash pan From underneath car, remove generator adjusting bracket bolt. Loosen generator-to-compressor mounting bolts, swing generator inward, and disengage the two belts from generator and compressor pulleys. Disconnect generator leads, remove generator mounting bolts and remove generator from car. Remove generator-to-cylinder block bolt and compressor-to-lower bracket bolt. Lower car and complete operation in engine compartment. Disconnect high and low pressure hoses from compressor. Remove compressor mounting bolts. Loosen angle bracket bolt and remove compressor from engine.

COMPRESSOR INSTALLATION: Reverse removal procedure. Adjust compressor belts (see ADJUSTMENTS above). Connect high and low pressure hoses *(NOTE–* Be sure to replace metal gaskets in hose connections). Evacuate compressor and attaching hoses (see "Evacuating Compressor & Adding Partial Charge of Refrigerant" above).

CONDENSER, RECEIVER & RELATED PARTS: *(NOTE–* Removal and installation of these parts requires that the system be discharged before removal and recharged after the parts are reinstalled).

Condenser: Condenser can be removed without removing grille assembly or lock support plate. To remove condenser, disconnect solenoid hot lead from connector. Disconnect lines at four fittings and remove four mounting bolts. Remove condenser by lifting it straight up. To install, reverse removal procedure *(NOTE–* Make sure metal gasket is replaced in high pressure service valve connection).

Receiver: Removal of receiver requires removal of right-hand grille bar; however, it is not necessary to remove the lock support plate. Disconnect copper tube from top of receiver, and disconnect hose from fitting at the bottom of the receiver. Remove the four mounting bolts and the receiver from the right-hand side air deflector. Install caps on the two receiver fittings and plugs in the tube and hose fittings to prevent air from entering the receiver and the refrigeration system. To install, reverse removal procedure.

PARTS REPLACEMENT

With the exception of the compressor, replacement rather than repair of the individual unit is recommended by the manufacturer. In the case of the compressor, replacement kits for certain components are available. When such kits are unable to eliminate the trouble, the compressor must be replaced.

COMPRESSOR REPLACEMENT: Isolate compressor. Rause car on hoist or on jacks, and remove splash pan. From underneath car, remove generator adjusting bracket bolt. Loosen two generator-to-compressor mounting bolts, swing the generator inward, and disengage the two belts from the generator and compressor pulleys. Disconnect the three leads from the generator, remove the two generator mounting bolts, and remove the generator from the car. Remove the generator-to-cylinder block bolt and the compressor-to-lower bracket bolt. Lower the car and complete the operation in the engine compartment. Disconnect the suction and discharge hoses from the compressor. Remove the compressor mounting bolts. Loosen angle bracket bolt and remove compressor from engine. With compressor on work bench, remove suction and discharge fittings. Mark the position of each fitting, and remove two retaining screws at each fitting. Remove two pulley disconnect screws, install a puller to pulley, attaching puller to the two disconnect holes. Remove pulley from shaft, then remove key from shaft. Remove retaining bolt and the "S" shaped bracket from compressor. Invert compressor, remove twelve retaining bolt, compressor adapter plate, and gasket. Scrape old gasket from adapter plate. Remove shipping base and screws from replacement compressor, position gasket, and install adapter plate with twelve retaining screws. Install "S" shaped bracket to new compressor (loose). Install suction and discharge fittings (with new gaskets) to compressor. Mount fittings in positions that correspond to the markings on the old compressor, then secure each fitting with two screws. Lubricate shaft and pulley bore with compressor lubricating oil, then install key to compressor shaft. Force pulley on shaft with bolt and large washer by screwing bolt into center of shaft. Install two pulley disconnect bolts. Position new compressor to engine block, and install two compressor mounting bolts. Tighten mounting bolts and angle bracket bolt. Raise car on hoist or jacks, install compressor ty cylinder block bolt and to lower bracket bolt. Connect three leads to generator, mount generator to mounting brackets on compressor, and install bolts (loose). Install generator adjusting bracket bolt but do not tighten. Engage two belts with generator and compressor pulleys, and adjust belt tension. Tighten generator adjusting bracket bolt, then tighten two generator-to-compressor mounting bolts. Install splash pan, and attach generator leads to clip. Lower car, connect suction and discharge hoses to fittings on compressor. Be sure to replace metal gaskets in hose connections. Evacuate compressor and attaching hoses, then cut compressor back into system.

COMPRESSOR BELT REPLACEMENT: Raise car on jacks or hoist, remove splash pan. From underneath car, loosen but do not remove the two generator-to-compressor mounting bolts. Remove, generator adjusting bracket bolt and swing generator inward. Disconnect the two belts from compressor, generator, crankshaft, and water pump pulleys. *(NOTE–The two belts must always be replaced in matched pairs).* Install new belts around compressor, generator, crankshaft, and water pump pulleys. Install generator adjusting bracket bolt, adjust belt tension, then tighten bolt. Tighten generator-to-compressor mounting bolts, install splash pan, and lower car.

COMPRESSOR SHAFT SEAL, VALVE PLATE, SUCTION & DISCHARGE LINE FITTINGS, SUCTION STRAINER SCREEN, OIL SIGHT GLASS REPLACEMENT: S *"1954-55 Parts R plac ment" und r "1953-55 Lincoln & M rcury" Air C nditi ning.*

1954-55 HUDSON & NASH AIR CONDITIONING

Hudson (1955)
Nash (1954-55)
Rambler (1954-55)

►CHANGES, CAUTIONS, CORRECTIONS

►*1954 EVAPORATOR MOISTURE SPILL-OVER CORRECTION*–Effective Serial No.R-735750 "Ambassador" and No. K-630592 "Statesman" Evaporator Core Water Seal & Retainer Assembly Part No. 3141479, Drain Pan Seal Part No. 3141476, and Drain Pan Seal Retainer No. 3141475, have been added in production and *must be installed* on all air-conditioned cars prior to these serial numbers.

►*1954 EVAPORATOR HOUSING CONDENSATION CORRECTION*–Effective Serial No. R-735074 "Ambassador" and No. K-630270 "Statesman", Insulation Part No. 3141290, has been added in production (on inside of evaporator cover) and *must be installed* on cars built prior to these serial numbers. Weatherstrip Cement, Part No. 4990086, is used to cement this insulation to inside of cover.

►*1954 RADIATOR CAP PRODUCTION CHANGE*–Effective Serial No. R-735973 "Ambassador", No. K-630767 "Statesman" and D-193935 "Rambler", 14 lb. radiator cap, Part No. 3141371, is installed in production on all air-conditioned cars.

►*1954 AIR-CONDITIONING SWITCH PRODUCTION CHANGE*–Effective Serial No. R-735892 "Ambassador," No. K-630739 "Statesman", and No. D-196405 "Rambler", an improved Air-Conditioning Switch, Part No. 4383893, is installed on all air-conditioned cars and *must be installed* on all cars built prior to these serial numbers. Permits blowers to have two speeds instead of one. Resistor, Part No. 3142128, is also being installed on blower motor housing on Rambler models.

►*1955 HUDSON & NASH EVAPORATOR COVER DRAIN TUBE & SEALING PRODUCTION CHANGE (To Prevent Condensation On Evaporator Dripping Onto Floor Mat):* Following parts have been incorporated in production to correct above condition and may be installed on earlier models not so equipped: Evaporator Cover Upper Gasket, Part No. 3143397, is used in addition to Seal, Part No. 3146246; Evaporator Cover Lower Gasket, Part No. 3146404, replaces Part No. 3143397 as a lower gasket; Evaporator End Gaskets (2), Part No. 3146405, replace Part No. 3143396. A larger diameter drain tube, Part No. 3147430, replaces old type and includes an adapter, Part No. 3147429, and a prestite washer, Part No. 4363633, which is installed on the flared portion of the adapter. Adapter is installed into drain hole in evaporator cover in place of original drain tube and retained in position with a stud type ratchet plate. Drain tube hole in floor panel must be enlarged to accommodate the larger hose.

►*1955 DEFECTIVE COMPRESSOR REPLACEMENT CHANGE:* In case of failure of shaft seals, valves, or gasket leaks it is no longer necessary to replace compressor. Compressor can be repaired with kits listed below:

Kit	Part No.
Seal Kit	See below
Valve Plate Kit	3118919
Gasket Kit	3118920

Seal Kits–Three different kits used during production. Their applications are as follows:

Car Model	To Car Serial No. ©	Seal Kit Part No.
Rambler	D-239276	②3119125
Hudson Hornet 6	X-4478	3119056
Hudson Hornet V8	Y-4609	3119056
Hudson Wasp	W-4385	3119056
Nash Amb. 6	R-746827	3119056
Nash Amb. V8	V-5948	3119056
Nash Statesman	K-639472	3119056

©–Cars built effective with above serial numbers use Seal, Part No. 3119126 (bearing housing cover and seal face assembly not included in kit with seal, as proper type assembly is on compressor and seal only is required).

②–Supersedes Seal Kit, Part No. 3118918.

Kit Installation Note–Compressor need not be removed when replacing valve plate and valves, but should be removed when replacing the seal or a gasket. In either case, compressor should be evacuated after installation made by leaving service valves closed to lines. Leave suction service valve port cap closed and remove discharge service port cap. Run compressor 2 to 5 minutes to pump out air that may have entered the compressor. Shut off compressor and engine. Crack suction service valve to allow Freon-12 to drift through compressor and bleed out of open discharge service valve port. This will force out air in cylinder head. Install discharge service valve port cap after gas has been allowed to escape for a brief interval. Back-seat both service valves, attach gauge set, operate system and check pressures and for normal operation.

►*1955 RAMBLER DISCHARGE FLEXIBLE HOSE CLAMP CAUTION (Early Cars):* Clamp fastening discharge flexible hose to front engine crossmember was inadvertently omitted on cars built prior to Serial No. D-239769. Hose may be damaged by idler pulley if clamp not installed. Parts required are: Clamp, Part No. 3138580; Screw, Part No. GM 180018, Nut, Part No. GM 120375; Lockwasher, Part No. GM 120380.

►*1955 EVAPORATOR SEALING CAUTION:* Whenever system checked, check seal around evaporator cover. At lower left and right hand corner of evaporator retainer housing, it is possible that flanged edges leave an opening. Seal with suitable waterproof sealer. Sealer installed over top edge of bottom seal will also aid in preventing air and water leakage.

►*1955 V8 COMPRESSOR BRACE PRODUCTION CHANGE (To Correct Vibration when Compressor Operating):* Compressor Brace, Part No. 3146385, became effective at Nash Ambassador V8 Serial No. V-10150 and Hudson Hornet V8 Serial No. Y-6448 and is available for installation on cars prior to the above serial numbers. Brace is installed with large mounting hole of brace to the tapped hole in front side of compressor cylinder head. Use screw, Part No. 3109944, and lockwasher, Part No. GM 120384, to secure this end of brace. Opposite end of brace is attached with bolt that retains idler pulley or power steering pump bracket to cylinder head.

►*1955 COMPRESSOR CLUTCH BRUSH ASSEMBLY PRODUCTION CHANGE:* An improved clutch brush assembly, Part No. 3146691, has been incorporated in production and is available to replace original brush assembly, Part No. 3143945. New assembly is identified by a daub of green paint located between screw mounting holes on top side of brush mounting bracket.

DESCRIPTION

The All Season Air Conditioning System is designed to cool, heat, and defrost with basically the same unit. Basically, the function of the unit as an air conditioner is to filter, cool, dehumidify, and circulate the air within the car. The air conditioner is the compression cycle type, using Freon 12 as refrigerant. The air conditioning part of the All Weather Eye System consists of the following elements:

Refrigerating: Compressor–2 cylinder, reciprocating type, located at right side of engine. Operation causes and maintains necessary high pressure in system needed to increase Freon vapor temperature.

Condenser–Located in front of radiator. Condenses refrigerant vapor discharged from compressor, through action of fast moving air over metal surfaces of condenser.

Solenoid By-pass Valve–In engine compartment between condenser and receiver. When cooling system is "off" the valve operated by the solenoid is open, thereby removing the restriction between high and low pressure sides of system, and preventing compressor from reducing pressure in cooling unit necessary to permit vaporization of Freon.

Check Valve–Located between condenser and receiver. Prevents liquid refrigerant from entering by-pass and low pressure lines when solenoid valve is open. Protects compressor against possible damage caused by liquid entering compressor.

Receiver–Located at bottom and to right of condenser. Stores liquid refrigerant and maintains supply more than that needed normally.

Sight Glass–Located in right side of engine compartment adjacent to filter. Provides means for determining adequacy of refrigerant charge.

Filter–Located in right side of engine compartment. Filters the circulating Freon.

Expansion Valve–Part of evaporator assembly located beneath dash on right side. Supplies liquid to cooling unit at same rate that refrigerant is removed from it in a vaporous state.

Cooling Coils–Part of evaporator assembly located beneath dash on right side. Container for refrigerant which readily absorbs heat from surrounding area when temperature of refrigerant liquid is reduced. Refrigerant is changed to vapor in cooling coils.

Air Circulating: Blowers (1954)– Two used on Nash, one on Rambler. One blower (All Models) is located directly over evaporator core. The other (Ambassador & Statesman) is at left hand side of dash and is connected to the evaporator unit by a duct. Fans are squirrel cage type.

CONTINUED ON NEXT PAGE

1954-55 HUDSON & NASH (C nt.)

Blow rs (1955)—One blower is used on all models

Dischargr Air Ducts—In dash directly above blowers. Ducts have two open positions, "high" or completely open, and "low".

R turn Air Duct—At bottom of evaporator housing. Fresh outside air entering through cowl vent mixes with air returning from car interior.

Outside Air Duct—Outside fresh air is admitted to evaporator housing through vent in cowl.

Control: Nash & Hudson means for controlling fresh air inlet and recirculation of air differ from that used by the Rambler Series

Nash Amb. & Stsmn. (1954)—A single knob control operates both heater and air conditioning systems. The cooling system is placed in operation by having the water valve control knob in the far left or 'OFF" position, and by rotating the knob counter-clockwise to the "Low" and "High" position, "Low" being the first position. The cowl air intake ventilator damper is in closed position as control knob marked "Heat or Vent ' is pushed in. Damper in heater and return air duct is in straight up and down position. This is controlled by knob marked "Pull-Defroster". During air conditioning this knob is pushed in. Windows and ventilators should be closed during time air conditioner is in operation.

Nash & Huds n Mod ls (1955)—Lever control is used Control panel is marked "Air Cond ", "Vent-Heat", "Defrost", and "Forced Heat" from left to right Movement of lever control knob to each position will place dampers in correct position for each operation

Rambler—When controls are adjusted for air conditioning the left knob or knob marked "A.C.-Vent" is pushed in (opens damper door located under left smaller shroud and permits air in car to be recirculated through system). The right hand knob or knob marked "A.C.-Def." should be pulled out (closes damper control in heater cover and prevents ram air through cowl vent from entering and passing through heater and evaporator core). Turn fan knob counter-clockwise to operate fan and refrigerating unit. Windows and ventilators should be closed during time air conditioner is in operation.

T mperatur Control Th rmostat (All Models)—Located at top of evaporator housing. Controls cycling operation of air conditioning system. By cycling the refrigeration, the evaporator core is allowed to warm up during "OFF" cycles Thermostat cuts out at 32°F on Nash & Hudson models, and at 34°F, on Rambler, as sensed by the capillary tube and current to the solenoid by-pass valve is closed off and valve de-energized. The by-pass circuit is opened permitting high pressure refrigerant to by-pass the expansion valve and cooling coils and return to compressor. As this continues, pressure on high and low sides of system partially equalizes Thermostat cuts back in at 37°F on Nash & Hudson models and at 39°F, on Rambler, and solenoid by-pass valve is again energized and closed Normal cycle is again in operation until temperature in evaporator core reaches 32°F (Hudson & Nash Models), and 34°F (Rambler)

Magnetic Clutch (All Models)—Mounted on crankshaft of compressor. Clutch permits compressor to free-wheel when air conditioning system is not in operation. With Air Conditioning Switch "ON", current is directed to electro-magnet on forward face of pulley and clutch plate is held in contact with compressor pulley. Clutch plate drives compressor. In the "OFF"position of Air Conditioning Switch, electro-magnet is not energized and clutch plate does not contact pulley permitting compressor to free-wheel.

OPERATION

With Air Conditioner Switch "ON" and engine and compressor operating, heat laden, low pressure Freon is compressed by compressor and discharged into condenser where it is cooled to remove the "sensible" heat of compression. The Freon is forced into receiver under pressure when solenoid by-pass valve is energized and closed. After passing through filter and sight glass Freon enters expansion valve in evaporator housing. At orifice in expansion valve, high pressure liquid Freon changes to low pressure liquid, then enters cooling coils. The "boiling" Freon, while in the cooling coils, absorbs heat from the surrounding air and vaporizes. The vapor is drawn through the low pressure line to compressor where cycle is repeated.

MAINTENANCE & INSPECTION

►*NOTE*—Manufacturer recommends that any part or unit found faulty in operation be replaced as a unit. No attempt should be made to adjust any of the units except as noted below Compressors may be repaired as indicated in "Changes Cautions Corrections" above and in "Parts Replacement" below

SEASONAL OPERATION: Winter—It is not necessary to remove air conditioner pully belt. Magnetic clutch prevents operation of compressor when air conditioner is "OFF '.

Summer—Keep condenser core clean of bugs, leaves, dirt, or anything that may catch in condenser core.

Operation With Car Standing—Under conditions where system is operated with car standing, for more efficient cooling, run engine well above idle speed, preferably at 750-800 RPM.

ADJUSTMENTS: Compressor Belt—The idler shaft or power steering pump (if so equipped), is adjustable by a slotted link to engine Some models require that compressor mounting bracket be adjusted in addition to idler shaft Belts require a tight adjustment Reduce "flex" to a minimum

Dampers (1955): (Except Rambler)—Place damper control knob in "Air Cond" position Close cowl ventilator damper Move inlet damper control arm to upper position of travel The defroster control arm is moved to the right (*NOTE*—Each cable has a specific length and the end loop diameters will only fit damper control arm which it operates) After dampers are placed in position, place Boden wire loops on damper control arms Install cable housings in clip brackets, allowing enough room for each control arm to complete arc of travel

Rambler—Push "A C -Vent" control knob in Place recirculation damper in open position Insert and tighten cable in damper arm Pull knob and check to see that damper closes completely (*NOTE*—Knob should not be pulled out farther than lower edge of air conditioning control escutcheon on instrument panel) Place cowl ventilator damper in closed position, close evaporator shroud damper Place right hand control knob marked "A C -Def ")even with left hand knob when it is pulled out Insert cable to the cowl ventilator damper arm and tighten Insert and tighten evaporator shroud damper cable to opposite end of cowl ventilator control arm Place Boden wire loop on evaporator shroud damper Dampers should be open when control knob is pushed in

Magnetic Clutch (All Models): Shims are available (010" thick) to adjust the air gap between the clutch plate and pulley to 010- 040 Later type clutch plates have three adjusting screws and locknuts to accomplish this adjustment Torque tighten clutch plate capscrew to 18-20 ft lbs and lock in place with lock plate

PRECAUTIONS, LEAK TESTING & TROUBLE SHOOTING

See "Air Conditioning Service Cautions", "Trouble Shooting", and "Leak Tests"

CHECKING

BUBBLES IN SIGHT GLASS: Bubbles of vapor passing through sight glass indicate a low or short charge of refrigerant. There is no actual way of determining how much refrigerant is required if sight glass is checked and vapor bubbles are present.

CHECKING PRESSURE-GAUGE MANIFOLD SET (TOOL J-5725): 1) Close both hand valves on gauge manifold set.

2) Attach a gauge line to high pressure connection on manifold.

3) Open discharge service valve, remove cap from gauge port, and attach gauge line.

4) Cap center connection.

5) Attach a gauge line to low pressure connection on manifold set.

6) Open suction service valve, remove cap from the gauge port and attach gauge line. "Crack" service valves.

7) Without system operating, both gauge readings should be the same. System is in by-pass cycle and pressures on high and low side are equalized. For example, if ambient temperature is 70°, pressure readings on both gauges should read 70 lbs. gauge pressure. Reference to temperature-pressure table below will give readings for other temperatures.

Temp. of Surrounding Air	Gauge Press. Both Gaug s
65°	63 lbs.
70°	70 lbs.
75°	76 lbs.
80°	83 lbs.
85°	90 lbs.
90°	98 lbs.
95°	106 lbs.
100°	115 lbs.
105°	124 lbs.
110°	133 lbs.
115°	143 lbs.
120°	155 lbs.

CONTINUED ON NEXT PAGE

1954-55 HUDSON & NASH (C nt.)

CHECKING COMPRESSOR OPERATION: Run compressor so that crankcase is thoroughly warmed and comparatively free of refrigerant. Run engine at slow idle; close suction service valve by turning valve stem until it seats. Suction pressure should show 12-18" vacuum in a short time. Shut off compressor and engine. Suction vacuum will rise a few inches quickly if discharge valves are not holding. The above vacuum cannot be reached if suction valves are not holding

CHECKING SYSTEM OPERATION: *(NOTE*–Test is made on road. Long copper tubes to replace gauge lines on Gauge Set J-5725 should be fabricated to enable operator to have gauge set in car). Remove gauge port caps from compressor. Close both hand valves on Gauge Manifold Set (J-5725). Connect gauge lines to Gauge Set and compressor gauge ports. "Crack" service valves. Place thermometers at air discharge outlets. Road test system, operating car at **30 MPH.** Temperatures at air discharge outlets and pressures of system should be as shown in following chart *(NOTE*–Should temperature vary between those given in chart, a mean average should be worked out).

Hudson Hornet & Nash Ambassador

Ambient Temp. °F.	Average Disch. Air Temp. °F.	Head Press. PSI	Suct. Press. PSI
80	47	148	22
85	48	150	22
90	50	155	22

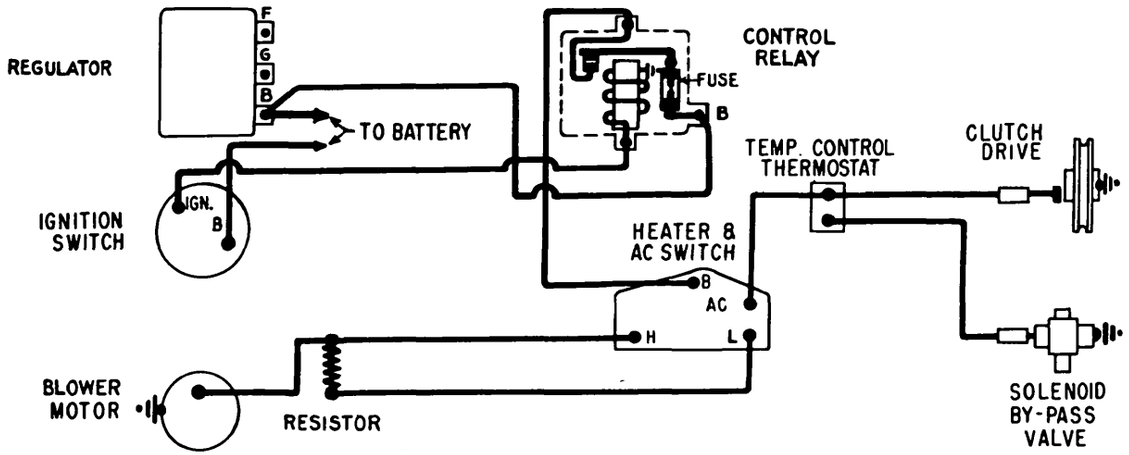
Hudson Wasp & Nash Statesman

80	52	160	22
85	53	180	22
90	54	200	22

Rambler

80	45	148	20
85	48	160	20
90	53	175	20

DISCHARGING THE SYSTEM



This procedure should be followed in service operations where components are removed. In subsequent service operations, "Discharging The System" will be mentioned as a step in the procedure.

1) Open discharge service valve by backing stem out all the way.

2) Remove cap from gauge connection. Open system to atmosphere by turning valve stem in one to three turns. *NOTE–Rapid release will cause oil to foam up out of the compressor and should be avoided.*

►*CAUTION*–Compressor lubricant is soluble in Freon-12. To prevent pulling too much oil out of system, release charge slowly so that oil remains as the Freon vaporizes into atmosphere. If there is no oil foaming out with the Freon, valve may be opened wider to allow gas to escape more rapidly. *It is advisabl to r l as charge in an pen area, th r than area in which subs qu nt s rvic p rati ns, such as t sting for leaks, would tak plac . This prev nts contamination of th ar a with Freon gas and erroneous and false leak detection.*

3) Repeat above operation on suction service valve to assure complete release of charge in system.

1954-55 RAMBLER AIR CONDITIONING WIRING DIAGRAM

EVACUATING THE SYSTEM

The system should be evacuated every time it has been opened for a service operation such as replacement of a part or line. Air and moisture may have entered the system when it was opened. It is advisable to evacuate the system every time a part has been removed from the system; also, whenever a charge has been lost through a leak or loose connection. System should be evacuated prior to charging if it has been standing for a period of time without a charge. To evacuate the system proceed as follows:

1) *CAUTION*–Compressor may be used to evacuate the system. Procedures given below must be followed very carefully to avoid damage to the compressor and its parts. Make certain that system is completely discharged; no Freon gas should be present during this operation.

2) Remove protective caps from both service valve stems. Open suction and discharge service valves to the gauge port fittings by backing the stem out all the way. Remove protective caps from gauge port fittings.

3) Install gauge line, Tool J-5418, from suction service valve port to compound gauge fitting on gauge manifold set (Tool J-5725).

4) Install gauge line from discharge service valve port fitting to high pressure gauge fitting on gauge manifold set.

5) Install gauge line to center connection on gauge manifold set.

6) Close hand valve on compound gauge between gauge and center connection on gauge manifold set (compound gauge will still register low side pressure).

7) Open hand valve on pressure gauge between gauge and center connection on gauge manifold set.

8) Move suction service valve to "cracked" position by turning valve stem in two or three turns.

9) Close discharge service valve by turning valve stem in all the way. Open discharge service valve gauge port to atmosphere by turning hand valve on gauge manifold set. Gauges should register "O" at this time as there is no pressure present in the system.

NOTE–With discharge service valve closed and gauge port open, air pumped out by the compressor is exhausted through open gauge line attached to center connection. With discharge service valve closed, the system is closed off so that as the compressor pumps the system is evacuated back to the closed valve.

10) Check oil level in compressor.

11) Start engine and operate compressor a minute or two at a time for three or four times to slowly reduce internal pressure. Then run continuously, observing the compound gauge. If compressor is operating satisfactorily, it should pump down to 12-18" vacuum quickly. If not, compressor is defective or there is a leak in the system.

►*CAUTION–Do not run compressor m re than 10-15 minutes as it is possible to damag compr ssor.*

12) After pumping a good vacuum for 10-15 minutes, close hand valve on high pressure gauge on gauge manifold set. Immediately shut system off and stop engine. There should only be a brief interval between these two operations.

13) Return discharge service valve to "cracked" position by turning valve out two or three turns. Both hand valves on the gauge manifold set remain turned off. Vacuum reading on the compound gauge should remain constant at 12-18" or better vacuum.

14) Let system stand for about 10-15 minutes and, if vacuum remains constant, the system is sealed from the atmosphere. If vacuum drops off, there is probably a loose connection or leak in the system. Correct by tightening or replacing and repeat the procedure.

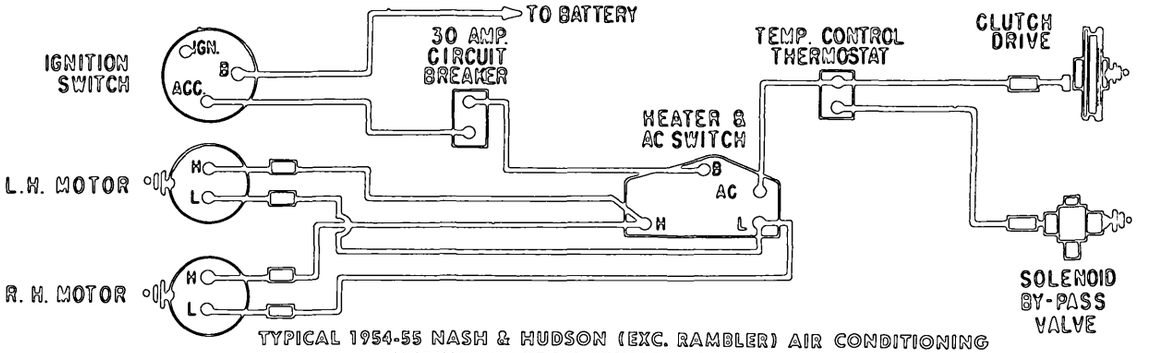
15) Heat a Freon-12 drum with a four pound charge in a container of hot water (125°F) or with rags soaked in hot water. Then attach the drum to the center connection gauge line.

16) Loosen the gauge line fitting to center connection slightly. Crack the drum valve, purging air from the gauge line with Freon vapor. Tighten the gauge fitting

CONTINUED ON NEXT PAGE

1954-55 HUDSON & NASH (Cont.)

and close drum valve.
17) Open the hand valve on the pressure gauge side of the gauge manifold. With the drum in an upright position, crack the drum valve slightly to admit the vaporized Freon gas from top of drum into system. Close drum valve.
18) Note internal pressures which should correspond with that given in table under "Checking" (preceding).
19) Test system for leaks. If leaks found, repeat procedure above after corrections made.
20) Recharge system. See "Adding Refrigerant—Complete Charge" following.



EVACUATING COMPRESSOR

Remove gauge port caps and attach gauge manifold set and lines. Close hand valve on compound gauge and open hand valve on pressure gauge. Start engine and run compressor for 1 or 2 minutes to pump air out of compressor through open hand valve and center gauge line. Stop compressor and engine. "Crack" suction service valve slightly to force air in cylinder head out of compressor with Freon gas. Close hand valve on pressure gauge. "Crack" both service valves; operate and check system for pressures and normal operation. After running compressor for 10 to 15 minutes, shut off system and check for leaks. Oil around seal at this time does not indicate a seal leak since there is a considerable amount on the new parts when installed. *CAUTION*—Do not put pressure on the crankcase unless pulley and clutch are held firmly in place by spacer, capscrew, and lock plate. Excessive crankcase pressure and a defective snap ring will allow seal to be blown out of compressor.

CHARGING THE SYSTEM

▷*NOTE:* Normal charge of Freon-12 for system is 4 lbs. (Nash & Hudson Models), 3½ lbs. (Rambler). For each lb. 2 c.c. of Methanol are added to lower freezing point of any moisture that may be in the system. Without Methanol, moisture would freeze and block the system, particularly at the expansion valve orifice. *See "Moisture & Air in System" following for additional information.* The Anhydrous Methanol is added to the compressor crankcase at oil filler plug prior to evacuation in cases where it is not already added to Freon in drum.

Adding Partial Charge: Proceed as follows:
1) Leak test system. Correct conditions as required.
2) Open both suction and discharge service valves to service port fittings by backing valve stem out all the way.
3) Remove cap from discharge service valve port fitting and install gauge line, Tool J-5418, to the fitting and to the high pressure gauge fitting on the gauge manifold set, Tool J-5725.
4) Remove cap from suction service valve port fitting and install a gauge line to the fitting and to the compound gauge fitting on the gauge set.
5) Close gauge hand valves to center gauge fitting.

TYPICAL 1954-55 NASH & HUDSON (EXC. RAMBLER) AIR CONDITIONING WIRING DIAGRAM (SINGLE BLOWER IN 1955)

6) Install a gauge line to center fitting on gauge set.
7) Install gauge line to Freon drum. Check all connections to see that they are tight.
8) Heat Freon drum in bucket of hot water (125°F.) or hot rags wrapped around the drum to vaporize Freon.
9) With drum in upright position, open drum valve slightly.
10) Open gauge hand valves on gauge set; this will open center charging line to each charging line to the compressor.
11) With both service valves to gauge fittings closed, loosen flare nut connections of charging lines at service valves to purge air from lines and gauge set. These should be cracked open only momentarily. Retighten connections.
12) Close hand valve on high pressure gauge (of gauge set) to close gauge to center fitting (gauge will still record pressure on high side when compressor is running and charge installed).
13) Open discharge service valve on compressor by turning valve stem in three or four times to "cracked" position. Open suction service valve to "cracked" position in same manner.
14) Freon drum valve has been cracked slightly until this time. With drum in upright position open valve completely.
15) Operate engine and compressor at slow idle speed.
16) Observe sight glass until a solid liquid column appears. Then add approximately ½ lb. additional refrigerant. Close drum valve.
17) Operate engine for five minutes at approximately 1500-1800 R.P.M.
18) Observe gauges, sight glass, and entire system for proper performance.
19) After unit operates satisfactorily, stop engine, close service valves to service valve port fittings by backing stems out all the way. Disconnect lines, cap fittings, and leave service valves in this position.

Adding Complete Charge: Proceed as follows:
1) Check all connections to see that all flare nuts are tight.
2) Open both suction and discharge service valves to the service port fittings by backing the valve stem out all the way.
3) Remove cap from discharge service valve port fitting and install a gauge line, Tool J-5418, to the port fitting and to the high pressure gauge fitting on gauge manifold set, Tool J-5725.
4) Remove cap from suction service valve port fitting and install a gauge line to the fitting and to compound gauge fitting on the gauge set. Close gauge valves to the center gauge manifold fitting.
5) Install a gauge line to the center fitting on the gauge manifold.
6) Evacuate the system. See "Evacuating The System".
7) After evacuation, install gauge line to Freon drum. Check all connections to see that they are tight.
8) Place drum in upright position; open drum valve slightly.
9) Open gauge hand valves on gauge manifold set. This will open the center gauge line to each gauge line to compressor.
10) Close service valves to gauge port fittings. Loosen flare nut connections of the gauge lines at gauge port fittings on both service valves. This will serve to purge the air from gauge lines and gauge set. These should be cracked open only momentarily. Retighten connections.
11) Close hand valve on compound gauge of gauge set. This will close the gauge to center fitting and to high pressure gauge. The gauge will still record pressure when compressor is running.
12) Open discharge service valve to "cracked" position. Suction service valve remains closed.
13) Full open valve on Freon drum. Heat drum in hot water (125°F.) or with hot rags wrapped around the drum.
14) Charging with liquid refrigerant is done at the high pressure side of the compressor at the discharge service valve. *After heat has been applied to drum, turn off compressor.* Invert drum (vapor in drum will force liquid refrigerant into the system).
15) Close drum valve after complete charge is in system. This can be readily determined by the stopping of the hissing noise as refrigerant is fed into system. Close hand valve on high pressure gauge on gauge set. *NOTE*—Normal charge of system is 4 lbs. (Nash & Models), 3½ lbs. (Rambler).
16) Open suction valve to "cracked" position.
17) Turn air conditioner on "High" blower. Run engine at 1500-1800 R.P.M. Observe the sight glass and the high and low pressure gauges. The engine should run

CONTINUED ON NEXT PAGE

1954-55 HUDSON & NASH (Cont.)

10-15 minutes to normalize system. If no bubbles appear at the sight glass and pressures are normal, shut off engine. NOTE—Head pressure on high pressure side should not exceed 275 lbs. at normal room temperatures, Excessive pressure would indicate air or excessive charge in system. Purge air from system or release excessive charge. See "Air & Moisture in System" for procedures.

18) Leak test system. Correct as required.

19) If system operates normally, close service valves to gauge port fittings. Remove gauge lines and cap gauge port fittings.

CHECKING & ADDING OIL

In normal operation, a small amount of oil is always circulating throughout the refrigeration system. An oil sight glass is provided in the compressor so that splashing oil can be seen when compressor is running. It does not indicate oil level when compressor is stopped. Oil level is determined by stopping compressor and closing suction and discharge service valves to lines. This isolates compressor from rest of system and seals system from atmosphere.

1) Loosen gauge port cap on discharge service valve slightly and let gas in compressor purge to the air slowly until suction pressure gauge shows 0 lbs. Relieve crankcase pressure by loosening oil filler plug slowly. Remove it when the oil has stopped foaming. Using a straight piece of wire as a dipstick, check at oil filler hole, keeping dipstick as near vertical as possible.

2) Add oil to bring it to the recommended level. Use refrigerant type oil of 280 to 300 Seybolt. To avoid adding too much oil, add slowly and check with dipstick; take 2 or 3 readings, each time wiping the dipstick dry. Correct oil level with compressor warm and stopped should be:

Engine	Amount of Oil	Dipstick Reading
6 Cyl.(Compr.Vertical)	9-10 ozs	1 1/8-1½"
V8(Compr.Horizontal)	9-10 ozs	1¼-1 9/16"

Replace filler plug.

3) Open suction service valve slightly for a few seconds until hissing sound is heard from valve. This allows system to purge air from compressor through discharge service port. Tighten discharge service valve port cap. Open service valves.

4) Install valve stem caps, then operate system for a few minutes. Observe oil splash in sight glass of compressor. There should be oil splash if there is sufficient oil in system.

5) Check refrigerant charge.

►*CAUTION*—Oil in container originally is packed moisture-free and every effort should be made to keep it moisture-free. The oil will quickly absorb moisture with which it comes in contact. Container should not be opened until ready for use, and recapped immediately after use. Tools, tubes, gauge sets, and replacement parts should be kept clean. System should not be open any longer than necessary.

Oil Level When Replacing Compressor: Precautions should be taken to prevent an over or under charge of oil when compressor is replaced. The oil charge in a new compressor is sufficient for the entire system. In a system that has been running, there is always some oil circulating through it. When compressor replaced proceed as follows:

1) Purge gas pressure in crankcase of original compressor to 0 lbs. pressure slowly after line valves are closed.

2) Check oil level without running compressor. Running compressor will cause a sudden drop in pressure in crankcase and may cause oil pumping. Oil pressure in crankcase would then be temporarily lowered putting an over charge of oil in the evaporator and giving an erroneous reading when oil level checked.

3) Check oil level in new compressor and add or remove oil from it until oil level is same as it is in compressor to be replaced.

4) Run new compressor 10-15 minutes,recheck oil level.

MOISTURE & AIR IN SYSTEM

Moisture In System: An excessive amount of moisture in the system, above that which can be handled by the Methanol injected into the Freon-12 will cause intermittent refrigeration and quick and serious corrosion of metals used in the system. Too, moisture mixes with oil causing "sludging" which seriously affects the lubricating ability of the oil. The best assurance against moisture is to prevent its entry into the system. This can be done by keeping all components sealed prior to installation and during repair procedures. Should the system be opened, seal openings and lines with plastic caps. If symptoms of moisture are evident in an unopened system, release charge, evacuate system, and recharge.

Air In System: Air which consists of gases that cannot be condensed in the refrigeration system causes excessively high head pressures in the high side of the system and reduces operating efficiency. Install gauge set to determine pressures. The presence of air is always indicated by high head pressure.(NOTE— High head pressure caused by air in system could be confused with an excessive amount of refrigerant which also causes high head pressure; although an excessive amount of refrigerant would still give adequate cooling effect). If system is known to have correct amount of refrigerant, but during operation and using the gauge set the head or high pressure builds up, air is certain to be in the system.

PURGING AIR FROM SYSTEM

Allow system to remain idle for several minutes after compressor has been operating. The air can then be discharged through discharge service valve on compressor. This is done by first making sure that the valve is shut off to the gauge port. Then remove gauge connections. Turn valve stem in toward the "cracked" position for a few moments, thus allowing air to escape through the gauge port. *Cover port opening with a cloth when purging system of air to prevent refrigerant and oil from contacting persons or car.* Repeat procedure if necessary. (*CAUTION*–Care should be exercised to be sure that purging is done slowly to prevent drawing oil out of system). Check oil level after bleeding. Air may also be bled from system at receiver. Crack top connection flare nut slightly for a few moments. Close connection and operate engine and compressor. Observe sight glass, and gauges. Check system for satisfactory performance. If operation unsatisfactory, repeat operation.

PURGING EXCESS REFRIGERANT

Install gauge set and operate system to determine pressures. Excessive amount of refrigerant will be indicated by high head pressure although the cooling effect is adequate. Place hand on receiver while system is operating. If entire receiver is cold, the indication is that receiver is filled with liquid refrigernat. Open hand valve to pressure gauge. This will open discharge valve to center gauge line. Freon-12 will vaporize upon entering the atmosphere. *Bleed slowly to prevent oil in the system from foaming and b ing pulled out of system.* After it is felt that proper amount of refrigerant has been bled off to bring it to normal charge, close hand valve on pressure gauge. Operate system again and observe sight glass and gauge. If not satisfactory, repeat process. *CAUTION*–When bleeding off excess refrigerant, place cloth over gauge line opening to prevent refrigerant or any oil from coming in contact with car or persons.

REMOVAL & INSTALLATION TO WORK IN ENGINE COMPARTMENT

COMPRESSOR: Proceed as follows:

To Perform Engine Repairs: Clean dirt, oil,or any foreign matter from around service valves. Close both service valves. Loosen gauge port cap on discharge service valve and allow gas to escape from compressor slowly. Remove service valve assemblies from compressor. The lines, both high and low pressure, remain attached to service valves. Shift service valves with lines attached carefully to one side. Loosen compressor belt adjusting lever screw and idler shaft adjusting link screw. (If equipped with power steering, the adjusting link is the same as for the idler shaft). Remove compressor belt from compressor pulley and idler shaft or power steering pump pulley. Remove compressor from compressor mounting bracket. The compressor and idler shaft or power steering bracket can be removed from the engine. Upon installation, new gaskets are necessary between service valve assembly bodies and compressor. After compressor is reinstalled, operate system. Purge air from compressor. Check oil level and the charge. Add charge as necessary. CAUTION—Close service valve openings on compressor while it is off car (use platic plugs or tape) to prevent air, moisture, or dirt from entering system.

CONDENSER: Clean all connections of dirt and oil, then discharge system. Drain cooling system and remove radiator from car. Disconnect high pressure line from compressor to inlet connection of condenser (at top of condenser). Use two wrenches of proper size on these connections to prevent twisting of copper lines. Remove splash pan assembly. Disconnect outlet connection from condenser outlet-to-check valve manifold line. Remove condenser from its mounting on radiator air baffles. Remove condenser from below car. Upon reinstallation, install gauge manifold set, evacuate, leak test, and charge the system. Run engine at idle for

CONTINUED ON NEXT PAGE

1954-55 HUDSON & NASH (C nt.)

10-15 minutes to normalize system. High pressure should not exceed 275 lbs. Should the pressure exceed 275 lbs., there is air in the system. Purge air from system by cracking or slightly opening high pressure gauge to the center connection of the gauge manifold set and *bleed air to atmosphere with system shut down and not op rating.*

RECEIVER: Clean all connections of all dirt and oil, discharge system. Disconnect connection from check valve manifold line to receiver inlet. Disconnect connection from receiver outlet. Remove receiver from front engine cross-member. Upon replacement, install gauge manifold set, leak test, and charge system. Start engine and operate at idle for 10-15 minutes to normalize system. Observe gauges. High pressure should not exceed 275 lbs. Should it exceed this amount, purge air from system.

PARTS REPLACEMENT

COMPRESSOR: Follow procedure outlined for "Compressor" under "Removal & Installation To Work In Engine Compartment" above Purge air from new compressor, check oil level, and charge

MAGNETIC CLUTCH & FLYWHEEL: Loosen compressor adjusting lever screw and idler shaft, remove compressor belt Remove compressor mounting bolts and move compressor without shutting off lines or otherwise disturbing remainder of system Movement required should be sufficient to allow removal of magnetic clutch assembly, remove clutch assembly *NOTE*– Pulley and center bearing are a tight fit on compressor crankshaft Brush holder bracket of the magnetic clutch is mounted on front bearing and seal plate of compressor For adjustment of clutch see "Adjustments" above Clutch plate cap screw is torque tightened to 18-20 ft lbs and locked in place with the lock plate

COMPRESSOR VALVE PLATE & VALVE: *(NOTE*– Compressor need not be removed when replacing valve plate and valves) Close discharge and suction line valves to isolate compressor Loosen gauge port cap on discharge service valve and slowly release gas in compressor to atmosphere until there is no pressure present Remove cylinder head bolts and tap cylinder head and valve plate to loosen and remove Remove and discard all gaskets and clean gasket surfaces Examine cylinder walls and top of pistons if there has been any valve breakage Compressor should be replaced if there are any scores or marks Always use new gaskets Before reassembling, dip gaskets in clean refrigerant oil Replace suction valve leaves (included in replacement kit) Dip valve leaves in clean refrigerant oil Install suction valve leaves on pins on bottom side of new valve plate Discharge valves are furnished installed on valve plate *(NOTE*–Due to position of compressor in the V8 Series, it is necessary to assemble the parts on a bench and install to the compressor Be sure suction valves are in place on pins of valve plate when installed) Install valve plate gasket Install valve plate with suction valves in place on compressor Install cylinder head gasket, cylinder head, and cylinder head bolts Torque tighten cylinder head bolts to 15-20 ft lbs Suction and discharge valves remain closed Evacuate compressor See "Evacuating Compressor Only" above *NOTE*– Although a test indicates a leaky valve plate, unless valve plate has been damaged or has been in service a long time, dirt or foreign particles in the system will cause valve plates to appear faulty Check system to see if oil is clean Dirt small enough to go through the suction screens can cause valve trouble Valve plates that appear good may be made to function properly by washing in clean solvent and drying with dry air or clean cloth

COMPRESSOR SHAFT SEAL: 1) *(NOTE*–A small amount of oil around the seal bearing is normal and does not indicate a seal leak When seal was originally assembled, all parts were dipped in oil and operation may only be forcing out surplus oil) Run compressor for a short time to warm up compressor and allow the crankcase oil to contain a minimum amount of refrigerant Shut off system and engine Close service valves, stems all the way in, to isolate compressor Loosen gauge port cap on discharge service valve and bleed refrigerant vapor from compressor, leaving line valves on their respective lines Move lines aside, remove compressor and place on bench

2) Install plastic plugs in inlet and outlet holes in compressor, or cover with masking tape Remove clutch and pulley from compressor shaft Tilt compressor backwards to prevent loss of oil while performing following operations Remove shaft snap ring with "Truarc" pliers Remove seal ring seat either by hand or, if tight on shaft, pry off with a screwdriver Remove seal bellows by forcing a screwdriver behind brass stamped flange at various points and prying it out of seal plate Remove neoprene "O" ring from seal plate Discard seal bellows and "O" ring Wash seal plate and shaft with clean cloth and solvent, and coat both with clean refrigerator oil

3) Dip new "O" ring in clean refrigerant oil and install in seal plate Press seal bellows assembly into place It is not a metal-to-metal press fit but rests only on the neoprene "O" ring in the seal plate and must go in perfectly square and the flange must bottom all the way around against the seal plate Wash seal seat in clean solvent, dip in clean refrigerant oil with neoprene "O" ring in place Press onto shaft evenly with lapped surface toward compressor body After seal face is over spline of shaft, install snap ring over spline with "Truarc" pliers Do not spread snap ring more than necessary Slide seal ring and snap ring together only shaft until snap ring snaps into its groove in the shaft Install flywheel and clutch plate The capscrew lock plate is installed behind flat washer in clutch hub Tighten capscrew to 18-22 ft lbs and lock in place with lock plate

4) Install compressor on mounting bracket, connect magnetic clutch wire lead Install belts and adjust brackets and idler shaft or power steering pump to tighten belt tension Install suction and discharge service valves with flexible lines intact to compressor using new gaskets Torque valve body capscrews to 12-15 ft lbs The suction and discharge service valve remain closed Evacuate compressor See "Evacuating Compressor Only" above

COMPRESSOR GASKETS: Follow removal and installation procedures outlined above in pars 1) and 4) for "Compressor Shaft Seal"

OTHER SYSTEM PARTS OTHER THAN COMPRESSOR (Involving Breaking of Refrigerant Lines): Removal and installation of these parts involves discharging, evacuating and recharging system (see procedures above)

1953-55 LINCOLN & MERCURY AIR CONDITIONING

Lincoln (1953-55)
Mercury (1955)

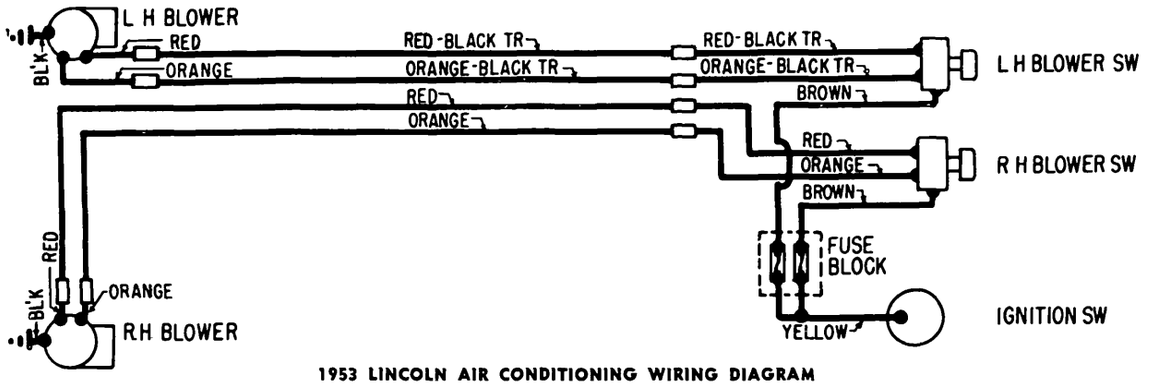
►CHANGES & CORRECTIONS

►*1954 FAN & AIR COMPRESSOR BELT DESIGN CHANGE (To Reduce Noise):* Steel Core Belts, Part Nos. EAD-8620-F and EAD-2890-C, are now being cogged with unequal spaces between notches to reduce or eliminate noise. NOTE—New belts will carry same part numbers as the old type but can be identified by a 1" wide red band across back side. Modified belts are available for service.

►*1954 EVAPORATOR DRAIN CORRECTION (To Minimize Possibility of Wet Luggage Compartment):* It is recommended that the three drain traps be removed. These traps are accessible from underneath car and can be removed by merely pulling them off the drain tubes.

►*1954 COMPRESSOR PULSATING NOISE CORRECTION:* Larger internal diameter flexible low pressure valve-to-compressor line, Part No. LE-19971-B, and compressor-to-condenser inlet line, Part No. LE-19972-B, are available to correct above complaint on 1954 models. New lines are installed on 1955 models.

►*1954-55 COMPRESSOR REPAIR CHANGE:* Later 1954 and all 1955 Compressors may be serviced as indicated under "Parts Replacement" below Those 1954 compressors that may be serviced are identified by a 3/8" diameter tapped hole drilled in the end of the compressor pulley shaft The decal on the head of 1954 Compressors prohibiting repair may be ignored to the extent indicated above.



►*1955 OIL BAFFLE INSTALLATION (To Facilitate Checking Compressor Oil Level):* Oil baffle is available for installation on all 1955 Air Conditioning units *See "Checking Compressor Oil Level" below.*

►*1955 COMPRESSOR PULLEY-TO-SHAFT LOCKING CORRECTION (Early Cars)·* Some early production compressor units were not provided with a positive lock between compressor pulley and shaft Compressors should be checked and, if necessary, modified as follows Secure large flat washer (Part No EAA-6278-B) to face of pulley and pulley shaft by screwing bolt 20348-S8, with lockwasher 34807-S8 in place, into tapped hole in end of compressor shaft Torque to 23-28 ft lbs

►*1955 LINCOLN DESIGN CHANGE (High Pressure Service Valve):* Position of valve has been changed over that of 1954 The 1955 High Pressure Valve has been inverted and, for this reason, direction which valve stem must be turned during service operations will be reversed

DESCRIPTION

Compression process cycle type, using Freon as refrigerant. System consists of basic groups of elements as follows

1953 LINCOLN AIR CONDITIONING WIRING DIAGRAM

Refrigerating. Compressor—Located to right front side of engine. Operation causes and maintains necessary high pressure in system needed to increase Freon vapor temperature.

Condenser—Located in front of radiator. Condenses refrigerant vapor discharged from compressor, through action of fast moving air over metal surfaces of condenser.

Modulator Valve—Located on top left of condenser. Controls compressor pressure by maintaining a uniform inlet or "low pressure side pressure" by bypassing "high pressure side pressure" to low pressure side of compressor, thereby preventing compressor from reducing pressure in evaporator necessary to permit the vaporization of Freon. Manual control of valve from lever on dash provides temperature control.

Receiver—Mounted to floor pan beneath rear of car. Stores liquid refrigerant and maintains supply more than that needed for normal operation.

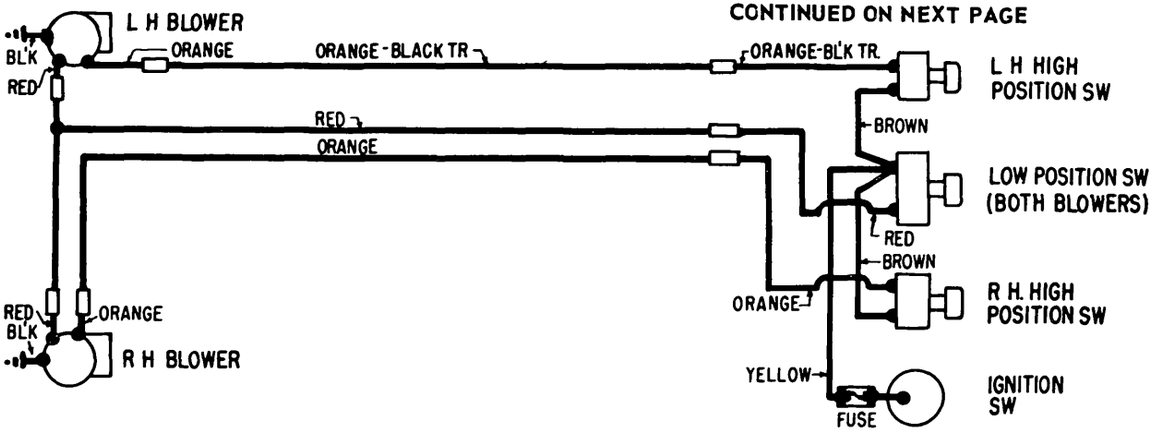
Sight Glass—Located in evaporator assembly above expansion valve. Provides a means for determining adequacy of refrigerant charge.

Dehydrator—Mounted beside receiver on floor pan beneath rear of car. Filters and dehydrates Freon as it passes through system.

Expansion Valve—Part of evaporator assembly located in trunk of car. Supplies liquid to evaporator core at same rate that refrigerant is removed from it in a vaporous state.

Evaporator—Part of evaporator assembly located in trunk of car. Container for refrigerant which readily absorbs heat from surrounding area when temperature of refrigerant liquid is reduced. In the core of the evaporator refrigerant is changed from liquid to vapor.

Air Circulating: Blowers—Located in evaporator assembly in trunk of car. These squirrel cage type fans, two in number, are located on each side of car, and force air from refrigerated area in evaporator assembly to ducts leading to car interior.



Discharge Air Ducts—Connected to grille, located on each end of package shelf. Entry point of refrigerated air to interior of car.

Return Air Ducts—Located on either side, at bottom of rear seat. Return point of air to evaporator.

Air Filter—Located on evaporator assembly front. In normal operation air returning to evaporator for recooling causes electrostatic pick up of dust particles.

Control—Control panel consists of two 2-speed controls, one for each blower motor, and a modulator

CONTINUED ON NEXT PAGE

1954-55 LINC LN AIR C NDITI NING WIRING DIAGRAM

1953-55 LINCOLN & MERCURY (C ntinued)

valve control lever. Modulator valve control lever determines degree of coolness when Air Conditioner is "On," position farthest to right providing maximum coolness. Another control element is:

T mp ratur Tube—Located between expansion valve and outlet of evaporator (low pressure side). If temperature at evaporator outlet falls below predetermined value, substance in temperature tube contracts. This reduces pressure on expansion valve diaphragm which in turn permits a coil spring to force needle towards its seat. This action reduces flow of liquid into evaporator. Result is a slowing up of refrigerating action and a rise in temperature of evaporator. The tube serves to check liquid state Freon to build up in low pressure side with possible resultant damage to compressor. With valve closed the build up of Freon on the high pressure side would result in no refrigeration.

OPERATION

With Air Conditioner "On" and engine and compressor operating, heat laden, low pressure Freon is compressed by the compressor and discharged into the condenser where it is cooled to remove the "sensible" heat of compression. The Freon is forced into receiver under pressure when modulator valve is closed. After passing through dehydrator and sight glass Freon enters expansion valve in evaporator assembly. At orifice in expansion valve high pressure liquid Freon changes to low pressure liquid, then enters evaporator core. The "boiling" Freon, while in the evaporator core, absorbs heat from the surrounding air and vaporizes. The vapor is drawn through the low pressure line to compressor where cycle is repeated.

PRECAUTIONS, LEAK TESTING & TROUBLE SHOOTING

Se "Air Conditioning S rvice Cautions", "Trouble Shooting", and "Leak Tests".

CHECKING & ADJUSTMENT

CHECKING: Bubbles in Sight Glass—Appearance of bubbles in sight glass when engine idling or by-passing is not unusual and does not indicate a shortage of refrigerant. Remove cover from sight glass. Run engine and compressor for 5-10 minutes, with engine at fast idle, temperature control at maximum cold, then observe sight glass for one minute. If no bubbles appear in sight glass (system not by-passing) it may be assumed that there is sufficient Freon-12 in the system, providing cooling system is in working order. If bubbles appear, add Freon-12 to system until bubbles disappear, then add one lb. additional as a safety factor. See "Adding Partial Charge of Refrigerant" following.

C mpr ss r Oil L vel & Adding Oil (1953): Pump system down (see below). Loosen compressor crankcase filler plug and release pressure slowly. Remove filler plug, check and add oil as necessary *(CAUTION*—Use special compressor lubricant only). Replace filler plug. Release "Pumped Down" pressure by opening shut-off valves counter-clockwise in following order: Receiver shut-off valve, then, when no more liquid Freon is flowing past sight glass open low pressure valve. Open high pressure valve.

Compressor Oil Level & Adding Oil (Without Oil Separator—1954-55): *(CAUTION*— Oil filler plug on compressor should never be removed to check the oil level **as a maintenance procedure.** Should any portion of system be removed and reinstalled or replaced, oil level should be checked **only** at time of reinstallation or replacement). To check oil level and add oil, operate system for 30-35 minutes. Turn off engine, and turn both service valves clockwise until seated. Loosen high pressure service valve gauge port cap slightly to to let compressor gas pressure reduce to air pressure (observe "Service Precautions"). Remove oil filler plug, insert a 1/8" diameter rod (do not use coated welding rod) in the oil filler plug hole until it bottoms, holding rod vertically. Rod should show ¾" (Mercury, 7/8" (Lincoln). Add Suniso 4-G Refrigerant Oil as required. Replace oil filler plug, then evacuate and purge compressor (see below).

Compressor Oil Level & Adding Oil (With Oil Separator): Make sure compressor pulley disconnect bolts are in place. Run engine at approximately 1500 RPM, full air conditioning, for 15 minutes in 60°F. ambient (surrounding air) temperature or above. Check evaporator sight glass for bubbles (see above) to determine if Freon-12 charge is sufficient (save for future reference). Shut engine off and isolate compressor by turning both service valve stems fully clockwise until seated. Loosen high pressure service valve gauge port cap slightly to let compressor pressure bleed off (observe "Service Cautions"). On Lincoln, disconnect compressor end of the oil separator drain hose. On Mercury, remove the cap from drain hose fitting in compressor. Insert a clean 1/8" diameter rod (flat on one side for approximately 3" at bottom end—do not use coated welding rod) into compressor crankcase through fitting until it bottoms (approximately 8" will be required to reach bottom). *(NOTE*—Compressor crankshaft may have stopped with counterweights in position to prevent rod from bottoming on compressor base. If so, remove rod and tap starter to rotate compressor slightly Try dipstick rod again. Repeat, if necessary, until rod bottoms, being careful never to rotate compressor with rod inserted). Oil level, measured from bottom of dipstick rod, should be 1½-2" (Lincoln), 2-2¼" (Mercury). *(NOTE*—This represents 8-12 ozs, of oil). Add oil, as necessary, to bring oil level to maximum amount specified (Suniso 4-G). If level above normal, foaming of oil may be causing a false reading Allow open compressor to set for 15 minutes and recheck. If still high, remove enough oil to bring oil level to maximum amount specified. On Lincoln, reconnect oil separator drain hose to compressor fitting, using new ¼" gasket. On Mercury cars, replace cap on drain hose fitting in the compressor, using new ¼" gasket under cap. Evacuate and purge compressor (see below).

Evacuating & Purging C mpressor—*(NOTE*—Since only Freon vapor is present in the compressor, very little Freon is lost when checking and adding oil, or when compressor only is removed and reinstalled to work on engine. Normally, it will be necessary to purge air and moisture from the compressor and hoses but not evacuate and add Freon-12 (partial charge) unless there is evidence of a low charge of Freon, as shown by checking liquid sight glass for bubbles (see CHECKING above). If additional charge of Freon required, see "Evacuating Compressor & Adding Partial Charge of Refrigerant" below . To purge compressor of air and moisture loosen cap on service port of high pressure valve, open low pressure valve slightly and allow Freon to purge suction hose, compressor, and discharge hose Tighten service port cap. Open both service valves fully. Run engine at fast idle for at least five minutes (air conditioning fully on) and make "Bubbles in Sight Glass" check (see CHECKING above). If Freon charge low follow procedures under "Evacuating Compressor & Adding Partial Charge of Refrigerant" (see below).

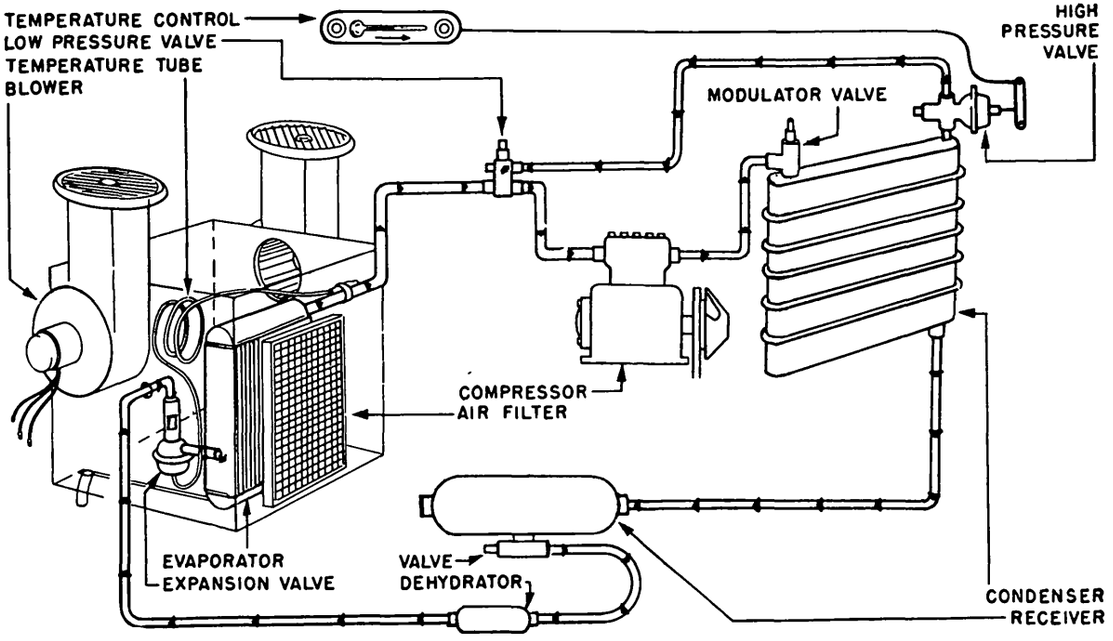
BELT ADJUSTMENT: Adjust compressor belt by pulling idler against belt to allow approximately 1/2" deflection at point midway between water pump and compressor pulley.

AUTOMATIC THROTTLE CONTROL: With engine warm, air conditioning system operating, and transmission in neutral, adjust knurled nut at end of operating rod of the control assembly to obtain idle speed of 800 RPM, tighten locknut. Check idle to make sure that it returns to normal whenever air conditioning is turned off or the transmission is shifted out of neutral. *NOTE*— Engine idle should be checked and set to specifications before attempting to adjust fast idle device.

Compressor Valve Operation (1954-55): Start engine and run with system set at maximum cooling for at least 15 minutes so that compressor crankcase is warm and comparatively free of refrigerant. Turn low pressure fender apron valve clockwise until seated. With engine running at slow idle, low pressure gauge reading should drop to at least 15" Hg. vacuum in a short period of time. *(CAUTION*—Compressor crankcase oil will be pumped out of compressor and into system if this test is unduly prolonged). If it is impossible to get this reading, it indicates that either the compressor intake, or the fender apron valve is at fault. To determine which valve is at fault, disconnect and cap flexible low pressure hose at fender apron valve fitting. With this line capped, again attempt to pump to 15" Hg. vacuum. If it is now possible to attain this reading, the fender apron valve is leaking; if not, the compressor intake valve or hose is leaking. When the engine is stopped, the low pressure gauge reading will jump several inches immediately if the discharge valves are not holding. The above vacuum reading cannot be reached if the suction valves are not holding.

PRESSURE TESTING SYSTEM

Place temperature control lever on instrument panel in full cold position. Shut off engine for at least 5 minutes before starting test. Check valves located on condenser and right front fender apron to make sure service ports are shut off. This is done by removing valve stem covers and turning stems counter-clockwise until valves seat. Remove protective caps from ser-



CONTINUED ON NEXT PAGE

1953-55 LINCOLN & MERCURY (Continued)

vice ports on condenser and fender apron valves. Clamp Pressure Test Gauge Manifold Tool ACL-53-3 to right hand side of radiator air deflector assembly. Attach high pressure gauge hose to service port on condenser valve, and low pressure gauge hose to fender apron valve service port. Turn both valves on gauge manifold clockwise until seated. Turn stems on both condenser and fender apron valves clockwise 1 1/2–2 turns. Both gauges should read neutral system pressure between 50-80 PSI depending on temperature of surrounding air. (High temperatures give higher readings). If gauge readings are below normal, check all connections and serviced parts for leaks. If system pressure is so low that it is impossible to detect leaks, increase system pressure as follows: Attach center hose of Test Gauge Manifold to a fully charged Freon tank. Open tank valve. Turn both valves on gauge manifold counter-clockwise one full turn. Freon will flow until system reaches tank pressure (approximately 50-80 lbs.). Shut off Freon tank valve and turn both manifold gauge valves clockwise until seated. Disconnect center hose from tank. Cap hose. Turn valve stems on both condenser and fender apron valves counter-clockwise until seated. Disconnect both gauge hoses from service ports, cap hoses and ports. Replace condenser and fender apron valve stem protector caps.

EVACUATING THE SYSTEM

If all pressure in system has been released, either for servicing or by accident, it will be necessary to completely evacuate to remove moist air and other contaminants which may have entered when fittings or assemblies were opened. Before evacuating make sure that all connections are tight so that no air will be drawn in. Before proceeding with the evacuation follow procedures under "Pressure Testing System" and "Leak Testing". Leave test gauge manifold attached, as it will be used in evacuating. Turn stems on condenser valve and right front fender apron valve 1 1/2–2 turns in a clockwise direction. Turn both gauge valves about one turn in a counter-clockwise direction and release all system pressure through center hose. When there is no more Freon flowing, connect center hose of gauge manifold to vacuum pump. *(CAUTION–Do not connect center hose to pump when there is still pressure in system. This could be harmful to pump).* Turn condenser valve counter-clockwise until it seats. Turn high pressure gauge valve clockwise until seated. Start vacuum pump and evacuate the system to a minimum of 24" Hg. in at least 20 minutes. This will be indicated on the low pressure gauge of the gauge manifold. Turn low pressure gauge valve clockwise and fender valve counter-clockwise until seated. Shut off vacuum pump and disconnect center hose at pump fitting. If it is necessary to remove Pressure Test Gauge Manifold, turn valve stems on both condenser and fender apron valves counter-clockwise until seated. Disconnect both gauge hoses from service ports. Cap hoses and ports. Replace condenser and fender apron valve stem protector caps.

LINCOLN & MERCURY AIR CONDITIONING SYSTEM

CHARGING THE SYSTEM

If gas pressure has been released either through accident or for servicing, it will be necessary to completely recharge the system. Before recharging system, follow procedures under "Pressure Testing System", "Leak Testing System", and "Evacuating System" in order given. Connect manifold center hose of Pressure Test Gauge Manifold to a charged Freon tank. Open tank valve. Loosen manifold center hose at manifold connection and allow Freon to escape for a few seconds. Retighten center hose connection. Turn low pressure gauge valve about two turns in a clockwise direction. Turn fender apron valve stem slowly about 1-1/2 turns in a counter-clockwise direction. When pressure neutralizes, place manual temperature control lever in full cold position. Start engine. Allow engine to run at fast idle. Place Freon tank on scale and charge until 7½ lbs. (1953), 6½ lbs. (1954-55) have passed into system. *(CAUTION–If pressure in Freon tank not sufficient to force total lbs. into system it may be necessary to stand tank in pail of hot water. Do not use excessive heat on tank as this could cause an explosion).* When system is fully charged there will be no bubbles visible in the evaporator sight gauge. The pressures will be between 25-40 (1953), 20-30 (1954-55) PSI on low side, 120-190 (1953), 135-160 (1954-55) on high side. To check high and low pressures, engine must be running on fast idle. Fender apron valve and condenser valve must be cracked open. Both valves on gauge manifold must be turned clockwise until seated. To remove Pressure Test Gauge Manifold, turn valve stems on both condenser and fender apron valves counter-clockwise until seated. Disconnect both gauge hoses from service ports. Cap hoses and ports. Replace condenser and fender apron valve stem protector caps.

PUMPING DOWN THE SYSTEM

1953 MODELS

1) Install Pressure Test Gauge Manifold, Tool ACL53-3 with both valves turned in full clockwise position, with high pressure gauge hose connected to high pressure valve service port, and low pressure hose to low pressure valve service port.

2) Turn low pressure valve located on right front fender apron and high pressure valve located on condenser, 1½ turns in clockwise direction, using Tool ACL53-5. Both gauges will read neutral system pressure (approximately 50-75 PSI at outside air temperature of approximately 70-75°F.).

3) Remove cap from shut-off valve on receiver and, using Tool ACL53-5 turn valve in full clockwise direction until seated. Start engine and run until there is no liquid visible in sight glass. Then run engine an additional 3 minutes. Turn low pressure valve clockwise until seated.

4) Shut off engine, then turn high pressure valve clockwise until seated. *CAUTION*–Never shut off high pressure valve with engine running. NOTE–When system is completely pumped down there is still approximately 15 PSI pressure in low pressure side. In pumped down condition high pressure gauge will read system pressure. The 15 PSI in low pressure side must be slowly exhausted when any low pressure fitting is opened.

CONTINUED ON NEXT PAGE

1953-55 LINCOLN & MERCURY (C ntinued)

1954-55 MODELS

When any assembly (except receiver tank or compressor) is to be replaced or serviced, most of Freon charge can be saved by pumping system down. This traps gas in receiver tank. Proceed as follows: Raise car and remove valve stem protector caps from both the receiver inlet and outlet valves. Turn stem on receiver outlet valve clockwise until seated. Lower car and start engine. Run engine on high idle for four minutes. At this point, there should be no more Freon visible in the evaporator sight gauge. While engine is still running, turn stem on receiver inlet valve clockwise until seated. Shut off engine. To release pumped down pressure turn receiver outlet valve counter-clockwise until seated. When system has neutralized, turn receiver inlet valve counter-clockwise until seated. Replace receiver valve stem protector covers.

ADDING PARTIAL CHARGE OF REFRIGERANT

Before adding a charge, follow procedures outlined under "Pressure Testing System", and "Testing for Leaks". Make sure both gauge valves are turned clockwise and condenser and fender apron valves counter-clockwise until seated. Connect center hose of gauge manifold to a charged Freon tank. Open tank valve. Loosen manifold center hose at manifold connection and allow Freon to escape for a few seconds. Retighten hose connection. Start engine and run at high idle. Turn fender apron valve about 1 1/2 turns in a clockwise direction. Place Freon tank on a scale. Turn low pressure gauge valve 1 1/2 turns in a counter-clockwise direction and add Freon 1/2 lb. at a time until sight glass remains clear at all engine speeds. At this point an additional lb. of Freon may be added as a safety factor. *(CAUTION–If pressure in Freon tank is not great enough to force gas into system, this pressure may be increased by standing tank in a pail of hot water. Do not use excessive heat on tank as this may cause an explosion).* Check system pressure. To check high and low pressures, run engine at fast idle. Open fender apron valve and condenser valve clockwise 1 1/2 turns. Turn both gauge valves clockwise until seated. Pressures should be 25-40 (1953), 20-30 (1954-55) PSI on low side, 120-190 (1953), 135-160 (1954-55) PSI on high pressure side. To remove Manifold, turn valve stems on both condenser and fender apron valves counter-clockwise until seated. Disconnect both gauge hoses from service ports. Cap hoses and ports. Replace condenser and fender apron valve stem protector caps.

EVACUATING A PUMPED DOWN SYSTEM

Clamp Pressure Test Gauge Manifold Tool 53-3 to radiator air deflector. Remove protector cap from condenser valve stem, and make sure stem is turned in the full counter-clockwise direction. Remove cap from condenser valve service port and low pressure service hose. Connect low pressure gauge hose to condenser valve service port. (NOTE–With system blocked at receiver, it will be necessary to evacuate from the high pressure side. The valve arrangement used in the compressor would block evacuation from the low pressure side. The low pressure gauge must be used, as it is the only one equipped to measure vacuum. Make sure high pressure gauge valve is turned in the full clockwise direction. Connect center hose of gauge manifold to vacuum pump. Start pump. Turn low pressure gauge valve counter-clockwise about two turns. Turn condenser valve stem clockwise about 1-1/2 turns. Evacuate system to a minimum of 24" Hg. after 20 minutes. Turn low pressure gauge clockwise until seated. Release pump down pressure by turning receiver outlet valve counter-clockwise until seated. When system pressure has neutralized, turn receiver inlet valve counter-clockwise until seated. Disconnect vacuum pump, and turn low pressure gauge valve counter-clockwise about 1/2 turn. Allow Freon from system to purge through gauge manifold for a few seconds to clear manifold of any air. Turn low pressure gauge clockwise until seated. Check system pressures and test for leaks (See "Pressure Testing System" and "Testing for Leaks"). If it is necessary to add to the charge of refrigerant, Follow procedures under "Adding A Partial Charge of Refrigerant". If Pressure Test Gauge Manifold is not going to be used further, it may be removed at this time. To remove, turn valve stems on both condenser and fender apron valves counter-clockwise until seated. Disconnect both gauge hoses from service ports. Cap hoses and ports. Replace condenser and fender apron valve stem protector caps.

EVACUATING COMPRESSOR & ADDING PARTIAL CHARGE OF REFRIGERANT

1954-55 MODELS

EVACUATING COMPRESSOR & ADDING PARTIAL CHARGE OF REFRIGERANT (After Checking & Adding Oil or After Re-installation of Compressor): Attach manifold gauge set, tank of Freon-12, and a vacuum pump to the system as follows: Remove service valve stem covers and make sure that both service valves are at maximum counter-clockwise position. Remove service port gauge port covers, and attach flexible hoses of gauge set to gauge ports and to a tank of Freon-12 (center line). Turn both manifold gauge valves to the maximum clockwise position. Attach vacuum pump to center connection of gauge manifold. Place both service valves at maximum clockwise position, and both gauge valves at maximum counter-clockwise position. Run vacuum pump until low pressure gauge indicates as close to 30" of vacuum as possible. Close pump valve, turn off pump. Open Freon-12 tank valve, then check all compressor connections for leaks. Shut Freon tank valve. Turn both service valves to maximum counter-clockwise position. Check quantity of Freon-12 in system (see "Bubbles in Sight Glass" under CHECKING above). Add partial charge of refrigerant as follows:

Adding Partial Charg f R frig rant: With manifold gauge set attached, open Freon-12 tank valve. Purge air from high pressure hose by loosening high pressure hose at service valve. Tighten connections and set high pressure gauge valve at maximum clockwise position. Set low pressure gauge valve at maximum counter-clockwise position. Loosen low pressure gauge hose slightly at low pressure service valve to purge air from hose. Tighten connection. Set both service valves at center position. Run engine at 1500 RPM with temperature control knob at maximum cold position. Charge system until liquid sight glass shows no bubbles. Continue to charge system until one additional lb. of Freon-12 has been removed from tank. It may be necessary to place Freon-12 tank in a container of hot water (not to exceed 125°F.) to force gas from tank. *(CAUTION–Never heat Freon-12 tank with torch. A dangerous explosion may result).* Set both service valves at maximum counter-clockwise position. Remove gauge set, cap service valve gauge ports and valve stems.

REMOVAL & INSTALLATION TO WORK IN ENGINE COMPARTMENT

1953 MODELS

COMPRESSOR: Removal—Follow steps 1 and 2 under Pumping Down The System. If both gauges read neutral system pressure continue with following steps and pump down system. If system pressure low, or there is no pressure, remaining steps of pumping down system may be omitted. Drain coolant from radiator and cylinder block. Loosen valve fitting on flexible low pressure hose, allow refrigerant to exhaust, disconnect hose, cap hose and fitting immediately. Disconnect flexible high pressure hose at compressor, cap compressor fitting and hose fitting immediately. Disconnect defroster blower motor bullet connectors, heat delivery chamber clips, turn motor clockwise, remove assembly. Disconnect water by-pass tube at water outlet connection, oil filler cap and oil lever indicator, exhaust manifold cross-over pipe and heater hose clamp attached to lower right stud on right hand exhaust manifold. Remove cap screw from compressor which secures oil level indicator tube bracket to compressor, then cap screw from compressor which secures compressor to manifold bracket. Loosen compressor head cap screw sufficiently to remove bracket supporting heater hose, retighten cap screw to 20 ft. lbs. torque. Disconnect heater hose connection at water pump, move out of way. Remove compressor belt from compressor pulley, remove generator. Remove two cap screws securing compressor mounting pad to cylinder block, allow compressor to rest against cylinder block and upper front suspension arm. NOTE—One attaching stud taps into engine water jacket. Lift compressor, with high pressure hose attached, from engine compartment. NOTE—When replacing defective compressor, remove high pressure hose and install immediately on replacement compressor. Cap fitting on defective compressor.

Installation: Install 3/8-2" stud in compressor pad rear mounting hole in engine block (locating stud, to be removed later). Position compressor on locating stud, replace cap screw in forward mounting pad hole. Remove locating stud, replace rear cap screw. Torque screws to 23-28 ft. lbs. NOTE—Apply water sealer to rear cap screw before installation.

CONTINUED ON NEXT PAGE

1953-55 LINCOLN & MERCURY (Continued)

Install generator, then idler and support assembly. Install and adjust generator belt, then compressor belt by pulling idler against belt to allow approximately ½" deflection at point midway between water pump and compressor pulley. Install heater hose connection to water pump, then install heater hose bracket under compressor head cap screw (torque cap screw to 25-30 ft. lbs.). Install oil level indicator tube to compressor bracket, then compressor to manifold bracket. Install flexible low and high pressure hoses. Install exhaust manifold cross-over pipe, using new gaskets, then attach heater hose clamp to lower right stud on right hand exhaust manifold. Install water by-pass tube using new gasket, then defroster blower and inlet duct assembly. Tighten cylinder block and radiator drain cocks, replace coolant. If system has been pumped down open shut off valves in following order (turn valves full counterclockwise direction to open): Receiver shut off valve; when no more liquid Freon is flowing past sight glass, open low pressure valve, then high pressure valve. If system has been exhausted, evacuate and charge (see above).

CONDENSER ASSEMBLY WITH MODULATOR VALVE & HIGH PRESSURE VALVE ATTACHED: Removal—Follow steps 1 and 2 under Pumping Down The System. If there is pressure in the system, open low pressure valve of Manifold by turning stem counterclockwise, exhaust refrigerant through center Manifold hose until low pressure gauge reads "0" PSI, then close low pressure valve of Manifold by turning clockwise until seated, open high pressure valve of Manifold slightly by turning stem counterclockwise and very slowly exhaust refrigerant through center Manifold hose until high pressure gauge reads "0" PSI, Close high pressure valve of Manifold by turning stem clockwise until seated. Whether pressure or no pressure was in system disconnect high pressure hose at high pressure valve on condenser, cap hose and valve fittings. Disconnect by-pass hose at modulator valve located on condenser. Cap hose and valve fitting. Disconnect condenser outlet tube from high pressure tube leading to receiver tank, cap both line fittings. Disconnect Bowdin wire at manual control on condenser modulator valve, then remove four cap screws (2 per side) securing condenser assembly to condenser mounting brackets. Remove condenser assembly with modulator valve and high pressure valve attached. NOTE—When removing condenser assembly, lift assembly upward being careful not to damage condenser outlet line and fitting or radiator core. Do not attempt to transfer or replace condenser outlet line, high pressure valve or modulator tube. When replacing condenser assembly, transfer modulator valve and bracket assembly to replacement condenser.

Installation: Position condenser assembly with modulator valve and high pressure valve attached in condenser mounting bracket, using care not to damage radiator core or condenser outlet tube. Secure condenser to condenser bracket with four cap screws—two each side. Remove caps from condenser outlet tube and high pressure line to receiver and, using new copper seals, connect tubes and tighten fitting. Remove caps from flexible high pressure hose attached to compressor, and high pressure valve fitting. Connect hose to high pressure valve using new seal, tighten fitting. Remove caps from by-pass hose and modulator valve fitting, connect hose to modulator valve using new seal, tighten fitting. Connect Bowden cable wire to manual control on condenser modulator valve. With instrument panel selector lever half way between cold and warm, manual cam lever on modulator valve should be at 90° to valve body. Tighten modulator valve bracket set screw, locking cable housing in position. Check opening of valve by moving selector lever to right. Install new dehydrator assembly (see below). Pressure test, evacuate and charge system (see above). Test for leaks.

1954-55 MODELS

CONDENSER ASSEMBLY WITH MODULATOR VALVE ATTACHED: Removal—Clamp Pressure Test Gauge Manifold Tool 53-3 to radiator air deflector. Remove protector caps from valve stems on condenser valve and fender apron valve. Turn both valve stems counterclockwise until seated. Remove service port caps. attach high pressure gauge hose to condenser valve service port, and low pressure gauge hose to fender apron valve service port. Make sure both valves on gauge manifold are turned clockwise until seated. check system pressure by turning valve stems on condenser and fender apron valves 1 1/2–2 turns in a clockwise direction. Both gauges should read between 50-80 PSI. If there is pressure in system, pump down system. Disconnect by-pass line at modulator valve fitting, cap line and fitting immediately. Remove cap screw holding by-pass line clamp to top of condenser. Disconnect high pressure hose at condenser valve fitting. Cap hose and fitting immediately. Loosen clamp holding Bowden wire housing to modulator valve mounting bracket. Slip wire down off pin on modulator valve actuating arm. Disconnect high pressure line at fitting on lower right hand corner of condenser assembly. Cap line and fitting immediately. Remove two bolts, nuts and flat washers holding hood lock support to upper radiator braces. Remove four bolts, nuts and washers holding lower hood lock support braces to radiator support and four nuts, bolts and washers holding hood lock support to fender apron. Remove acorn nut holding hood lock support to its rod, then remove support with two lower braces attached. (NOTE—It will be necessary to slip head lamp wiring loom out of clips on the under side of the hood lock support). Remove six cap screws, 3 each side, holding condenser mounting brackets to radiator support assembly. Remove condenser assembly with modulator and condenser mounting brackets attached. (NOTE—When replacing condenser assembly, transfer modulator valve and condenser mounting brackets to new condenser). If it is necessary to remove Pressure Test Gauge Manifold, turn valve stems on both condenser and fender apron valves counter-clockwise until seated. Disconnect both gauge hoses from service ports. Cap hoses and ports. Replace condenser and fender apron valve stem protector caps.

Installation: If Pressure Test Gauge Manifold Tool 53-3 has been removed, install as follows: Clamp manifold assembly to radiator air deflector. Remove protector caps from valve stems on fender apron and condenser valves and turn both stems counter-clockwise until seated. Remove caps from service ports. Attach high pressure gauge hose to condenser valve service port, and low pressure gauge hose to fender apron valve service port. Make sure both valves on gauge manifold are turned clockwise until seated. Place condenser assembly, with mounting brackets and modulator valve attached, in position on radiator support and attach with six mounting cap screws. Place hood lock support, with two lower braces attached, in position on fender apron mounting brackets and install four attaching cap screws. Install acorn nut holding hood lock support to hood lock support rod. Install four bolts, nuts and washers holding lower hood lock support braces to radiator support. Install two bolts, nuts and washers holding hood lock support to upper radiator braces. Slip headlamp wiring loom into clips on underside of hood lock support. Remove caps from high pressure line and fitting on right hand corner of condenser assembly. Using new copper seal, connect line to fitting. Remove caps from modulator valve fitting, and by-pass line. Using new copper seal, connect line to fitting. Remove caps from flexible high pressure hose and condenser valve. Using new copper seal, connect hose to fitting. Secure by-pass line clamp to top of condenser with cap screw and lockwasher. Place manual temperature control in full cold position. Rotate modulator valve actuating arm as far as it will go towards the right hand side without forcing it, and slip Bowden wire loop up over end of actuating arm pin. Clamp Bowden wire housing to modulator valve mounting bracket. Replace dehydrator (see Removal & Installation of Dehydrator Assembly). If system was pumped down, first evacuate (see Evacuating a Pumped Down System). Release pumped down pressure by turning receiver outlet valve counter-clockwise until seated. When system pressure has neutralized, turn receiver inlet valve counter-clockwise until seated. Test entire system for leaks (see Leak Testing Procedure). If there was no system pressure, perform "Pressure Test", "Leak Test" "Evacuate", and "Charge" system in this order. Turn valve stems on condenser valve and fender apron valve counter-clockwise until seated. Remove Pressure Test Gauge Manifold, replace protector caps on condenser valves, fender apron valves, and both valves on receiver. Cap service ports, and manifold hoses.

COMPRESSOR ASSEMBLY: Removal—Drain radiator and engine block. Disconnect battery ground cable. Remove protector caps from valve stems on condenser valve and fender apron valve. Turn valve stems clockwise until seated. Disconnect water by-pass line at thermostat housing. Remove oil filler cap and oil level indicator. Remove exhaust crossover pipe. Disconnect heater outlet tube at water pump connection and remove cap screw securing heater tube clamp to compressor. Raise car and remove generator as follows: Remove radiator splash shield, loosen gener-

CONTINUED ON NEXT PAGE

1953-55 LINCOLN & MERCURY (C ntinued)

ator idler to remove belt tension, loosen generator mounting cap screws, remove generator drive belt. Remove arm, field, and ground wires from connections on generator, remove generator mounting cap screws and generator. Remove two cap screws securing compressor. Note wiring harness clip on rear cap screw. Lower vehicle and disconnect flexible high pressure hose and flexible low pressure hose at compressor fittings. Cap hoses and fittings immediately. Remove exhaust manifold crossover pipe extension. Loosen compressor belt idler arm and remove belt. Remove two cap screws holding compressor to compressor mounting bracket. *(CAUTION–Support compressor ass mbly to keep it from falling when cap screws are removed).* Remove compressor by lifting up around heater connections and out through engine compartment.

Installation: Place a headless stud in one of the mounting holes in compressor. Place compressor in position in engine compartment with stud through bracket for support. Replace one compressor-to-bracket attaching screw. Remove headless stud and replace second cap screw. (NOTE–Slip oil dipstick tube brace over rear cap screw before installing). Place compressor drive belt in position over compressor and crankshaft pulleys. Connect heater return line to water pump. Secure heater tube clamp to compressor. Connect flexible low and high pressure hoses to compressor. Use new copper seals. Replace exhaust manifold crossover pipe extension, using new gasket. Make sure heater supply line clamp is installed on lower stud before tightening nut. Connect water by-pass line to thermostat housing, using new gasket. Install oil filler cover, and oil level indicator. Raise vehicle and secure compressor idler bracket to compressor with attaching cap screw. Replace two compressor to engine block mounting cap screws. Make sure wiring harness clip is placed on rear cap screw before installing. Place compressor belt over idler wheel. Install generator as follows: Place in position in mounting bracket and install rear cap screw. Install front cap screw with spacer between generator and mounting bracket. Install field, arm, and ground wires. Place generator drive belt in position on pulleys and up over idler wheel. Tighten idler in position, and adjust belt tension by pulling down on generator assembly and tightening generator mounting screws. Replace generator splash shield. Lower car and adjust compressor belt tension by loosening idler arm attaching cap screws, and pulling idler pulley up against belt. Final adjustment is made by tightening idler arm attaching screws, and turning idler arm adjusting screw down until there is approximately 1/2" deflection of the belt when it is pushed at a point about half-way between the two pulleys. Turn the valve stems on both the condenser and fender apron valves counter-clockwise until seated. Install a new dehydrator assembly (see Removal & Installation of Dehydrator Assembly). Pressure test system (see Pressure Testing System). Leak test system. If bubbles or foaming can be seen in evaporator sight glass with engine running on high idle, add refrigerant (see Adding a Partial Charge of Refrigerant). If there is no charge in system, "Pressure Test", "Leak Test", "Evacuate", and "Charge" in order given.

PARTS REPLACEMENT

1954-55 MODELS

►*NOTE:* Later 1954 and all 1955 Compressors may be serviced as indicated below. Those 1954 Compressors that may be serviced are identified by a 3/8" diameter tapped hole drilled in the end of the compressor pulley shaft. Compressor decals prohibiting repair may be ignored to the extent given below. 1953 and Early 1954 Compressors are serviced by replacement only.

COMPRESSOR SHAFT SEAL: *(NOTE–*A small quantity of oil around the compressor shaft seal is normal. An excessive amount of oil (to the point where it drips) indicates a leak. Always confirm a seal leak by checking with a leak detector). To replace compressor shaft seal, remove compressor and proceed as follows:
1) Remove two 1/8" Allen set screws from pulley hub. Both set screws are in the same hole, one on top of the other. Remove pulley with gear puller. *(NOTE–*The disconnect bolts may be removed from the 1955 pulley and the holes used in conjunction with an appropriate puller. A puller used on a 1954 pulley must grip the rear face of the pulley to prevent damage to the belt surfaces). Remove woodruff key from shaft. Check for and remove any burrs existing on shaft surface.

2) Compress seal bellows to clear snap ring and remove snap ring. Position compressor with pulley shaft upright. Remove seal seat *(NOTE–*White lead is used by manufacturer in assembling pulley to shaft and excessive white lead may cause seal seat to stick. If such a condition exists the seal seat can usually be loosened by tapping lightly to break bond. If this fails, a small gear puller may be used).

3) Clean seal plate and shaft thoroughly with a suitable solvent using care to prevent dirt or solvent from entering compressor. Remove seal bellows assembly. It can be pried free of seal plate with two screwdrivers. Remove "0" ring from groove in seal plate. Using new "0" ring, coat with clean compressor oil and insert into groove in seal plate.

4) Coat mating surfaces of new seal bellows assembly and shaft with compressor oil and reassemble seal bellows to compressor *(NOTE–*Brass cartridge enclosing seal bellows is a light press fit in front plate. The pressure seal is accomplished by the large "0" ring in the seal plate. Brass cartridge must go into front plate perfectly square and the flange must bottom against front plate all the way around). Wet seal seat with clean compressor oil and install with lapped surface towards seal bellows. Replace snap ring. Place woodruff key in compressor shaft slot. Lubricate shaft and pulley bore. Install pulley on shaft so that outer face of pulley hub is flush with end of shaft *(NOTE–*This must be accomplished without putting any pressure on the rear compressor shaft bearing. A puller can be made by using a 3/8"-16x1½" capscrew, nut and large flat washer. Install nut and then washer on capscrew. With washer next to pulley hub, bottom capscrew in tapped hole of shaft and use nut to press pulley into place). Replace both Allen screws in pulley hub.

COMPRESSOR VALVE PLATE: *(NOTE–*Valve plate assembly may be serviced with compressor on or off car. If compressor is removed, it should be serviced in an upright position). Proceed as follows:
1) Isolate compressor and relieve compressor pressure. Remove compressor cylinder head and valve plate *(NOTE–*Cylinder head or valve plate may stick to compressor body. Loosen with hammer and drift. All blows should be in an upward direction to prevent damage to pins that protrude from lower face of valve plate). Inspect valve plate, suction valve leaves and pins carefully. Check to see if tab on valve plate gasket was bearing against bottom surface of leaf rather than top surface. When assembling, use all new gaskets. *(NOTE–*Most valve malfunctions are caused by dirt or foreign particles working their way under the valves, causing them to remain open. Valve plate assembly and suction valve leaves may be cleaned in solvent. After cleaning, inspect valves closely. If there appears to be no damage to the valve plate sealing surface or suction leaves, they may be thoroughly dried, coated with refrigerant oil and reassembled. Use new gaskets. The oil will hold the suction leaves in place on their pins while valve plate is being assembled to the compressor body. Replace any parts that appear damaged. If cylinders, or tops of pistons show damage, compressor must be replaced).
2) To reassemble, coat all pieces with refrigerant oil and assemble in the following order (compressor upright): Valve plate gasket, valve plate with leaves attached, head gasket, and head *(NOTE–*Order of reassembly is important, since tabs on valve plate gasket serve to anchor the suction leaves in place).

SUCTION & DISCHARGE LINE FITTINGS: Fittings are retained to compressor body with two Allen screws. A 7/32" Allen wrench is required to remove a fitting. Use new gaskets whenever a fitting is replaced. Wet gaskets with compressor oil.

SUCTION STRAINER SCREEN: Suction strainer is a finger strainer located in a recess under suction line fitting. After fitting and gasket have been removed, strainer and its gasket can be removed and replaced. Use new gaskets whenever a fitting is replaced. Wet gaskets with compressor oil.

OIL SIGHT GLASS: *(CAUTION–*If a broken or leaking oil sight glass is suspected, it should be thoroughly leak tested. This thorough check is recommended because a broken sight glass is rare and rather difficult to replace).

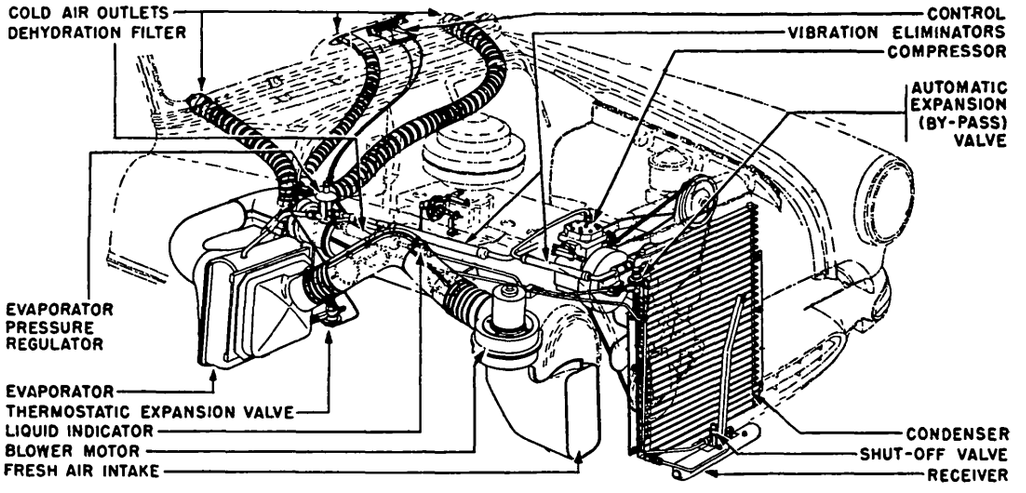
1954-EARLY 1955 PONTIAC AIR CONDITIONING

Pontiac (1954-Early 1955)①

①—See Production Changes below. For "Later 1955 Pontiac" see "1954-55 Frigidaire (G.M.)" Air Conditioning.

►CHANGES & CORRECTIONS

►*1954 PONTIAC COMPR. CLUTCH & PULLEY ASSEMBLIES PRODUCTION CHANGE:* After production of first 500 clutch and pulley assemblies, a change was made in the clutch plate and hub assembly. This change also made it necessary to change pulley, coil, and bearing assembly; and brush and bracket assembly. *New and old type parts are not interchangeable.* New type clutch plate can be identified by date stamped on clutch facing. New type pulley, coil, and bearing assembly has date stamped on coil. New brush and bracket assembly will be serviced in a dated bag. *Original or old type parts were not dated.*



►*1954 PONTIAC HYDRA-MATIC IDLE SPEED CAUTION & CORRECTION:* With idle speed of 375 ± 10 RPM on cars equipped with Hydra-Matic and air conditioning, clutch plate has tendency to slip on pulley assembly which wears clutch plate facing and also heats up entire magnetic clutch assembly due to intermittent slippage because setting is not sufficient to operate compressor and still maintain a relatively smooth engine idle speed when the increased compressor head pressures are attained. To correct this condition, the idle speed should be set at 470 ± 10 RPM.

►*1954 PONTIAC CONDENSER CHANGE (To Eliminate Vibration):* New condenser is identical in design to that previously released except that condenser mounting support is now separated by rubber. Early and late type condensers are interchangeable except that new type mounting support (with rubber), Part No. 520219, must be used with late type condenser, Part No. 8522905.

►*1954 PONTIAC COMPR. CYLINDER HEAD PROD. CHANGE (To Dampen Compressor Pulsation and Smooth Out Operation of System):* A larger volume compressor cylinder head and some related parts have been released under Service Kit Package No. 3133304. It is necessary to install this kit on cars having the earlier type compressor cylinder heads. When installing the cylinder head spacer, during installation of the above kit, it is imperative that spacer be installed with smooth side up towards cylinder head. To reduce possibility of gasket leaks when installing kit, it is recommended that all gaskets used in kit be coated on both sides with refrigeration or compressor oil before installing. Use one of oils listed under Checking Compressor Oil Level & Adding Oil.

►*1954 PONTIAC COMPRESSOR CYLINDER HEAD TORQUE CHANGE:* Cylinder head bolts should be tightened to 25 ft. lbs. rather than 12-15 ft. lbs. originally specified.

►*1955 PONTIAC RECEIVER & DEHYDRATOR-FILTER PRODUCTION CHANGE:* A combination unit (after first 800 cars) replaces two units used previously. The combination unit has no shut-off valve at the receiver which changes certain service procedures. Freon capacity of system with combination type is 3¾ lbs. instead of 5¼ lbs. with early type unit with separate receiver. *For service procedures on later 1955 type see "1954-55 Frigidaire (G.M.)" Air Conditioning.*

1954 PONTIAC AIR-CONDITIONING INSTALLATION

►*1955 PONTIAC COMPRESSOR CHANGE:* A five cylinder, horizontal, reciprocating type compressor (Frigidaire), replaces the twin cylinder, vertical, reciprocating type used in 1954. *For service procedures on 1955 Compressor see "1954-55 Frigidaire (G.M.)" Air Conditioning.*

►*1955 PONTIAC OTHER CHANGES & CORRECTIONS: See "1954-55 Frigidaire (G.M.)" Air Conditioning.*

►*1955 AUTOMATIC FAST IDLE PRODUCTION CHANGE:* Automatic fast idle, which was actuated by placing selector lever in neutral, is not used in 1955.

►*1955 OUTSIDE AIR INTAKE PRODUCTION CHANGE:* Outside air is supplied to system through cowl air intake. All outside air passes through filter before entering evaporator, whether to be cooled or by-passed.

►*1955 AIR RECIRCULATION PRODUCTION CHANGE:* An air recirculation system has been included to increase cooling capacity or eliminate outside odors when necessary. Exclusive use of outside air or recirculation of air within car may be selected by movement of one push-pull control. When pulled out, air in the car and system is recirculated, with a small amount of outside air still being admitted to pressurize the inside of the car. Pressure prevents warm air from entering any openings in body. With control button pushed in, only outside air passes through system into car. Positions between full out and in will give mixed outside and recirculated air. Fan must be on full speed (switch fully down) when recirculation is used. Recirculation should only be used after car has started to cool.

►*1955 PONTIAC COMPRESSOR BELT MISALIGNMENT CORRECTION:* To correct, elongate the two front inner insulator bracket (Part No. 521086) bolt holes by ¼" back toward compressor mounting flange, then place a 1/16" thick flat washer at each of the two insulator bolts to space bracket out from rubber insulator. Bend outer end of front outer insulator bracket back and in towards compressor 1/8". Condition has in later production.

DESCRIPTI N

Compression process cycle type, using Freon-12 as refrigerant. System consists of following elements:

Refrigerating: Compressor—Located at top right front of engine is twin cylinder, vertical, reciprocating type with leaf type intake and discharge valves. Operation causes and maintains necessary high pressure in system needed to increase Freon vapor temperature.

►*NOTE: For Early 1955 Compressor, see "1955 Pontiac Compressor Change" above.*

Condenser—Located in front of radiator. Condenses refrigerant vapor discharged from the compressor, through action of fast moving air over metal surfaces of condenser.

Receiver—Located in front of radiator and beneath condenser. Stores liquid refrigerant. Stores liquid refrigerant and maintains supply more than needed normally.

Liquid Indicator—Located between receiver and dehydrator-filter. Provides means for determining adequacy of refrigerant charge.

Dehydrator-Filter—Located to rear of liquid indicator. Filters and dehydrates circulating Freon.

Thermostatic Expansion Valve-Located to left of evaporator. Supplies liquid to cooling core of evaporator at same rate that refrigerant is removed from it in a vaporous state.

Evap rat r (Boiler)—Located in rear of right front

CONTINUED ON NEXT PAGE

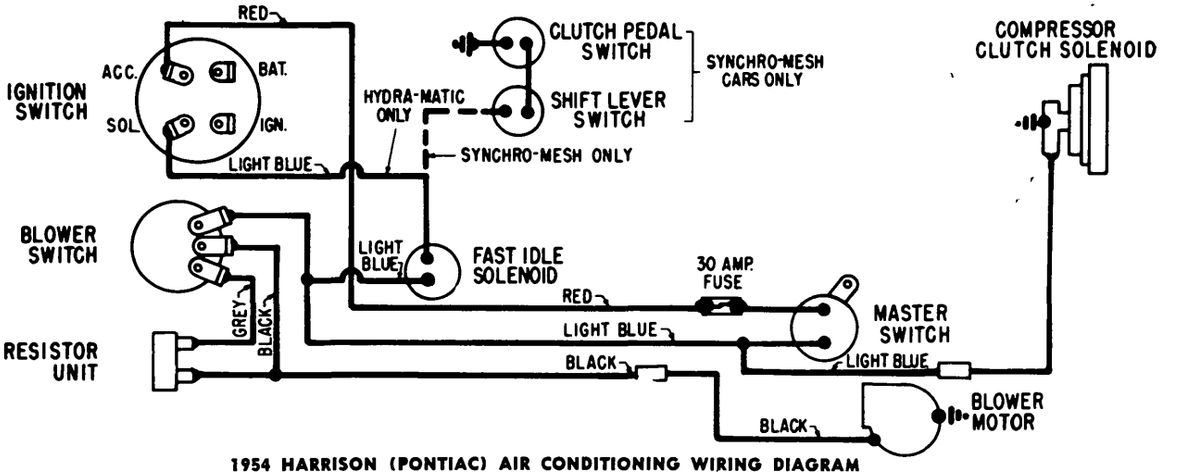
1954-EARLY 1955 PONTIAC (C ntinu d)

fender baffle. Container for refrigerant which readily absorbs heat from surrounding air when temperature of refrigerant liquid is reduced. In core of evaporator refrigerant is changed to liquid.

Evap rat r Inl t Ass mbly: In front of evaporator. Provides means for removing dust and other foreign material from air passing through evaporator core into car. Can be removed and cleaned.

Evap rat r Pressur R gulator Valve: Located above and forward of evaporator. Prevents evaporator pressure from falling below 30 psi. thereby keeping boiling temperature of Freon above 32° F.

By-Pass Valv –Located at top right of condenser. Provides automatic opening and closing of by-pass cycle. With evaporator pressure regulator valve closed, pressure in suction pipe drops rapidly until a pressure of 15 psi. is reached. At this point the by-pass valve opens permitting Freon flow to the compressor, and through system except that the evaporator is by-passed.



Vibrati n Eliminat rs–Enlarged flexible portions of compressor suction pipe and compressor-to-condenser pipe. Required because compressor is mounted on engine. The flexible portion of the compressor-to-condenser pipe also serves to reduce vibration caused by pressure pulsations of compressor. The vibration eliminator in compressor suction pipe is covered with rubber to prevent frosting which, if permitted to occur would cause serious damage to the copper bellows of the vibration eliminator.

Air Circulating: Bl w r–Located behind air intake at front of car. System can be operated without use of fan when car speed is sufficient to provide circulation.

Air Circuits–Warm air is drawn into car from outside through air intake at front of car, passes over evaporator core, and enters car through three adjustable air outlets mounted in dash of car.

Air Outl ts–There are three outlets located on the instrument panel of the car. Each of these outlets can be controlled to provide a direction of air flow desired. Center outlet contains a valve deflector plate which may be moved to shut off the air, or to change the vertical deflection of air flow. The others consist of adjustable nozzles mounted in ball sockets at each end of instrument panel.

C ntrol: R gulating–Mounted on instrument panel above heater controls. A sliding lever is the basic control. Movement of the control lever between "OFF" and "ON" activates a valve in the air duct permitting the entry of outside air. When position "ON" is reached, compressor is activated and circuit to blower is closed so that blower may be used if desired. Movement of the control lever between "ON" and "COLD" varies the amount of air traveling over the refrigerating coils of the evaporator, and as a result, varies the degree of cooling within the car according to the amount of cooled air mixed with uncooled air. A switch, marked "FAN", at right of control lever may be moved down to turn on the blower for forced ventilation. Two blower speeds are available–medium

1954 HARRISON (PONTIAC) AIR CONDITIONING WIRING DIAGRAM

when switch is horizontal, high when switch is full down.

►*NOTE: For Early 1955 Clutch, see "1954-55 Frigidaire" Air Conditioning.*

Compressor Clutch–Incorporated in compressor drive pulley assembly. When electrically energized by turning on the air conditioning, an electro-magnet in the pulley assembly locks the compressor drive plate to the pulley assembly. The drive plate which is fastened to the eccentric shaft then drives the compressor. When air conditioning is turned off, circuit to electro-magnet is broken and clutch releases. The compressor drive plate is pushed away from pulley assembly by release springs and thus, is no longer driven.

►*NOTE:* Fast Idle Diaphragm & Solenoid Assembly not used in 1955.

Fast Idle Diaphragm & Solenoid Assembly–An electrically controlled, vacuum operated mechanism that raises idle speed when car is in neutral and air conditioning is on. The fast idle mechanism is controlled so that it will operate only when transmission is in neutral with Hydra-Matic and only in neutral with clutch engaged with Synchro-mesh, and in both cases only when air conditioning control lever is open to, or past, the "ON" position. This control is accomplished by the starter neutralizer switch on Hydra-Matic. On Synchro-mesh cars two switches are required, a clutch pedal fast idle switch mounted on the dash-to-chassis frame brace directly under the clutch pedal, and a gear shift lower lever fast idle switch mounted at lower end of the steering column. When fast idle circuit is energized, fast idle solenoid opens vacuum passage to fast idle diaphragm. Diaphragm then moves inward and knurled adjusting nut on diaphragm stem contacts the carburetor throttle shaft lever, opening the throttle.

OPERATION

Freon gas under low pressure is drawn into the compressor, where it is compressed to high pressure. The process of compression also heats the gas. The hot Freon gas passes into the condenser where it cools by giving off heat to the air passing over the condenser surfaces. As the hot Freon gas is cooled it condenses into liquid at high pressure, and accumulates in the receiver below the condenser. Liquid Freon under high pressure passes to the expansion valve at the entrance to the evaporator. Freon passes through the expansion valve into the evaporator under a much lower pressure. Thus, due to the lowering of the pressure, Freon begins to boil, changing back to a gas. As the Freon passes through the evaporator, it continues to boil by absorbing heat from the air passing over the evaporator surfaces until by the time it leaves the evaporator, it is completely vaporized. From the evaporator the cool, low pressure Freon gas is drawn back to the compressor and the cycle repeated.

MAINTENANCE & INSPECTION

PRELIMINARY CHECK: Check compressor sight glass with compressor operating to see that compressor contains sufficient oil. Check compressor belt tension. Check operation of fast idle linkage. Check all air duct and hose connections for tightness. Operate system and check for correct operation in all control positions (*NOTE*–With control in "ON" position, clutch on front of compressor should engage). Check ambient air temperature and air temperature at outlets on instrument panel (See Table under Testing).

2,000 MILE INSPECTION: Check all connections for presence of oil which could indicate refrigerant leak. Check compressor belt tension and hose and air duct connections. Clean and recondition air filter. Check evaporator drain tube for dirt or restriction.

PERIODIC SERVICE: 1) Inspect condenser and radiator cores at 2000 mile intervals to be sure that they are not plugged with leaves or other foreign material.

2) Clean and recondition filter every 2000 miles or oftener in dusty areas.

3) Check evaporator drain tube for dirt or restrictions at 2000 mile intervals.

CONTINUED ON NEXT PAGE

1954-EARLY 1955 PONTIAC (Continued)

4) Every spring and fall or 10,000 miles give air conditioning unit a complete operational test (See Operational Test following).

AIR FILTER: Every 2000 miles, or more often in dusty areas, the filter should be cleaned and reconditioned as follows: Remove 5 access cover attaching screws and remove access cover from bottom of evaporator inlet behind right front wheel. Pull filter down out of evaporator inlet. (*NOTE*–In extreme cases where filter is lodged in place by an excessive accumulation of mud, it may be necessary to remove the evaporator inlet assembly to get the filter out. In such cases, some mud may have accumulated in the evaporator core and this should be flushed out with water). *CAUTION–Do not use steam or hot water since excessive pressure could be developed in the refrigeration system).* Clean filter by washing in a solution of water and any laundry detergent to remove the dirt laden filter conditioner oil. Re-coat filter by spraying with Pontiac Filter Conditioner. Spray both sides to make sure all of filter element is coated. (*NOTE*–Only Pontiac Filter Conditioner is recommended by manufacturer). Check drain tube in bottom of evaporator housing and clean out any mud which may have accumulated. Replace filter and install access cover.

TESTING

OPERATIONAL TEST: Remove caps from compressor gauge fittings and valve stems. Connect gauge set to compressor suction and discharge valve gauge fittings, then open suction and discharge valve gauge fittings by turning valve stems 1/4 turn clockwise. Purge gauge lines by cracking gauge set low and high pressure valves. Start engine, move air conditioning control lever to "COLD", and turn blower on high speed (Engine should be running at 1200 RPM.). Continue to run engine for ten minutes before checking for proper operation. While system is operating, check ambient (surrounding air) temperature. Also place fan in front of car to direct a stream of air against condenser and blower intake. After system has operated for ten minutes make following checks:

1) Observe liquid indicator to see that there is adequate Freon-12 in system. Bubbles may appear while system is by-passing, but liquid indicator should clear up when system is not by-passing.

2) Observe high pressure gauge. Compare pressure on gauge with pressure given in table below for the ambient temperature recorded above. It should be kept in mind that the head pressure (high pressure gauge) will increase as the temperature in the condenser increases. Thus, the pressure will increase as the car is run, but after 10 or 15 minutes should stabilize.

3) Observe low pressure gauge. With ambient air temperature below approximately 85° F. the system will by-pass periodically. The lower the ambient air temperature is, the more frequently the system by-passes. The pressure when the system is not by-passing will be as shown in table below. *NOTE*–When system by-passes, compressor suction pressure should drop to between 0-15 psi. The suction pressure will fluctuate somewhat if ambient air temperature is below 85° F. If pressure goes below 0 psi., remove cap from adjusting screw on by-pass valve and turn screw clockwise slightly to increase pressure to 0-15 psi. If pressure remains above 15 psi. when by-passing, turn screw counter-clockwise to decrease pressure to 0-15 psi. Proper setting should be obtained when top of adjusting screw is 1 9/64" above adjusting screw cap gasket.

4) Insert bulb of thermometer 1" inside either nozzle inside car. Hold there until temperature no longer drops (Be sure to read thermometer while bulb is 1" inside nozzle). Compare temperature of air leaving nozzle with temperature specified in table below.

1954 System Pressures & Temperatures ①

Ambient Temp. (°F.)	70	80	90	100
Compr. Discg. PSI	92-113	110-149	143-181	175-203
Compr. Suction PSI	5-7	5-16	5-25	12-25
Nozzle Max. Temp.	40	43	47	50
Evaporator Pressure	30	30	31	32

1955 System Pressures & Temperatures ①

Amb. Temp. (°F.)	70	80	90	100
Comp. Disch. (PSI)	140-170	150-200	180-240	230-290
Comp. Suct. (PSI)	10-25	11-29	17-34	25-42
Evap. (PSI-System By-passing)	23-28	23-28	23-28	23-28
Noz. Max. Temp. ②(RH)	50	53	58	64
Noz. Max. Temp. ②(LH)	49	52	56	61

①–With engine operating at 1200 RPM, hood open, recirculation knob pushed in, and after 10 minutes operation. Test to be made in a garage where sun load is not a factor and with auxiliary fan in front of radiator.

②–°F. measured 1" inside opening.

TEST & ADJUSTMENT OF EVAPORATOR PRESSURE: (NOTE–This test should be made with system operating and only after 10 minutes of operation). Remove protective cap from Schrader valve on side of pressure regulator. Assemble adapter J-5420 to end of low pressure gauge hose. Attach hose with adapter to Schrader valve on evaporator pressure regulator. Screw adapter on quickly to avoid excessive loss of Freon (Gauge shut-off valve should be closed). Observe pressure on gauge. If pressure does not agree with that given in table above, remove adjusting screw cap from top of evaporator pressure regulator valve. Adjust valve by turning clockwise to increase evaporator pressure, counter-clockwise to reduce evaporator pressure. *NOTE*–It is impossible to adjust evaporator pressure when compressor suction pressure is above 30 psi.

►**EVAPORATOR PRESSURE REGULATOR VALVE ADJUSTMENT NOTES:** In making adjustments of the Evaporator Pressure Valve note the following:

Extremely Warm Weather Adjustment–In extremely warm weather, it may be necessary to adjust the evaporator pressure regulator valve when ambient temperatures are in the vicinity of 100° F. or more. If the evaporator pressure regulator is adjusted to 30 psi. at these high temperatures, the actual evaporator pressure may drop to 27 or 28 psi. when the ambient temperatures fall to approximately 80° F. It is true that adjusting evaporator pressure at 30 psi. at 100° F. would give a little greater efficiency, but operation in slightly cooler weather would require a resetting or adjustment of the evaporator pressure regulator valve. If this is not done evaporator surface temperatures would be below 32° F. which would cause moisture deposits on the evaporator cooling surfaces to freeze rather than drain off, causing complaint of warm and cold air coming from the nozzles. To correct condition follow relationships in table above.

Slight Variation of Nozzle Temperature (Evaporator Freeze-Up)–Slight variation of the air temperature coming from the nozzles may be the result of a differential in the pressure between the chamber above the pressure regulator valve diaphragm (diaphragm to cap) and outside atmospheric pressure. This condition can be checked and corrected as follows: Attach low pressure gauge to the evaporator pressure valve, but **do not** remove the pressure regulator valve cap. Operate engine fast enough and long enough to insure the system is by-passing (blower motor must be set on low speed to perform this operational test). Check pressure reading and if pressure shows lower than 29 psi., watch gauge and remove cap over the adjusting screw. If no change in the gauge readings is noted, adjust pressure regulator valve in accordance with System Pressures & Temperatures table above. NOTE–In some cases removing the cap will correct the reading to 30 psi. (provided the valve was properly adjusted previously). This change in reading is the result of equalizing the pressure beneath the cap to that of atmospheric pressure. To guard against freeze-up condition, remove valve cap and drill a 1/16" diameter hole just off the center of the valve cap and also the valve cap gasket. (New valves presently in production now have this hole drilled in the cap and cap gasket.)

PRECAUTIONS, LEAK TESTING & TROUBLE SHOOTING

See "Air Conditioning Service Cautions", "Trouble Shooting" and "Leak Tests".

ADJUSTMENTS ON CAR

►*NOTE: For Early 1955 Adjustments, see "1954-55 Frigidaire (G.M.)" Air Conditioning*

COMPRESSOR BELT: Loosen two bolts retaining idler pulley support bracket (pump support bracket on power steering equipped cars). Insert torque wrench in square hole at end of bracket and apply 60 ft. lbs. torque to tighten belt. While holding 60 ft. lbs. torque, tighten retaining bolts securely.

FAST IDLE DIAPHRAGM & SOLENOID: Loosen lock nut on vacuum diaphragm stem. Set fast idle mechanism by turning knurled adjusting nut to give 750 RPM engine speed (hot) with transmission in neutral and air conditioning control lever in "COLD" position. Tighten lock nut.

FAST IDLE SWITCHES: On Hydra-Matic equipped cars the fast idle mechanism is controlled by the neutral-

CONTINUED ON NEXT PAGE

1954-EARLY 1955 PONTIAC (C ntinu d)

izer switch. On Synchro-mesh equipped cars the fast idle mechanism is controlled by a clutch pedal fast idle switch and a gearshift lower lever fast idle switch. For adjustment see Tune-Up on car model page.

CONTROL CABLES: Air Valve & Master Switch Control Cable—Move air conditioning control lever to "OFF" position. Loosen clamp which retains air valve and master switch control cable housing to bracket. Clamp should be loose enough to allow cable housing to slide freely. With another man holding control lever in "OFF" position, pull cable and control housing with control lever attached as far to the rear as possible. While holding in this position, tighten cable clamp. This will insure complete closing of the air valve in the "OFF" position.

Air Temperature Valve Control Cable—Move air conditioning control lever to full "COLD" position. Loosen clamp which retains air temperature valve control cable housing to bracket. Clamp should be loose enough to allow cable housing to slide freely. With another man holding control lever in "COLD" position, pull cable and housing with control lever connected as far to rear as possible. While holding in this position, tighten cable clamp. This will insure complete opening of air valve in duct to evaporator and oomplete closing of air valve in duct to air distributor in the "COLD" position.

PUMPING DOWN THE SYSTEM

When refrigeration pipes are to be disconnected on the low pressure side, the system can be pumped down to save the Freon. "Pumping Down" is the process of pumping all the Freon out of the low pressure side into the condenser and receiver, where it is stored while work is being performed. The evaporator pressure regulator valve, evaporator assembly, thermostatic expansion valve, dehydrator, liquid indicator, by-pass valve, and pipes connected to the above listed units can be removed after the system is pumped down. When compressor only is removed follow procedure outlined in "Pumping Down Compressor To Remove Compressor or Add Oil" below. To pump down system proceed as follows:

1) Close hand shut-off valves on gauge set by turning clockwise.

2) Remove caps from valve stems and gauge fittings on compressor suction and discharge valves. Connect hose from low pressure gauge to fitting on suction valve, and hose from high pressure gauge to fitting on discharge valve.

3) Open compressor discharge and suction valves by turning clockwise until they seat, then backing off one turn counter-clockwise. Use valve key J-5427.

4) Purge air from both gauge lines by cracking hand shut-off valves on gauge set. Close valves securely.

5) Remove valve cap and close valve on receiver outlet by turning clockwise.

6) Start engine, move air conditioning control lever to "COLD" and turn blower on (engine should be operating at 750 RPM). Operate air conditioning until low pressure gauge drops to "0" or below. Shut off air conditioning and observe low pressure gauge. Pressure will rise to some value and then stabilize. When low pressure gauge stops rising, move air conditioning control lever to "COLD" again (with engine running) and operate until pressure on low side again drops below zero. Shut off air conditioning and again allow pressure to rise until it stabilizes. Repeat this cycle until the pressure will no longer rise above zero. *CAUTION—Do not allow head pressure (high pressure gauge) to exceed 300 psi. If it does, shut off engine and wait for pressure to drop before proceeding.*

7) Shut off engine, immediately turn compressor suction and discharge valves clockwise as far as possible to close passage to suction and discharge pipes. The Freon has now been pumped into the receiver and condenser and is trapped in the high pressure side of the system. The low pressure side can be opened without loss of Freon.

8) Disconnect compressor clutch wire from connector on fender skirt so that compressor cannot be operated while system is pumped down.

PUMPING DOWN COMPRESSOR TO REMOVE COMPRESSOR OR ADD OIL: Operate engine at fast idle (750 RPM) and run air conditioning system for ten minutes. This will work Freon out of oil in compressor crankcase and stabilize system. After ten minutes stop compressor by disconnecting clutch wire at connector on fender skirt. Close suction valve on compressor by turning all the way clockwise. *(CAUTION—Engine should be turned off while closing valve to prevent possibility of injury and then started again).* Connect and disconnect compressor at 5 second intervals 4 times to pump all Freon out of compressor. That is; connect for 5 seconds, disconnect for 5 seconds, etc. Shut off engine and close compressor discharge valve by turning valve all the way clockwise. All Freon has now been pumped out of the compressor and it can be removed.

DEPRESSURIZING THE SYSTEM

When any of the units on the high pressure side of the system are to be replaced, it is necessary to release all the Freon from the system. The system must be depressurized to replace the compressor discharge valve assembly, compressor-to-condenser pipe, condenser, condenser-to-receiver pipe, and receiver. Proceed as follows: Remove caps from gauge fittings on compressor suction and discharge valves. Remove caps from valve stems. Crack both valves clockwise to allow slow escape of Freon from the system. If oil is noted around gauge fitting, Freon is escaping too rapidly. When hissing ceases (indicating all Freon has escaped) close off gauge fitting by turning discharge valve stem completely counter-clockwise.

EVACUATING THE SYSTEM

When the system is opened for service, some air will enter the pipes regardless of how quickly the pipes or openings are capped. *(CAUTION—Under no circumstances should alcohol be used in the system in an attempt to remove moisture).* When system has been depressurized, the complete system should be evacuated. When only the low pressure side had been opened, and the system has been pumped down to preserve the Freon, only the low pressure side should be evacuated.

EVACUATING LOW PRESSURE SIDE ONLY: Proceed as follows:

1) With system still pumped down, connect gauge set to compressor and close gauge valves.

2) Turn compressor suction valve completely counter-clockwise, then clockwise 1/4 turn to open passage to suction pipe. *CAUTION—Do not open compressor discharge valve or Freon will enter low side.*

3) Open high pressure valve on gauge set so that air pumped out of compressor discharge valve gauge fitting can pass out the center line of the gauge set. Place a clean, dry container under end of center line to collect any oil pumped out of compressor.

4) Start engine and turn on air conditioning system. Disconnect wire from fast idle diaphragm and solenoid assembly so engine will run at normal speed. Compressor will now evacuate the system, pumping the air out through the discharge valve gauge fitting and gauge set.

5) Observe low pressure gauge and operate compressor until gauge shows 26-28" vacuum. Continue to run compressor for 5 additional minutes. *NOTE*—If vacuum cannot be pulled to 26" or more, it indicates a leak in system or gauge connections, or a defective compressor. In this case it will be necessary to add a small amount of Freon to the low side of the system and check for leaks as follows:

a. Close high pressure valve of gauge set and turn off engine.

b. Open receiver shut-off valve momentarily to allow pressure to rise in low pressure side. *(NOTE*—Only a small amount of Freon should be passed into the low side to prevent wasting Freon).

c. Using leak detector J-5419, check all fittings in the low pressure side and on the gauge set for evidence of leakage. After leak has been found and corrected, evacuate the system again.

6) Close high pressure valve of gauge set and stop engine. Carefully check low pressure gauge to see that vacuum remains constant. If vacuum reduces, it indicates a leak in the system or gauge connections.

7) Check container placed under center line of gauge set to see that compressor has not pumped out an appreciable amount of oil. If more than one ounce of oil has been pumped out it should be poured back into the compressor following instructions for adding oil following.

8) If vacuum pulled down satisfactorily and held steady, (Steps 5 & 6 above), purge air from compressor head as follows: Open shut-off valve on receiver to allow Freon to enter low side. Open high pressure valve of gauge set for approximately 15 seconds to allow Freon to force air out of compressor discharge valve through gauge set. When air has been purged, close high pressure valve of gauge set.

9) Turn compressor discharge valve stem counter-clockwise to outlet to discharge pipe. Leave valve 1/4 turn clockwise for operational test.

CONTINUED ON NEXT PAGE

1954-EARLY 1955 PONTIAC (Continued)

10) Start engine, turn on air conditioning system and allow it to operate for ten minutes. While system is warming up, check for leaks with leak detector.
11) Check compressor sight glass to see that oil splashing is visible. If not, add oil.
12) After system has operated for ten minutes make operational test.

EVACUATING COMPLETE SYSTEM: Proceed as follows:
1) Connect gauge set to compressor the same as for pumping down system. Make sure shut-off valve on receiver is completely open (turned completely counter-clockwise).
2) Turn compressor suction valve 1-1/2 turns clockwise from full counter-clockwise position.
3) Turn compressor discharge valve all the way clockwise to seal passage to discharge pipe.
4) Open high pressure valve on gauge set so that air pumped out of compressor discharge valve gauge fitting can pass out center line of gauge set. Place a clean, dry container under end of center line to collect any oil pumped out of compressor.
5) Start engine and turn on air conditioning system. Disconnect wire from fast idle diaphragm and solenoid assembly so engine will run at normal idle speed. Compressor will now evacuate the system, pumping the air out through the discharge valve gauge fitting and gauge set.
6) Observe low pressure gauge and operate compressor until gauge shows 26-28" vacuum. Continue to run compressor for five additional minutes. *NOTE*–If vacuum cannot be pulled to 26" or more, it indicates a leak in the system or gauge connections, or a defective compressor. In this case it will be necessary to add a small amount of Freon to the low side of the system and check for leaks as follows:
a. Close high pressure valve of gauge set and turn off engine.
b. Connect flexible line from center of gauge set to Freon drum (drum should be at room temperature). See Step 2 under "Charging System" following for connecting Freon drum.
c. Open shut-off valve on drum and "crack" flexible line at center fitting on gauge set so that Freon will purge air from line. Retighten fitting when certain all air is purged from line.
d. Open both valves on gauge set. This will allow Freon to pass from the drum into the system. When pressure stops rising close both valves on gauge set (Since Freon drum is not heated, only a small charge will enter the system).
e. Using leak detector, check all fittings in the system for evidence of leakage. Also check compressor shaft seal. After leak has been corrected, evacuate the system again and charge as outlined under "Charging The System".
7) Close high pressure valve of gauge set and stop engine. Carefully check low pressure gauge to see that vacuum remains constant. If vacuum reduces, it indicates a leak in the system or gauge connections.
8) If vacuum pulled down satisfactorily above close valves tightly and turn off engine.
9) Check container placed under center line of gauge set to see that compressor has not pumped out an appreciable amount of oil. If more than one ounce of oil has been pumped out it should be poured back into compressor following instructions for adding oil following.
10) If vacuum remains constant after gauge valves are closed, purge air from compressor head as follows: With compressor discharge valve still turned completely clockwise, connect flexible line from center fitting of gauge set to Freon drum. Open valve on Freon drum and "crack" line at center fitting of gauge set to purge air from line. After air has been purged, tighten fitting. Open low pressure valve of gauge set to allow Freon to enter low side of system. When Freon stops entering system (only a small amount will enter since drum is not heated), close valve on Freon drum and low pressure valve of gauge set. Remove flexible line from Freon drum. Open high pressure valve of gauge set for approximately 15 seconds to purge air from compressor head (*NOTE*–Freon which has entered system will force air out of compressor head through compressor discharge valve gauge fitting and gauge set). When air has been purged, close high pressure valve on gauge set.
11) Turn compressor discharge valve stem completely counter-clockwise then clockwise 1 1/2 turns. System is now ready for charging. *NOTE*–System can be checked for leaks at this time by adding a small amount of Freon. This, however, will not eliminate the necessity of checking for leaks after system has been fully charged, since the low pressures obtained by adding a small amount of Freon at room temperature would show up only the relatively large leaks.

CHARGING THE SYSTEM

The system should be charged only after being evacuated as outlined above. To charge system proceed as follows:
1) See that both compressor valves are turned 1 1/2 turns clockwise and that both valves on the gauge set are closed.
2) Connect center flexible line of gauge set to Freon drum. It may be necessary to use reducer J-5462-4 with sealing washer J-5462-3 and fitting J-5462-9 to attach flexible line to Freon drum.
3) Place Freon in a pail of water which has been heated to 125° F. It may not be necessary to use hot water if a large drum is used (over approximately 100 lbs.) *Do not allow temperature to exceed 125° F. since high temperature will cause excessive pressure and possible softening of the fusible safety plugs in the Freon drum.*
4) Place Freon drum (in pail of water) on scales (bathroom or commercial scales) and weigh accurately.
5) Loosen line at center fitting on gauge set and "crack" valve on Freon drum to evacuate air from line. Retighten line at center fitting.
6) Open valve on Freon drum and both valves on gauge set to allow Freon to flow into system. Continue charging until scales show that 5 lbs. of Freon have been transferred from Freon drum to system. (*NOTE*–If full charge cannot be attained, close both valves on gauge set, start engine, and turn on air conditioning system to run compressor. Open low pressure valve on gauge set until full charge (5 lbs.) is taken in). *CAUTION–Observe high pressure gauge whil charging with compressor running, and do not let pressure exceed 300 psi.*
7) Close both valves on gauge set (high pressure valve will already be closed if charge was completed by running compressor) and close valve on Freon drum.
8) Operate engine at approximately 750 RPM with air conditioning control lever at "COLD" and blower on high speed. After at least 5 minutes of operation, observe appearance of Freon in liquid indicator. If bubbles are observed, open low pressure gauge valve and valve on Freon drum to allow more Freon to enter system. Close valves when liquid indicator clears up.(*NOTE*–If room temperature is below 75° F. when this check is made, bubbles may appear even though the proper amount of Freon is in system). Room temperature must be 75° F. or above to make an accurate check. It should also be observed that if suction pressure drops to 15 psi., the by-pass valve will open, allowing system to by-pass. (*NOTE*–When system is by-passing, outlet pipe leaving by-pass valve will be cold.) This may cause bubbles to appear in liquid indicator, but does not indicate an under-charge. If in doubt, remove cap from adjusting screw on by-pass valve and turn screw counter-clockwise until free, counting the number of turns. (Do not remove screw completely.) If bubbles still appear, add Freon until liquid indicator clears up, then turn adjusting screw clockwise, back to its original position. (See Operational Test preceding for proper adjustment of by-pass valve.) In no case should system be charged with more than 5 1/2 lbs. of Freon.
9) When Freon has been installed, continue to operate system and test for proper operation as outlined under "Operational Test" preceding.
10) When satisfied that air conditioning system is operating properly, stop engine, turn suction and discharge valve counter-clockwise securely to close gauge fittings, and remove gauge set. *NOTE*–A considerable amount of Freon will collect in the high pressure gauge line. Since some of this Freon will have condensed into liquid Freon, it will require an appreciable amount of time to allow pressure to bleed off. Open high pressure gauge valve slowly and let Freon out through center gauge line so that oil which has collected in lines can be directed onto floor.
11) Using leak detector, check complete system for leaks.

ADDING PARTIAL CHARGE OF REFRIGERANT

The following procedure should be used in adding small amounts of Freon that may have been lost due to leaks or while opening system for service. Before adding Freon to replace that lost by leaks, check compressor oil level and add oil if necessary (See Checking Compressor Oil Level & Adding Oil following). To add Freon proceed as follows:

CONTINUED ON NEXT PAGE

1954-EARLY 1955 PONTIAC (Con.inued)

1) Remove caps from compressor suction and discharge valve gauge fittings and valve stems. Attach gauge set to gauge fittings.
2) Attach flexible hose from center fitting of gauge set to Freon drum. With both valves on gauge set closed, open valve on Freon drum. "Crack" flexible line at center fitting of gauge set to allow Freon to expel air from line. Tighten fitting when satisfied that all air has been removed.
3) Start engine, move air conditioning control lever to "COLD" and turn blower on high speed. Operate for ten minutes to stabilize system.
4) Operate compressor suction valve gauge fitting by turning valve stem 1-1/2 turns clockwise. Turn compressor discharge valve 1/4 turn clockwise so high pressure gauge can be observed.
5) Place Freon drum on scales, note weight, and open low pressure valve only on gauge set.
6) With compressor operating, allow Freon to pump into system until liquid indicator clears up and immediately shut off valve on Freon drum. Check weight of Freon drum and pail of water. Then open valve on Freon drum and add 1/2 lb. of Freon if room temperature is below 85° F., or 1 lb. of Freon in temperature is above 85° F. Note total amount of Freon added.
7) Test for leaks and make operational check of system as outlined under "Operational Test" preceding.

CHECKING & ADDING OIL

The refrigeration system contains a total of 10 ozs. of oil. Originally all oil is in compressor, but after the system is once operated, a certain amount of the oil will circulate through the system with the Freon. For this reason it is impossible to merely drain the oil from the compressor and then add 10 ozs. of oil. The procedure outlined below must be used in order to assure the proper amount of oil in the compressor. It is never necessary to drain and refill the compressor since the system is sealed and therefore the oil cannot be contaminated. When adding oil use one of following refrigeration oils: Suniso 4G, Capella D, Ansul Chemical Co. #300, Frigidaire #300 or #300 LT. Refrigeration oil has an affinity for moisture and should be kept tightly capped when not in use to prevent absorption of moisture. No periodic check of oil level is necessary. As long as splashing of oil is visible in the sight glass, at each 2000 mile lubrication, no oil level check is necessary. Oil level should be checked at time Freon is added to system to replace that lost by leakage. This is necessary because some of the oil circulates through the system with the Freon and therefore, will be lost if a Freon leak develops. Always check oil level and add oil, if necessary, before adding Freon. To check oil level and add oil proceed as follows:

1) Operate engine and air conditioning system for ten minutes. This will remove Freon which mixes with oil in compressor crankcase when car is standing. If Freon is not pumped out of crankcase, it will boil out violently when oil filler plug is removed, causing excessive loss of oil.
2) Pump down compressor. See "Pumping Down Compressor To Remove Compressor or Add Oil " preceding.
3) Slowly remove oil filler plug from compressor. Any Freon left in compressor will escape when plug is being removed.
4) Insert a clean, black iron wire vertically in filler hole, until it bottoms in crankcase (Insert wire between compressor and suction pipe). Compressor shaft may be revolved to allow wire to clear oil slinger on shaft. Remove wire and measure height of oil from bottom of wire. Oil level should be 7/8" or more from bottom of compressor crankcase. If low, add recommended refrigeration oil to bring level to 7/8" from bottom of crankcase.
5) Install filler plug. While tightening filler plug, "crack" suction valve slightly to allow Freon to enter compressor. Freon, being heavier than air, will go to bottom of crankcase, expelling air through loose filler plug.
6) Turn compressor suction and discharge valve stems all the way counter-clockwise to open suction and discharge pipes and seal gauge fittings.
7) Replace valve stem caps. System is now ready for operation.

REMOVAL & INSTALLATION

►*NOTE: For 1955 Compressor Data, see "1954-55 Frigidaire (G.M.)" Air Conditioning.*

COMPRESSOR CLUTCH & PULLEY ASSEMBLY: Remove cap screw and lockwasher retaining clutch plate and hub assembly to compressor shaft. Slide clutch plate and hub assembly off shaft to remove. Remove retainer washer from hub of clutch plate (*NOTE*–if only clutch plate and hub assembly are to be replaced (which can be done only on dated assemblies), install new assembly as covered below). Loosen idler pulley or power steering pump retaining bolts to remove belt tension. Remove pulley, coil, and bearing assembly from compressor shaft. Remove clutch assembly spacer ring from compressor shaft, if it is to be replaced, and install new spacer ring. Install pulley, coil, and bearing assembly on compressor shaft, positioning belt on pulley as it is installed. Position retainer washer in hub of clutch plate, making sure it seats squarely against clutch hub (Be sure burred edge is against hub). Slide clutch plate and hub assembly onto compressor shaft. Make sure that retainer washer is still squarely in place against hub. Install plate and hub assembly to shaft retainer bolt with lockwasher and tighten securely. Rotate plate and hub assembly by hand to observe spacing between clutch plate and pulley. Clearance should be .015-.040". Adjust belt tension to 60 ft. lbs. torque.

COMPRESSOR BRUSHES: The positive (large) brush is available separately, but the ground brush is not since it is part of the brush and bracket assembly. Brushes should be replaced as follows: Remove compressor clutch plate and hub assembly as outlined above. Slide pulley, coil, and bearing assembly forward on shaft to provide access to brushes. Check to see if clutch plate and pulley are new type or old type. New type pulley and clutch plate must be installed when brushes are replaced. (See Changes, Cautions, Corrections). If brushes are dirty, but not worn excessively, clean brushes and contact surfaces on pulley with carbon tetrachloride or other suitable solvent. If brushes are worn, remove brush and bracket assembly, and install new assembly. NOTE–If only the positive (large) brush is worn, it can be removed from the bracket and replaced by unscrewing the plastic cap from the back of the bracket. Assemble brush and bracket assembly to compressor. Install pulley, coil, and bearing assembly and clutch plate and hub assembly as outlined under "Compressor Clutch & Pulley Assembly" above.

COMPRESSOR (TO PERFORM OTHER SERVICE): (*NOTE*–Do not use this procedure if new compressor is to be installed. See Installation of New Compressor following.) In order to remove engine cylinder head for various services, the compressor must be removed. To remove compressor and mounting bracket assembly, proceed as follows: (*CAUTION–Be sure all refrigeration fittings and connections are thoroughly cleaned before beginning to remove compressor.*) Pump down compressor to prevent loss of Freon or compressor oil. Loosen idler pulley attaching nuts and remove compressor belt. On cars equipped with power steering, remove power steering pump from bracket and lay on battery cover and fender skirt. Drain radiator core and remove upper radiator hose. Remove suction and discharge valves from compressor by removing two allen screws from each valve. Do not loosen pipe fittings on valves. Cover compressor and valve openings with masking tape. (*CAUTION–Loosen screws slowly in case there is pressure in crankcase. If pressure exists, allow pressure to bleed off slowly. Do not loosen screen from inlet beneath suction valve.*) Remove bolt from brace at bottom of compressor and bolt from brace at idler pulley end. Remove nuts holding compressor mounting bracket to cylinder head. Disconnect compressor clutch wire at connector on fender skirt. Remove compressor and bracket as an assembly. To install, reverse removal procedure using new gaskets on compressor suction and discharge valves (Make sure screen is in place in suction opening. CAUTION–Extreme care must be used to tighten valve attaching screws evenly to prevent distortion and resultant leakage between valve and seat.) Purge air from compressor as follows: After suction and discharge valves have been attached, open suction valve by turning all the way counter-clockwise. Loosen gauge fitting cap on discharge valve to allow air to escape. Air will pass out at this point since it is lighter than Freon. After air is purged approximately ten seconds, tighten gauge fitting cap. Open discharge valve by turning all the way counter-clockwise. Compressor is now ready for use.

INSTALLING NEW COMPRESSOR: New compressors are serviced with 10 ozs. of oil and charged with dry air. If all this oil is left in the compressor when it is installed, there will be an excessive amount of oil in the system. That is due to the fact that some of the oil from the original compressor has circulated in the system with the Freon. Even if system is de-

CONTINUED ON NEXT PAGE

1954-EARLY 1955 PONTIAC (Continued)

pressurized, oil will remain in system. Too much oil can cause damage to the compressor. To insure the proper amount of oil in the system use following procedure when replacing a compressor:

1) Pump down compressor unless low pressure side has been pumped down or system has been depressurized. (NOTE–If compressor is inoperative, it will be impossible to pump it down. In this case close passages to suction and discharge pipes by turning both compressor valves completely clockwise. Then bleed Freon from compressor by "cracking" gauge fitting caps on suction and discharge valves. Bleed pressure slow enough so that no compressor oil is lost).

2) Remove compressor with mounting bracket as outlined in "Compressor (To Perform Other Service)" above. This leaves suction and discharge valves attached to suction and discharge pipes.

3) Remove compressor from mounting bracket.

4) Remove oil filler plug and check oil level in compressor crankcase.

5) Remove drain plug from new compressor and empty enough oil from new compressor to provide same oil level as old compressor had (Oil should be poured into clean, dry container so it will be uncontaminated if some has to be poured back into the compressor). *NOTE*–If old compressor was known to have insufficient oil due to a Freon leak, pour sufficient oil into new compressor to bring level to 7/8" from bottom of compressor (See Checking Compressor Oil Level & Adding Oil). If old compressor was dry, and there was no evidence of leakage, proceed as follows:

a) Remove evaporator, dehydrator, receiver and compressor suction pipes.

b) Drain oil from each of above units. This will remove all oil from the system since these are the only units which can collect the oil which has been lost from the compressor.

c) Re-install evaporator, dehydrator, receiver and compressor suction pipes.

d) Since oil has been completely drained from the system by the above steps, leave all the oil in the new compressor when it is installed.

6) Position new compressor on mounting bracket, install mounting bolts with lockwashers and tighten securely.

7) Remove suction and discharge valves from new compressor and immediately cover openings in compressor with masking tape. Attach new valves to old compressor so that no oil will be lost and no moisture will enter compressor while it is being returned to factory.

8) Install compressor and mounting bracket and purge air from system as outlined under "Compressor (To Perform Other Service)" above. *NOTE*–If system has been pumped down or depressurized for other work in combination with compressor replacement, it will not be necessary to purge air from compressor. This air will be evacuated, in this case, when the system is evacuated.

9) After system has been operating for ten minutes, check compressor sight glass to see that oil splash is visible. If not, add oil as outlined previously.

CONDENSER: Depressurize system. Remove screws from radiator baffle, baffle support brace, and hood pilot bracket so that baffle can be moved out of way. To re-install, reverse removal procedure. *NOTE*–It is not necessary to remove radiator.

RECEIVER: Depressurize system. Remove receiver, pour any oil it contains into a clean, graduated beaker or similar measuring device. Measure out an equal quantity of new compressor oil and pour into receiver which is to be installed.

DEHYDRATOR-FILTER: If dehydrator-filter is warm on the entering end and cool at the outlet end, it indicates that it has become partially plugged and needs replacing. If the system is open for more than 15-20 minutes, as in the case of collision, the dehydrator-filter must be replaced when unit is repaired. Pump down system before replacing dehydrator-filter.

THERMOSTATIC EXPANSION VALVE: Pump down system. Carefully remove moulded fibreglass insulation from the thermostatic expansion valve and foam rubber insulation from capillary tube bulb on evaporator outlet pipe by using a knife to cut at cemented joint (to permit re-use). When installing insulation on new thermostatic expansion valve make sure valve is completely covered. Cement the seams and then tape them securely with water proof tape. Wrap capillary tube bulb and evaporator outlet pipe connection with foam rubber insulation and cement the seams. Wrap the insulation completely with water proof tape. *CAUTION–Be sure that capillary tube bulb is held securely and snugly to evaporator outlet pipe so that there is good thermal conductivity between the two parts.*

EVAPORATOR ASSEMBLY: When evaporator is to be replaced, remove the evaporator and thermostatic valve as an assembly. (The system should be pumped down before removing the evaporator and thermostatic expansion valve assembly.) After the evaporator is removed, transfer the thermostatic expansion valve to the new evaporator (See "Thermostatic Expansion Valve" above). To remove the evaporator, it is necessary to remove the evaporator inlet assembly from the front of the fender baffle, and disconnect the baffle so it can be moved forward. Extreme care should be exercised when replacing and removing the evaporator assembly to prevent damage to the thermostatic expansion valve or capillary tube. When evaporator is removed, drain any oil it contains into clean, graduated beaker. Measure out an equal amount of new compressor oil and pour into compressor through filler hole (See "Checking Compressor Oil Level & Adding Oil" for recommended oils). After new evaporator has been installed, seal outside of evaporator outlet pipe to evaporator pressure regulator fitting with "Press Tight Perma Gum" or similar non-hardening mastic. Perma Gum should be packed around connection to provide a water tight seal. If any water is allowed to contact both aluminum evaporator outlet pipe and brass flare nut, rapid corrosion will result.

COLLISI N SERVICE

Severity and circumstances of the collision will determine extent of repair work required. Good judgment must be used in deciding what steps are required to put system back in operation. Each part of system must be carefully inspected. No attempt should be made to straighten kinked pipes or repair any bent or broken units. Check especially for cracks at soldered connections. Broken pipes or units will allow air, moisture, and dirt to enter. These parts should be sealed as soon as possible until such time as they are replaced. If system is open for more than 15 or 20 minutes, the dehydrator-filter will absorb an excessive amount of moisture and should be replaced.

Inspecting Compressor: If there is no visible evidence of damage, rotate compressor shaft by hand to test for normal reaction. If shaft appears to rotate normally, remove drain plug and pour oil out into clean container. Inspect oil for foreign material which would indicate internal damage to compressor. If no foreign matter is found in oil, compressor can be used. Add the same amount of new compressor oil as was removed. See "Checking Compressor Oil Level & Adding Oil" for recommended oils.

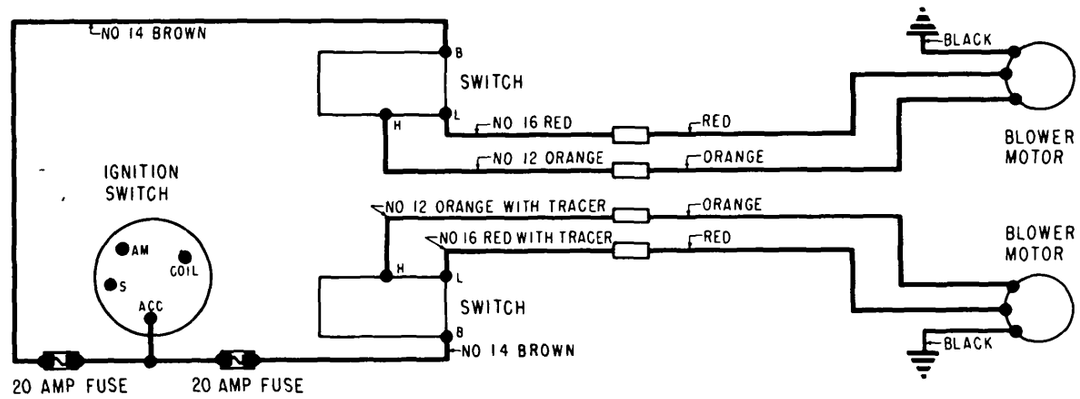
S9973-1	3/8"	Neoprene	1539719
Others		Metal	1539717



DESCRIPTION

Similar in design and operation to other systems using Freon-12 as a refrigerant. Air from inside car is led through two openings in the rear package shelf to refrigeration unit on ledge of trunk compartment. In the refrigeration unit air passes over the evaporator where it gives up much of its heat to the Freon-12 gas which is flowing through the evaporator coils. Humidity from the air condenses on the evaporator coils and drains away. The cooled, dried and filtered air is then forced by either or both blowers back into the car through two cold air outlets mounted on the package shelf.

C ntr ls: Control panel is mounted beneath and at center of the instrument panel. There are three controls on the panel. The center control, through a modulator valve, regulates the cooling action the system is to furnish; the farther out it is pulled, the cooler will be the air delivered from the outlets. The other two controls operate the blower motors. The push-pull switches have three positions: "In" is off, first position out is slow blower speed, second position out is high blower speed. Fresh outside air can be admitted by opening one of front window vents or right fender vent (Climatizer cars) with inside vent closed.

STUDEBAKER AIR CONDITIONING SYSTEM

STUDEBAKER AIR CONDITIONING CONTROL DIAGRAM

OPERATION

With engine and compressor operating, heat laden, low pressure Freon is compressed by the compressor and discharged into the condenser where it is cooled to remove the "sensible" heat of compression. The Freon is forced into the receiver under pressure when the modulator valve is closed. After passing through dehydrator and sight glass Freon enters expansion valve in evaporator assembly. At orifice in expansion valve high pressure liquid Freon changes to low pressure liquid, then enters evaporator coils. The "boiling" Freon, while in the evaporator coils, absorbs heat from the surrounding air and vaporizes. The vapor is drawn through the low pressure line to compressor where cycle is repeated.

PRECAUTIONS, TROUBLE SHOOTING & LEAK TESTING

See "Air Conditioning Service Cautions", "Trouble Shooting" and "Leak Tests".

CHECKING & ADJUSTMENT

MAINTENANCE & INSPECTION: Seasonal Operati n— Manufacturer recommends that compressor belt not be removed to assure that compressor seals do not dry out. To make system inoperative during winter months, make sure that center control on dash panel is all the way in (controls modulator valve).

Air Filter: Clean at regular intervals. To remove filter,

CONTINUED ON NEXT PAGE

1955 STUDEBAKER (Cont.)

first remove wing nuts and washers from studs near top of blower housing (in trunk compartment). Remove back panel and slide filter out of blower housing. Wash filter in cold, soapy water and rinse in clear water. When reinstalling filter, be sure it is properly positioned under spring clips before sliding it into place.

COMPRESSOR DRIVE BELT ADJUSTMENT: To adjust, use an open-end wrench on hexagonal part of left idler pulley shaft (right idler pulley is not adjustable) between pulley and pulley bracket. Loosen shaft slightly, and move pulley to loosen or tighten belt. Drive belt should have a 1/2" deflection midway between compressor and adjustable idler pulley when a force of 25 lbs. is exerted at that point with a spring scale, pulling outward.

CHECKING: Bubbles in Sight Glass–*(NOTE*–Before checking sight glass, in event blowers are operating properly and system is providing only partial cooling, check temperature control cable adjustment to make sure it provides full movement of lever on modulator valve on compressor). To check for possible refrigerant shortage, turn blower motors off and push temperature control all the way in. Run engine at fast idle for about 5 minutes at 1000 RPM. Pull temperature control all the way out, turn both blowers on high speed. Continue to run engine at fast idle. Check sight glass. If empty, or if bubbles are passing through it, system may be low on refrigerant. System should be checked for leaks and recharged.

Compressor Oil Level: There should be just enough oil in crankcase of compressor so that splash is visible in compressor sight glass whenever compressor is running. *CAUTION–If compressor filler plug is removed, entire system will have to be purged and recharged.*

REMOVAL & INSTALLATION TO WORK IN ENGINE COMPARTMENT

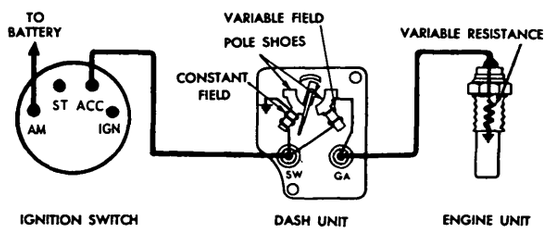
COMPRESSOR & BRACKET REMOVAL & INSTALLATION (To Work on Engine): *(CAUTION–Do not disconnect refrigerant hoses).* Drain radiator, loosen idler pulley (left) and remove compressor drive belt. Remove hand control cable at modulator valve. Remove two capscrews which hold compressor bracket to water pump manifold. The lower screw, which is longer, also retains idler pulley bracket. When screw is removed, do not remove spacer which is between brackets. Take out two Allen-head screws which hold compressor mounting bracket to water outlet fitting, and remove capscrew at base of oil filler pipe. Remove compressor and bracket with hoses still attached, and place assembly on front of right front fender. Keep unit as nearly as possible as when mounted, so that oil in compressor crankcase will not run up past compressor piston. When installing compressor, and before putting on belt, turn drive pulley several times by hand to pump out any excess oil that may have collected at top of piston. After system is in operation, check sight glass for bubbles. *NOTE*–If an excessive amount of bubbles appear in sight glass, system probably does not have sufficient Freon-12. *Do not operate system until proper amount of Freon has been added.*

AUTO-LITE ELECTRIC TEMPERATURE GAUGE

DESCRIPTION & OPERATION: This is a Gauge of the electric (or magnetic) type consisting of a Dash Unit which registers the temperature of the coolant in the engine and an Engine Unit which is installed in the coolant, and transmits coolant temperatures to the Dash Unit

Dash Unit–This unit has two magnetic poles. One winding is connected to "IGN" switch and to ground This winding holds a steady pull on gauge pointer to the left or "Cold" position The second winding connects to ground through the Engine Unit, and exerts a magnetic pull to the right or "Hot" side of Gauge. The strength of this magnet is determined by the amount of current allowed to pass through the Engine Unit resistor.

Engine Unit–This unit is equipped with flat disc that changes resistance as its temperature changes. The resistance is greatest when it is cold and resistance reduces as temperature rises. The reduction in resistance permits more current to flow to ground through the second winding of the Dash Unit, increasing the pull on the Gauge pointer toward the "Hot" position



►*CAUTION: When gauge hand fails to move at all, Dash Unit is damaged or has been installed incorrectly. Reinstall correctly or replace as necessary.*

TROUBLE SHOOTING: Consists of testing circuits by elimination process. **Follow tests in sequence given and replace any unit found defective.** Turn *"IGN" on* and off for each test.

1) Remove wire at Engine Unit, gauge pointer should stay at left side (Cold) stop pin.

2) Remove ground wire from Engine Unit. Gauge pointer should move to right (Hot) stop pin.

3) In test (1) if gauge hand does NOT stay at left stop pin, wire is grounded between Dash Unit and Engine Unit, or Dash Unit is defective. Remove wire from "GA" terminal. Wire is defective if pointer now stays *at left stop pin, otherwise replace Dash Unit.*

AUTO-LITE ELECTRIC TEMPERATURE GAUGE

4) In test (2) should pointer not move to "Hot" position, there is an open circuit in wire between Dash Unit & Engine Unit, the Dash Unit is defective, or no power is reaching Dash Unit Ground "GA" terminal, if pointer now moves, replace wire. If it does not move, connect test lamp (6 or 12 volt as applicable) between Dash Unit "IGN" terminal and ground. Replace Dash Unit if lamp lights. Test the wire between "IGN" switch and Dash Unit by connecting test lamp to "Accessory" terminal at "IGN" switch and to ground Test lamp should light.

5) If gauge pointer operates correctly in test (1) & (2) but does not indicate temperature changes correctly, Engine Unit is defective or Dash Unit not calibrated correctly. Use Engine Unit known to be OK If Dash Unit still fails to indicate correctly, replace Dash Unit.

6) If the gauge pointer stays at right stop pin (maximum) at all times in test (1) & (2), wiring & Dash Unit are OK. Replace Engine Unit.

AC ELECTRIC TEMPERATURE GAUGE

SPECIAL SERVICE NOTE: 1939-40 Pontiac. When a sealed type pressure cooling cap installed on these cars, a thermogauge adapter (#1510965 resistor unit) is installed on 'ENG' terminal of dash unit. This unit lowers reading on temperature gauge 16° at 212° to compensate for increased boiling point caused by pressure cap. Temperature gauge will then indicate boiling point correctly. This adapter installed at factory on cars equipped with pressure type cap. On cars where pressure cap is installed in the field, this adapter is packaged with the replacement cap, and should be installed on thermogauge dash unit to avoid incorrect gauge reading (if this adapter not installed and a pressure cap is used, gauge will read 212° although cooling water will not be at boiling point).

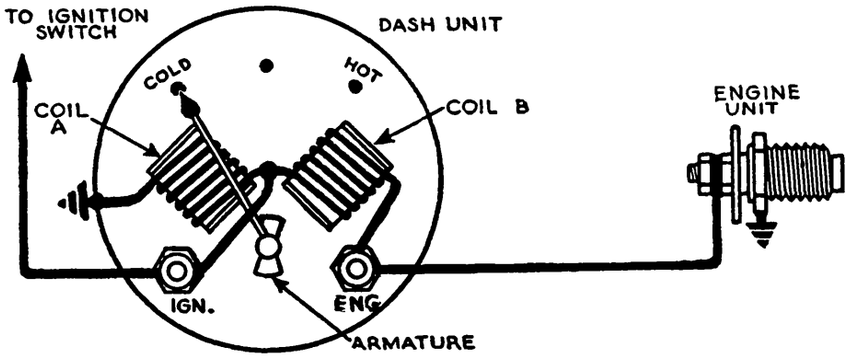
DESCRIPTION: This is an electric gauge of the 'balanced coil' type and consists of a Dash Unit or recording gauge and an Engine Unit or temperature reacting unit mounted in the cylinder head or engine block in contact with the cooling water in the engine. Dash unit is connected to the 'Gauge' side of the ignition switch (controlled by switch and operative only with switch on) and to the engine unit and each unit is grounded (see wiring diagram). Dash unit consists of two coils at a 90° angle with an armature (on which the pointer is mounted) at the intersection of the coil axis. One coil is connected directly between the 'IGN' (feed) terminal and ground on the gauge case, the other coil being connected between the two gauge terminals (in series with the engine unit). Engine unit consists of a fixed resistance unit which has a high resistance value Cold and a relatively low resistance value Hot (gauge operated by this change in resistance due to temperature changes in the engine—gauge engine unit has no moving parts).

Pressure Cooling Note—Gauges used on cars with pressure cooling (pressure valve in radiator filler cap) are calibrated so that dash unit reads 212° (boiling point) when the cooling system water is actually at the temperature at which water boils with the pressure at which the system is designed to operate (boiling point increase with increase in pressure) which will be somewhat higher than 212°. This is done so that the dash unit will not indicate 'boiling' before the cooling water actually reaches the boiling point and must be kept in mind if the gauge is tested by immersing the engine unit in a heated pan of water.

OPERATION: When the ignition switch is turned on with the engine cold, current flows directly through coil 'A' to ground. The high resistance of the engine unit causes a relatively smaller current to flow through coil 'B' (which is connected in series with this resistance) so that the pointer is deflected toward the 'Low' or coil 'A' side of the scale. As the engine warms up, the resistance of the engine unit decreases, allowing an increasingly greater current flow through coil 'B' so that the pointer is drawn over toward the 'High' end of the scale. The balanced action of the two coils compensates for battery voltage variations and in addition an inertia dampener is built in the armature assembly to prevent pointer vibration on rough roads, etc.

SERVICING: All defective units should be replaced.

TROUBLE SHOOTING: If gauge operation not satisfactory, check as directed under correct heading in following table, being careful to turn ignition switch off when disconnecting or re-connecting leads on terminals and using extreme care not to reverse connections at dash unit terminals. Do not allow dash unit to be placed in strong electric field which will affect magnetic armature.



CONNECTION NOTE—Left hand (small diameter) terminal on dash unit should be connected to ignition switch, right hand (large diameter) terminal connected to engine unit. Terminals marked for identification.

Gauge does not register with Ignition Switch turned on:

1. Lead between Ignition Switch and Dash Unit broken or grounded (open or short-circuit). Check by connecting test lead between these two points with regular lead disconnected at both ends.

Gauge register 'Cold' under all conditions:

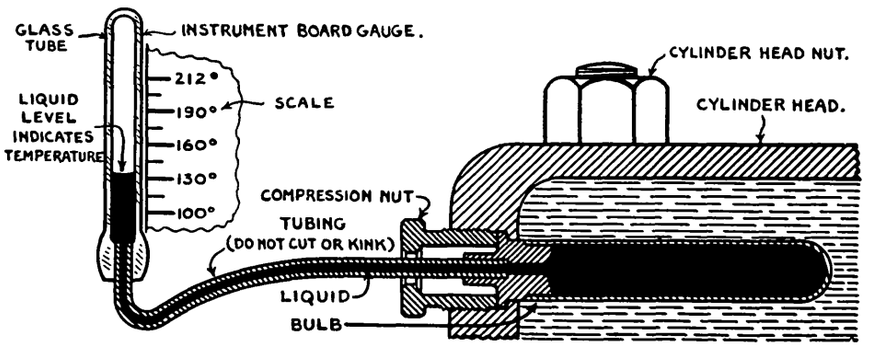
1. Lead between Dash Unit and Engine Unit broken (open-circuit). Check by connecting test lead between these two units.
2. Coil 'B' (right hand coil) in dash unit defective or lead to coil broken.

Gauge registers 'Hot' under all conditions:

1. Lead between Dash Unit and Engine Unit short-circuited. Check by disconnecting this lead at engine unit terminal and noting gauge reading. If gauge still reads high, this lead is shorted. If gauge reads low, engine unit is shorted and must be replaced.
2. Dash Unit not grounded. Clean all paint from under dash unit mounting flange, tighten mounting screws.
3. Engine Unit burned out. See check under (1) above or install replacement engine unit and note operation.
4. Coil 'A' (left hand coil) in dash unit defective or lead to coil broken.

Gauge registers Inaccurately:

To check, disconnect lead at engine unit terminal, remove engine unit, ground engine unit shell to car frame with test lead, re-connect engine unit, immerse inner end of unit in pan of water at known temperature (use reliable thermometer and heat water as required), note gauge reading.
CAUTION—When making this test, do not completely immerse engine unit in water which may allow leakage within shell or short-circuit lead on terminal.



KING-SEELEY HEAT INDICATOR

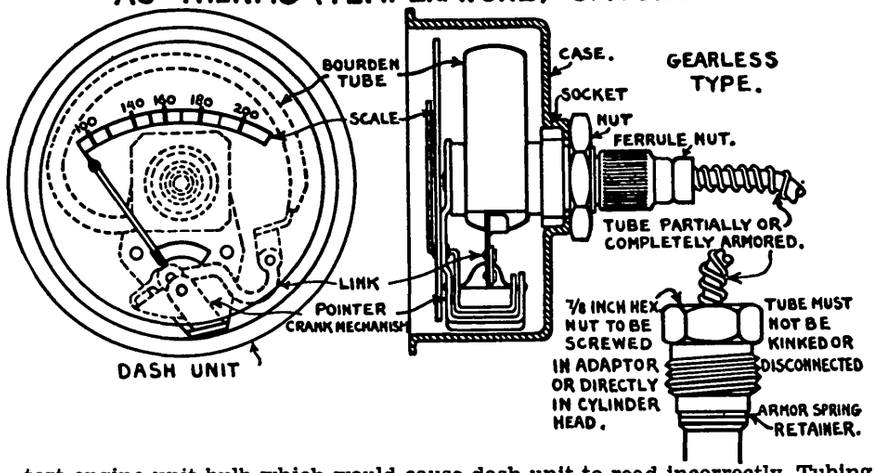
DESCRIPTION: The K-S Heat Indicator or temperature gauge is a thermometer in which the glass tube or indicator (dash unit) and the bulb (engine unit) are connected by a sealed copper tube. The entire device is assembled as a unit and the copper tubing must not be cut or the joints broken.

OPERATION: The liquid with which the bulb and tubing are filled expands evenly with temperature increases and rises into the glass tube so that a reading is obtained when the engine warms up. The location of the bulb in the cylinder head is selected to accurately indicate the cooling water temperature and should not be changed.

SERVICING: No service operations are necessary. The entire unit must be replaced if found to be defective as a result of mutilation or breakage.

Removal of Bulb from Engine—To disconnect gauge when removing cylinder head, loosen corrosion or sediment around bulb by tapping on cylinder head with a ball-pein hammer, take out compression nut, withdraw bulb. If bulb cannot be withdrawn without great effort, pry gently with a screwdriver. Bulb must not be distorted and must retain its original round shape in order to read correctly.

AC TEMPERATURE GAUGE (NOT ELECTRIC)



DESCRIPTION: A.C. Temperature Gauges are of the Bourdon tube type and consist of a dash unit in which the Bourden tube is mounted, together with the gauge pointer and connecting mechanism, and an engine unit or bulb. The units are connected by a hermetically sealed copper tube and the entire assembly is filled with a special liquid. The engine unit is mounted on the cylinder head and is immersed in the cooling water. As the temperature of the water increases the liquid in the bulb is vaporized causing a pressure to be exerted in the Bourden tube. The Bourden tube consists of a curved tube mounted rigidly at one end and connected to the gauge pointer through a crank mechanism or gear system at the other. The pressure within the Bourden tube results in a movement of the free end causing the pointer to move across gauge dial which is calibrated in degrees.

INSTALLATION: Gauges are made in three types; Gearless, in which the gauge pointer is connected to the Bourden tube through a simple crank mechanism; Gear Type,, employing a smaller Bourden tube which is connected to the pointer through a sector and pinion gear system to amplify the tube movement, and a Gear Type Heavy Duty design.

SERVICING: No service operations required and units cannot be repaired. Replace all defective gauges as an assembly (dash unit and engine unit).
CAUTION—Do not cut tubing or attempt to disconnect dash unit or engine unit. The entire assembly is a sealed unit and will not operate satisfactorily if disturbed.

REMOVAL & INSTALLATION: When removing gauge for work on engine or other parts of car, use extreme care not to kink or damage connecting tubing or to distort engine unit bulb which would cause dash unit to read incorrectly. Tubing should not be bent at sharp angles (loop tubing where change in direction required) and must not be flattened or kinked. When installing new gauge do not attempt to remove excess tubing (form tubing into fairly large loop).

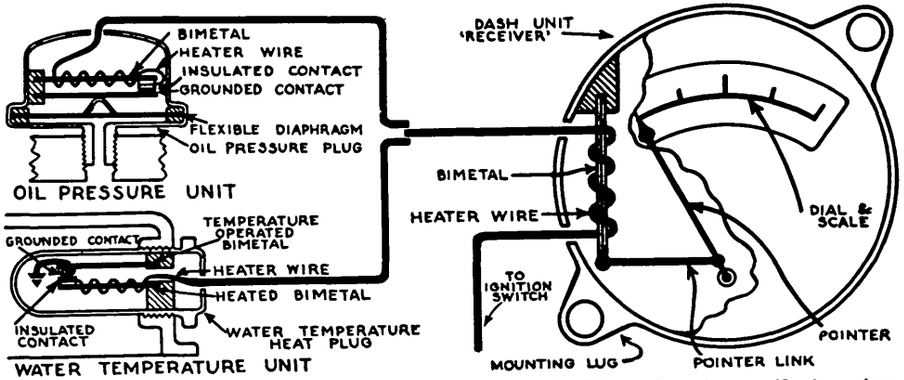
AC THERMO (TEMPERATURE) GAUGES.

KING-SEELEY OIL PRESSURE GAUGES (NOT "CV" CONSTANT VOLTAGE TYPE)

DESCRIPTION: This is an electric oil pressure gauge comprising an engine unit, and a dash or recording unit connected by a wire. The dash unit is also connected to the ignition switch (gauge operative only with engine turned on) and the gauge circuit is completed to ground through the engine unit contacts. The dash unit consists of a thermostatic bi-metal arm linked to the instrument pointer around which is wound a heating coil. The engine unit has a similar bi-metal arm and heating coil.

►**NASH RAMBLER (1950) NOTE:** Engine unit consists of a switch which operates an instrument panel warning light. When engine oil pressure reaches 13 lbs., the circuit in the engine unit opens and warning light goes out.

OPERATION: When the engine is operated and oil pressure is built up, the pressure deflects the diaphragm in the engine unit and, with the contacts closed, a current flows through the heating coils of the dash and engine unit. The heating effect of the coil in the dash unit tends to bend the bi-metal arm which is linked to the pointer and record a reading on the gauge. At the same time, the heating coil in the engine unit causes the bi-metal arm to flex to a point where the contacts open and the current is interrupted. When this occurs the bi-metal arm in the engine unit flexes in the opposite direction and again closes the contacts. Contact pressure and length of time (amount of flexing necessary to open contacts) is directly proportionate to the oil pressure in the engine, and as this determines the amount of current flowing in the gauge circuit and the deflection of the bi-metal arm in the dash unit, the dash unit indicates the oil pressure. Contacts open and close at approx. 120 cycles per min. with 25 lbs. pressure.



SERVICING: No service operations are necessary other than to see that connections are tight and that lead is properly connected to engine unit. If readings unsatisfactory, check Trouble Shooting Table and Testing (All Units).

Trouble Shooting Table

1. **Gauge pointer is erratic.** Engine unit probably defective.
2. **Gaug reading inaccurate.** Engine unit probably defective.
3. **Gauge does not register.** Engine unit defective or dash unit burnt out
4. **Gauge registers with ngine not running (ignition on).** Short-circuit in lead between dash unit and engine unit or short-circuit in dash unit (a short-circuit of this type will usually result in dash unit burning out, resulting in no reading).

TESTING (ALL UNITS):—Use a gasoline gauge tank unit which is known to be OK. for test purposes. Connect flexible test lead to terminal on this test unit and second lead to test unit mounting flange (for ground circuit). Make tests in order as given below before removing units from car.

Testing Dash Unit Receiver. Disconnect engine unit Sender, connect test unit terminal lead to this wire, ground test unit to engine block. Turn on ignition switch. With float of test unit at bottom (tank empty) position, dash unit receiver pointer should be even with lowest mark on dial. Move test unit float rod up to top position. Dash unit receiver pointer should move to top mark on dial (allow one minute for pointer to come to rest). If dash unit receiver does not operate satisfactorily, see that connections at receiver and ignition switch are tight, check line to ignition switch and line to engine unit, then replace receiver. NOTE—When testing temperature gauges, readings will be reversed (Hot reading with test unit float at bottom, Cold reading with float at top).

Testing Engine Unit Sender. If receiver tests OK. (above), see that motor unit is well grounded, disconnect and check radio condenser (shorted condenser will cause high reading on dash unit). Then replace engine unit sender.

KING-SEELEY ELECTRIC TEMPERATURE GAUGES (NOT "CV" CONSTANT VOLTAGE TYPE)

IMPORTANT PRODUCTION CHANGES: Engine Unit—Two different types of engine units have been used—**No. 7000—1939 & Later, Nos. 5700 & 6540—1938** and before. These units operate differently and must be used with the particular type of Dash Unit designed to be used with them. Earlier type engine units are not furnished for service and when it is necessary to replace them the new type (No. 7000) Engine unit must be installed. This requires installation of a ½"-⅜" No. 7113 adapter bushing. CAUTION—New type Dash Unit must be installed whenever the engine unit is changed to the new type. Service Kits are furnished which include a new type Dash Unit, replacement type Engine Unit, and Adapter Bushing.

IMPORTANT NOTE: 1939 & Later Models. Gauge will read "HOT" or 212° with the ignition switch turned off (engine not running). This reading does not mean that gauge is defective and is caused by the linkage design which is designed to conserve current (less current consumed when engine is at normal running temperatures). Gauge readings should only be taken with the ignition switch turned on.

Ford V8 & Mercury 1941 Models. A temperature switch King-Seeley No. 8355, Ford No. 01A-10990, is used in the temperature gauge circuit (between the dash unit and the engine unit) so that temperature can be measured in both engine blocks. The regular engine unit or heat plug King-Seeley No. 7000, Ford No. 99A-10884, is used in conjunction with this temperature switch.

Willys 48 1939. Temperature gauge on this model consists of a tell-tale light on the instrument panel which is controlled by a thermostatic type engine unit similar in appearance to those used on other King-Seeley gauges. This engine unit must never be used with regular thermostatic type dash units (as used on Willys Overland Model 39) as it will result in the dash unit burning out. NOTE—These engine units may be identified by groove around hexagonal head of the engine unit plug. Regular type engine unit for Willys-Overland Model 39 is not marked by these grooves.

DESCRIPTION: Dash unit or receiver same design as for Oil Pressure Gauge. Two types of Engine Units have been used. Both types consist of a heat bulb which is designed to be screwed in the engine block so that cooling water temperature actuates the bi-metal arms within the bulb. A heating coil (connected to dash unit) is wound on the bi-metal arm and connected to the insulated contact at the free end of the arm. The ground contact is mounted on the free end of a second bi-metal arm (Types 5700 & 6540), or on a stationary support (Type 7000). Contacts are normally closed (with arms not flexed) and gauge circuit is completed through heating coil and contacts to ground when the ignition is turned on.

OPERATION:—**Types 5700 & 6540.** When heating coil in engine unit is energized, the temperature rise tends to flex the arm and open the contacts. This interrupts current flow, allows bi-metal arm to cool off and flex back so that contacts are again closed. This action is extremely rapid and arm has a vibrating motion. Second bi-metal arm is longer and thinner than heater arm so that flexing action, as engine temperature increases, is greater and tends to increase contact pressure and length of time contacts are closed. Consequently current flow in gauge circuit increases in proportion to the rise in engine temperature and this increased current produces a greater deflection of the dash unit bi-metal arm so that a higher reading is indicated on the dial.

Type 7000. This type operates similarly to earlier types (above) except that contact pressure and current are at maximum when engine unit is cold. Increase in engine unit bulb temperature (as engine warms up) tends to flex the bi-metal arm away from the stationary contact support so that contact pressure and length of time contacts are closed tend to decrease. The consequent decrease of current in the gauge circuit causes the dash unit pointer to move toward the "hot" end of the scale.

TESTING & SERVICING:—Manufacturer recommends use of a regular Gasoline Gauge Tank Unit as a test "Sender" to check operation of units which do not operate satisfactorily. Make tests as directed below.

CAUTION—When testing later type temperature gauges (with No. 7000 Engine Unit), dash unit readings will be reversed (HOT with tank unit float in "empty" position, COLD with tank unit float in "full" position).

Testing Sender:—Disconnect lead of Sender unit on car, connect this lead to test Sender and ground this Sender to the car frame. Turn on ignition, move Sender float up to 'full' position and note reading on Receiver. If Receiver reading is correct (after 10-15 seconds time), check following points before replacing Sender unit:

1. **Ground.** Sender is grounded through case. See that all paint and grease are removed under flange and both surfaces make good contact.
2. **Radio By-pass Condenser Shorted.** If by-pass condenser is connected at Sender on cars with radio, test for short-circuit by disconnecting condenser and noting gauge operation. If gauge is satisfactory, replace condenser.

If reading secured with test Sender is same as that with Sender on car, check wire connecting Sender and Receiver. Replace if open-circuited or grounded.

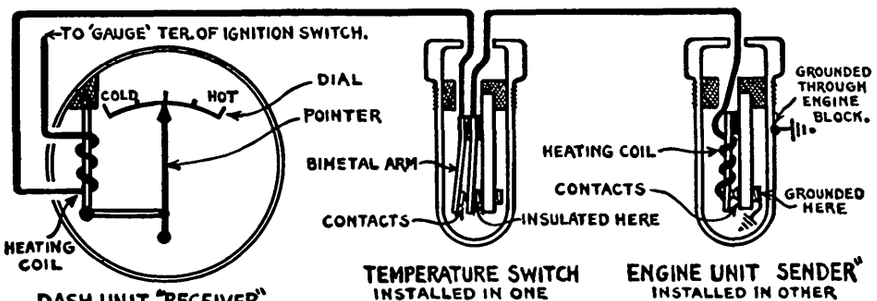
Testing Receiver—Disconnect wires on Receiver on car and connect to same terminals on test Receiver. Turn on ignition switch and note reading on gauge. If test Receiver reading is correct, replace Receiver on car. If test Receiver reading is same as car Receiver, repeat tests on Sender and wiring.

SERVICING:—No service operations are required other than to see that wires are properly connected and terminals are tight. No repair operations are possible and defective Senders and Receivers should be replaced.

KING-SEELEY ELECTRIC TEMPERATURE GAUGE (FORD V8 & MERCURY) (NOT "CV" CONSTANT VOLTAGE TYPE)

NOTE: The Temperature Gauge Switch listed below was furnished as an accessory in Temperature Gauge Kit, King-Seeley No. 8464, Ford No. 11A-18381, and will be found installed on Ford and Mercury Pass. Cars and Ford Trucks. This Temperature Switch was Std. Equipment starting on late 1941 V8 models.

DESCRIPTION: This special Temperature Gauge installation is designed to detect overheating of the cylinder bank in which the regular temperature gauge Engine Unit is not installed (Engine Unit normally installed in one bank of Vee type engines and will not detect overheating occurring in the other cylinder bank only). Installation consists of a special Temperature Gauge Switch installed in one cylinder bank and connected in series with the regular Temperature Gauge Engine Unit installed in the other cylinder bank.



Temperature Gauge Switch—This unit resembles a conventional engine unit in appearance but differs in internal construction. One contact is mounted on a stationary insulated arm with the other contact mounted on a special bimetal insulated arm. A lead is connected to each arm so that the contacts are in series in the circuit between the Temperature Gauge Dash Unit and regular Engine Unit (see illustration).

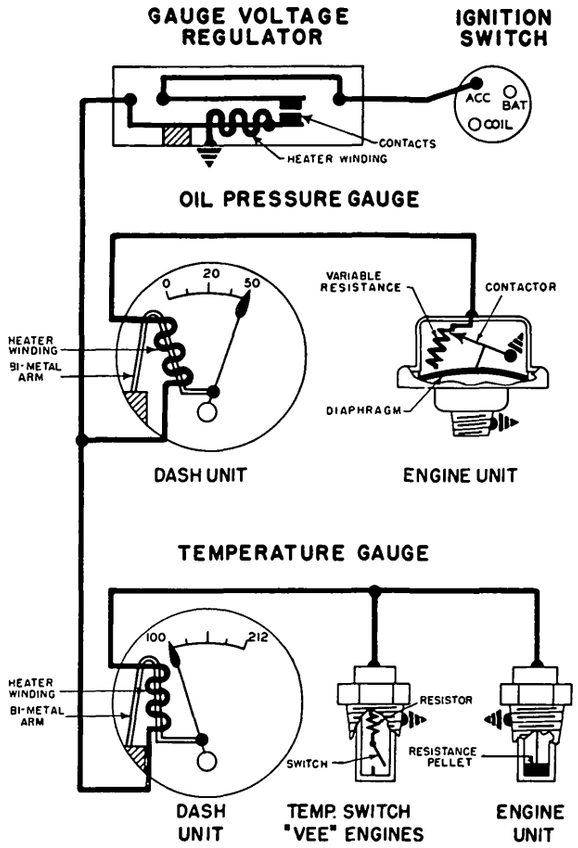
Temperature Gaug Engine Unit—This unit is same type used on other gauges with movable contact mounted on bimetal arm on which the heating coil is wound and grounded contact mounted on a stationary arm.

OPERATION: At all normal temperatures, the contacts of the special Temperature Gauge Switch are closed and engine temperature is recorded by the regular Engine Unit in the usual manner. When the temperature in cylinder bank in which the Temperature Gauge Switch is mounted reaches the point for which the unit is set, the flexing of the bimetal arm opens the contacts and breaks the temperature gauge circuit. This causes the dash unit to read 'hot'. The switch is merely a circuit breaker which opens the circuit at this predetermined temperature so that the dash unit reads hot, it does not control dash unit operation at temperatures below this point.

Setting—Temperature Gauge Switch contacts open at 195°F. (plus or minus 5°). NOTE—A special switch designed for use with a special cooling liquid opens at 240°F.

SERVICING:—No servicing required. Replace defective units.

KING-SEELEY "CV" CONSTANT VOLTAGE OIL & TEMPERATURE GAUGES



DESCRIPTION & OPERATION: King-Seeley "CV" or constant-voltage gauges differ from previous types in that "CV" engine gauge units (senders consist of variable resistances (rheostats) which regulate the current in the heating coil of the receivers (dash units) and control the deflection of the bi-metal arm linked to the gauge pointer. All dash units are of similar design. The feature of these gauges is the "Gauge Voltage Regulator" which regulates input voltage in the gauge circuits and insures accurate gauge readings regardless of the line voltage fluctuations.

Gauge Voltage Regulator: Consists of a vibrating unit (contacts controlled by bi-metal arm on which a heater winding is located) connected in the line between the ignition switch and the gauges. Regulator produces a pulsating voltage, at an effective constant amperage value, of 5.0 volts for all normal input voltage variations (between 5.6 and 8.0 volts). Input voltages lower than 5.0 volts will result in proportionately lower gauge readings while voltages greater than 8.0 volts will not affect gauge accuracy but will overload regulator contacts and may cause premature wear. Regulator is temperature compensated and is intended to be mounted near the gauge dash units and at approximately the same ambient temperature.

Gauge Indicators (Dash Units): All units are of similar design. Gauge pointer is linked to a bi-metal arm on which a heater coil is wound. This coil is connected in series with the tank or engine unit rheostat so that the gauge reading is in proportion to the current in the circuit (zero reading with maximum resistance and minimum current, high reading with minimum resistance and maximum current).

Oil Pressure Gauge Engine Unit—The rheostat contactor acts as a ground for the gauge circuit and is linked to a diaphragm which is deflected by the engine oil pressure so that it sweeps across the resistance as the diaphragm flexes with the engine oil pressure. When pressure is low, the entire resistance is in the gauge circuit and the current is at a minimum. When pressure rises, resistance is cut out of gauge circuit and the increase in current causes dash unit to read higher.

Temperature Gauge Engine Unit—New design (no moving parts). Gauge circuit is grounded through a small block of special sintered material which has a variable resistance in response to temperature changes. This block is sealed in the end of the engine unit bulb in close contact to the engine coolant. It has a comparatively high resistance when cold so that the current in the gauge circuit is at a minimum. This resistance decreases as the engine temperature increases and the consequent increase in current in the gauge circuit causes the dash unit to read higher.

KING-SEELEY "CV" GAUGES

►**Auxiliary Temperature Gauge Switch (for "V" Engines)**—The regular temperature gauge engine unit is mounted in one block of the engine, and the auxiliary switch is intended to be mounted in the other block as a warning of abnormal temperatures in this block. Switch is connected in parallel with the regular engine unit (see diagram) and consists of a switch (normally open) and resistance. At high temperatures, the switch closes and the resistance is shunted across the regular engine unit and causing the dash unit to read "hot."

TROUBLE SHOOTING: Units should not be removed from the car until testing has been done to determine which units are defective. See Testing (following).

All Gauges read Too High or Too Low—Voltage Regulator defective (see Regulator Test) or not properly grounded (regulator MUST be grounded). Battery voltage at regulator (or ignition switch) below 5.0 volts (check with voltmeter).

►***CAUTION—Gauge Voltage Regulator provides an intermittent voltage averaging 5.0 volts and regulator output voltage can not be tested with a voltmeter.***

One Gauge Reads Too High or Too Low—Test unit as directed below.

TESTING: Use a Fuel Level Gauge Tank Unit which is known to be OK. as a test unit. Connect one test lead to the terminal on the unit and a second test lead to the case to act as a ground wire (CAUTION—unit will not operate if not properly grounded). Make tests as follows:

Voltage Regulator: Requires use of an OK. dash unit also. Connect these test units together (dash unit and tank unit) in normal manner and ground tank unit, connect the other dash unit terminal to the output terminal of the voltage regulator. Check battery voltage (must be within operating limits). Hold tank unit float in Empty position, turn on ignition switch, note reading on test dash unit (should read at low end of scale). Start engine and run at faster than normal idle speed. Gauge reading should not change if voltage regulator functioning normally. Move tank unit to full position. Dash unit gauge should read at upper end of scale. If Voltage Regulator not operating correctly, replace original unit with correct type unit.

Gauge Units: Disconnect lead at engine (sender) unit on car and hook test unit in circuit at this point (CAUTION—make certain test unit is grounded.) Move test unit float to Empty position, turn on ignition switch, note dash unit reading (gauge pointer should be at lower end of scale—Empty, Zero, Cold, etc.). Move float to Full position, gauge pointer should then be at upper end of scale. If dash unit reads OK. in both positions, replace original tank or engine unit with correct type unit. If dash unit does not test OK., connect test unit directly to terminal on dash unit (eliminating the car wire). If dash unit then tests OK., check lead between dash unit and tank or engine unit for broken wire or shorted insulation and replace this wire. If dash unit still does not function correctly, replace original dash unit with correct type unit.

REPAIRING UNITS: Repair or calibration of units is not practical in the field and defective units should be replaced.

WINDOW & SEAT REGULATORS HYDRO-LECTRIC TYPE

1946-53 Buick, Cadillac, Oldsmobile
1954 Buick, Series 66C & 100 (Convertible)
1954 Oldsmobile, Early Super 88 & 98. See Note below.
1946-Early 1950 Chrysler Crown Imperial
1946-48 Ford & Mercury Sportsman
1948-53 Hudson
1954 Hudson 5D & 7D (Convertible)
1946-51 Lincoln
1949-51 Mercury
1948-54 Packard

▷**PRODUCTION CHANGE: Two different pumps have been used, a low pressure pump (200-210 p.s.i.), and a high pressure pump (250-260 p.s.i.). These pumps can be identified by relief valve plug at rear of pump: low pressure has cadmium plated plug, high pressure a copper plated plug.**

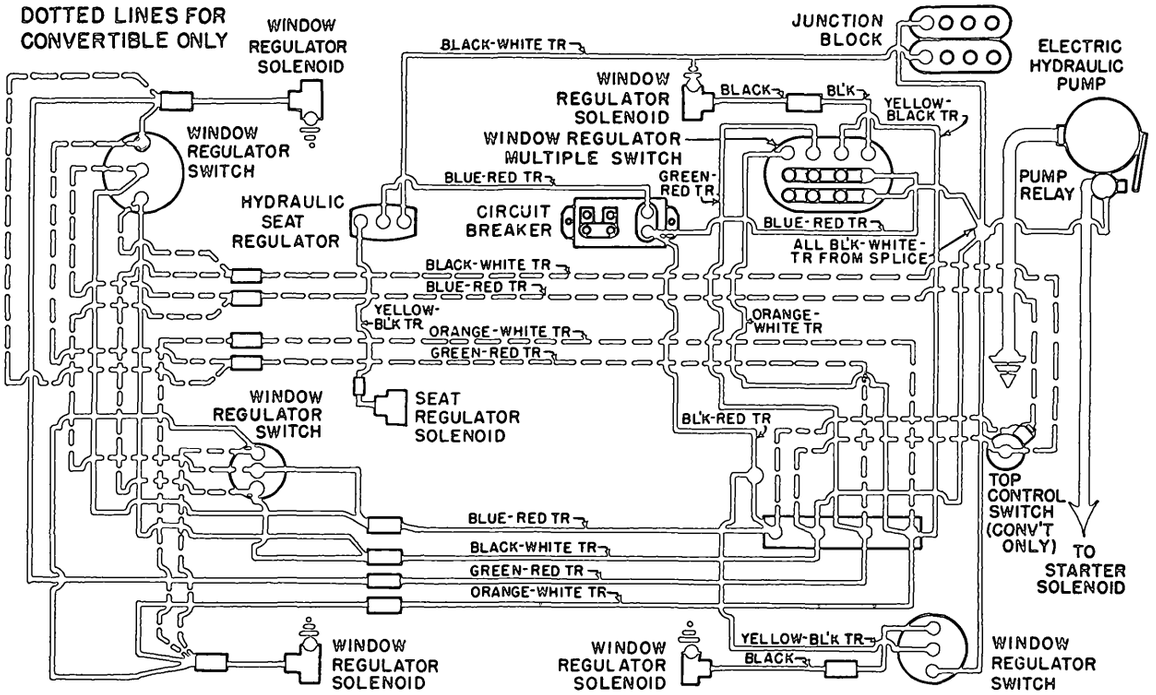
DESCRIPTION: This type control consists of an electric motor with direct-connected hydraulic pump which supplies fluid under pressure to a single acting power cylinder incorporated for each window regulator used (additional cylinder located under front seat for front seat adjustment on some models). Fluid is pumped into the cylinders by the motor to raise windows or move seat forward, but windows are lowered and seat moved backward by spring hooked to regulator (switch operates solenoid valve in cylinder only—the motors does not operate). When the switch is in the "off" or center position, the solenoid valve is closed and fluid is trapped in the cylinder to hold windows or seat in desired position. The system has the following control units:

Power Unit—Consists of motor, hydraulic pump, and fluid reservoir assembly. This unit is same as type used for Convertible Top Control on these same cars. *See "Power Operated Tops, Hydro-Lectric Type (With Window & Seat Control)."*

Control Switches—Consist of simple two-way switches (one for each window and one for seat adjuster—duplicate switches for rear window control located on left front door) Switch lever is normally in "off" or center position and must be held in the "up" or "down" ("forward" or "back" for seat adjustment) position while window (or seat) is operating.

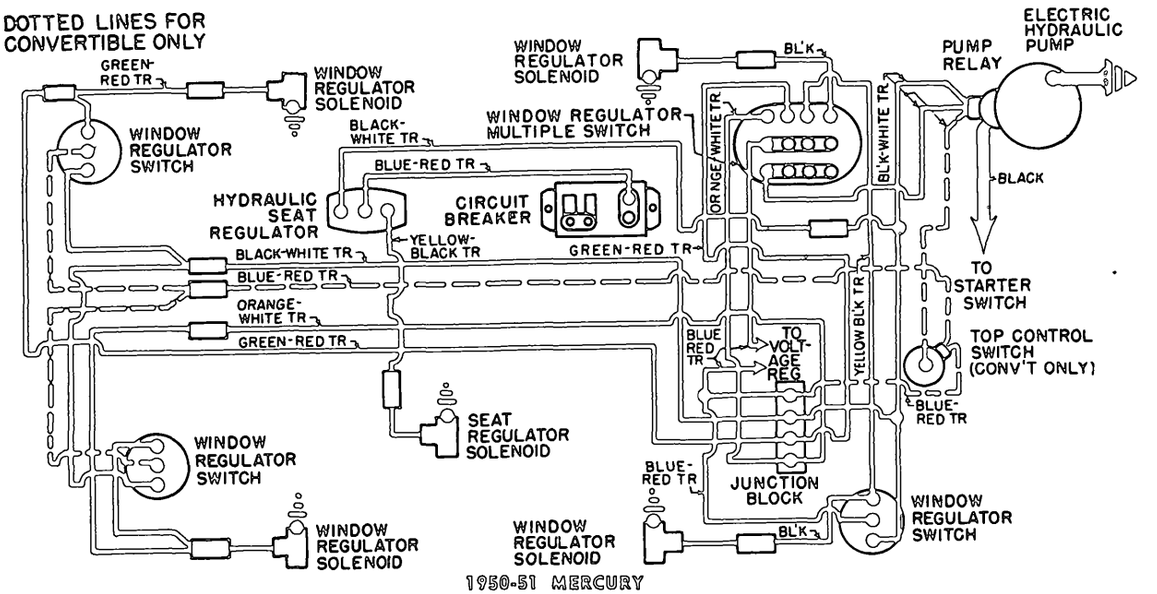
Hydraulic Cylinders (Window Regulator & Seat Adjuster)—Single acting, solenoid valve controlled. Cylinders raise windows or move seat forward. When solenoid valve in cylinder is opened (to lower windows or move seat rearward) power unit does not operate and windows and seat are retracted by springs.

NOTE—This cylinder is a "vented" type, making the periodic changing of hydraulic fluid necessary. Water and other foreign matter will cause sludging and deterioration of fluid. (See Draining & Refilling).



REMOVAL: Control units can be removed for servicing or replacement as follows:

▷*CAUTION*—Before any repairs are made to the regulators, hydraulic system or electrical system, battery terminal should be disconnected to avoid injury or damage to the car.



Power Unit: Disconnect battery cable as a safety precaution. Disconnect ground strap and wire at motor. Disconnect hydraulic tubing at pump and cap tubing ends. Remove bolts from rubber mounting, (it may be necessary to remove fluid reservoir for access to lower mounting bolts). Lift unit out.

Window Regulators: Lower window to extreme open

CONTINUED ON NEXT PAGE

1950-51 LINCOLN

1950-51 MERCURY

WINDOW & SEAT REGULATORS HYDRO-LECTRIC TYPE (C nt.)

position. Remove switch from trim panel and remove wires from switch (Mark wire to insure correct reassembly). Remove remote control handles and door trim panel. Remove wire from solenoid connection and disconnect fluid line at cylinder (care should be taken to catch any fluid remaining in cylinder), cap end of fluid line tubing. Loosen bolts holding glass channel to regulator arm and slide rollers out of channel. Raise window by hand and secure in raised position by wrapping several strips of masking tape over top of door and sticking ends to glass. Remove nuts securing regulator assembly to door panel. Regulator can be removed from door through the elongated hole provided.

Removal of Hydraulic Cylinder—Place regulator assembly firmly in vice. Remove lower cylinder retaining clip (Spring type clip or bolted clamp). Remove upper clip or clamp and take cylinder out of assembly. NOTE—Cylinder cannot be repaired, replace complete cylinder assembly if necessary.

►***CAUTION*—Two different valves used:** Check color of relief valve plug at rear of pump.

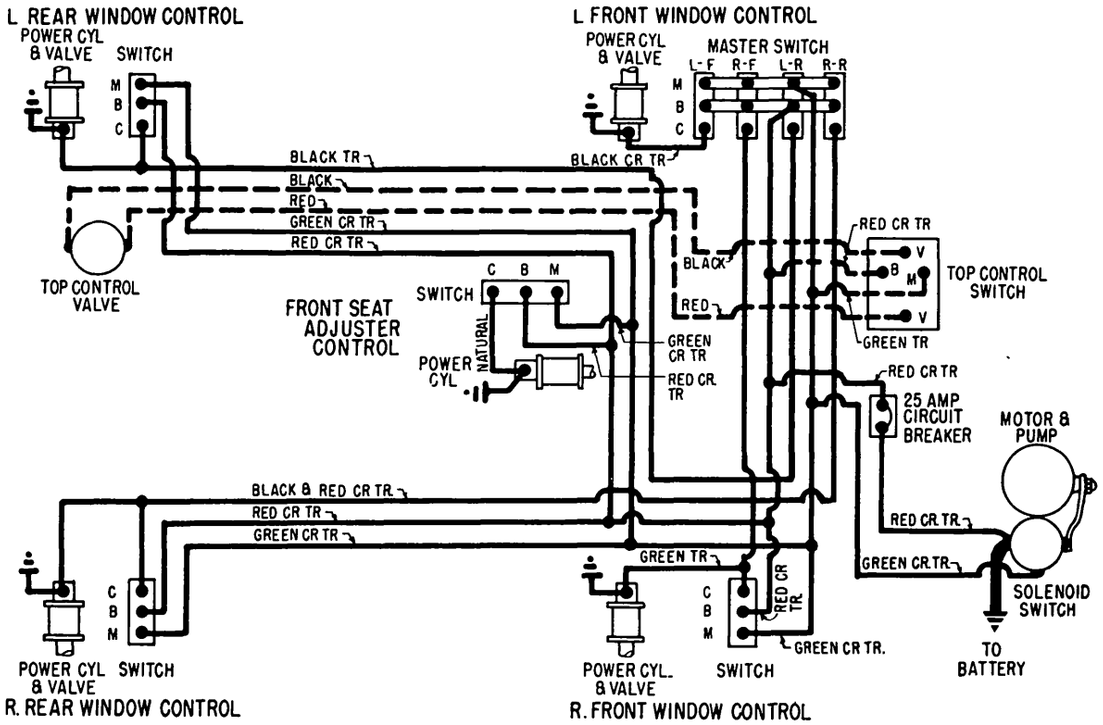
1—Cadmium plated plug. Valve set for maximum pressure of 210 lbs. for use with low pressure pump.

2—Copper plated plug. Valve set for maximum pressure of 260 lbs. for use with high pressure pump. See PRODUCTION CHANGE NOTE above.

These valves are not interchangeable.

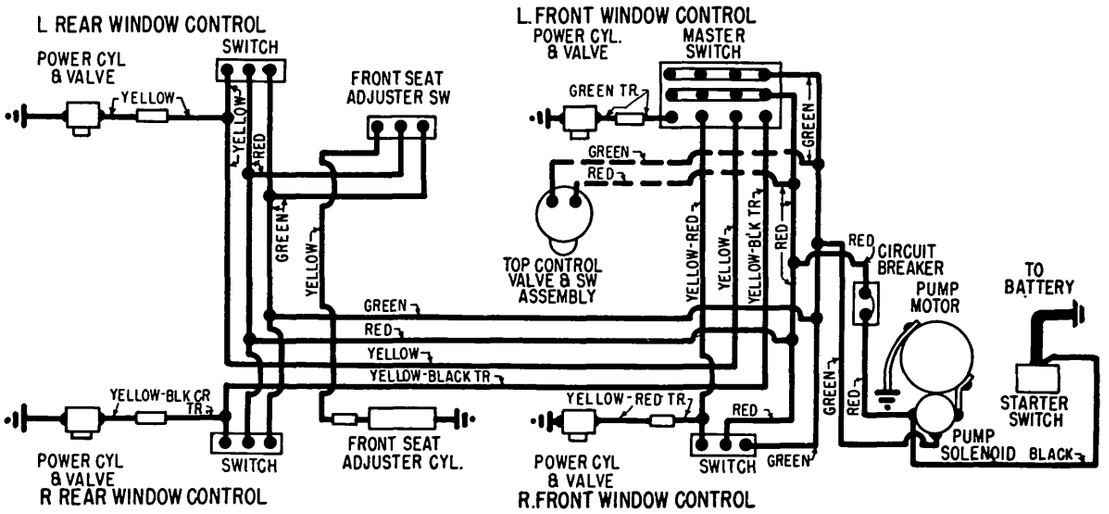
NOTE—If plug removed and washers are used under plug, these same washers must be reinstalled on reassembling plug.

Seat Adjuster Regulator Assembly—With seat in extreme rear position, remove front seat cushion and disconnect positive terminal of battery. Disconnect solenoid valve wire at connector in lead from seat actuating switch. Remove nut and washer joining forward end of regulator to support on seat frame, then remove entire seat frame from body. Turn back rear floor carpet and remove screws and seat adjuster cover. Disconnect hydraulic lines from regulator and cap the ends. Remove nut and washer holding rear end of regulator to floor pan support brackets, then remove regulator.



OVERHAUL

►**1952 PUMP UNIT PRODUCTION CHANGE**—Early production used same type pump rotor as for 1951 consisting of a 4-lobe inner (driving) rotor and a 5-lobe outer (driven) rotor. Later type pumps used a 10-lobe inner rotor and an 11-lobe outer rotor. At start of second type production, inner rotor was "one piece" type, later production was changed to a "split" or two piece rotor. First type 4-5 lobe rotors are of different thickness than 10-11 lobe rotors. Later type rotors can not be used in early type pump body. Later 10-11 lobe rotors, solid or "split" are interchangeable.



►**SPUR GEAR TYPE PUMP NOTE**—Disassembly and reassembly of this type pump is similar to rotor type. See procedure below.

PUMP UNIT DISASSEMBLY: Remove bail and pump reservoir from housing. Remove capscrew securing upper cushion bracket to motor frame and remove bracket. Loosen cover band and slide off end of motor frame. Remove field brush from holder and take out three cap screws securing motor frame to

CONTINUED ON NEXT PAGE

TPYICAL G.M. CONTROL WIRING DIAGRAM

TYPICAL PACKARD CONTROL WIRING DIAGRAM

WINDOW & SEAT REGULATORS HYDRO-LECTRIC TYPE (Cont.)

motor head. Remove motor head. Remove armature. Remove the four cap screws holding pump housing to motor frame and remove the pump. Remove reservoir fluid retainer and retainer plate by taking out two sheet metal screws in retainer. Remove the six cap screws securing pump bottom plate to pump housing and remove bottom plate, then remove rotor spring, plate, inner and outer rotors, port plate and bottom seal. Remove relief valve plug and plug washers (same number and size washers must be replaced when assembling pump), remove relief valve spring and relief valve.

PUMP UNIT REASSEMBLY: Wash all parts in alcohol and examine for wear, scoring and excessive play. Check relief valve for scores and free movement. Replace any parts that indicate wear. Blow all parts dry and blow out all passages in pump housing. Install port plate, inner and outer rotors and rotor plate. Install bottom seal and place rotor spring in position on rotor plate with nib of spring in hole in rotor plate. Place pump bottom plate in position and secure with six cap screws. Place fluid retainer plate in position between pump inlet tubes, and secure reservoir fluid retainer to retainer plate with two sheet metal screws. Install relief valve, spring, and valve plug with the same amount of washers that were removed. ***(CAUTION***—Do not drop or remove these washers as they were put there by the manufacturer to adjust the valve to a minimum fluid pressure of 250-265 lb., P.S.I. ***Under no circumstance should this pressure be changed to provide higher pressure).*** Place pump in position on motor frame with relief plug 180° from solenoid, and secure pump to frame with four cap screws. Install one fibre washer on commutator end of armature shaft and two washers on drive end and install armature in motor frame. Place motor head in position and secure with three cap screws. Lift ends of brush spring and install brushes in holders. Check action of brushes to make sure they move freely under spring tension. Install cover band and tighten band screw. Install upper cushion bracket on motor head, and install fluid reservoir. (See "Draining and Refilling").

INSTALLATION (Of above assemblies): Reverse the removal instructions. NOTE—Align window regulator assembly so that window glass is free in channel in all positions.

LUBRICATION

DRAINING AND REFILLING: Entire hydraulic system should be drained and refilled with clean fluid at least once each year. Use the best grade of hydraulic brake fluid or window regulator fluid recommended by the car manufacturer, and proceed as follows: Lower all windows to extreme bottom, (if car has seat adjuster, move seat to extreme rear position). Remove ground cable from battery. Remove fluid reservoir and wash with alcohol. (**For cars with hydraulic top lift units,** hold container under pump and manually lower and raise top, with top control knob in proper positions. This will drain both cylinders). **To Refill System**—Fill reservoir to fluid line with correct fluid, connect battery then operate the top up and down to pump fluid into cylinders (replenish fluid in reservoir frequently as top lift cylinders have a capacity about 2½ times greater than reservoir). With reservoir filled to level line, operate the top up and down until all air is exhausted from lines, (if air is present in lines, a chattering noise will be produced when top is operated). After all air is expelled from top hydraulic system, operate front seat and all windows until air has been exhausted from these systems. Remove reservoir and fill to fluid level line. Install reservoir making certain that gasket is in good condition and that reservoir makes contact all around.

HYDRO-LECTRIC MOTOR & PUMP ASSEMBLY (DURA PUMP)

HYDRA-LECTRIC PUMP ASSEMBLY (MORAINE PUMP)

AUTO-LITE ELECTRIC

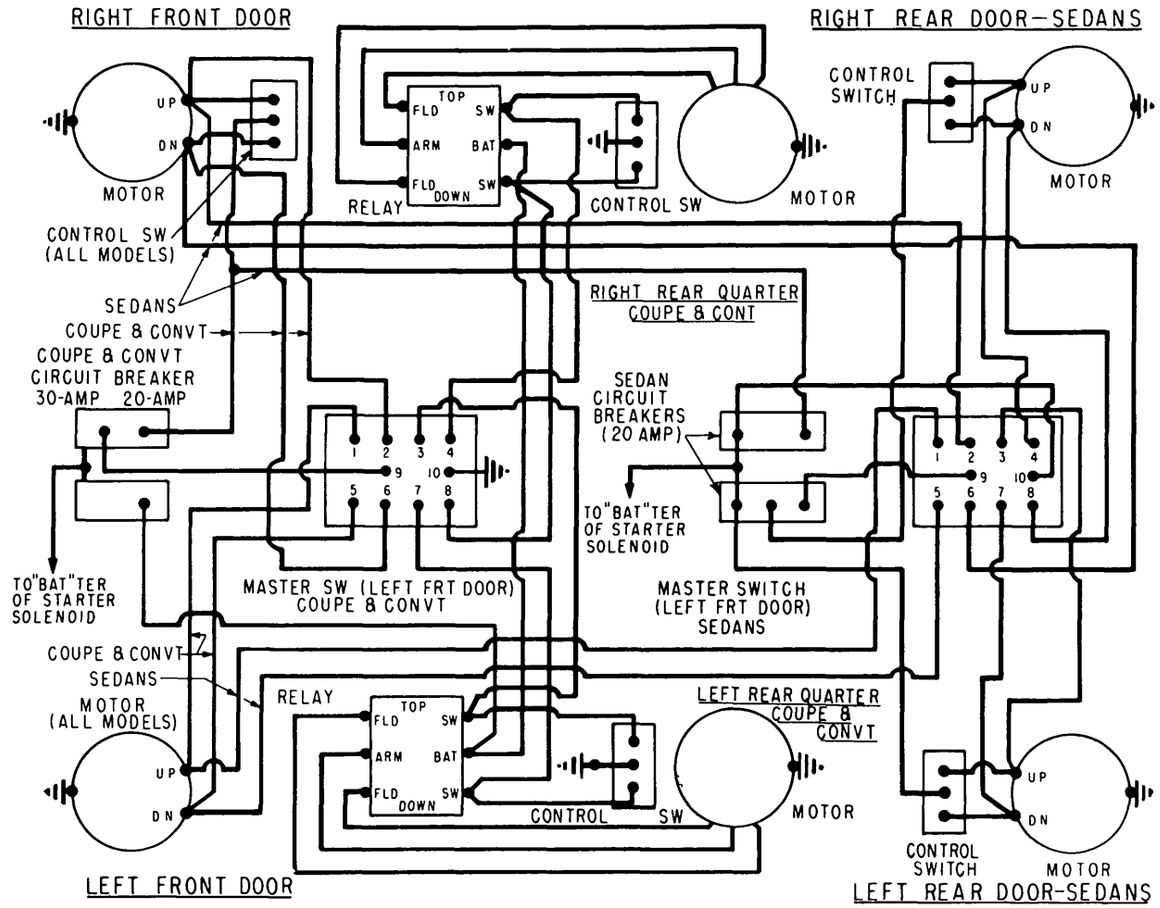
Chrysler & Imperial (1955)
DeSoto (1955)
Dodge (1955)
Packard (1955)
Plymouth (1955)
Studebaker (1955)

DESCRIPTION: Window regulators are individually powered by a reversible electric motor connected to a worm gear by a flexible shaft. Motor is controlled by a two-way switch (on trim panel) and a master switch (on left front door) operating through a relay or directly to the motor. 30-ampere circuit breakers are used with relay circuits and 20-ampere circuit breakers are used in circuits without relays.

REMOVAL & INSTALLATION: Proceed as follows:

Window Lift Motor (Except Studebaker): Remove door handle, escutcheon plate, garnish molding, arm rest and trim panel. Disconnect wires from motor. Remove attaching nuts that hold motor to gear box, pull motor down and away from drive shaft. To reinstall, reverse removal procedure.

Studebaker–Remove regulator assembly (see below). Remove motor-to-regulator bracket capscrews. Slip motor off bracket and disengage motor shaft from coupling. To install, make sure coupling fully engages gear shaft. Then align motor shaft and coupling, slip motor into position. Install retaining capscrews. Install regulator (see below).



Window Lift Assembly (Except Studebaker): Removal–Disconnect battery, remove garnish molding, door handle and escutcheon plate. Remove arm rest and window lift control switch, then door trim panel. Remove wires from motor. Remove clips from regulator pins holding lower glass channel. Raise glass manually and prop the glass. Raise glass before loosening capscrews so that it is out of working area. Remove four regulator-to-door attaching screws. Remove pivot guide retaining pin. Lower motor and regulator assembly out through opening in door.

►*CAUTION:* If gear box is to be replaced, remove regulator counter balance spring before removing. Counter balance spring has 220° of wrap. Use large pliers when removing. Failure to remove spring before disassembly can result in personal injury.

Installation–Place motor and regulator assembly through opening in door, insert intermediate pivot arm pin into guide inside door shell **(there is no clip)**. Install four regulator attaching screws finger tight. *(NOTE*–After regulator screws installed, check to see that intermediate pivot arm did not slip out of guide during installation). Remove window prop, lower window and insert control arms into glass channel, using leather washer on each side of channel, secure with clip. Connect motor wires and battery cable, operate window up and down several times to help align glass in channel. Stop window half way and tighten regulator attaching screws. Check glass for alignment. Replace trim panel and other parts in reverse order of removal.

Wind w Lift Ass mbly (Stud bak r): R m val–Raise window, remove door handle and arm rest. Remove trim panel, disconnect wires from switch, then remove trim strip from door. Remove sealing tape from inspection holes and tape edges of large inspection hole with masking or friction tape. Remove window stop bracket bolts, turn bracket as required and remove from door. Remove relay bolts, and remove relay, leaving wires attached. If window is in up position, turn ignition switch on and lower window by holding ground wire to dark green wire at relay terminal. Lower window just enough to expose regulator arms and window lift channel. Turn ignition switch off. On all doors, except President 4-Door rear doors, remove hairpin clip and plain washer from each regulator arm guide pin, then disengage lift channel from guide pins. Lift glass all the way manually and insert a punch or small screwdriver through one of trim strip retainer holes to hold glass up in position. On the President rear door, remove ventilator window assembly on Y6 models, and window rear run on Y4 models. Remove window glass from door to provide clearance within door for regulator removal. Disconnect motor-to-relay wires at relay, remove relay. Loosen idler track rear screw just enough to keep it snug. With a hand inside door, hold idler track or end of regulator arm. *(NOTE*–Because regulator arm which engages idler track is springloaded make certain idler track or end of regulator arm is well supported). Remove idler track front screw and carefully lower arm and track until pivot point can be seen through access hole. Then, while holding end of track, remove track rear screw and lower track until it rests against regulator sector. Remove four regulator-to-door panel screws and lower regulator. Then, by revolving drive coupling, move sector to provide clearance required to permit tipping regulator for removal. On front door regulator, move sector to approximately the center position. On rear door regulator, move sector about 1/3 of its total travel from down position. Shift regulator assembly forward on all doors except President sedan rear door (on this model shift assembly forward). Keep motor end down. Turn and tip assembly and start reg-

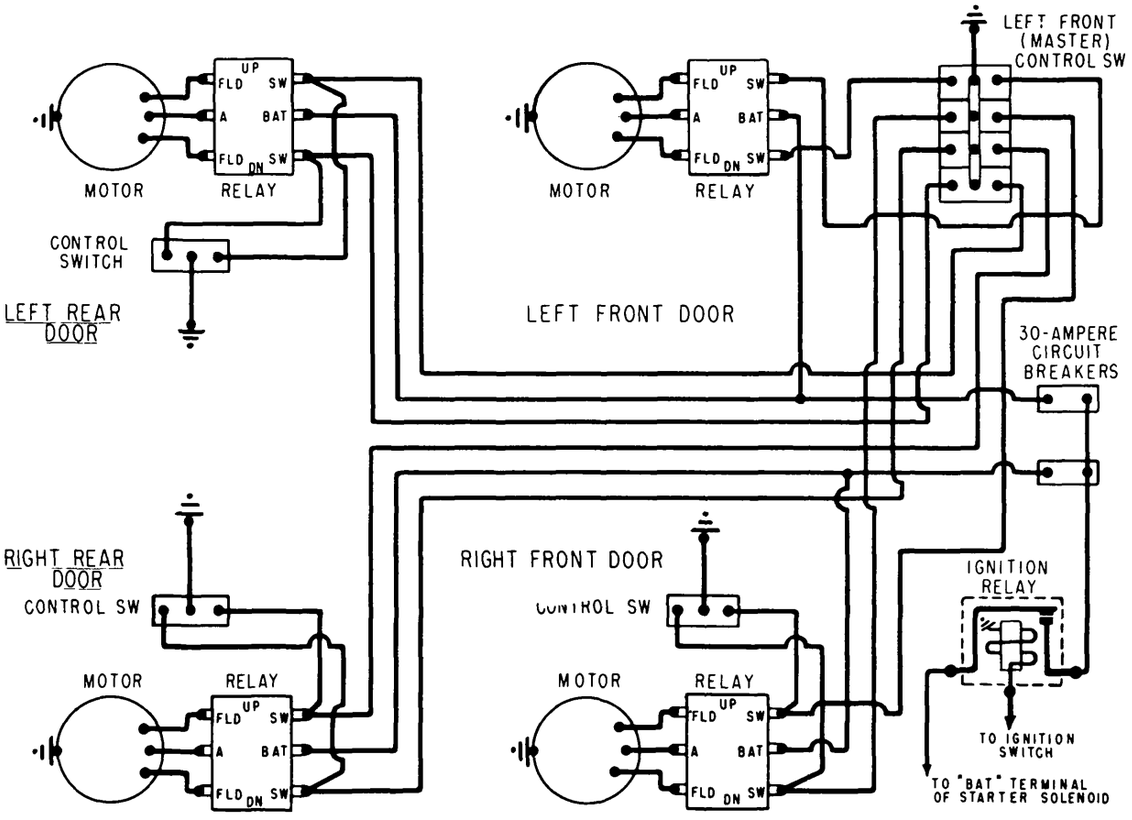
CHRYSLER, DE SOTO, DODGE, PLYMOUTH WINDOW CONTROL WIRING DIAGRAM

AUTO-LITE ELECTRIC
(Continued)

ulator arms out through inspection hole. Continue to turn and, at same time, lower ends of regulator arms and lift assembly out of door

Installati n—Apply Lubriplate or high melting point grease to sector gears, idler track, arm guide pins, and balance spring. Place sector in approximately same position as for removal (center position for front doors, 1/3 of its travel from down position for rear doors) Insert motor end through inspection hole Keep ends of regulator arms down, move assembly into door As mounting bracket clears edge of inspection hole, lower motor and move assembly forward (rearward on rear door of President). Turn assembly and insert regulator arms in door On front door, make sure sector clears window front guide channel. Sector must be positioned between guide channel and door inner panel. Position regulator on door panel and install retaining capscrews Swing idler track into position with arms nearly vertical but with front track screw clear, install but do not tighten front track screw. Lift idler track, using front screw as a pivot, align the bracket with hole in panel, install track rear screw. Tighten both front and rear track screws securely. Connect motor wires to relay Turn ignition switch on and lower sector and regulator arms by touching ground wire to dark green wire relay terminal. On President rear door, place window glass within door On Y6 model, install rear ventilator frame assembly, on Y4 model, install window rear run. On all models, except President, remove punch or screwdriver and lower glass carefully. Engage lift channel with regulator guide pins and install plain washers and retaining clips. Hold ground wire on upper terminal of relay and raise window. Position window stop bracket within door and install retaining bolts Loosen bolts and move stop and bumper down. Lower glass until top of glass is flush with bottom of window opening on all front doors and approximately 2" above bottom of opening on rear door of 4-Door models. Then raise stop until stop bumper contacts lift channel, tighten bolts. Make sure all connections on relay are tight and install relay within door. Install door panel trim strip, connect wires to switch in trim panel, and install trim panel.

OPERATIONAL TEST: Connect ammeter in electrical circuit and operate window. Ammeter reading should be constant and without fluctuation. If reading fluctuates, there is a bind in either glass or linkage



TROUBLE SHOOTING: Diagnose trouble as follows:

All Wind ws Inop rativ : Loose connection or break in wires from power source, defective ignition switch relay (Studebaker), all circuit breakers defecitve.

Both Right Windows or B th Left Windows Inoperative (Stud bak r 4-Do r Mod ls); Both Front Windows Or B th R ar Windows Inop rative (Others): Faulty circuit breaker or circuit breaker wire.

On Window Inop rative: Faulty relay (if so equipped) or operating switch; bind in regulator linkage or window glass; *motor burned out.*

Window Operable In One Dir cti n Only: Faulty relay (if so equipped) or operating switch; broken wire or loose connection; faulty motor.

STUDEBAKER WINDOW CONTROL WIRING DIAGRAM
(STUDEBAKER SEDANS SHOWN—PACKARD SIMILAR)

Window Operates In Wrong Direction From Master Or Door Switch: Field wires from motor reversed at relay (if so equipped).

Window Operates In Wrong Direction From Either Master Or Door Switch, Correctly From Other Switch: Operating wires reversed at switch.

Window Operates From One Switch Only: Defective switch, broken or grounded wire or loose connection.

Circuit Breaker Cuts In & Out Continuously—Window Will Not Operate: Grounded wires, relay (if so equipped) points stuck, faulty switch.

Window Operates Sluggishly Or Circuit Breaker Cuts In & Out When Window Is Operated: Bind in regulator assembly or window channel, broken wire, loose connection, or partial ground, defective motor.

►CHANGES, CAUTIONS, CORRECTIONS

►*1954 REGULATOR JAMMING CORRECTION (On Early Models):* If this condition is due to motor jumping at the end of up and down cycle, the condition can be corrected by replacing motor and gear assembly with a later type having a reduced operating speed, an additional bearing on armature shaft and a wider nylon gear.

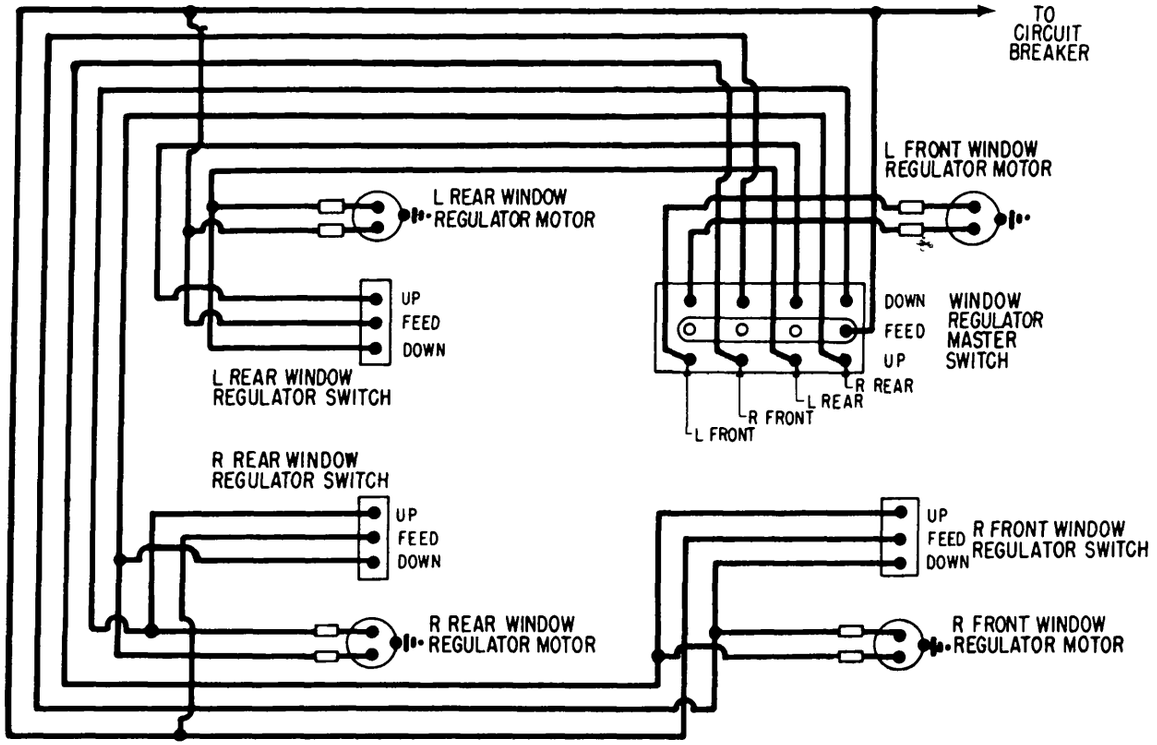
►*1954-55 INOPERATIVE ELECTRIC WINDOW REGULATOR CAUTION:* First check electrical circuit (see "Trouble Shooting" below). If no defects found in electrical circuit, check regulator assembly installation to determine whether or not motor pinion gear is jammed at end of regulator sector gear. After motor pinion gear to regulator sector gear relationship has ben established, carefully remove regulator assembly from body (see below). Check regulator assembly as outlined under "Trouble Shooting" below.

►*1954-55 REPLACEMENT MOTOR & MOTOR MODIFICATION CAUTION:* (NOTE—Nos. 5, 6, 7, or 8 are stamped on motor gear housing web. These numbers are for identification but do not indicate sequence of issue). Service packages (see below) have been issued to modify the following motors by replacing nylon gear and pinion assembly with a gear and rubber pinion assembly.

1) Nos. 5, 7, and 8 motors which have jammed due to nylon gear binding on worm gear and those in stock to be used as replacement motors (modify at time of installation).

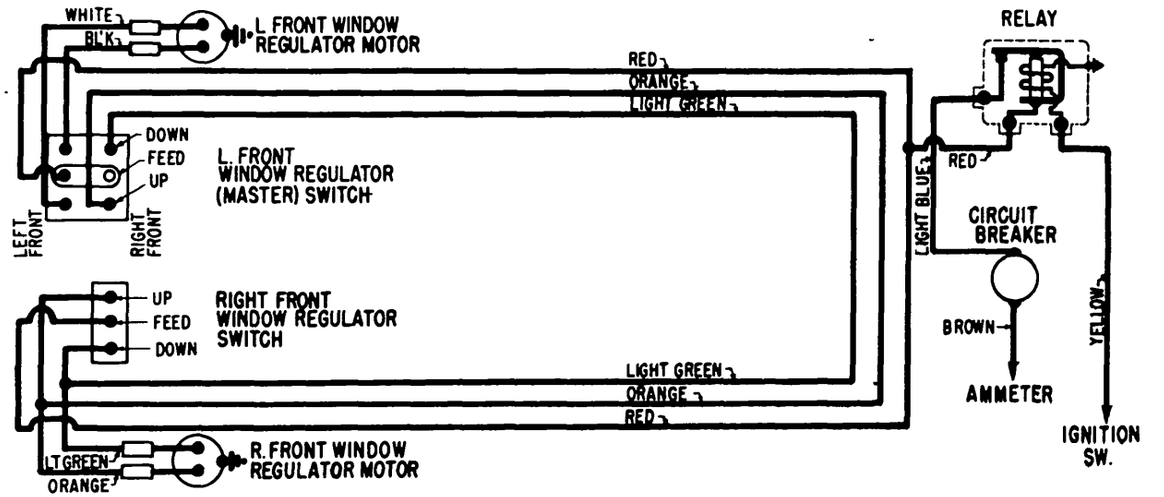
2) No. 5 motors which operate very slowly in cold weather.

3) No. 6 motors which require replacement of a defective gear and rubber coupling assembly.



Year & Model	Window	Service Pkg. No.
1954-55 All	Door	5097959
1955 Sp. Cpe., 2-Dr. Sed.	Rr. Qrtr.	5097959
1955 Convertible	Rr. Qrtr.	5097960

Installation Note—With motor in upright position and gear housing positioned below motor, wash out gear housing and worm gear with a suitable solvent such as mineral spirits. Use a small brush to clean around worm gear. Relubricate with grease type lubricant furnished in service package.



►*1954-55 FRONT DOOR WINDOW BUMPER CHANGE (Sedan Models):* Effective production of 1955 Models, a new, larger bumper approximately 1 5/16" square and ½" thick, Part No. 4609684, was used. On 1954 sedan models, front door window lower stop bumper should be checked whenever motor modification or replacement made. If bumper is approximately 1 3/16" square and ¼" thick, it should be replaced with new bumper.

DESCRIPTION: Door window regulators (and rear quarter windows on some cars) are individually powered with reversible motors geared directly to regulator assembly. A two-way switch on door trim panel and a master control switch (on left front door) control operation of windows. A circuit break-

TYPICAL 1954-55 G.M. WINDOW CONTROL WIRING DIAGRAM (EXC. 1954 CHEVR LET & PONTIAC

1954 CHEVROLET & PONTIAC WIND W C NTR L WIRING DIAGRAM

G.M. ELECTRIC (Continued)

er built integral with the motor protects against overloading when up or down cycle is completed. Ignition switch must be "ON" or turned to the "accessory" position for window operation.

DOOR WINDOW REGULATOR ASSY. REMOVAL (Except Buick Mod. 43 & 63 Rear Windows): Operate window to down position. Remove door trim pad, loading hole covers and tape covering access hole, then disconnect motor leads from wire harness. Remove bolts securing window assembly to regulator cam. Disengage window assembly from regulator cam and prop window in "up" position (on Convertibles & Hardtop Models, remove window glass from door). ***(CAUTION—After window regulator assembly is disengaged from the regulator DO NOT OPERATE REGULATOR MOTOR).*** Remove ventilator division channel lower adjusting nut and stud (front windows). Remove stationery cam attaching screws and remove cam. Disengage cam from regulator and remove from between door panels. Remove regulator attaching screws and carefully remove regulator from between door panels. To install, reverse removal procedure. Seal door inner panel. *NOTE*—Regulator lift arm should be in "down" position when installing regulator.

REAR DOOR WINDOW REGULATOR ASSEMBLY REMOVAL (Buick Model 43 & 63): Remove door belt finishing molding, door trim assembly, regulator attaching screw (at access hole cover) and access cover. With windows in raised position, remove two window lower sash channel screws through access hole. Lower window. Mark location of radius arm screw on door inner panel, then remove screw. Remove two window lower sash channel cam screws, disengage cam from window frame and regulator arms ***(CAUTION—After window regulator assembly is disengaged from regulator DO NOT OPERATE REGULATOR MOTOR).*** Lift window and prop in "up" position. Remove regulator attaching screws, disconnect regulator lead wires, and remove attaching screws securing lift arms to door panel. Position regulator radius arm and balance arm so that regulator assembly can be removed from door through access hole. To install, reverse removal procedure.

REAR QUARTER WINDOW REGULATOR ASSEMBLY: Remove rear quarter window ***(CAUTION—After window regulator assembly is disengaged from regulator DO NOT OPERATE REGULATOR MOTOR).*** Disconnect motor leads from wire harness, remove regulator attaching screws. Remove regulator and motor assembly through access hole. To install, reverse removal procedure. Apply medium-bodied sealer around attaching holes on quarter inner panel side of regulator.

REGULATOR MOTOR REMOVAL (WITH REGULATOR ASSEMBLY REMOVED FROM CAR): ***(CAUTION—The regulator arm which is under tension from the counterbalance spring can cause serious injury if motor assembly is removed without locking sector in position).*** Clamp regulator assembly securely in a vise so that arm is free and motor is in an upward position. Drill a ¼" hole through regulator backplate and sector at a point which will miss motor housing and teeth in sector (not closer than ¾" to edge of backing plate or sector). Insert a ¼" bolt through holes in backing plate and sector. Install nut and run up to backing plate only (DO NOT TIGHTEN NUT). Remove the three bolts attaching motor to backing plate and remove motor from backing plate. To install, reverse the removal procedure and remove temporary nut and bolt before installing assembly in door.

►***CAUTION: Motor is a sealed unit and is serviced only as an assembly and should not be disassembled.***

DOOR SWITCH ASSEMBLY REMOVAL: Remove garnish or belt finishing molding and door inside handles. Disconnect terminal block with attached wires from switch assembly by carefully pulling block to disengage it from switch studs. With a suitable tool, pry open the retaining tabs at each end of switch and remove complete switch assembly from trim pad. Remove switch from escutcheon by depressing the four tabs with a sharp pointed tool inserted through holes in end of escutcheon and prying them free.

QUARTER WINDOW SWITCH ASSEMBLY REMOVAL: Remove garnish molding and pull trim panel out slightly, then proceed as outlined for "Door Switch Assembly Removal" above.

TROUBLE SHOOTING (ELECTRICAL):

Window Will Not Operate From Immediate Control Switch, But Will Operate From Master Control Switch: Check as follows:
1) Feed wire to immediate switch.
2) Immediate control switch.
3) Motor leads from intermediate switch to motor.

Window Will Not Operate From Master Switch But Will Operate From Intermediate Switch: Check as follows:
1) Operation of master switch.
2) Motor leads from master switch to motor.

Window Will Not Operate From Intermediate Nor Master Switch. Operation of Other Windows Is Satisfactory: Check as follows:
1) Operation of intermediate and master switches.
2) Motor leads from each switch to motor.
3) Operation of motor.

Windows Will Not Operate From Master Switch But Will Operate From Intermediate Switches: Check as follows:
1) Feed wire from circuit breaker to master switch.
2) Operation of master switch.

Windows Will Not Operate: Check as follows:
1) Battery.
2) Circuit from battery to circuit breaker.
3) Circuit breaker.
4) Feed wire from circuit breaker to switches.
5) Operation of all switches.

TROUBLE SHOOTING (MECHANICAL) & CORRECTIVE MEASURES: Diagnose trouble and correct as follows:

Evidence of Pinion Gear Overtravel on Sector Gear: If check of regulator assembly reveals that motor pinion gear jammed at end of regulator sector gear, extra teeth may be filed at end of sector gear. *CAUTION*—It is important that extra teeth conform to rest of teeth to prevent recurrence of condition. Carefully check added teeth for proper fit with pinion gear teeth

►*NOTE:* On car models and windows listed below, above operation is to be performed **only** if this one operation will make regulator standard. If regulator is found to have additional defects, it should be replaced with a new regulator (Part Nos. indicated below):

Car Model & Year	Window Regulator	Regulator No. Right	Left
1954 Buick Convt.	Rear Quarter	4157308	4157309
1954 Chevrolet	Front Dr.	4157312	4157313
1954 Pontiac	Front Dr.	4157312	4157313

Extreme Sideplay of Sector Gear: If backplate or side of sector gear next to backplate shows that surfaces are contacting on any portion of travel of sector gear, assembly should be replaced (paint will be scraped off at areas of contact).

Lift Arm Pins Too Loose: If any of the lift pins (studs which retain nylon roller to regulator assembly) are loose, they should be tightened to prevent pins from falling off and disengaging window from regulator during operation. Tighten by using normal riveting procedure. If they cannot be tightened satisfactorily, replace regulator.

Nylon Rollers Binding in Channels: If rollers do not slide easily in their channels, greater clearance can be obtained by filing edge of channel or aligning channel to roller with pliers.

Bent or Distorted Regulator Backplate: Replace regulator assembly.

Lubrication: If operation noisy due to lack of lubrication between coils of counter-balance spring, lubricate between coils with a graphite grease. Lubricate all studs with a medium grade oil.

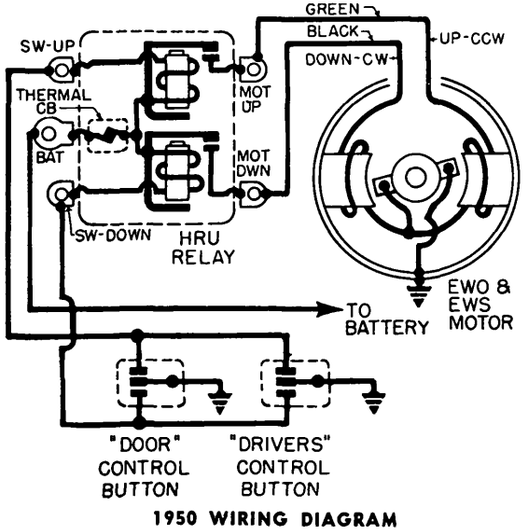
1950-53 CHRYSLER & DE SOTO ELECTRIC WINDOW REGULATORS

Chrysler (1950-53)
DeSoto (1951-53)

DESCRIPTION: Window regulators are individually powered by a reversible electric motor connected to a worm gear by flexible shaft. The motor is controlled by a two-way switch (on trim panel) and a master switch (on left front door) operating through a relay circuit breaker mounted within the door panel.

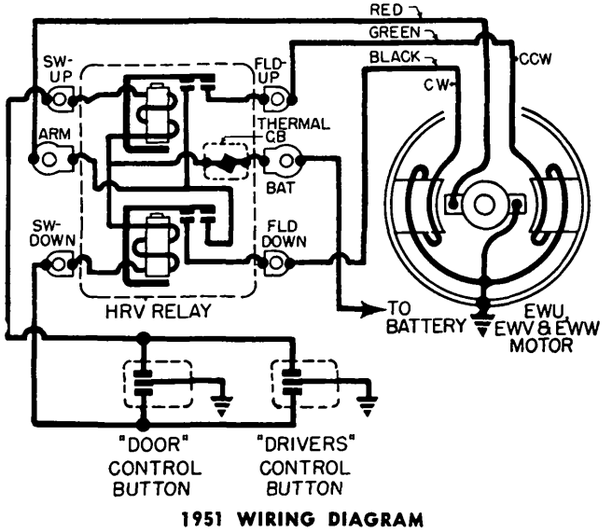
REMOVAL & INSTALLATION: Proceed as follows

Window Lift Door Switch: Chrome bezel of each switch is held in place by four springs To release bezel, depress springs through notches on side of switch After removing bezel, remove switch wires and switch. To install, reverse removal procedure using care to make sure that wire terminals are positioned away from each other



Window Lift (1950-51): Lower window and remove remote control handle, garnish moulding, arm rest & trim panel. Disconnect switch wires in trim panel, and disconnect battery terminal (NOTE—Mark wires and terminals to insure correct reassembly). Remove attaching screws and dismount relay circuit breaker bracket and relay, then disconnect the three wires from motor relay. Remove retainer and leather washer attaching regulator arm to glass channel and disconnect glass channel from regulator arm. Raise window and insert block in panel opening to retain window. Remove the four screws attaching regulator to inside of door panel and remove regulator through opening. On rear doors, remove adjusting screw from glass channel guide To re-install, install regulator assembly through door panel opening and attach regulator to inside of panel with four screws and lockwashers. On rear doors, install adjusting screw at bottom of window glass channel guide. Remove block from panel opening and lower glass. Connect regulator arm to glass channel and install retainer and leather washer. Connect RED motor lead wire to ARM terminal on relay and the GREEN and BLACK wires to FLD terminal on relay. Connect battery terminal and run window up and down using master switch on left front door. If direction of window travel does not correspond with direction indicated by switch, reverse GREEN and BLACK wires. Install relay circuit breaker and bracket in door panel opening Connect all wires to trim panel switch, connect battery terminal, install trim panel, arm rest, garnish moulding and remote control handle.

Window Lift (1952-53): Disconnect battery, remove garnish moulding, door handle control and escutcheon plate Remove arm rest and window lift control switch, then door trim panel **NOTE—Check control arm position. If control arm stud locking retainer cannot be easily reached, remove sector gear box. Lower or raise glass manually so that locking retainer can be positioned for removal. On rear doors, reach in through door lock opening, remove retainer.** Raise glass manually and prop glass so that it is out of working area. ***(CAUTION—To avoid personal injury and slipping of preload spring, install gear box to control unit immediately after lowering or raising glass.)*** Remove battery, armature and both field wires from relay, remove relay bracket attaching cap screws, remove relay Remove regulator-to-door attaching cap screws, remove regulator. To reinstall window lift, reverse removal procedure, with particular attention to following points



Relay—Be sure relay installed in position marked "down" to allow for proper drainage if water should seep under cover

Gear Box—Gear box should be reinstalled as soon as control arm clips are removed.

Pivot Arm Type Regulator—Glass and channel assembly should be perfectly lined up in glass run channel Raise and lower glass and channel assembly manually a couple of times to check for ease of operation and alignment, before control arm is finally assembled to window channel

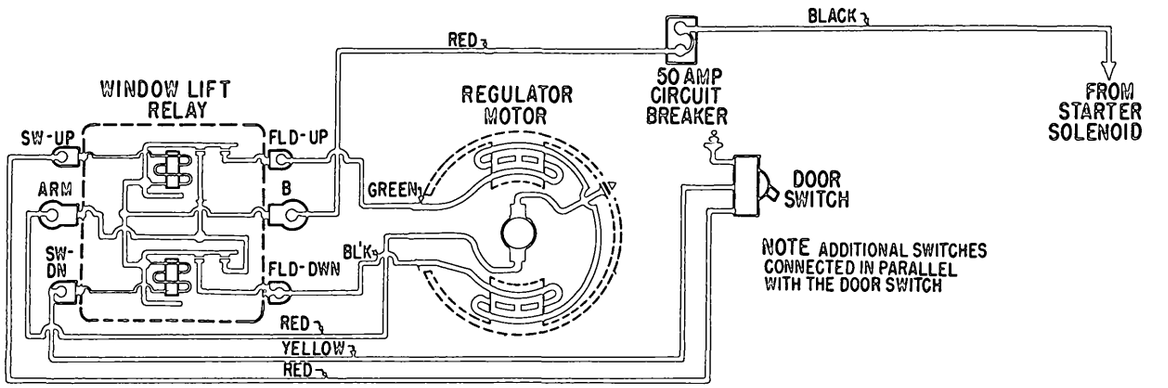
Relay Specifications—HRU, V, Z

HRU, V, Z Relays consist of two separate units, one controlling the "UP" operation and the other the "DOWN" operation. A 30 ampere thermal circuit breaker is connected between the battery terminal and relay yoke.

NOTE—HRU relay to be used with WL & WLA type window lift devices and HRV, Z relays to be used with WLB & WLC type window regulators.



Contacts Open—0 5 volts min.

Contacts Close—1.5-3.0 volts. Set by bending hinge ear.

Contact Point Gap— 026". Adjust by bending armature stop.

Armature Air Gap—.016-.020". Have contacts closed but not sealed and adjust by varying height of stationary contact.

Armature Seals to Core—4.0 volts min. Set by bending hinge ear.

1952-53 WIRING DIAGRAM

1954 CHRYSLER & DESOTO WINDOW REGULATORS

Chrysler (1954)
DeSoto (1954)

DESCRIPTION: Window regulators are individually powered by a reversible electric motor connected to a worm gear by flexible shaft. Motor is controlled by a two-way switch (on trim panel) and a master switch (on left front door) operating through a relay circuit breaker mounted within the door panel.

REMOVAL & INSTALLATION: Proceed as follows:

Window Lift Door Switch: Chrome bezel of each switch is held in place by four springs. To release bezel, depress springs through notches on side of switch. After removing bezel, remove switch wires and switch. To install, reverse removal procedure using care to make sure that wire terminals are positioned away from each other.

Window Lift: Disconnect battery, remove garnish moulding, door handle control and escutcheon plate. Remove arm rest and window lift control switch, then door trim panel. NOTE—Check control arm position. If control arm stud locking retainer cannot be easily reached, remove sector gear box. Lower or raise glass manually so that locking retainer can be positioned for removal. On rear doors, reach in through door lock opening, remove retainer. Raise glass manually and prop glass so that it is out of working area. *(CAUTION—To avoid personal injury and slipping of preload spring, install gear box to control unit immediately after lowering or raising glass.)* Remove battery, armature and both field wires from relay, remove relay bracket attaching cap screws, remove relay. Remove regulator-to-door attaching cap screws, remove regulator. To reinstall window lift, reverse removal procedure, with particular attention to following points:

Relay—Be sure relay installed in position marked "down" to allow for proper drainage if water should seep under cover.

Gear Box—Gear box should be reinstalled as soon as control arm clips are removed.

Pivot Arm Type Regulator—Glass and channel assembly should be perfectly lined up in glass run channel. Raise and lower glass and channel assembly manually a couple of times to check for ease of operation and alignment, before control arm is finally assembled to window channel.

NASH & HUDSON ELECTRIC WINDOW REGULATORS

Hudson Wasp & Hornet (1955)
Nash Ambassador & Statesman (1953-55)

►CHANGES & CORRECTIONS

►*1955 WINDOW REGULATOR PRODUCTION CHANGE:* Effective with following listed model and body Nos., a new electric window regulator and cross arm assembly has been incorporated in production in front doors of 4-door models and doors of 2-door models. Rear door and quarter regulators remain unchanged over first production units. However, two separate electrical circuits are employed, using a new relay and wiring harness.

Car Model	Model No.	Body No. Hudson	Nash
Wasp & Statesman	35545-1, 2	1228	2983
Hornet 6 & Amb 6	35565-1, 2	1690	2123
Hornet 8 & Amb. 8	35585-1, 2	2248	2651
Wasp & Statesman	35547-2	1354	1356
Hornet 6 & Amb 6	35567-2	1237	1178
Hornet 8 & Amb. 8	35587-2	1549	1320

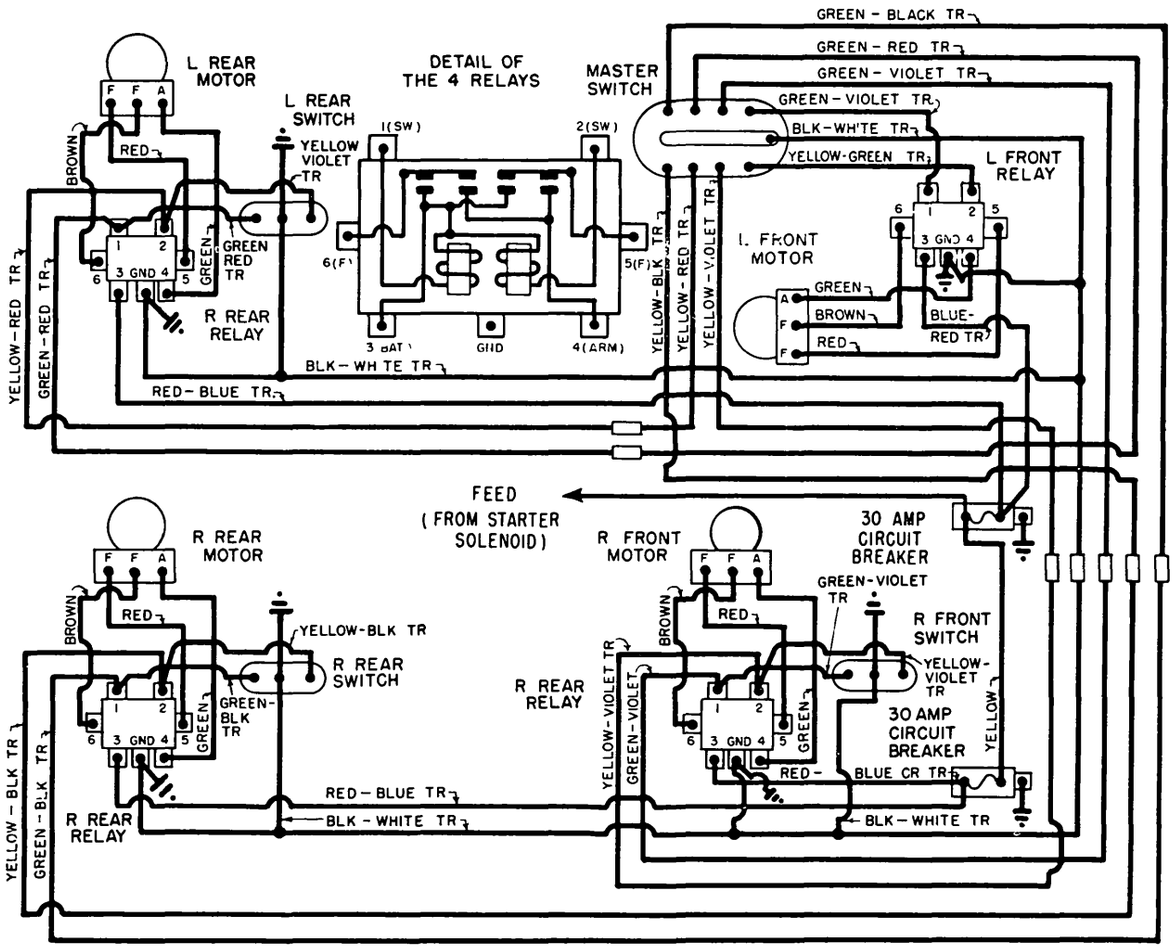
On later circuits (see "Changes & Corrections" above), all window switch circuits are directed through and protected by the 20 ampere accessory circuit breaker (30 ampere on cars with air conditioning). On these later circuits, window switches are energized by the ignition switch through the accessory circuit breaker.

DESCRIPTION: Window regulators are individually powered by a reversible electric motor connected to the window regulator and transmission assembly by a rubber coupling. The motor is controlled by a two-way switch (on trim panel) and a master multiple switch (on left front door) operating through a relay mounted within the door panel. Two 30 ampere circuit breakers, one mounted to left side of dash behind instrument panel, and the other to the right front body pillar, are in the circuits supplying current to the left and right windows respectively.

REMOVAL & INSTALLATION: Proceed as follows:

Window Lift Door Switch: Master multiple switch is held in mounting plate by four combination inner and outer retaining springs, one at top and bottom of each end switch unit. Single switches are held by two combination inner and outer retaining springs, one at top and bottom of switch. To remove, compress retaining springs by inserting pointed tools in notches between switch housing and mounting plate (on master switch—rear first then front) and with prying and pressure action remove switch. To install, insert switch springs in notches and press.

CAUTION—Inspect all terminals to see that they will not touch the door metal panel.



Individual Switches from Switch Housing—Remove ground bar from all switches in assembly. Insert pointed tool into spring retaining holes on each side of housing, compress springs, lift switch from housing. End switches can be removed in same manner by lifting end springs to expose hole. Individual door switches are retained in single housing in same manner as end switches of master control switches.

Window Regulator Assembly: *NOTE*—Procedures for removal and installation of all door window regulator assemblies on early cars differ from those for later front door (4-door models) and 2-door models. See "Changes & Corrections" above.

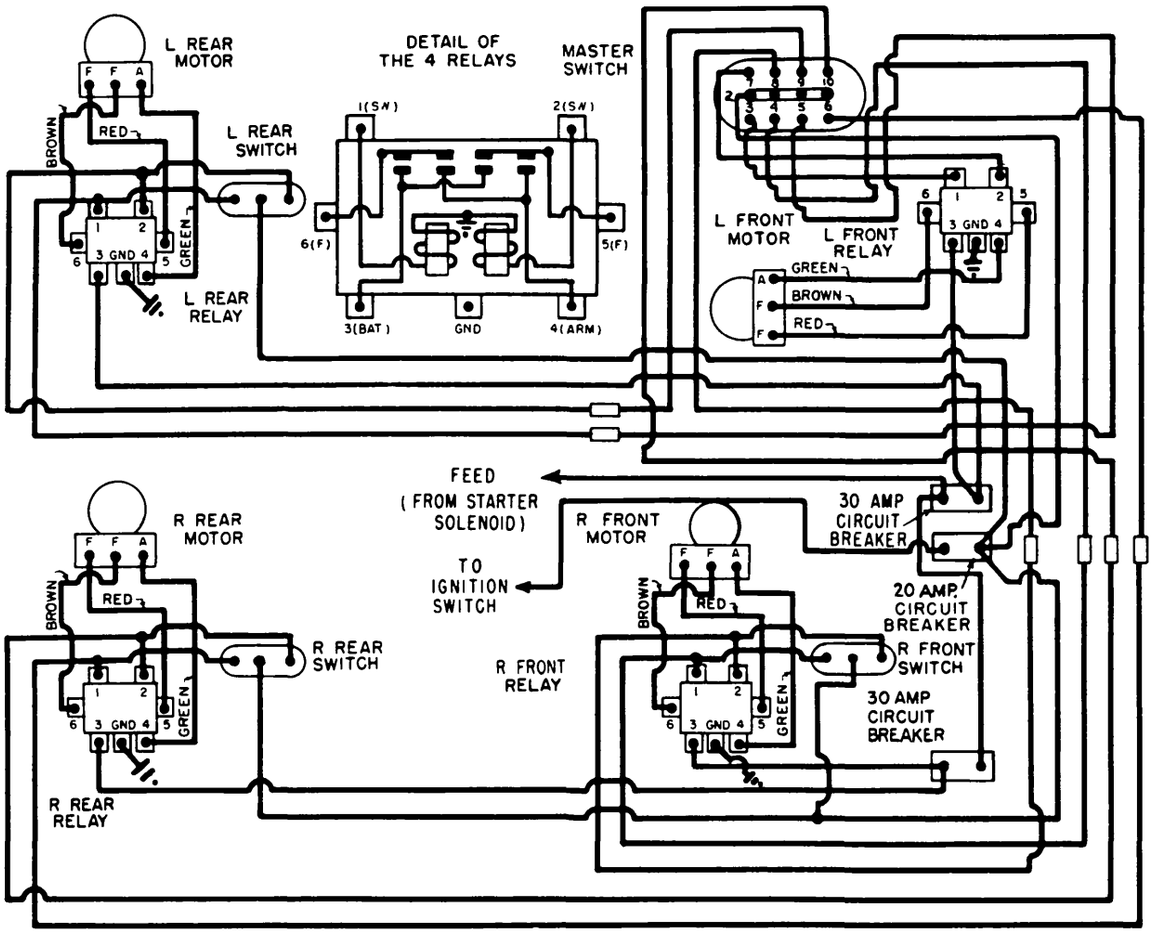
All Doors (Early Cars), Rear Doors (Later Cars)—Raise window (*NOTE*—If window cannot be raised automatically, raise it manually by turning the motor-to-transmission coupling (rubber). This operation can be performed by inserting hands through cut-outs in door panel after trim panel is removed). Disconnect battery, remove trim panel and window regulator arm-to-bottom channel retainers. Pull each arm from bottom channel and remove fibre and spring washer from arm stud. Set arm back into bottom channel (to prevent misplacement of parts). Insert wood block to support glass in raised position, remove window regulator arm screws ***(CAUTION—This arm is under spring tension and must be held firm while removing screws. Release arm carefully to prevent injury).*** Support window regulator and motor assembly to prevent falling and possible damage as regulator-to-door panel screws are removed. Door window regulator with arms in raised position can be removed or installed through front opening of door inner panel. To install, reverse removal procedure. ***CAUTION—Before regulator arms are attached to glass bottom channel, glass assembly should be raised and lowered by hand to insure free operation. Glass slide and adjusting screws control alignment of these units so that the glass will raise and lower without binding. Lubricate channel section of guide channels.***

Front Doors (Later 4-Door Models), Both Doors (Later 2-Door Models)—Disconnect battery, remove door trim panel. Disconnect regulator arm from cross arm assembly by removing key slotted retainer from grooved stud riveted in cross arm assembly. Move glass to fully raised position. Remove relay from door inner panel and disconnect motor-to-

CONTINUED ON NEXT PAGE

1953-EARLY 1955 NASH & EARLY 1955 HUDSON WINDOW REGULATOR WIRING DIAGRAM

NASH & HUDSON ELECTRIC (Cont.)



relay wires Remove regulator-to-door screws and remove assembly through large opening in panel To install, reverse removal procedure and note the following Before reinstalling, glass should be raised and lowered by hand to insure free operation, cross arm and regulator moving parts must be lubricated with Lubriplate Door glass should be moved down to align hole in end of regulator arm with stud in cross arm assembly. Install spring washer, then fibre washer to stud, install arm onto stud and fasten with retainer A rubber bumper is inserted into cross arm slide which acts as a glass stop when glass is in down position

Window Regulator Assembly (Rear Quarter): Disconnect battery, remove rear seat cushion and back assembly. Remove switch from trim panel and disconnect wires. Remove armrest trim panel and finish moulding. After trim panel parts removed, particular attention should be given to the removal of the sealing tape and putty so that when resealing is being done, no seams are left unsealed (to prevent entry of water). Mark window regulator panel and adjoining pillars at two or three places on each side and at bottom to permit ready adjustment of regulator at reinstallation. Remove guide channel fastening-to-body bracket screw and window regulator bracket-to-panel screws. Then remove all screws holding window regulator panel to body. Remove complete assembly after disconnecting relay wires (complete assembly can be turned around without disconnecting wires should operation of the regulator and the guide channel require inspection or the glass assembly be removed). To install, reverse removal procedure. NOTE—Regulator arms must move freely in bottom channel and regulator panel Also, bottom channel studs must move freely in the channel section of the guide channel. Check for proper clearances and lubricate with lubriplate.

Window Regulator Transmission Assembly: *NOTE*—Transmission assembly used on front doors of later 4-door models and doors of later 2-door models differs from that used on all doors of early models See "Changes & Corrections" above Quarter window transmission assemblies remain unchanged.

All Doors (Early Cars), Rear Doors (Later Cars), Quarter Windows (All Cars)—Remove the window regulator assembly, then move regulator arms to fully lowered position. Then remove three screws holding transmission assembly to window regulator assembly (screws are inserted through window regulator from gear side and screwed into threaded sections of transmission cover). NOTE—When window regulator-to-transmission screws are removed, transmission cover is loosened and may loosen cover gasket causing leakage of lubricant In this event, inspection should be made to see that all transmission gears have a coating of lubricant. When transmission is reinstalled to regulator, **a new cover gasket should be used.**

Front Doors (Later 4-Door Models), Both Doors (Later 2-Door Models)—(*NOTE*—Transmission housing is integral with motor housing). Remove window regulator assembly. Place regulator and motor assembly in a vise. Loosen three bolts that secure motor and transmission assembly to bracket on regulator assembly so that bolt ends do not protrude beyond anchor plate, to provide space for moving motor outward. (*CAUTION*—Regulator sector gear is under spring tension and must be held to prevent injury when disengaging pinion gear from sector). Hold regulator and move motor and transmission assembly away from regulator far enough to disengage pinion gear from sector ***Release spring tension gradually.*** Then remove cam plate assembly from regulator.

LATE 1955 HUDSON & NASH WINDOW CONTROL WIRING DIAGRAM

WINDOW LIFT MOTOR: Different motors used as follows.

Windows	Hudson & Nash Part No.
All—Early Cars①	4377198
Rear Doors & Quarters—Later Cars①	4377198
Front Doors—Later 4-Door Models①	4476024
Both Doors—Later 2-Door Models①	4476024

①—See "Changes & Corrections" above.

Specifications

Torque	R.P.M.	Volts	Amperes
35 ft .ozs. min.	3200	5 5	42 max.
90.02 ft. ozs. min.	Lock	5.5	115 min.

Shaft End Play—.005-.015".

Color Code—Red and Green Wire to one side of line with opposite side of line grounded for **clockwise rotation** (shaft end); Brown and Green Wire to one side of line with opposite side of line grounded for counter-clockwise rotation (shaft end).

1953-54 FORD, LINCOLN, MERCURY ELECTRIC TYPE

Ford (1954)
Mercury (1952-54)
Lincoln (1952-54)

►***WINDOW REGULATOR ASSEMBLY INTERCHANGEABILITY:*** Two types of electric window regulator assemblies used, "A" and "B." The two assemblies are interchangeable but "B" type only furnished for service. Installation of the two types is different (See Installation below). Arm and plate assembly not an integral part of "A" type but is integral on type "B".

DESCRIPTION: Window regulators are individually powered by a reversible electric motor which operates gear sectors through pinion or worm gears. Motor is controlled by a two-way switch (on trim panel) and a master switch (on left front door) operating through a relay circuit breaker mounted in door panel.

REPLACEMENT ELECTRICAL UNITS: As indicated below:

Window Lift Motor

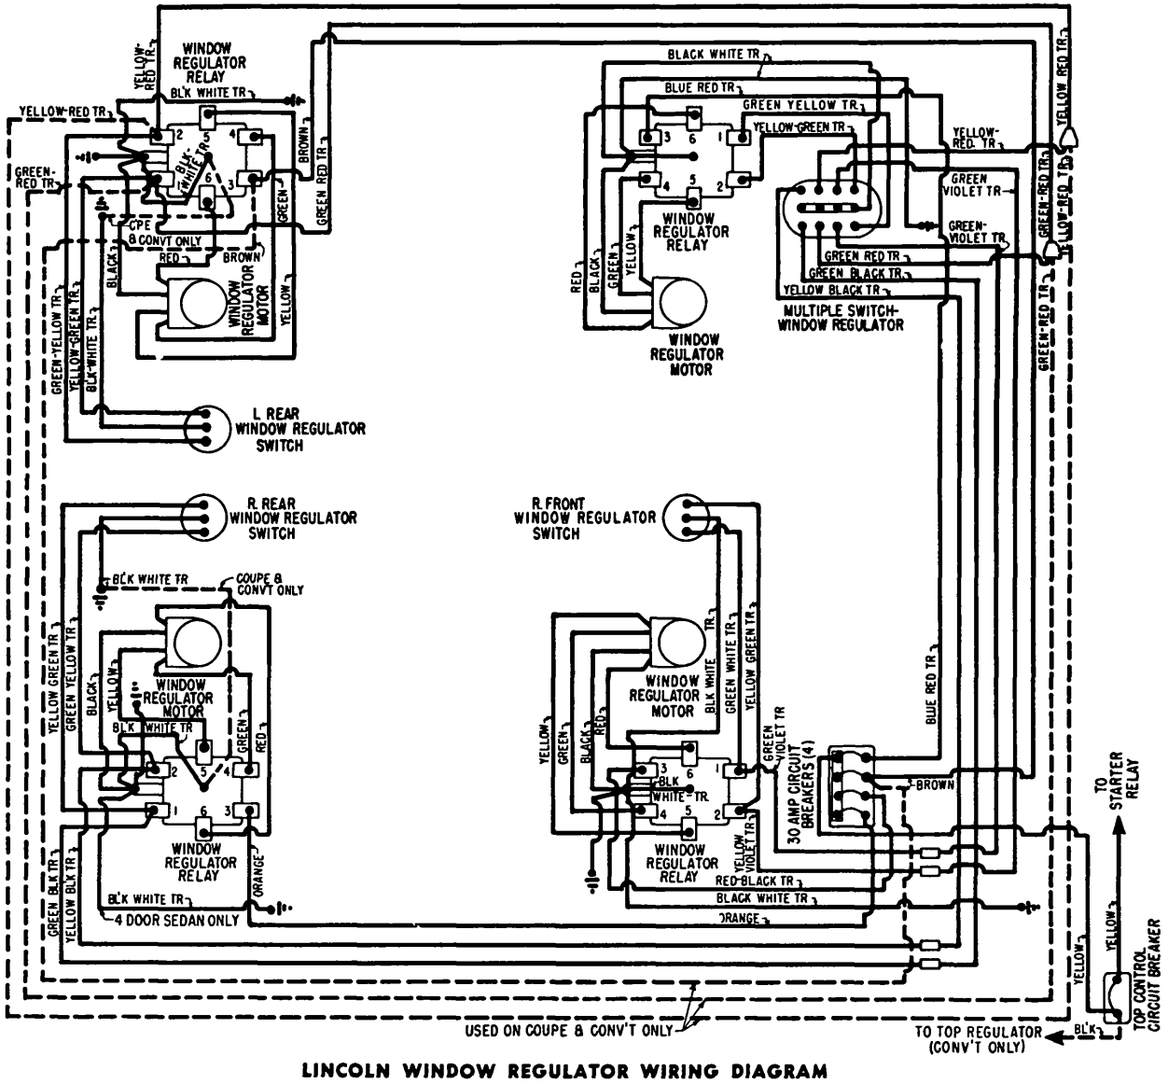
	Part No.
Type "A"—Right Hand①	FAA-14549-A
Type "A"—Left Hand①	FAA-14553-B
Type "B"—Right & Left Hand②	FAA-14553-A

①—Bracket mounted on window regulator.
②—Stud mounted on window regulator.

Window Control Switches

Single	FAA-14529-A
Multiple	FAA-14540-A

Window Control Relay



All Models	FAA-14512-A

REMOVAL: Proceed as follows:

Window Lift Door Switch: Lower window glass as far as possible by operating switch on door, then disconnect ground cable from positive battery terminal post. Pry switch from trim panel, remove wires from switch. To install reverse removal procedure.

Arm & Plate Assembly (Type A Front Door): Disconnect battery ground (positive cable) to prevent shorts. Remove two screws that secure arm rest to door panel, remove arm rest Remove inside handles by pressing escutcheon plate or trim panel inward exposing spring type retainer. While holding escutcheon plate or trim panel in this inward position, release the retainer with Tool 21812 and remove the handle. Remove inside lock button. (On Mercury Model 73B, remove the six sheet metal screws along upper edge of door that secure upper garnish moulding to door. Remove garnish moulding. ***Note order in which screws were removed and replace in same order.*** Then remove four sheet metal screws on front door, that secure lower garnish to door. Remove lower garnish moulding. ***Note order in which screws were removed and replace in same order).*** On other models remove garnish moulding. With window glass in closed position, disconnect ground cable from positive battery terminal post. Remove the wires from the switch, and remove switch from trim panel. Remove two sheet metal screws and washers from lower edge of trim panel, pry trim clips free along sides of door, lift up trim panel and remove. Remove inside panel cover plate. Remove two cap screws that secure window stop to inner door panel, remove stop. Lower window to open position, remove two spring type retainers that secure glass channel rollers to arms. Remove rollers from arms. Raise window glass to closed position; wrap several strips of masking tape over top of door and stick the ends to each side of the glass to hold glass in closed position. Remove spring retainer that retains regulator arm to arm and plate assembly. Remove three cap screws that secure arm and plate to inner door panel. Slide assembly toward

CONTINUED N NEXT PA E

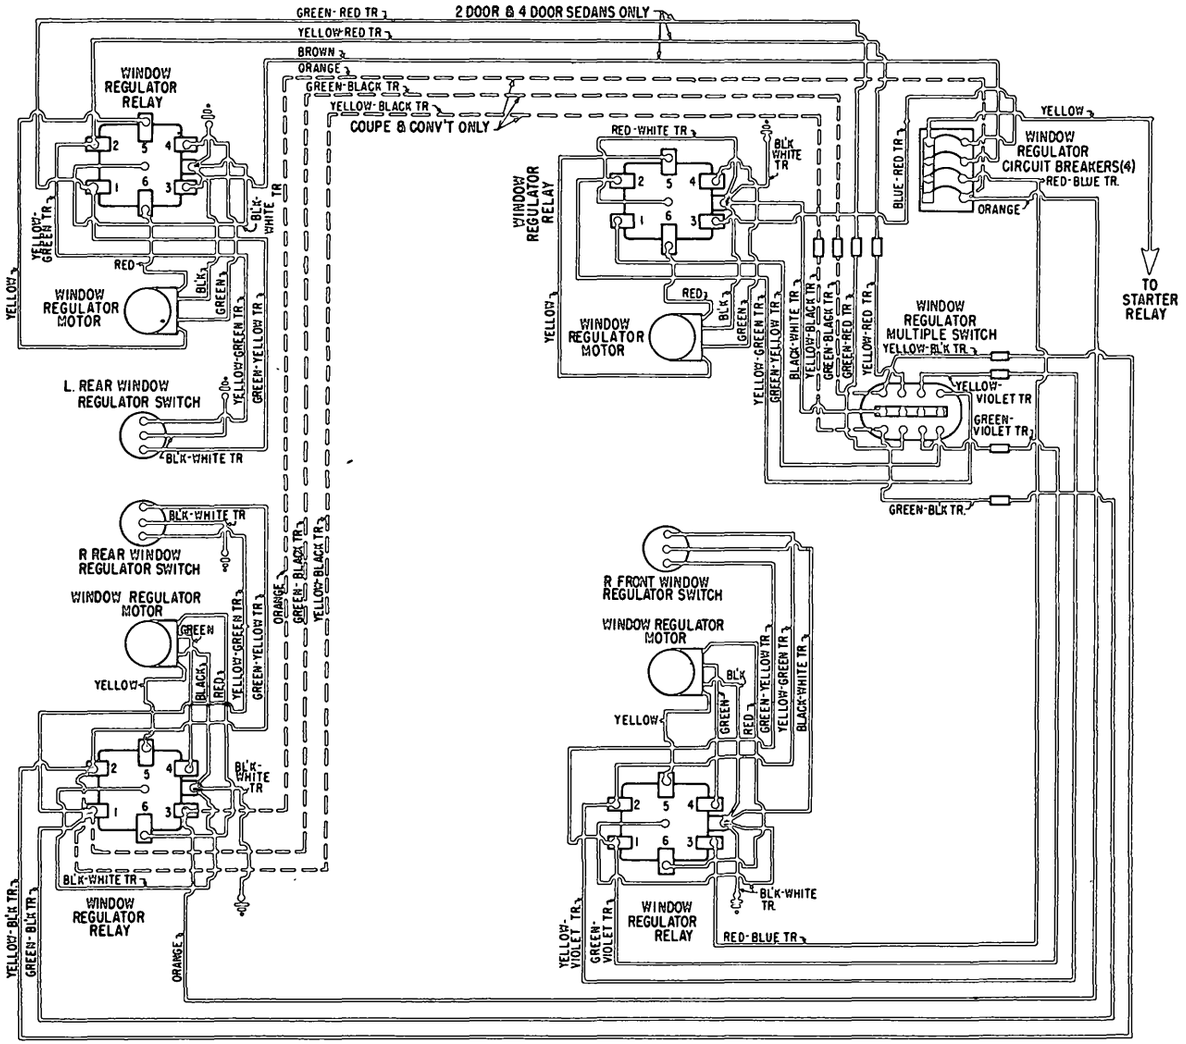
LINCOLN WINDOW REGULATOR WIRING DIAGRAM

1953-54 FORD, LINCOLN, MERCURY ELECTRIC (Cont.)

regulator to release roller from guide on inner door panel. Lower assembly and remove through door access hole.

Window Regulator Assembly (Type A Front Door): Remove trim panel, inside panel cover plate, window stop, window glass, and spring retainer. Remove four cap screws that secure regulator assembly to inner door panel. Lower assembly and remove through access hole. Remove cover plate with relay attached and disconnect wires from motor to relay.

Motor & Bracket Support Assembly (Type A Front Door): Remove trim panel cover plate, window stop, window glass, spring retainer, and vent window glass. Remove window regulator assembly (above). Clamp window regulator assembly tightly in vise and unload spring by pulling hooked end away from, and up over stop. Remove three screws and lockwashers holding motor and bracket support to regulator assembly, remove motor and gasket. Remove cover and shaft from motor and bracket support. Remove coupling and pinion and shield assembly from regulator assembly.



Window Regulator Assembly (Type B Front Door): Remove trim panel, inside panel cover plate, window stop, window glass, spring retainer, and vent window glass. Remove four cap screws that hold window regulator assembly to inner door panel. Lower assembly and remove through access hole. Remove cover plate with relay attached, disconnect wires from motor to relay.

Motor Assembly & Coupling (Type B Front Door): Remove trim panel and inside cover plate. Remove two attaching nuts and washers which hold motor to window regulator assembly. Remove motor and rubber drive coupling through access hole. Remove cover plate with relay attached and disconnect wires from motor to relay.

Drive Assembly (Type B Front Door): Remove trim panel, inside panel cover plate, window stop, window glass, spring retainer, and vent window glass. Remove three cap screws that hold window regulator assembly to inner door panel. Lower assembly and remove through door access hole. Remove cover plate with relay attached. Disconnect wires from motor to relay. Clamp window regulator assembly tightly in vise, and unload spring by pulling hooked end away from, and up over stop. Remove three cap screws and lock washers holding drive assembly to window regulator mechanism, remove drive assembly.

Window Regulator Mechanism (Type A Rear Door): Remove trim panel, inside panel cover plate, window stop and window glass. Remove six cap screws that secure window regulator to door panel. Remove bracket with relay attached. Lower assembly and remove through access hole. Disconnect wires from motor to relay. Clamp window regulator assembly tightly in vise, unload spring by pulling hooked end away from, and up over stop. On Mercury, remove three screws and lockwashers holding motor and bracket support to regulator assembly, remove motor and gasket. Remove coupling, and pinion-shield assy. from regulator assembly.

Window Regulator Mechanism (Type B Rear Door): Remove trim panel, inside panel cover plate, window stop, and window glass. Remove four cap screws that secure window regulator to door panel.

FORD & MERCURY WINDOW REGULATOR WIRING DIAGRAM

Slide regulator arm off track, lower assembly and remove through access hole. (NOTE—Position of wires connecting relay and door switch within door panel is for ease of assembly.) Remove bracket with relay attached. Disconnect wires from motor to relay. Clamp window regulator assembly tightly in vise, unload spring by pulling hooked end away from, and up over stop. Remove two attaching nuts and washers which hold motor to window regulator assembly. Remove motor and rubber drive coupling. (NOTE—Motor and drive coupling may be removed through access hole without removing window regulator assembly.) Remove three cap screws and lockwashers holding drive assembly to window regulator mechanism, remove drive assembly.

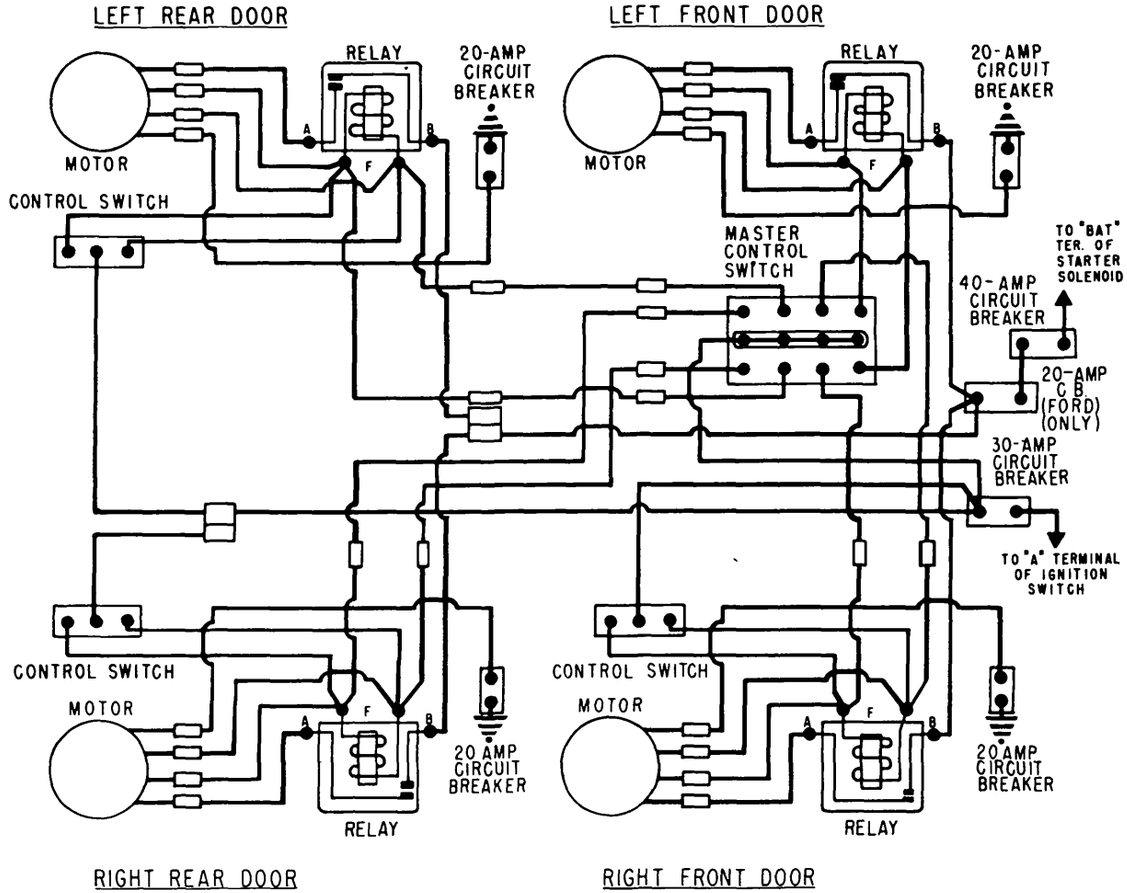
Quarter Window Regulator: Remove rear seat cushion, and rear seat back cushion. Pry cover off assist strap, remove assist strap screw, then assist strap. Remove seven sheet metal screws that secure garnish moulding to quarter panel, remove garnish moulding. Remove two screws that secure quarter arm rest, remove arm rest. Pry trim clips free along front edge of trim panel, remove trim panel. Remove two cap screws that secure quarter window stop to quarter window regulator panel, remove stop. Lower window as far as possible. Remove two spring type retainers that secure glass channel rollers to window regulator arms, remove rollers from arms. Window glass is now free and can be lowered to bottom of quarter panel. Remove four cap screws that secure regulator assembly to quarter window regulator panel. Disconnect wires from motor to relay, remove regulator assembly.

INSTALLATION: Reverse removal procedures.

1955 FORD, LINCOLN, MERCURY

Ford (1955)
Lincoln (1955)
Mercury (1955)
Thunderbird (1955)

►CHANGES, CAUTIONS, CORRECTIONS



►*1955 CIRCUIT BREAKER PRODUCTION CHANGE (To Correct Overload Burn-out):* Circuit breakers, Part Nos. 1A-14526 or 1A-14526-A (40 amps.) and FDH-14526-A2 or B5A-14526-A (30 amps.) have been modified to include a copper-colored rivet in center of base between studs. This change will accommodate the necessary overloads of the system. Circuit breakers (Early type) with white (cadmium) colored rivets in stock should be checked before installation, as follows: Connect a pair of wire leads three feet long (10 gauge for 40 amp. circuit breaker, 12 gauge for 30 amp. circuit breaker) to terminals on circuit breaker. Connect other end of leads to terminals of a fully charged battery (80% charged throughout test). Defective breakers will fail within approximately ten seconds. Failure of breaker will be evidenced by an audible click and lack of sparking after jumper wires are touched to terminals. Failure may also be evident by a rattle of breaker arm inside case. A good circuit breaker will open and close repeatedly for a period of four hours minimum.

►*1955 WINDOW LIFT SWITCH REPLACEMENT CAUTION:* Window switches used on 1955 models are identical in appearance, but are constructed differently. Switches used in Ford and Mercury circuits have silver-plated points in order to provide a minimum resistance, while those used in Lincoln circuits have copper-plated points which, if used in Ford and Mercury circuits, would offer too great a resistance and greatly lower efficiency of the motor. See "Window Control Switches" table below.

►*1955 FORD & MERCURY WINDOW LIFT RELAY PRODUCTION CHANGE:* Window Lift Relay, Part No. B5A-14512-A, has been modified in production to include a molded plastic base. Part No. remains unchanged but new relay is identified by new base. Old relay had stamped base. Replacement should be with new type relay.

►*1955 FORD & MERCURY WINDOW LIFT RELAY & MOTOR FAILURE CORRECTION (When Due to Water Damage):* The following procedure should be used to correct replacement relays not dipped in waterproof plastic and motors not covered with a plastic shroud: On relays, place vinyl tape, No. M-6478-A, or a good grade of plastic electrical tape on lower edge of relay so that approximately ⅛" overlaps bottom face of the plastic base. The motor may be satisfactorily protected by wrapping it with plastic shroud, Part No. FDL-14484-A, and holding shroud in place with rubber band.

►*1955 FORD WIRING HARNESS INTERFERENCE WITH DOOR CHECK ARM CORRECTION:* On all cars, except Thunderbird, wiring harness leading to each front door should be checked for interference with door check arm inside door. If harness too close or resting on check arm, harness must be removed and moved away from check arm. Unclip harness at opening normally used for manually operated window. Raise harness to next hole and install clip.

FORD & MERCURY WINDOW CONTROL WIRING DIAGRAM

►*1955 FORD WINDOW LIFT RELAY "FLUTTER" CORRECTION:* If "flutter" or rapid clicking sound noted, proceed as follows: Check door glass alignment. If glass has noticeable sag at rear corner as glass is raised, adjust regulator in elongated holes in inner panel (three holes are on face of inner panel; other hole can be reached through access hole in inner panel) On some early production Thunderbirds it may be necessary to elongate four mounting holes approximately ¼" downward to eliminate sagging condition. If clicking noise continues, relay should be replaced.

DESCRIPTION: Window regulators are individually powered by a reversible electric motor which operates gear sectors through pinion or worm gears. Motor is controlled by a two-way switch (on trim panel) and a master switch (on left front door) operating through a relay circuit breaker mounted in door or quarter panel.

REPLACEMENT ELECTRICAL UNITS: As indicated below:

Window Lift Motor

	Part No.
Ford & Mercury, Type "B"	B5S-14553-A
Lincoln, Type "B"	FAA-14553-B

Window Control Switches

Ford & Mercury, Single	B5A-14529-A
Lincoln, Single	FAA-14529-A
Ford & Mercury, Multiple	B5A-14540-A
Lincoln, Multiple	FAA-14540-A

Window Control Relay

Ford & Mercury	B5A-14512-A
Lincoln	FAA-14512-A

TROUBLE SHOOTING: Diagnose trouble as follows:

Window Will Not Operate From Either Master or Window Switch: Shorted or open lead from starter solenoid; broken ground connection to relay; shorted or open armature or field coil windings.

Window Will Go Up But Not Down, or Down But Not Up When Either Switch Is Activated: Shorted or open coil in relay; loose connections or open motor control circuit.

CONTINUED ON NEXT PAGE

1955 FORD, LINCOLN, MERCURY (Continued)

Window Operation Is Sluggish & Noisy: Motor brushes chipped or improperly seated; excessive armature end play; insufficient clearance between armature and field coils.

REMOVAL: Proceed as follows:

Window Regulator Assembly (Type B Front Door): Remove trim panel, inside panel cover plate, window stop, window glass, spring retainer, and vent window glass. Remove four cap screws that hold window regulator assembly to inner door panel. Lower assembly and remove through access hole. Remove cover plate with relay attached, disconnect wires from motor to relay.

Motor Assembly & Coupling (Type B Front Door): Remove trim panel and inside cover plate. Remove two attaching nuts and washers which hold motor to window regulator assembly. Remove motor and rubber drive coupling through access hole. Remove cover plate with relay attached and disconnect wires from motor to relay.

Drive Assembly (Type B Front Door): Remove trim panel, inside panel cover plate, window stop, window glass, spring retainer, and vent window glass. Remove three cap screws that hold window regulator assembly to inner door panel. Lower assembly and remove through door access hole. Remove cover plate with relay attached. Disconnect wires from motor to relay. Clamp window regulator assembly tightly in vise, and unload spring by pulling hooked end away from, and up over stop. Remove three cap screws and lock washers holding drive assembly to window regulator mechanism, remove drive assembly.

Window Regulator Mechanism (Type B Rear Door): Remove trim panel, inside panel cover plate, window stop, and window glass. Remove four cap screws that secure window regulator to door panel. Slide regulator arm off track, lower assembly and remove through access hole. (NOTE—Position of wires connecting relay and door switch within door panel is for ease of assembly.) Remove bracket with relay attached. Disconnect wires from motor to relay. Clamp window regulator assembly tightly in vise, unload spring by pulling hooked end away from, and up over stop. Remove two attaching nuts and washers which hold motor to window regulator assembly. Remove motor and rubber drive coupling.

Quarter Window Regulator: Remove rear seat cushion, and rear seat back cushion. Pry cover off assist strap, remove assist strap screw, then assist strap. Remove seven sheet metal screws that secure garnish moulding to quarter panel, remove garnish moulding. Remove two screws that secure quarter arm rest, remove arm rest. Pry trim clips free along front edge of trim panel, remove trim panel. Remove two cap screws that secure quarter window stop to quarter window regulator panel, remove stop. Lower window as far as possible. Remove two spring type retainers that secure glass channel rollers to window regulator arms, remove rollers from arms. Window glass is now free and can be lowered to bottom of quarter panel. Remove four cap screws that secure regulator assembly to quarter window regulator panel.

INSTALLATION: Reverse removal procedures.

1946-51 Oldsmobile, All Series
1952-Early 1954 Oldsmobile, Super 88 & 98. See Note below.
1948-54 Packard

▷Oldsmobile Super 88 Note—*For type used without window and seat control see separate "Hydro-Lectric Type (Without Window & Seat Control)" for data.*

▷PRODUCTION CHANGE: Two different pumps have been used, a low pressure pump (200-210 p.s.i.), and a high pressure pump (250-260 p.s.i.). These pumps can be identified by relief valve plug at rear of pump: low pressure has cadmium plated plug, high pressure a copper plated plug.

DESCRIPTION: This type control consists of electric pump with direct-connected hydraulic pump which supplies fluid under pressure to two double-acting hydraulic cylinders which raise and lower the top. Motor operation and directional control (to raise or lower top) is controlled by a button on the instrument panel. Top design is conventional with top bows and side-irons modified for power actuation. On cars listed above, motor is not reversible and selective control (to raise or lower top) is secured by use of a hydraulic valve by which the fluid is directed to the bottom of the hydraulic cylinders (to raise the top), or to the top of the cylinders (to lower the top). Opposite end of cylinder is vented to fluid reservoir through valve.

Power Unit—Consists of motor, hydraulic pump, and fluid reservoir assembly on front of dash with magnetic motor switch on side of motor and thermostatic relay type circuit breaker (for motor circuit protection) is mounted near the motor. This unit is same as type used for Window & Seat Control on some of these cars.

Top Control Valve & Switch—Either a double solenoid type valve located under seat and controlled by self-centering switch located below instrument panel or a combination switch and distributing valve located on inside of dash panel. With the under-seat type valve solenoids operate valve to direct flow of fluid, under pressure, to either upper or lower ends of top lift hydraulic cylinders. Solenoid switch also actuates solenoid switch controlling power unit. With dash-mounted type valve, moving switch control from the center position starts power unit and directs flow of fluid to either top or bottom of hydraulic top lift cylinder.

Power Cylinders—Double acting type, two used. Mounted on each side of car body, at rear, with piston rod linked to top mechanism. Cylinders are mounted on pivot bracket to permit rocking action as top is raised and lowered and the hydraulic tubing is looped at the pivot to permit this movement. Cylinders are plain piston type and cylinder ends are crimped in place to provide a fluid tight assembly (upper end rubber piston rod seal and also provides bearing for piston rod).

NOTE—Cylinders are "vented" type, making the periodic changing of hydraulic fluid necessary. Water and other foreign matter will cause sludging and deterioration of fluid. (See Draining & Refilling.)

ADJUSTMENT (TOP CONTROL): No adjustment required other than adjustment of control rod to provide proper operation of the control valve.

Control Valve Rod Adjustment (Dash-mounted Valve Type)—Control valve rods should be set to provide 1/8" over-travel in each direction. To adjust, loosen setscrew holding control rod in control valve lever, position control rod so that distance from ferrule on control support bracket at instrument panel to forward end of control rod knob (this is distance along shaft from bracket ferrule to knob) is 1 3/32" maximum, tighten operating valve setscrew. NOTE—If control rod is not long enough to permit this adjustment, rod can be lengthened by removing retaining nut at bracket, and removing entire control rod assembly from the bracket. Clamp control rod securely in vise, loosen locknut and unscrew control knob assembly from rod as necessary.

ADJUSTMENT (CONVERTIBLE TOP) EXCEPT FORD, LINCOLN & MERCURY: If top not correctly positioned in up or down position, adjust as follows:

Forward-and-Backward Adjustment (Clearance at windshield header when top up)—If top is too far forward or does not move far enough forward to permit windshield header dowels to enter dowel holes in roof rail, adjust as follows: Raise top slightly above windshield header, loosen attaching bolts in corner braces at front end of side roof rail, move front roof rail forward or backward to align dowels and dowel holes (attaching bolt holes are slotted to permit this adjustment), tighten attaching bolts.

Up & Down Adjustment (Clearance at top of door and quarter window)—If side roof rail too high or too low when top is up, unlatch top at windshield and raise top approximately halfway. Remove rear seat cushion and back, and quarter trim panel, loosen three plate attaching screws in top adjusting plate at rear quarter section of body, move adjusting plate down to raise side roof rail or up to lower side roof rail (attaching screw holes are slotted to permit this adjustment).

PACKARD NOTE—For above adjustment, loosen 3 retaining nuts which are accessible without removing rear quarter trim panels.

Folded Top Position Adjustment—If top does not contact bumper in each side of top compartment when lowered, loosen attaching screws in top adjusting plate (see Up-and-down adjustment above), and move plate to rear slightly but do not raise or lower the plate. Moving plate to rear will allow top to lower further into the top compartment.

Side Rail Center Hinge Hump or Sag Adjustment (on Packard)—If side rail humped or sagged above door window, adjust by means of slotted screws at

CONTINUED ON NEXT PAGE

HYDRO-LECTRIC TOP CONTROL (WITH HYDRAULIC WINDOW & SEAT CONTROL) (Cont.)

rear quarter of body (provide stop for short curved arm at this point). Turning screws in moves top away from window, turning screws out removes gap at windows.

ADJUSTMENT (CONVERTIBLE TOP) FORD, LINCOLN & MERCURY: Adjust as follows:

Header Bracket Adjustment (Ford)—Raise top slightly to relieve strain on top material. Pry weatherstrip out of retainer along bottom of front side rail assembly. Remove screws at header bracket. Move header forward or backward to align header with windshield frame or to remove excess slack from top material. Tighten screws at header bracket. Re-install weatherstrip. NOTE—It may be necessary to relocate hole in front side rail at forward end of weatherstrip retainer in order to install self-tapping screw.

Header Bracket Adjustment (Lincoln & Mercury)—Loosen cap screws securing top slot iron side rail-to-header bracket to front side rail. With header assembly in proper position over dowels on windshield header, slide side rail forward or backward as required. Tighten cap screws. Then readjust tension of side rail by loosening nut and bolt passing through serrated nut at pivot bracket. Move balance link up or down as required, position serrated nut, tighten bolt and lock nut.

Front & Rear Side Rail Adjustment (Ford)—If top has sagged between front and rear side rails directly above door glass, it can be corrected as follows: First check stop screw at rear control link to make sure it is properly adjusted. This can be determined by fastening top down and checking position of stop screw. Assuming side rails are not sagged or bowed, stop screw should be adjusted so that it just contacts rear control link. If side rails are bowed, turn stop screw counterclockwise to lower side rails. If side rails sag, turn stop screw clockwise to raise side rails. *(NOTE—If side rails are sagged and the stop screw does not contact rear control link, it is necessary to adjust the balance link as follows).* Raise top above windshield until tension is removed from balance link. Place block between header and windshield frame to hold top in raised position. Loosen shoulder bolt at lower end of balance link, allowing balance link to slide downward in slot provided in main pivot bracket. If balance link does not move in slot of own weight, pull balance link down by hand about ¼", then tighten shouldler bolt, remove block and fasten top down. Check for sag at front and rear side rails after adjustment made. If necessary repeat above procedure until sag has been eliminated. *NOTE—Pay particular attention to stop screw at control link. If necessary, readjust after making balance link adjustment.*

Front & Rear Side Rail Adjustment (Lincoln & Mercury)—To obtain proper spacing between side rails and window frames, loosen locknut holding adjusting screw located at rear control link.. Turn screw counterclockwise to raise side rail or clockwise to lower rail.

Main Pivot Bracket Adjustment (To maintain Proper Clearance Between Pillar Rail and Quarter Window)—Proceed as follows:

Ford—If quarter window binds along top of pillar rail when it is lowered, loosen all screws that secure main pivot bracket to body. Raise main pivot bracket just enough to eliminate bind at quarter window. When raising main pivot bracket, use spacers under main pivot bracket at rear mounting screws to prevent tilting the bracket when tightening the screws. If necessary, repeat adjustment at other main pivot bracket. If complete top assembly requires shifting toward front or rear of body, loosen all the mounting screws at both main pivot brackets. Shift top assembly to desired position and tighten mounting screws. *CAUTION—Use care, when making above adjustment, to avoid disturbing "up" and "down" adjustment.*

Lincoln Model EL 76 & Mercury—Loosen cap screws (5) holding main pivot bracket to body. Move bracket forward or rearward as required to obtain proper spacing. If necessary, use shims at rear cap screws. Tighten cap screws securely.

Lincoln Model EH 76—Loosen lock nut securing adjusting screw located forward and at top of main pivot bracket. Turn adjusting screw clockwise to increase space between pillar rail and quarter window frame, and counterclockwise to decrease space. Tighten lock nut securely.

REMOVAL: Units can be removed for replacement or repair as follows:

Power Unit—(Removal, Disassembly, Reassembly & Installation)—*See "HYDRO-LECTRIC" WINDOW & SEAT REGULATORS.*

Control Valve—Disconnect battery cable as a safety precaution. Disconnect control rod at operating lever by removing setscrew. Disconnect two switch wires. Disconnect hydraulic tubing and cap ends of tubing (CAUTION—fluid is inflammable—soak up spilled fluid with absorbent cloths). Remove screws holding valve on mounting bracket.

Top Control Hydraulic Cylinders—Remove nut on bolt linking piston rod to top mechanism while top is up, but do not remove the bolt. Lower the top and disconnect battery cable. Remove rear seat cushion and back, remove rear quarter trim panel assemblies. Disconnect hydraulic tubing at hydraulic cylinder, and cap tubing ends. Remove bolt linking piston rod to top mechanism, take out clevis pin and remove lower mounting bolt from anchor plate. Work cylinder back and forth until free from mounting bracket, lift cylinders out.

NOTE—It may be necessary on some cars to disconnect hydraulic cylinder tubing at body "T" or at solenoid valve. In that case, remove cylinder and tubing as an assembly.

Top Control Hydraulic Valve (Under-seat Type)—Remove rear seat cushion, disconnect positive battery cable, and disconnect wiring at valve. Disconnect tubing at valve and cap the ends. Soak up any fluid that leaks out. Remove screws attaching valve to floor pan.

DRAINING AND REFILLING: *See "HYDRO-LECTRIC" WINDOW & SEAT REGULATORS.*

PRESSURE REGULATOR VALVE: Pressure in system controlled by combination maximum pressure relief and flow control valve in the power unit.

►*CAUTION*—**Two different valves used: Check color of relief valve plug at rear of pump.**
1—Cadmium plated plug. Valve set for maximum pressure of 210 lbs. for use with low pressure pump.
2—Copper plated plug. Valve set for maximum pressure of 260 lbs. for use with high pressure pump. See PRODUCTION CHANGE NOTE above.

These valves are not interchangeable.
NOTE—If plug removed and washers are used under plug, these same washers must be reinstalled on reassembling plug.

TROUBLE SHOOTING: Failure of any part of the power system can result from three major classes of failure, namely: Mechanical, Electrical or Hydraulic. Before doing any work on the electrical or hydraulic systems, it is advisable to make sure the fault is not mechanical.

Top Will Not Operate—
Mechanical interference due to luggage or other objects; hold-down straps not removed, or top not free from windshield header studs.
Electrical shorts or loose connections in control switch circuit; dirty control switch contacts; inoperative power unit motor.
Hydraulic fluid low; power unit pump inoperative; stoppage in fluid lines; faulty control valve; broken port plate in pump.

Top Operates in One Direction Only—
Mechanical interference, same as above.
Electrical shorts or loose connections in control switch circuit; dirty control switch contacts; improperly adjusted control rod (See Control Rod Adjustment).
Hydraulic power cylinder faulty; stoppage in fluid lines; faulty control valve.

HYDRAULIC MOTOR UNIT SPECIFICATIONS: *See "HYDRO-LECTRIC" WINDOW & SEAT REGULATORS.*

▷CHANGES & CORRECTIONS

▷*1955 MOTOR & PUMP ASSEMBLY PRODUCTION CHANGE:* Early Motor & Pump Assembly was gear type, later assembly is rotor type. Later rotor type may be used to replace the early gear type, but special service adapter hoses must be used when making the installation.

DESCRIPTION: This unit used on convertible models not having hydraulic window regulators. Unit consists of reversible type motor directly connected to hydraulic spur gear type pump which supplies fluid under pressure to two double acting hydraulic cylinders which raise and lower the top. Motor and pump assembly are accessible through rear compartment after shield is removed. Fluid reservoir is mounted above pump and motor. Hydraulic system is not vented to the atmosphere and it is therefore not necessary to replace hydraulic fluid periodically.

Control Switch—Self-centering type directly connected to pump motor by two electrical leads. One lead provides current for raising top, and the other for lowering top. Switch mounted below instrument panel.

Power Cylinders—Two double acting hydraulic cylinders used. Mounted on each side of body at rear, with piston rod linked to top mechanism.

ADJUSTMENT (TOP CONTROL): No adjustment required.

CHECKING FLUID LEVEL: With top in raised position, disconnect battery ground cable. Remove pump and motor shield (in rear compartment on some models) and place absorbent material below reservoir. Remove filler plug. On horizontally installed unit, fluid level should be to lower edge of filler hole. On vertically installed units, fluid level should be 2" below top of reservoir. If fluid low, replenish with hydraulic brake fluid.

▷REFILLING (After Repairs) CAUTION—Cylinders and hydraulic system contain more fluid than one filling of reservoir will supply. It is important that reservoir be checked frequently during refilling of system. Air in system wil automatically bleed out with a few operations of top.

CHECKING HYDRAULIC PRESSURE: For an inoperative or slow operating top, check fluid pressure as follows:

Hydraulic Lines—With top in a raised position, install a standard pressure gauge between pump port and "T" of hydraulic lines leading to bottom of lift cylinders *(NOTE—In order to get necessary slack to connect gauge, remove all tubing retainers).* Check fluid level and replace filler plug. With top in the full "UP" position, push control switch knob and hold a few seconds. Pressure should read 220 to 260 lbs. per sq. in. *(NOTE—If top slow or inoperative in the "DOWN" cycle, connect gauge to lines leading to upper end of cylinder and place top in full "DOWN" position and make test as above).* If pressure indicated is below prescribed maximum range, pump is not delivering required pressure or there is fluid leakage past the piston in one or both cylinders.

Pump Pressure—Install gauge in hydraulic lines leading to bottom of cylinders, then pinch or "kink" the hydraulic tubing to completely shut off fluid to bottom of cylinder. Push switch knob forward and hold a few seconds. Pressure should be 220 to 260 p.s.i. Check fluid pressure to top of lift cylinders by connecting gauge to lines leading to top of cylinder, then make test as indicated above. If pressure reads below the maximum, pump must be repaired or replaced. If pressure is within the maximum range, fluid is leaking by cylinder pistons.

CHECKING CYLINDER PISTON LEAKAGE: With top in fully raised position and with gauge installed in lines leading to bottom of lift cylinder, test cylinder on right side of car by pinching lines leading to lower end of left hand cylinder. Push control switch forward and hold a few seconds. If pressure reads 220-260 p.s.i., then right hand cylinder is not defective, however, if pressure reads below maximum, cylinder must be replaced. Test left hand cylinder by pinching lines to right hand cylinder and make same test as with right hand cylinder. Lower top to full lowered position and install gauge in lines leading to upper end of cylinders. Repeat test as for lower end of cylinders (pull control switch rearward).

REMOVAL & INSTALLATION (Top Lift Cylinder): Raise top to full "UP" position. Disconnect battery positive cable or battery-to-top switch wire. Remove rear seat cushion and seat back *(CAUTION—* In addition to hangers and bend-over tabs, rear seat is secured with a screw at each upper corner). Remove nut and secure end of piston rod to top linkage. Push piston rod down into cylinder to full bottom limit. Remove all retainers from hydraulic tubing leading to cylinder. Remove cotter pin and clevis securing cylinder to floor bracket. Lift top cylinder up through access hole in top compartment and then out through cutout in rear seat back compartment panel. Remove filler cap from reservoir and disconnect tubing from top and bottom of cylinder. Cap ends of hydraulic lines to prevent dripping of fluid. To install, reverse removal procedure. Make sure piston is at bottom of travel when installing. Seal hydraulic fittings with a thread sealing compound, and check fluid level in reservoir.

Motor & Pump Assembly—Raise top to full "UP" position. Remove power unit cover plate shield and disconnect battery cable or battery-to-switch wire. Remove rear seat cushion and back and fold back the insulating pad on right side of body. From inside body, carefully pull wiring harness through cutout in seat frame. Remove insulation from "jack-knife" unions and disconnect red and green wires. Disconnect ground wire at floor panel screw. Remove the two hydraulic line retainers adjacent to power unit. Remove filler cap. Disconnect hydraulic lines at pump and cap open fittings. Loosen four rubber grommets securing power unit to floor pan and lift out power unit. To install, reverse removal procedure. Seal hydraulic fittings with a thread sealing compound and check fluid level in reservoir.

ADJUSTMENT (CONVERTIBLE TOP) BUICK, CHEVROLET, OLDSMOBILE & PONTIAC: Adjust as follows:

Forward & Backward Adjustment—If top needs adjustment forward or rear to permit windshield header dowels to enter dowel holes in roof rail, adjust as follows: Raise top slightly above windshield header, loosen attaching bolts in corner braces at front end of side roof rail, move front roof rail forward or backward to align dowels and dowel holes (attaching bolt holes are slotted to permit this adjustment) tighten attaching bolts.

Up & Down Adjustment—If side rail too high or low when top up unlatch top and raise approximately half-way. Remove rear seat cushion, back, and quarter trim panel, loosen three plate attaching screws in top adjusting plate at rear quarter section of body, move adjusting plate down to raise side roof rail or up to lower side roof rail (attaching screw holes are slotted to permit this adjustment).

Folded Top Position Adjustment—If top does not contact bumper in each side of top compartment when lowered, loosen adjusting screws in top adjusting plate (see Up-and-Down Adjustment above), and move plate to rear sligthly but do not raise or lower plate. Moving plate to rear will allow top to lower further into compartment.

ADJUSTMENT (CONVERTIBLE TOP) CHRYSLER, DESOTO, DODGE, PLYMOUTH MODELS (1949-54): Adjust as follows:

▷Chrysler, DeSoto, Dodge, Plymouth Note—Four adjustments are provided on each side of the top as follows: (1) Set screw at the first joint of top side rail to rear of windshield. (2) Set screw to rear of second joint of top side rail to rear of windshield. (3) At rear end of power guide link (power piston rod connects to this link), plate is movable in slotted holes. (4) Main control prop (link from body plate to top side rail) has slotted holes for adjustment.

CONTINUED ON NEXT PAGE

HYDRO-LECTRIC TOP CONTROL (WITHOUT HYDRAULIC WINDOW & SEAT CONTROL) (Cont.)

Clearance Between Side Rail and Door Glass—Close window. Loosen set screw locknut (adjacent to first joint of top side rail). Turn set screw in or out as required, so that top rail is true with top of door glass frame. Tighten set screw locknut.

Side Rail to Quarter Window Contour—Close quarter window. Loosen set screw locknut (adjacent to the second joint of top side rail). Turn screw in or out as required until top fits correctly over the quarter window.

►***NOTE—When making this adjustment, overall length of top may be affected by as much as ¼". After adjusting, check alignment of top locking pin holes and locking pins on header. If misaligned, see "Moving Top Ahead or Back" (below).***

Leveling Top Across Windshield—Close rear quarter windows, then raise top to allow two blocks 2½" wide to be inserted between rear quarter window and top side rail. Blocks must be positioned exactly the same on both side (about 1½" from leading edge of window). Lower top to rest on blocks. Loose main control prop anchor plate screws (see NOTE above). Raise or lower control prop until measurement of 6" is obtained on both sides. Tighten main control prop anchor screws securely. Remove blocks and lower top down on windshield. Locking pins should be aligned with holes and drop straight down for engagement.

Moving Top Ahead or Back—Loosen power guide link anchor plate bolts (one plate at a time). Move the top in the desired direction or until locking pin holes are in alignment with locking pins. Tighten guide link anchor plate bolts securely.

ADJUSTMENT (CONVERTIBLE TOP) CHRYSLER, DESOTO, DODGE, PLYMOUTH MODELS (1955): There are six adjustments on each side of the roof rail to control top alignment with windshield header, doors, roof rail and quarter windows. Adjust as follows:

►***BODY ADJUSTMENT NOTE:*** Before making top adjustments, tighten all body-to-frame bolts to 18 ft. lbs. Shimming the body to obtain proper top alignment should only be done in extreme cases where there is doubt of correct body-to-frame alignment.

Power Link Adjustment—With top and all door and quarter windows in raised position, check for correct fit at side rails and vertical seals. Increase or decrease clearance between quarter window glass and roof rail weatherstrip by loosening the power link adjustment bolts located in link above power cylinder and spread or shorten the link as required to obtain the desired clearance.

Roof Side Rail Alignment—The adjustment of the center side rail and header panel to windshield locking plunger cam and stops is controlled by the rear control link which is fastened to the quarter panel compartment. Also affecting the side rail weather strip sealing at the top of the door glasses are the front side rail hinge adjusting screws and the rear side rail hinge adjusting screws. If front side rail joints are fully open when the top is fully raised, turn the front side rail hinge adjusting screws counter-clockwise until the joints are closed. If, after making this adjustment, the clearance between door glass and side rail is increased or decreased, adjust the center side rail adjusting screw to obtain the desired clearance. Leveling the top can be accomplished by raising the rear control link bracket. When adjusting the rear control link, care should be taken to adjust both sides equally. Before making this adjustment, loosen the top header at the windshield to remove tension from linkage.

Top Header Panel—If header panel does not close easily on locking stops, loosen header panel-to-side rail screws and shift header panel forward or backward as required. If this is not possible, it will be necessary to adjust the power link to obtain desired clearance.

ADJUSTMENT (CONVERTIBLE TOP) 1951 FORD: Adjust as follows:

►***LATE 1953 FORD CONVERTIBLE TOP ADJUSTMENT NOTE—Adjustment of Late 1953 Ford Convertible Tops follows procedures outlined under "TOP MECHANISM ADJUSTMENTS" in "FORD, LINCOLN, MERCURY TOP CONTROL" Article following.***

Before attempting to align top, determine if any linkage is binding, and if necessary, faulty linkage should be replaced or freed from binds. After top is aligned, adjust door and quarter window to assure proper fit along top side rails. ***Do not adjust windows unless top has been aligned.***

Header Bracket Adjustment—***(NOTE—This adjustment is only minor and will not correct serious misalignment. If complete assembly requires shifting, it is necessary to adjust main pivot bracket as outlined below).*** To adjust header bracket, raise top about half-way to permit easy access to weatherstrip retaining nuts. Remove three retaining nuts and weatherstrip from front side rail. Lower top to a sligthly raised position to relieve strain on top material. Loosen two tapping plate screws. Move front side rail-to-header bracket either forward or backward. After making adjustment, tighten tapping plate screws. Position weatherstrip on front side rail, install flat washers, lockwashers, and nuts.

Balance Link Adjustment—***(NOTE—If side rails are sagged, it is necessary to adjust the balance link).*** To adjust balance link, raise top above windshield until tension is removed from balance link. Place a block between the header and windshield frame to hold top in raised position. Loosen balance link bolt nut. Bend tab of star washer up, then turn balance link adjusting bolt to either raise or lower the balance link. If balance link does not move in slot of its own weight, pull balance link down by hand about ¼", then bend down tab on star washer and tighten balance link bolt nut. Remove block previously installed under header. Fasten top down. Check for sag at front and rear side rails after adjustment made. If necessary, repeat above procedure until sag has been eliminated.

Main Pivot Bracket Adjustment—To provide proper clearance between pillar rail and quarter window or to shift complete top assembly proceed as follows: If quarter window binds along top of pillar rail when it is lowered, loosen all screws that secure main pivot bracket to body. Raise main pivot bracket just enough to eliminate the bind at the quarter window. When raising the main pivot bracket, use spacers under the main pivot bracket at rear mounting screws to prevent tilting the bracket when tightening the screws. If necessary, repeat the adjustment at the other main pivot bracket. If complete top assembly requires shifting toward the front or rear of the body, loosen all the mounting screws at both main pivot brackets. Shift top assembly to desired position, tighten mounting screws. ***NOTE—When making above adjustment use care to avoid disturbing "Up" and "Down" adjustment.***

POWER OPERATED TOPS AUTO-LITE ELECTRIC TYPE

Used On Convertible Models:
Chrysler, DeSoto, Dodge (1941-48)
Ford, Lincoln, Mercury ('41-48)—except Sportsman

CHRYSLER, DE SOTO, DODGE
(Auto-Lite Equipment List)

Year	Top Motor	Control Relay
1941	EWG-4002	HRF-4001
1942-46	EWG-4003	———
1947-48	EWG-4004	———
1947-48	EWG-4005, 6	①

①—Each motor grounded through separate 30-ampere thermal circuit breakers.

DESCRIPTION & OPERATION: This type of control consists of two electric motors each mounted as a unit with its worm-and-gear type power screw at sides of car with the power screw linked directly to the top frame (conventional top bows and braces are modified for this power connection).

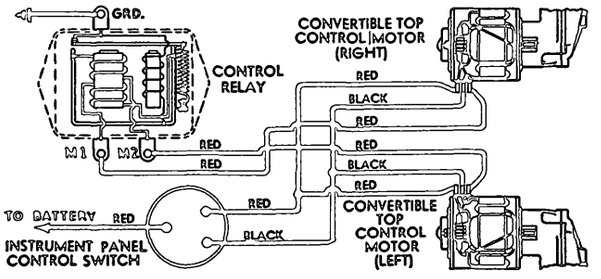
Control Relay (for EWG-4002 motors). Two opposed windings, 1 connected in series with each top one of which is connected in series with each top control motor. This results in relay contacts remaining closed as long as load and current of each motor is equal. A differential of 20-30 amperes between the two motor circuits (caused by binding or obstruction on one side of top) causes relay contacts to open so that the motors stop.

SERVICING: To check operation of top, disconnect top from power screw, see that folding arm assembly works freely without binding at any point. Check control switch to make certain that circuits are completed through switch in 'up' and 'down' positions. To check power screw for sticking or binding, remove motor (see below) and operate screw by inserting screwdriver in slot in pinion shaft. Shaft should turn easily and freely. If it does not, check for bent power screw. See that power assembly is not binding on base pivot.

Power Unit—To replace power unit, remove trim side panels in rear seat compartment, disconnect motor wires, remove bolt linking power screw to top and pivot bolt in mounting bracket, lift out power screw and gear box assembly. Install new assembly in same manner, taking great care not to kink or bend the power screw and see that power screw installed in top bracket so that it is perfectly straight between top attaching bolt and body mounting pivot bolt. Connect motor leads and check top operation before replacing trim panels.

CONTINUED ON NEXT PAGE

POWER OPERATED TOPS AUTO-LITE ELECTRIC TYPE (Cont.)



TESTING: If top control does not operate satisfactorily, test each unit as follows:

Control Switch—Disconnect motor leads at switch. Connect one test lamp lead to ground, touch other lead to switch 'up' terminal, place switch in 'up' position. Lamp should light. Test 'down' terminal in same manner.

Top Motor—Disconnect guide mechanism from top slat irons and operate motors. If motors do not run freely when disconnected, check motor brushes for sticking or wear, see that commutator clean check field coils for grounds and open-circuits.

Motor Performance

Torque	R.P.M.	Volts	Amperes
2 oz. ft.	4000-5000	6.0	29-34

EWG-4002 MOTORS WITH HRF-4001 RELAY

Control Relay—If motor does not operate with switch in up or down position, ground relay terminals. If motors run, check relay contacts. If contacts are open and motors run when contacts held closed, check motors for unequal load (relay should operate in this manner if motor loads unequal). If relay buzzes and contacts do not hold open, check relay voltage coil for open-circuit.

Relay Specifications (Auto-Lite HRF-4001)

Contacts Open—25-35 amperes through either series winding at 5.0 volts (or 20-30 ampere differential between both coils). Opening amperage for each coil must be equal within 2 amperes. Adjust by bending lower spring hanger.

Contacts Close—.2 volt minimum.

Air Gap—.030-.034" with contacts closed. Measure between current coil (series winding) core and armature. Adjust by shifting upper stationary contact up or down. CAUTION—See that both sets of contacts open and close simultaneously.

Contact Servicing—Clean contacts with strip of clean linen tape moistened with carbon tetrachloride and then rub with clean dry tape (draw tape through between contacts). If contacts burned or pitted, resurface by filing lightly with very fine contact file (ST-290) parallel and lengthwise of armature and then clean contacts as directed above. See that no lint is left on contact surfaces.

Voltage (Shunt) Winding—Winding resistance is 4.68-5.18 ohms. Measure between stationary contact and movable contact with contact points held open.

POWER OPERATED TOPS STUDEBAKER ELECTRIC TYPE

1947-52 Studebaker, Champion & Commander

DESCRIPTION: Consists of two worm-and-gear type power screws pivoted on floor brackets inside rear quarter panels, one on each side of car. Gear boxes coupled together through flexible drive shaft.

Motor—Reversible type. Drives left gear box through rubber and steel coupling with engaging slot in motor shaft and gear box shaft at right angles to each other.

Control Switch—Two-way type under left edge of instrument panel. Move lever to left to raise top, to right to lower.

Circuit Breaker—75 ampere. On engine side of dash.

REMOVAL OF POWER UNIT: Lower top. Disconnect battery ground. Remove rear seat (cushion and back) and trim panel. Remove spacer and bolt (secured by cotter pin and castellated nut) at upper end of lift shaft. Disconnect motor ground strap from body brace. Disconnect and remove flexible drive shaft from side of gear box. Take out clevis pin in floor bracket under gear box. Disconnect green and black wires from junction block on motor. Lift out power unit assembly.

INSTALLATION OF POWER UNIT: Reverse removal directions above, connecting green wires to top terminal and black wires to middle terminal on motor junction block.

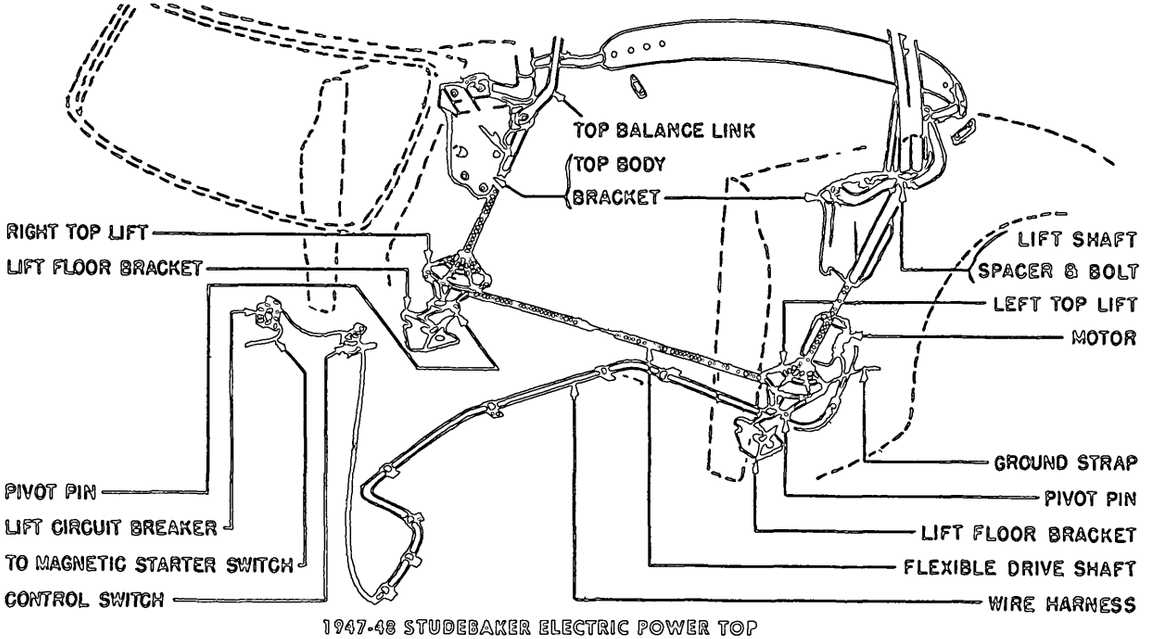
▷*CAUTION—Check Worm Screw Adjustment, No. 3 under Top Adjustment (following) when Power Unit reinstalled.*

REMOVAL OF MOTOR: Disconnect battery ground. Remove rear seat (cushion and back) and trim panel. Take off two nuts and lock washer from each motor-to-gear box through bolts (2 used). Lift motor (with through bolts) off gear box.

MOTOR COUPLING REPLACEMENT: Remove motor (see above). Take out coupling. Install coupling with slot in gear box shaft at right angles to slot in motor shaft.

INSTALLATION OF MOTOR: Reverse removal directions above (align slot in motor shaft with coupling).

MOTOR JUNCTION BLOCK WIRE TERMINALS:
Top Terminal—Green wires.
Middle Terminal—Black wires.



ADJUSTMENT OF TOP: Three adjustments provided:

1—Top Balance Link Adjustment (clearance at top of door and quarter windows and top tension). Support side rails, lift top off windshield header bolts, loosen master adjustment bolt (secured by serrated nut) at top balance link (see illustration). Move top toward front or rear for proper fit (bow assembly slotted to permit this adjustment).

2—Header Adjustment (clearance at top of windshield). 3 bolts in slotted holes at front end of side rail on each side. Loosen these bolts, move header to front or rear for proper fit.

3—Worm Screw Adjustment (one side rail higher than the other). Equalize worm screw length using special crank tool (see below) inserted in gear box at flexible drive shaft connection on side to be adjusted (requires removal of rear seat and back, and trim panel). Load must be equalized on each worm without putting a strain on top linkage.

Special Crank Tool. Use 3/16" rod stock, file one end to ⅛" male square, ¾" back from end. Bend 1" throw in rod about 2" long for handle. Use a 3/16" I.D. piece of tubing 2½" long, hammer over squared end of rod to give ⅛" square I. D. 1" long on one end of tube. Take tube off rod, insert round end of tube on opposite end of rod and weld in place. Over-all length of tool approx. 7".

1947-48 STUDEBAKER ELECTRIC POWER TOP

RAMBLER TOP CONTROL

Nash Rambler (1951-54)

DESCRIPTION: This type top control consists of a reversible motor, located behind rear seat back; two-way self-centering control switch connected to car battery through a resistor. The motor powers two flexible nylon covered cables that operate over four pulleys to raise and lower the top.

OPERATION: To Lower the Top. Check the top well in back of the rear seat and remove any article that might obstruct the movement of the top. Unzip the rear curtain and fold into the well. Release both toggle clamps that hold the front bow to the windshield header bar and pull out on the control switch, holding it in the out position until the top folds completely into the well. Install the top boot.

►*CAUTION:* The top should not be lowered when the material is damp.

REMOVAL OF TOP CONTROL SWITCH: Disconnect battery cable. Remove two bolts holding control switch to support bracket under instrument panel, disconnect wires. To remove switch from mounting bracket, loosen lock nut between switch and mounting bracket, unscrew switch. When installing, be sure knob and bracket are securely fastened to switch and wires installed to correct terminals.

REMOVAL OF POWER UNIT: Remove the right and left pulley guard screws and raise the guard upward to disengage the flange on the guard from the flange on the top well. Remove the rear seat cushion and from inside the car, push down on the bottom of the top well. This will release the ragboard panel covering the power unit. Tape the cables securely to the drum and loosen the right and left cable tensioners located at either side on the body braces. Remove the drum and cable assembly from the drum shaft by removing the retaining nut in the center of the drum. The power unit can then be taken out by removing the three cap screws holding the unit to the mounting bracket.

Installation: Reverse removal procedure.

►*NOTE:* Make sure thrustwasher lugs are in recess in the drum hub. Lubricate the worm and needle bearings with No. 110 Lubriplate before installing.

REMOVAL OF TOP AND BOW ASSEMBLY: Remove the four top boot fasteners, (two on either side) which hold the rear bottom of the top to the body and remove the screws under the rear of the top, holding the stay pads to the body. Unzip the back curtain from the stay pads. Release the front bow to windshield header toggles and lower the top just enough to turn up the front bow. Bend the retainer upward and remove the pellet and cable from the rear half of the front bow hinge. Remove all bows from the sliding channel by pushing each bow in at the roof rail at the same time spring the bows up at the center. The top can then be removed.

Installation: Reverse the removal procedure.

REMOVAL OF ONE CABLE: Remove the top and bow assembly from the body and remove the rear pulley guards. Remove the pulley mounting bracket guides from the rear pulleys and remove the rear cushion and ragboard panel covering the power unit. Pull the inside cable out of the cable guide channel to provide slack, then remove cable from drum by removing cable lock clip. Remove cable guard at front corner of body rail, then remove the cable from the pulley.

INSTALLATION OF ONE CABLE: Lubricate the front pulley and install on body then place the cable on the pulley with the pellet and short end of the cable in the outside cable guide channel. Replace the pulley guard. Place the pellet approximately 1" from the pulley guard, making sure the opposite cable pellet is in the same position. Keep both cables in the guide channels and place cables on rear pulleys. Replace rear pulley mounting bracket guides. Wind the outside cable 1½ turns around the drum and insert the pellet into the bottom hole and replace the lock clip. Keeping the inside cable taut, pull the control switch out; holding it until the pellets come within 2" of the rear pulleys. Wind the inside cable counterclockwise and insert the pellet into the top hole of the drum and replace the lock clip. (If additional slack is needed, pull the inside cable out of the cable guide channel). Tighten the rear pulley tensioners to take up cable slack. Push the control switch in until pellets come about 4" from the front pulley guards. Then replace the top. Be sure both pellets are the same distance from the front pulley guards.

►*CAUTION:* Do not run pellets around pulleys.

INSPECTION & ADJUSTMENTS: 1. Check cable tension and retighten tensioners if necessary, release toggle clamps.

2. Operate control switch, check for front header to drip rail clearance.

3. Lower top to see that bow strainer supports contact one another. If out of alignment, correct by bending into proper place.

4. Check bow strainer loop attached to front header hinge for free movement. If binding, release retaining tabs slightly.

5. Inspect cable guide channels for alignment. With block of wood and hammer, tap channels to inside or outside, as necessary, so that they line up with front and rear pulleys and cables.

6. Check front header hinge and cable guide support to which cable is attached. It must ride in outside of groove of cable guide channel. It can be bent to inside by using "C" clamps or vise grip pliers.

7. Lubricate front and rear pulleys with Lubriplate. Every spring Lubriplate power unit worm drive and power unit motor with light engine oil at 5000 mile intervals or twice a year.

SERVICE PARTS: Parts are as follows:

Motor: Nash No. 4356370.

Motor Specifications①

Torque	R.P.M.	Volt	Amperes
0 ft. ozs.	4700 min.	5.0	60 max.

①—Test in both directions of rotation.

Brush Spring Tension—42-53 ozs'

Resistor: Nash No. 4356759.

DODGE & PLYMOUTH ELECTRIC TOP CONTROL

Dodge (1952-54)
Plymouth (1951-54)

DESCRIPTION: This type top control consists of a reversible type motor, mounted on rear seat riser beneath cushion; a two-way, self-centering switch with circuit breaker, two flexible cables, and two mechanical screw jacks.

►*NOTE—Replacement parts and units are available.*

BROKEN CABLE REPLACEMENT: If cable breaks when top is partially raised or lowered, cycle cannot be completed until cable is replaced because screw jack on failed side will lock and bind. Method of replacement of broken cable varies with position of top at time of cable failure, and whether long or short cable is to be replaced.

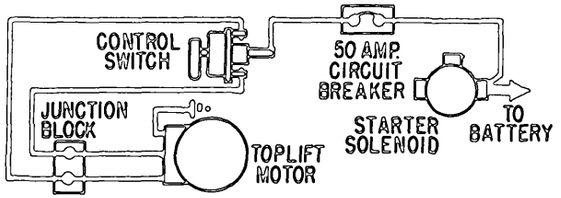
Top Up—If short cable fails, remove broken cable. Attach new cable to transmission unit and leave motor end free. Synchronize cables. If long cable fails, remove broken cable. Install new cable and attach both ends. Disconnect short cable at motor. Synchronize cables.

Top Down—If either long or short cable fails, replace. Carefully raise top by momentarily applying power "on" and "off" (this avoids possibility of breaking cable). With locking handle in released position, let top lightly bottom so that dowel pins enter their mating holes. Disconnect short cable at motor end. Synchronize cables.

Top Partially Raised: If either long or short cable fails it will be necessary to raise top manually. Do not raise top with screw jacks connected to top linkage. Remove clevis bolts at top of each screw jack, Then raise top to complete "Up" position by hand. Rotate sleeves of screw jacks to their normally extended position. Reconnect with clevis bolts to top linkage. Replace broken cable. Synchronize cables.

TOP OPERATING CABLE SYNCHRONIZATION: Place top all the way up onto header. Disconnect short cable at motor end. Apply power momentarily in direction to raise top with top locking handle in released position. This takes slack out of long cable. Reconnect short cable. To recheck synchronization of cables, run top all the way down. Jack screw sleeves should seat on transmission units. If still not synchronized, repeat procedure.

TOP MECHANISM ADJUSTMENTS: ***NOTE—Correct fitting of top at header panel depends on proper alignment of doors in relation to header. If shimming is necessary to obtain proper door alignment, this should be done before making adjustments of top at side-rail screws.***



►**ADJUSTMENT POINTS**—Top adjustment points are as follows: (1) **Locking Pin and Dowel**—on windshield header. Draws top tight against windshield header. (2) **Front Side Rail Pivot Bracket**—between windshield and Front Side Rail Hinge. Small movement forward or backward for smooth raising or lowering of top, and fit on header bar.

CONTINUED ON NEXT PAGE

DODGE & PLYMOUTH ELECTRIC TOP CONTROL (Cont.)

(3) Front Side Rail Hinge—to rear of Front Side Rail Pivot Bracket. Stop screw permits proper alignment of Side Rails. (4) Rear Side Rail Hinge—on curve of Side Rail. Stop screw permits adjustment of side rails to fit quarter window. (5) Side Pivot Bracket—on body bracket ahead of rear wheel housing. Provides vertical adjustment for leveling and centering of top. (6) Rear Pivot Bracket—above rear wheel housing. Provides horizontal adjustment for forward and rear movement of top.

Top To Header Adjustment: Face slot on center dowel anchor pin toward back of car to assure locking of top. Side dowel pins should have large end of tapered hole facing centerline of car. Further adjustment of top can be made by adjusting stop screws on Front Side Rail Hinge and Rear Side Rail Hinge with top half open. Slight adjustment of forward part of Side Rail, forward or backward, can be made by loosening bolt through Front Side Rail Pivot and Side Rail. If dowel pins do not line up with locking pin, loosen screws which hold dowel and shim dowels so they will tilt toward outer edge of car.

DODGE & PLYMOUTH TOP CONTROL WIRING

Rear Pivot Brackets: About one inch fore-and-aft adjustment is provided to bring holes in header bar directly over dowels. Loosen bracket attaching bolts and pivot bolt. Move brackets forward to move header bar forward and backward to move it to rear. Adjust one or both brackets until dowels and header holes line up.

Side Pivot Brackets: If header bar is off center, side to side, to the right, and right corner is away from dowels, adjust bracket on right side. If to the left, adjust left bracket. Raise top. Loosen appropriate side bracket attaching bolts and pivot bolt. Move bracket up or down until header is level and centered from side to side. If adjusting one bracket does not level header, try adjusting both side brackets, raising one and lowering other until header is centered and level. Side Pivot Brackets should be adjusted with top in both raised and lowered positions.

▷*NOTE—To permit proper lowering and raising of top and to obtain a good fit at windshield and side windows, horizontal and vertical adjustments at Rear and Side Pivot Brackets should be made at same time. The distance between pivot pin center (at junction of linkage and screw jack connecting rod) and a straightedge placed on a line through centers of pivot pins on Rear Pivot Brackets and forward end of straight link (running from linkage-connecting rod junction) is approximately one inch.*

Front Side Rail Pivot Bracket: To correct stalling when header bar has lifted only five or six inches off windshield check spacing between ends of front top bar and top of side rail. If spacing is less than 5/16" pivot is probably adjusted too far forward. Loosen Front Pivot Bracket attaching screws and tap bracket to rear about 1/16". It may be necessary to adjust pivot bracket on other side.

SERVICE PART NUMBERS: Dodge and Plymouth numbers as follows:

MOTOR

Plymouth (1951-52) ..... Plymouth No. 1370585
Dodge (1952) ..... Dodge No. 1370585
Dodge & Plymouth (1953) ..... Dodge & Plymouth No. 1491035

FORD, LINCOLN, MERCURY ELECTRIC TOP CONTROL

Ford (1951-Early 1953). See Note below.
Lincoln & Mercury (1952-55)

▷*LATE 1953-55 FORD TOP CONTROL CHANGE:* Late 1953 and 1954-55 convertibles use Hydro-Lectric type control previously used in 1951. See instructions below for adjustment of convertible tops on these models. *See "Hydro-Lectric Top Control (Without Hydraulic Window & Seat Control" for data on items other than Top Mechanism Adjustment.*

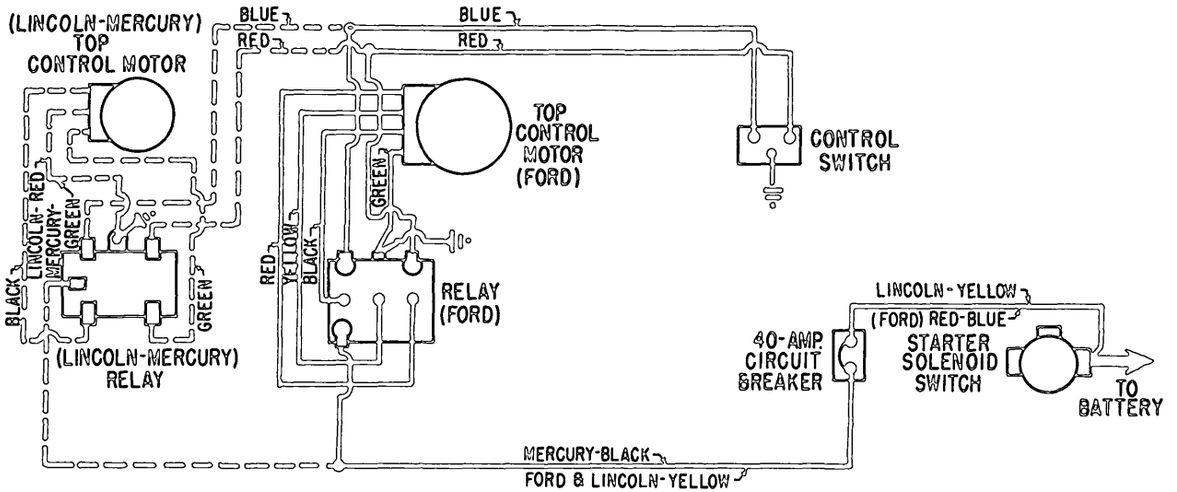
▷*1953 IMPROPER RAISING OF TOP CORRECTION (Due to Disengagement of Flexible Shaft)*—Insert piece of wire, ¼" long and .145" in diameter, into the drive receptacle of the lift worm and housing assembly. This will act as stop and limit end travel of flexible drive shaft.

▷*1953 TOP CONTROL SWITCH PRODUCTION CHANGE:* Beginning approximately March 1, 1953, a Two-terminal Top Control Switch, Part No. FAA-15668-B, was used on convertible models and the Top Control Limit Switch discontinued.

REPLACEMENT SWITCH NOTE—The Three-terminal Top Control Switch, Part No. FAA-15668-C, can be used as a replacement for the two-terminal switch by attaching one end of an insulated 16-gauge wire to the single terminal on right hand side of the switch and grounding the opposite end of the wire to a convenient point.

DESCRIPTION: This type top control consists of a motor, relay, limit switch, and flexible drive cables that operate two lifting jacks. The reversible type motor has double driving ends to which are attached the drive cables. Each drive cable operates a lifting jack located at each side of the quarter panel. Motor and relay are mounted under rear seat. Motor is operated by switch on instrument panel. Lifting jacks have worm nuts which act as stops, at top and bottom, to limit length of travel. Limit switch, located on windshield header, prevents motor operation when top is locked to windshield header. Limit switch also breaks circuit when contacted with top.

REPLACEMENTS:



Top Control Switch: Disconnect battery cable. Remove knob and bezel. Remove control switch from mounting bracket. Disconnect wires at switch. Remove switch. Connect wires to new switch. Position switch on mounting bracket. Install bezel and control knob. Connect battery. Check top operation.

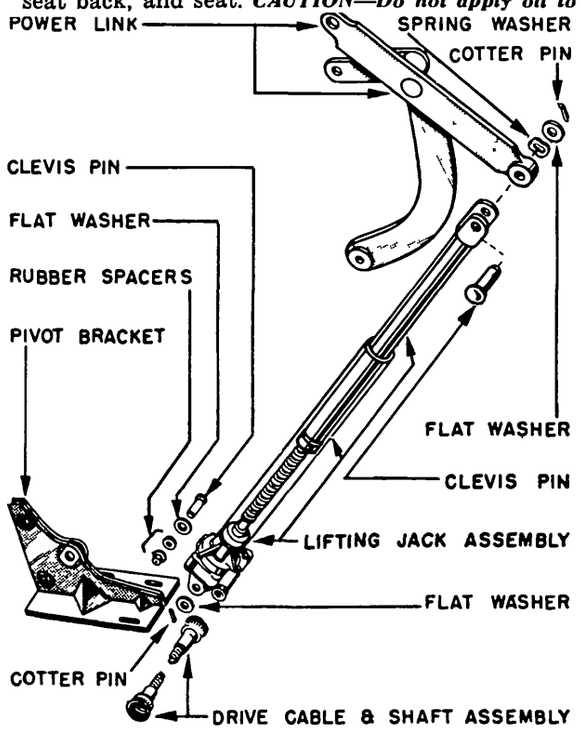
Circuit Breaker: Located on right front fender apron. Disconnect battery cable. Disconnect wires at circuit breaker. Remove retaining screws and circuit breaker. Position new circuit breaker on fender apron and install retaining screws. Connect wires to circuit breaker. Connect battery. Check operation.

▷*SEE LINCOLN & MERCURY TOP CONTROL SWITCH PRODUCTION CHANGE above.*

Limit Switch: Located along top of windshield header. Raise top off windshield header. Carefully pry limit

CONTINUED ON NEXT PAGE

1951-EARLY 1953 FORD & 1952-55 LINCOLN & MERCURY TOP CONTROL WIRING



FORD, LINCOLN, MERCURY TOP CONTROL (Cont.)

switch out of hole with screwdriver. Disconnect wire and remove limit switch. Tape wire to prevent shorting. Connect wire to new limit switch. Insert switch on hole and press shoulder until it snaps firmly in hole. Check top operation.

Relay: Located on inner side of rear seat riser.

Top Operating Motor: Located under rear seat. Serviced as an assembly. No lubrication required on motor. Disconnect battery cable. Remove rear seat. Disconnect drive cables at each end of motor. Disconnect motor to relay wires at relay terminals. Remove motor mounting screws.

Top Lifting Jack: Raise and lock top header. Remove rear seat and seat back. Remove quarter trim panel. Disconnect drive cable at lifting jack. Remove clevis pin at upper and lower ends of lifting jack. Remove jack. Before installing lifting jack, place rubber spacers in each mounting hole at lower end of lifting jack. Shoulders on both rubber spacers must be on inner side of mounting holes. Align lifting jack with lower pivot bracket. Insert flat washer and clevis pin. Then install flat washer and cotter pin. Align upper end of lifting jack with power link by turning jack screws. Install clevis pin, spring washer, flat washer, and cotter pin. Connect drive cable at lifting jack. Check top operation before installing quarter trim. Install quarter trim panel, seat back, and seat. ***CAUTION—Do not apply oil to any points mounted in rubber. A light coat of vaseline is suggested.***

TOP CONTROL (ADJ. POINTS)

Drive Cable and Shaft Assembly: Drive cable and shaft similar to speedometer drive cable. Lubricate cable with graphite grease when service operations are performed. Loosen knurled retaining nut at each end of cable. Remove assembly. To reinstall, insert driving ends of cable into motor and lifting jack. Tighten knurled retaining nuts.

TOP MECHANISM ADJUSTMENTS:

Preliminary Inspection: Before attempting to align top, operate it to determine if any linkage is out of line or binding. Replace or free from binding any faulty linkage.

Header Bracket Adjustment: Loosen set screws on dowels, located along top of windshield. Rotate dowels to proper height. Tighten set screws, making sure screws are seated in slots on studs, locking dowels in position. If striker plates, on header, need alignment with side header dowels, loosen cap screws, position striker plates by hand, and tighten screws.

Balance Link Adjustment: Loosen six cap screws that secure pivot bracket support to quarter panel. Move pivot bracket up or down, fore or aft as required. Tighten cap screws. To correct sagging or excessive crowning of the side rails at front hinge point, loosen three cap screws that secure balance link adjusting bracket to main pivot bracket support. Turn vertical adjusting screw, on balance link bracket, in to reduce sag and out to reduce excessive crowning. Tighten cap screws securely.

Main Pivot Bracket Adjustment: Space between quarter window and rear side rail is adjusted by loosening two cap screws and bolt that secure header bracket to front side rail. Slide header fore or aft on side rails until arc of rail over quarter window is parallel with top edge of window. Tighten cap screws and bolt. Space between side rail and quarter panel at rear corner of quarter window is adjusted by loosening four cap screws that secure main pivot bracket to main pivot bracket support. Move main pivot bracket in or out as required to obtain proper spacing. To adjust top to stack, lower into folded position, loosen three cap screws that secure balance link adjusting bracket to main pivot bracket support. Turn diagonal adjusting screw, on balance link bracket, out or in to lower stacked position of header. Tighten cap screws.

AUTO-LITE ELECTRIC SEAT CONTROL

Chrysler C67, C68, C69 (1955)
DeSoto (1955)
Dodge (1955)
Packard (1955)
Plymouth (1955)

DESCRIPTION: Seat adjusting mechanism is electrically operated, using reversible type motors. Motors operate worm shaft and sleeve through a worm head. Fore-aft and up-down movements are controlled individually, each having a separate but similar system, including a switch, motor, and regulator.

REMOVAL & INSTALLATION: Proceed as follows:

Front Seat Assembly: Remove front cushion, disconnect battery. Disconnect seat adjuster control wires. Remove floor pan-to-seat guide attaching capscrews, remove guide from seat assembly. To install, reverse removal procedure.

Left Seat Guide & Vertical Power Unit: Remove front seat cushion. Disconnect battery and seat adjuster control wires to relay (*CAUTION*—To facilitate removal of vertical bar clevis pin, the front seat assembly should be elevated to highest position of travel and blocked before attempting removal of pin). Remove vertical bar pins attaching vertical power unit shaft and sleeve to front seat frame. Remove power link pin Disconnect motor lead wires to relay. Remove floor pan-to-seat guide attaching capscrews and remove guide from seat assembly. To reinstall, adjust power unit to the two pins (adjustment made by turning unit coupling) Install rear of unit on rear pin and secure. Raise seat manually, install front end of unit into torque bar, attach clevis pin, and secure(*NOTE*—Length of unit may be varied by turning coupling manually) Reinstall wires and reconnect battery. Check operation of seat and replace seat cushion.

Horizontal Power Unit & Shaft Assembly: Remove front seat cushion, disconnect battery and seat adjuster control wires to relay. Remove power unit retaining snap rings, and disconnect relay lead wires to motor. Remove horizontal power unit assembly. *NOTE*—To facilitate removal of horizontal bar clevis pins, lower seat to lowest point before attempting to remove unit. To reinstall, reverse removal procedure.

Seat Tracks: Remove jack assemblies and the two rear and front retaining bolts that hold seat track to floor pan. Slide seat track outward, causing it to disengage from two horizontal torque rods. When removing right track, it will be necessary to disengage one connecting link from a pivot pin. To reinstall, engage torque rods in track assembly. Install rear seat track retaining screws, but do not tighten Install jacks, operate seat in all directions to properly align seat tracks and torque rods. Tighten front seat track retaining screws, raise seat, and tighten rear seat track retaining screws. *NOTE*—Do not lubricate vertical power unit shaft ball and nut.

SERVICE PART NUMBERS: Indicated as follows.

	Auto-Lite No.
Seat Control Motor	
Chrysler, DeSoto, Dodge, Plymouth (Horiz. Only)	
Vertical	EMM-4002
Horizontal	EPC-4001
Packard	
Vertical (12 Volt)	EPE-4001
Horizontal (12 Volt)	EPD-4001
Seat Control Relay	
Chrysler, DeSoto, Dodge, Plymouth	HRZ-4004
Seat Control Regulator (Incl. Motor)	
Chrysler, DeSoto, Dodge, Plymouth (Horiz. Only)	
Vertical	SGA-4003
Horizontal	SGA-4004
Packard	
Vertical (12 Volt)	SGA-4005
Horizontal (12 Volt)	SGA-4006

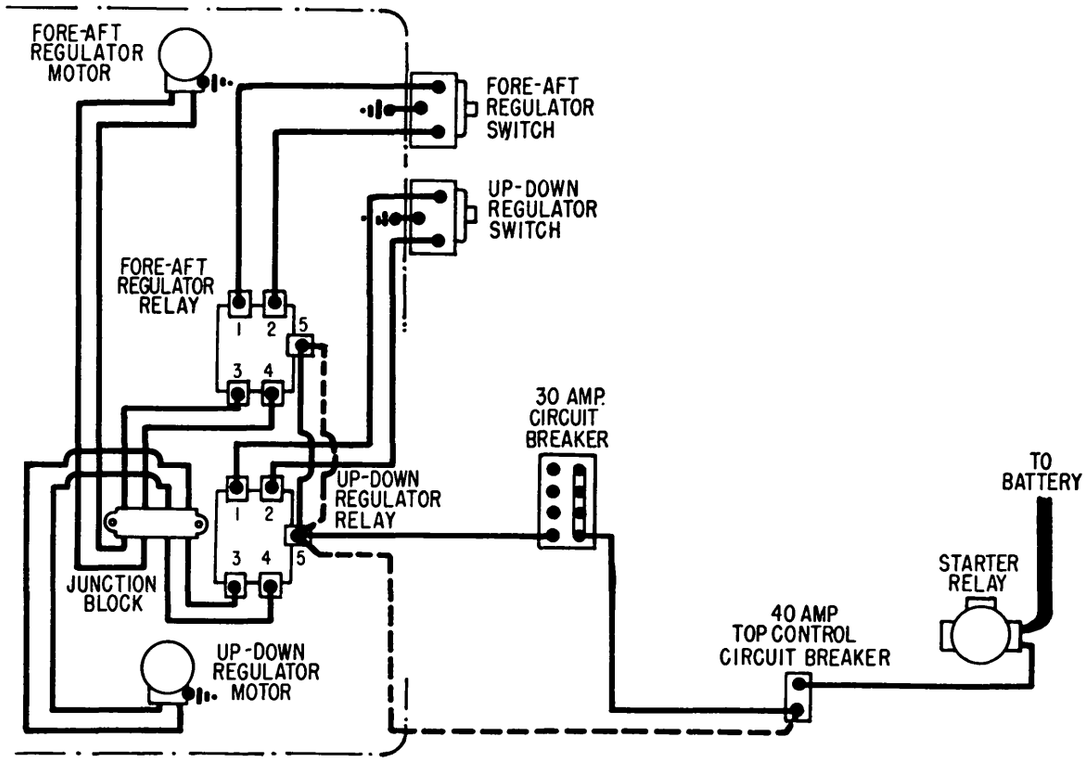
FORD, LINCOLN, MERCURY SEAT CONTROLS

Ford (1954-55)
Lincoln (1952-55)
Mercury (1952-55)
Thunderbird (1955)

►CHANGES, CAUTIONS, CORRECTIONS

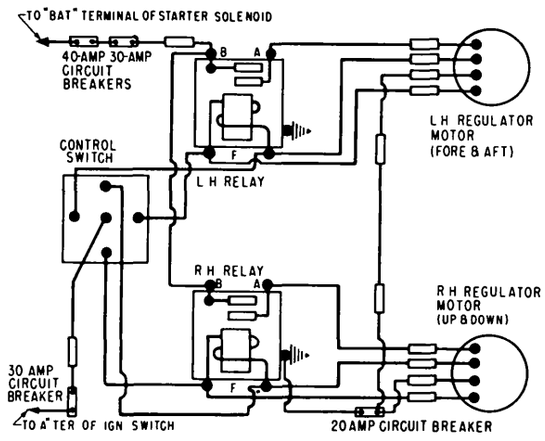
►*1955 MERCURY REGULATOR MOTOR WIRE CHAFING & SHORTING OUT CORRECTION:* To eliminate possibility of motor wires chafing and shorting out, rubber insulators should be cemented to the floor pan at points of wire contact. Insulators should be made from ¼" sponge rubber cut in 4" squares.

►*1955 THUNDERBIRD SEAT JAMMING IN EXTREME REAR POSITION CORRECTION & PRODUCTION CHANGE:* A change has been made in production to relocate seat track stop which restricts rearward travel and eliminates binding condition in power seat regulator shaft. To correct condition in field, raise seat to extreme upward and forward position. Locate and drill a 1/8" hole through seat track flange on both sides at a point 3 7/8" from forward end of track. *(NOTE*—Use a right-angle drive drill head to drill holes). Install a 1/8" x 1¼" pin (Part No. 353621-S100) through seat track flange. Pin must be installed so that it extends an equal distance on both sides of flange. Lubricate track and check seat operation.



DESCRIPTION: This seat adjusting mechanism is electrically operated, with reversible type motors driving screw-jack type regulators. Fore-aft and up-down adjustments are controlled individually, each having a separate but similar system, including a switch, relay, motor, and regulator. Control switches are located on seat side shield to left of driver (Lincoln), front left side of seat frame (Mercury). Forward switch (Lincoln), left switch (Mercury) controls fore and aft movement, other switch controls up and down movement.

REMOVAL & INSTALLATION: Proceed as follows:



Lincoln Front S at Assembly: After removing the front seat cushion, pull courtesy lamp wires from connectors at transmission hump, disconnect lead-in wire from relays, then remove four nuts that secure seat tracks to floor pan. Note in which of the three holes of floor bracket the clevis pin is located, then remove self-locking pin and clevis pin that retain fore-aft regulator to floor bracket. Loosen regulator in floor bracket. Note which of mounting holes are positioned over retaining studs, remove seat assembly from car. To reinstall, position front seat so mounting studs are located in same seat track mounting holes as originally. Pin used to secure rear end of fore-aft regulator must be installed through proper bracket holes to insure correct operation of regulator. Center holes in bracket must be used when seat brackets are installed using center mounting holes. Rear holes are used when seat tracks installed using forward holes. Forward holes are used when seat brackets installed using rear holes.

Mercury Front Seat Assembly: (NOTE—Seat cushion is integral with front seat frame). Disconnect bat-

1953-54 MERCURY SEAT CONTROL WIRING DIAGRAM (FORD SIMILAR)

FORD & MERCURY

LINCOLN

1955 FORD, LINCOLN, MERCURY SEAT CONTROL WIRING DIAGRAM

FORD, LINCOLN, MERCURY SEAT CONTROLS (Cont.)

tery ground cable to prevent shorts. Remove cap screws (one on each side of track assembly) holding front of seat track assembly to floor pan. Remove nuts and bolts (one on each side of track assembly) holding rear of seat track to floor pan. Remove clevis pin holding fore-aft regulator to floor bracket (may be done from rear and underneath front seat cushion). Tilt seat back, remove ground wires to relays, then remove seat track assembly with seat frame attached. To remove seat frame, remove four nuts, one on each side, front and rear, holding seat frame to seat track, then remove seat frame. To install, reverse removal procedure.

Ford & Thunderbird Front Seat Assembly: Disconnect battery ground cable and remove the two front seat shields. Remove seat track stud bolts from bottom side of floor pan. With the seats in forward position, remove the clevis pin holding fore-aft regulator to floor pan. Remove seat back and tilt the seat backward. Disconnect wire lead from circuit breaker-to-relay, at the relay. Remove seat track assembly with seat frame attached. To install, reverse removal procedure.

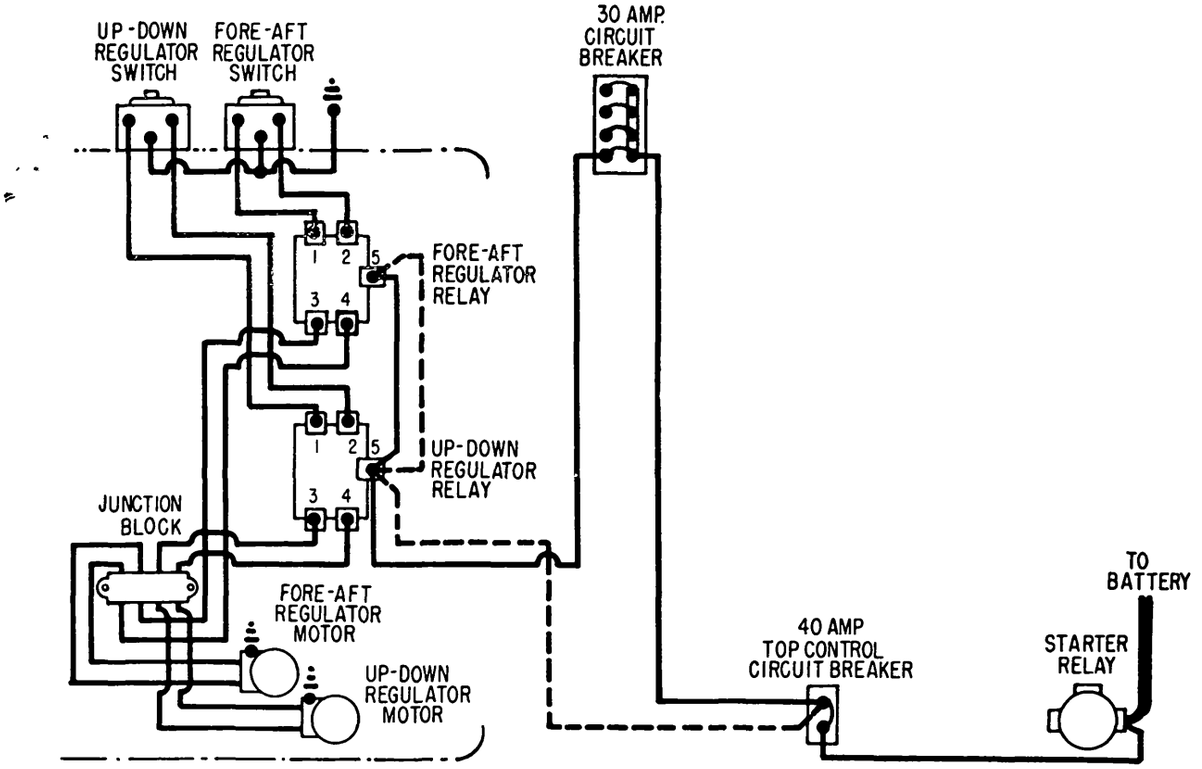
Fore-Aft Regulator: Follow Front Seat Assembly Removal procedures above, then disconnect motor field coil and ground wires from bullet connectors. Remove clevis pin holding regulator to seat frame assembly, remove regulator assembly. To install, reverse removal procedure.

Up-Down Regulator: Follow Front Seat Assembly Removal procedures above, then disconnect motor field coil and ground wires from bullet connectors. Pull large assist spring forward and unhook it from flange on regulator mechanism to release tension. Remove clevis pins holding regulator to seat track and seat frame, remove regulator assembly. To install, reverse removal procedure.

Activating Switches: Disconnect positive cable from battery to prevent shorts. Remove phillips head screws attaching switch mounting panel to seat frame assembly. Pull mounting panel with switches attached from seat frame, disconnect three wires from switch to be removed. Pinch metal clips together which hold switch assembly to mounting panel, pull switch assembly forward out of panel. To install, reverse removal procedure. See Wiring Diagram.

►*THUNDERBIRD ACTIVATING SWITCH NOTE:* Two separate switches are mounted on the floor panel instead of the four-way toggle switch used on conventional models.

Relay Assembly: Disconnect positive cable from battery to prevent shorts. Remove phillips head screws holding relay mounting to seat frame. Pull plate with relays attached forward and disconnect wires to relay which is to be removed. Remove two nuts and bolts holding relay to attaching plate, remove relay. To install, reverse removal procedure. See Wiring Diagram.



TROUBLE SHOOTING: Check as follows:

Seat Will Not Go Forward or Backward or Up or Down: Shorted or open lead from starter relay to circuit breaker.

Seat Will Go Forward or Backward But Not Up or Down (or vic versa): Shorted or open lead from relay to motor; shorted or open armature or field coil winding; open ground connection from motor; shorted or open seat regulator switch connections, or relay coil windings.

Seat Operation Sluggish or Noisy: Motor brushes chipped or improperly seated; excessive armature end play; insufficient clearance between armature and field coils; regulator mechanism binding or has chipped or broken threads.

SERVICE PART NUMBERS: Lincoln and Mercury numbers as follows:
Seat Control Motor—No. FAB-14547-A.
Seat Control Relay—No. FAA-14546-A.
Seat Control Switch—No. FAA-14545-A.

1953-54 LINCOLN SEAT CONTROL WIRING DIAGRAM

G.M. ELECTRIC SEAT CONTROL

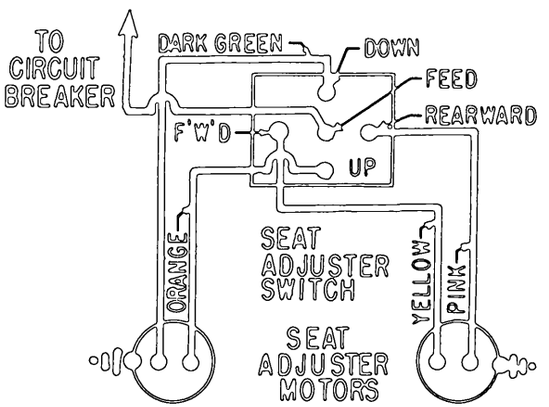
Buick (1954-55)
Cadillac (1954-55)
Chevrolet (1954-55)
Oldsmobile (1954-55)
Pontiac (1954-55)

▷CHANGES & CORRECTIONS

▷*1955 CADILLAC REGULATOR PRODUCTION CHANGE (To Reduce Seat "Chuck"):* Effective with Engine No. 57610 (approx.), tensioner springs have been installed between seat frame and seat adjuster to minimize free movement in the seat assembly. These tensioners may be installed on earlier cars to eliminate objectionable noise due to movement of seat adjuster parts. To install tensioner springs, remove front seat assembly with seat adjusters attached, drill and chamfer holes in horizontal equalizing links as follows:

4-D r Sedans—Drill a 5/16" diameter hole 1¾" from arm and link pivot and on centerline of link. Chamfer both sides 1/16" x 45°.

2-D r (With Horizontal Seat Control Only)—Drill a 5/16" diameter hole 1¼" from arm and link pivot (measured on centerline of link) at a point 11/32" from top (widest) edge of link. Chamfer both sides 1/16" x 45°.



2-D r (With Horiz ntal & Vertical Seat Control)—Drill a 5/16" diameter hole 1¾" from arm and link pivot and on centerline of link. Chamfer both sides 1/16" x 45°.

On 4-Door Sedans, in addition to hole drilled above, drill another hole 11/32" in diameter in seat frame 1 5/16" rearward of the centerline of the rear attaching hole of the horizontal equalizing rod support. On all cars, install spring retainer, Part No. 4672117, on seat frame as follows: On 2-Door models, remove rear attaching screw of support and secure retainer to seat using same screw. On 4-Door models, secure retainer to frame at drilled hole, using a screw, Part No. 4561558, and nut, Part No. 120368. On all models, install tensioner spring, Part No. 4672116, using a suitable lubricant at spring attaching points. Install seat assembly.

DESCRIPTION: Separate horizontal and vertical seat regulators consist of "jack-screw" type actuators powered by individual reversible type motors which have built in circuit breakers to prevent overloading when operation cycle is completed.

HORIZONTAL SEAT REGULATOR REMOVAL & INSTALLATION: Operate seat to a raised and forward position and disconnect regulator lead wires at connectors. On sedan models, detach tensioner spring from equalizer rod on left side of seat. Turn back carpet, remove regulator floor pan support cover and remove support screws. On sedan models, detach horizontal regulator seat frame support at front of seat. On coupes, remove support screws in floor pan and retaining ring securing regulator to seat front frame rail.

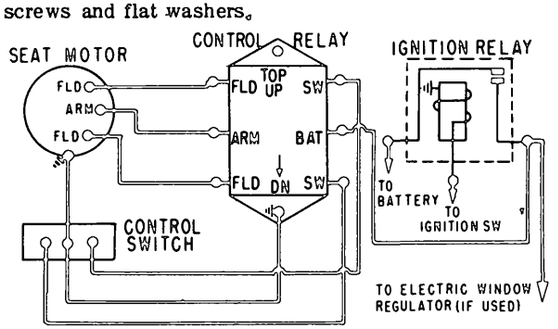
VERTICAL SEAT REGULATOR REMOVAL & INSTALLATION: Operate seat to a raised and forward position and remove retaining ring attaching regulator to floor pan support. Lower seat and detach vertical regulator lead wire connectors and ground wire. From under front of seat, remove regulator support screws then carefully remove regulator from support pin at rear of seat.

(G.M.) SEAT CONTROL WIRING DIAGRAM

STUDEBAKER SEAT CONTROL

Studebaker (1955)

DESCRIPTION: Seat adjusting mechanism is electrically operated, using reversible type motor which turns screw jack. Control of system is through a switch and relay. Seat adjuster provides fore-and-aft movement.



REMOVAL: Proceed as follows:

Torque Tube Assembly: Remove seat cushion. Remove cotter pins and take out clevis pins connecting torque tube arms with torque tube links. Remove torque tube clamps and remove torque tube.

Motor: Remove seat cushion and three motor operating wires at relay. Remove motor-to-adjuster bracket nuts and ground wire.

Seat Track: Remove seat cushion. Take out shoulder bolt fastening torque tube link to seat track support. Remove capscrews and washers holding seat track to floor pan. Support seat frame on wooden blocks, take out two seat frame-to-seat track screws, remove track.

Seat Frame: Remove seat cushion. Remove cotter pins and take out clevis pins connecting torque tube arms to torque tube links. Take out frame-to-seat track capscrews and flat washers.

DeSoto All (1942-48)	①EWH-5001, EWH-5003
Dodge D19 (1941)	①EWD-5001, EWD-5003
Dodge All (1942-48)	①EWH-5001, EWH-5003
Plymouth P11, P12 (1941)	①EWD-5001, EWD-5003
Studebaker Comm. 11A (1941)	EWD-5002
Studebaker Pres. 7C (1941)	EWD-5003
Studebaker Comm. 12A, Pres. 8C (1942)	EWH-5004

①—EWD-5003, EWH-5003 used on Convertible Models only.

▷NOTE: EWD Type Windshield Wiper Motors. This motor may continue to operate indefinitely after the switch has been turned OFF. This condition can be corrected without removing motor from car. Run the wiper motor for ten or fifteen minutes before making any adjustments, then stop the wiper with the blades at the top of their sweep by either turning off the ignition switch or opening the line between the battery and the wiper control switch. Insert a screwdriver underneath the cam (after removing the inspection cover) and bend it out .004" to .006". Extreme care must be taken that the cam is not bent out too far or it will strike either the side of the switch plunger or the switch case. Check the motor operation after this adjustment. If it still continues to operate with the switch off, repeat the procedure.

DESCRIPTION & OPERATION: Two speed type of same general design as 'EWB' type used on 1940 car models except for new wiring diagram (see illustration) and new "Parking" mechanism as follows:

Parking Switch—Consists of a simple pushbutton type switch mounted on a bracket on the drive gear housing and actuated by a cam on one of the crankarm shafts. When control switch is turned 'off' motor circuit is completed through parking switch and motor continues to operate until the blades reach the parking position when the cam strikes the push button and opens the switch.

Motor Resistor—Consists of a carbon block resistor in the drive gear housing (see illustration) which is connected in the field circuit. In the low speed position, the resistor is short-circuited by the switch, while in the high speed position, the resistor is in series with the motor field.

CIRCUIT BREAKER: Chrysler, DeSoto, Dodge, Plymouth Models—Windshield wiper is protected by a thermostatic type circuit breaker mounted on the back of the control switch. Circuit breaker begins to operate when the current reaches 12 amperes and vibrates to prevent an excessive current flow.

Studebaker 1941 Models—Circuit breaker is not used. Windshield wiper is protected by a 14 ampere

CONTINUED ON NEXT PAGE

EWD, EWE, EWH TYPES (C nt.)

fuse in a connector in the feed wire between the control switch and the regular car fuse block.

Studebaker 1942 Models—Circuit breaker is same as on Chrysler models (above).

ADJUSTMENT:—Park Angle—Crank arms must stop at correct parking angle to insure wiper blades being parked in correct position on windshield. See illustration for 'park angle' measurement.

CarModel	Parking Angle
Chrysler, DeSoto, Dodge, Plymouth.....	26°
Studebaker	18°
EWE (12 volt Types)	26°

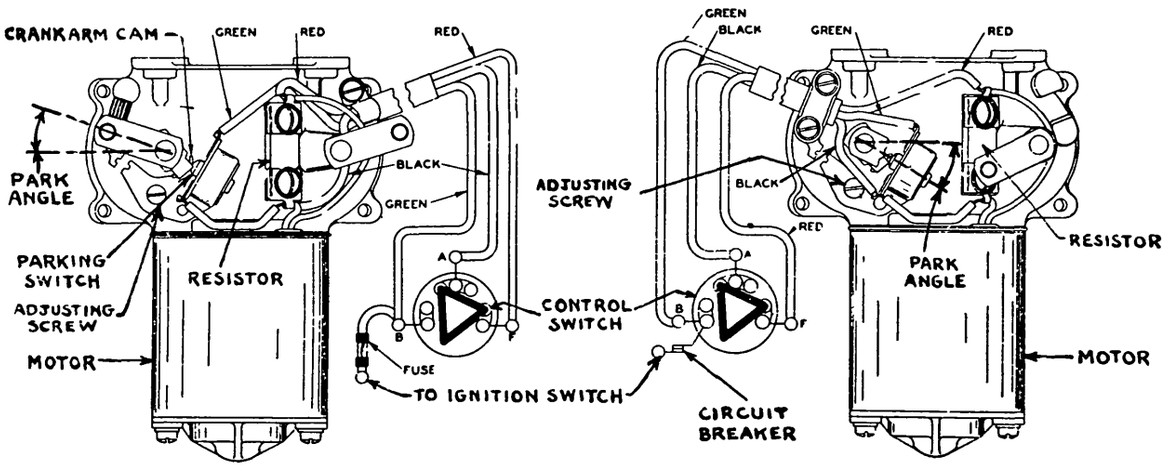
To Adjust—Remove motor cover, loosen adjusting screw (see illustration), turn parking switch bracket as required so that cam on crank arm opens switch contacts with crank arm in correct parking position, tighten adjusting screw securely.

SERVICING:—Armature & Gear Replacement—Complete armature and gear set must be installed together if either armature or gears requires replacement. Armature shaft worm gear and crank arm gears are run-in at the factory.

Crank Gear Assembly—When installing crank arms and gears, use Crank Aligning Tool ST-298 to insure correct position of crank arms. Turn crank arms so that they point toward each other, slip aligning tool over both arms so that pivot pins at ends of arms fit into holes in fixture, hold arms in this position and assemble gears on cross-shafts. See that gears are assembled with punchmark up and that the slot in the lockplate lines up with the flats on the side of the cross-shaft and that ears on ends of lockplate fit in holes in gears.

Bearing Alignment—After motor completely assembled (but before running), strike frame several sharp blows with rawhide hammer to insure correct alignment of bearings with armature shaft.

Armature Endplay—Must be .005" minimum, .010" maximum. To adjust endplay, remove gear housing cover, expand or contract armature stop button support arms (in housing at end of armature shaft).



Motor Lubrication—No oilers provided and motor bearings do not require lubrication in service. Gear box should be filled ¾ full with special Auto-Lite ST-295 gear grease (do not use any other type) before assembly and both crank cross-shafts should be coated for entire length with this same grease before installed in housing. Use care not to get grease on motor commutator or control contacts. CAUTION—See that both crank arms are installed in correct position.

Motor Specifications

Starting (Under Load)—4.0 volts (6 volt units), 8.0 volts (12 volt units) with control switch in High Speed position.

Current Draw—Depends on motor speed (less at high speed) as follows:

		Amperes	
	Voltage	Low Speed	High Speed
6 Volt Units.....	7.0 volts.....	5.0 max.....	4.0 max.
12 Volt Units.....	14.0 volts.....	2.5 max.....	2.0 max.

Field Current—2.45-2.85 amperes at 6.0 volts (6 volt units), 1.25-1.45 amperes at 12 volts (12 volt units).

Motor Speed (Full Load)—32-40 crank RPM. (Low speed), 55-60 crank RPM. (High Speed).

TESTING:—Control Switch—Use a test lamp with one lead connected to a 'hot' terminal (such as the ammeter), connect other lead as follows: With all wires disconnected from control switch, and switch turned off, connect test lamp lead to switch 'A' terminal and ground 'F" terminal. Lamp should light. Turn switch to Low Speed position, connect test lamp lead to switch 'B' terminal. Lamp should light when either 'A' or 'F' terminal grounded. Turn control switch to High Speed position, connect test lamp lead to switch 'B' terminal and ground 'A' terminal. Lamp should light.

Parking Switch—With control switch wires disconnected, connect test lamp lead to park switch lead (green wire), ground other park switch lead (black wire on Chrysler—on Studebaker, touch ground wire to other park switch terminal). Lamp should go out when parking switch contact button is pressed in and should light when button released (crank arms must not be in park position when this test made).

Motor—Connect wire from negative terminal of 6 volt test battery to black wire disconnected from control switch, ground positive terminal of battery to motor frame. Motor should operate at full speed. If motor does not run, check for open armature or field circuit, worn or stuck motor brushes, binding or jammed armature or gears (armature and gears should turn freely by hand).

TROUBLE SHOOTING: If wiper action not satisfactory, check as follows:

Motor Will Not Start or Run

1. **Fuse Blown (When Fuse used).** Before replacing blown fuse, check following possible causes: Check all connections, check motor ground, check all motor leads for grounds and open-circuits.

2. **Loose Connections in Wiper Circuit.** Check all wiring. Tighten connections at Windshield Wiper, Control Switch, and Ignition Switch.

3. **Crank Arm Shafts Binding.** Make certain that cross shafts greased for entire length with special ST-295 grease before installing.

4. **Linkage Binding.** Make certain that linkage between crank arm and pivot arms is not binding and that wiper blades and pivot arms operate freely.

Motor Stops with Blades in Wrong Position

1. **Park angle incorrectly set.** See adjustment section above.

Motor Will Not Stop

1. **Parking mechanism out of adjustment.** Check Park adjustment (see Adjustment section above).

▷*1951-53 DODGE & PLYMOUTH NOTE—See "Auto-Lite Windshield Wipers (Single End Motors)" and "Redmond Windshield Wipers" for other applications.*

▷*1953 WINDSHIELD WIPER PRODUCTION CHANGE & MODIFICATION OF EARLY UNITS:* Later windshield wipers have new design follower gears, crank and cross arm assemblies, pivot assemblies, and linkage. If trouble experienced with early units (bent linkage or hammered out grommets, broken or stripped gears, burned motors, or incorrect parking position not due to incorrect adjustment, *see Modification Data below.*

▷*FAILURE TO PARK CORRECTION ("EMG" TYPE WIPERS):* This condition is noticeable when load on wiper is decreased due to wet windshield and worn blades. Motor will coast past park position and continue to operate until ignition switch turned off. To correct, install a new cam, part of Kit STA-87, and adjust the gap to the maximum limit of .030" by bending the contact base plate (do not bend contact arm). Change both brush springs to Part No. EWF-18 to increase tension on armature. Install new wiper blades and wiper arm springs.

DESCRIPTION: Wiper assembly consists of a two speed shunt wound motor mounted between two gear assemblies, each driving a crank arm.

REMOVAL: Disconnect wires from switch. Disconnect linkage at each motor crank arm. Remove screws attaching wiper mounting bracket to body and remove wiper assembly.

▷*CAUTION—Do not move wiper blades across windshield manually. Damage to gear assemblies will result.*

DISASSEMBLY: Remove parking switch and gear case cover, gear retaining nuts, lockwashers, keys and plates. Then remove right and left hand worm follower gears by pressing the crank arm shafts out of heads. The long bolts through motor should be removed, thus allowing heads and armature to be disassembled, after unsoldering field coil lead wires.

INSPECTION: Inspect motor parts for wear or damage. Clean commutators with double or triple "O" sandpaper, or if necessary, turn down and undercut commutator. Undercut should be not deeper than 1/16". Use a very thin hack saw blade. Worn or oil soaked brushes must be replaced. Check the play of armature and crank arm shafts in their bushings and replace worn parts, if any looseness can be found. Replace any worn or damaged gears.

REASSEMBLY: Assemble motor frame, armature and heads, making sure field leads have been resoldered properly. Check armature end play, adjust by installing thrust washers inside head until desired clearance of .005-.010" is obtained. Rap motor frame sharply with a rubber hammer to align bushings, then check to see that armature turns freely. Slide washer over crank arm shaft and then apply a thin film of grease to shaft and install through head. Turn arms so that both point exactly toward the other, then place spring washer and thrust washer over shaft and install gears in position. The holes in the gears must be lined up with flats on shaft (NOTE —Have prick punch mark up, when gears are so marked). Fill gear housing ½ full with a light high temperature non-fibre grease. Install plates, gear case cover and parking switch. (CAUTION—When installing plate (with ramp), the ramp must be directly under plunger in the parking switch.

INSTALLATION: Reverse the Removal instructions given above.

PARKING ADJUSTMENT (Except EWJ Type): Adjust by moving arm extending from under parking switch cover. Operate wiper and note parking position when wiper is turned off. Obtain proper parking position by adjusting arm. *(CAUTION*—plate mounting rivet should be tight enough so that plate will not slip and will still allow movement of the adjusting arm.) Make certain that all parts are correctly assembled (see Reassembly above). Adjust switch so that cranks point outward on a line parallel to the motor centerline with tolerances as indicated in table below. Have motor cold and test with loads on each crank arm as indicated in table below.

PARKING ADJUSTMENT (EXC. EWJ TYPE)

Motor No.	Tolerances① Before	Tolerances① After	Crank Arm Load
EME-4001, A		17°	2 lbs.
EMF-4001		17°	2 lbs.
EMG-4001, A, B		17°	5 lbs.
EMG-4101, A, B		17°	5 lbs.
EMG-4102, A, B	11°	6°	3¾ lbs.
EMG-4103, A, B	11°	6°	3¾ lbs.
EMK-4001		17°	5 lbs.
EMK-4101	11°	6°	3¾ lbs.
EMK-4102	11°	6°	3¾ lbs.

①—Before or after point on line parallel to motor centerline.

PARKING ADJUSTMENT (EWJ Type): Loosen screw holding parking switch bracket in place. Turn bracket as required to obtain proper parking position, tighten screw.
Parking Angle (EWJ-4004)—17° ± 4° (angle between crank arm and centerline of motor). Crank arms park out away from motor.

PARKING SWITCH: Make sure both contact arms are in good condition and either straight or bent slightly toward each other, and that the spring washers have not been flattened or damaged. Nut on switch should be turned down until push rod just opens the contacts when it is on the high point of the cam. Check to make sure assembly is tight, then turn cam to close contacts. Adjust tension on contact arms to 1.5 to 3 ozs., by hooking scale to contact point and taking the reading just as points open. Adjust by bending contact arm, keeping points aligned.

LUBRICATION: At overhaul, add 10 drops of medium oil to the felts at armature shaft bearings. Drain off excess oil. At assembly, grease crank arm shafts and fill gear chambers ¾ full with ST-294A gear grease. Lubricate pivots with ST-294A grease at yearly intervals.

SPECIFICATIONS: Wiper Motor
Field Current Draw: (EWJ) 2.4-2.9 amperes at 6.0 volts, (EME, EMG) 2.3-2.5 amperes at 6.0 volts, (EMF, EMK) 1.1-1.3 amperes at 12.0 volts.

CONTINUED ON NEXT PAGE

AUTO-LITE "DOUBLE-END" (Cont.)

Low Speed

No-load Draw:	Amperes	Volts	R.P.M. (Approx.)
EWJ	5.0	7.0	
EME	4.0-4.6	6.0	40
EMF	1.9-2.3	12.0	40
EMG	4.4-4.8	6.0	46
EMK	1.9-2.3	12.0	44

High Speed①

EWJ	4.0	7.0	
EME	3.2-3.6	6.0	68
EMF	1.5-1.9	12.0	65
EMG	3.7-4.0	6.0	74
EMK	1.6-2.0	12.0	70

①—With resistors in field circuit as follows: (EWJ) 2.7-3.3 ohms, (EME) 3.5 ohms, (EMF) 14 ohms, (EMG) 2.8 ohms, (EMK) 12.5 ohms.

Endplay: .005-.010". Use EWJ-81, 81A or 81B thrustwashers as required to obtain this endplay. Place on drive end of armature shaft.

Parking Switch

Contact Pressure: 3-5 ounces.

MODIFICATION KITS: Furnished as follows:

Wiper No.	Chrysler Part No.
EMG-4001	1540494
EMG-4101	1540501

NOTE—Grommet and Nut Package, Chrysler Part No. 1450558 available for use when making above modifications.

Modification (Double End Motors except EWJ): Remove wiper motor, links and pivot from car, discard links and pivots, then proceed as follows:

End Head Modification—1) Remove thru bolt from crank side of motor only, **without disturbing other thru bolt.**

2) File sufficient material from screw bosses on end heads to provide clearance for new longer crank arms.

3) Countersink hole at switch end to receive new thru bolt, install new thru bolt and tighten securely.

Changing Gears & Crank Arms—1) Remove parking switch cover, lift switch and mounting bracket off end head. ***CAUTION—Do not lose parking switch plunger located on underside of switch plate.***

2) Remove cover from other end of wiper motor, save gaskets for re-use in assembly.

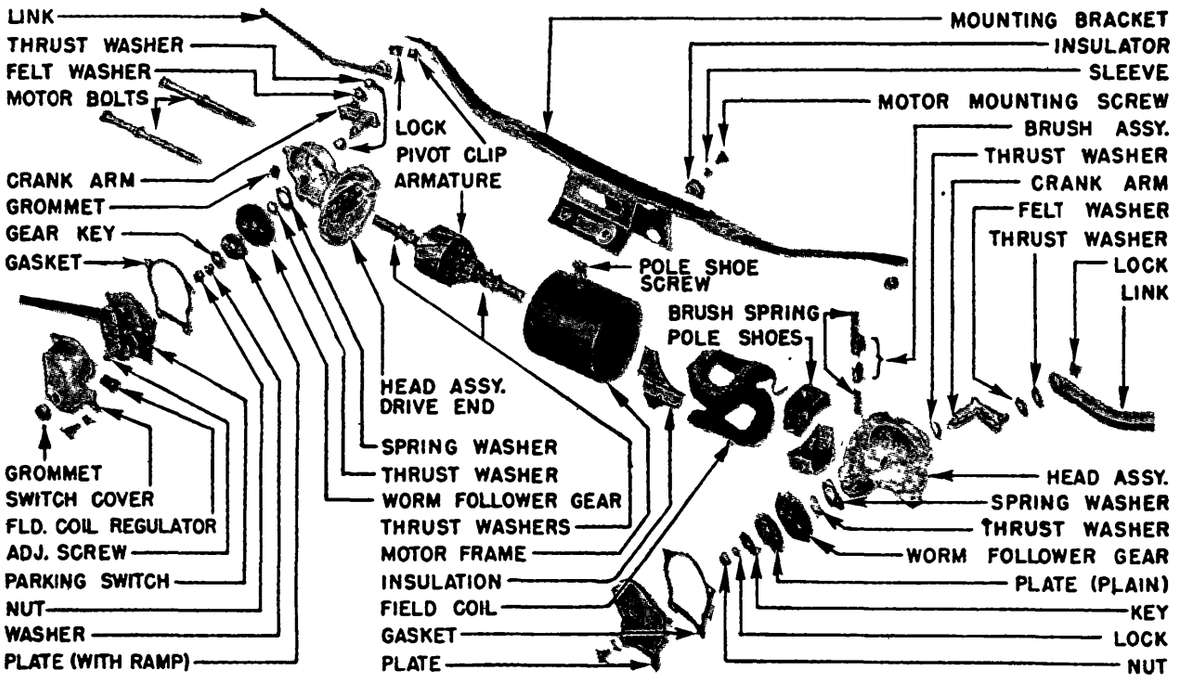
3) Take out old fibre gears by removing retaining nut, lockwasher, gear key and washer (at switch end parking cam used instead of washer).

4) Take out and discard crank arms but save two thrust washers and spring washer, clean out gear box. Assemble thrust washer on shaft of new crank arm, apply film of grease on crank arm shaft, insert shaft through end head.

5) Turn crank arms so that they point out and are parallel with frame, check gears to be sure which end of motor they fit (mesh gears with armature worm). Gear for switch end is to have parking cam between gear and gear lock, while other gear has plain washer between gear and gear lock. Tap gear lock into holes in gear.

6) Assemble spring washer and thrust washer on crank arm shaft, then, holding crank arm pointing out and parallel to frame, carefully assemble gear and gear lock by meshing gear teeth in worm and gear lock to flats on shaft. Be sure gear at switch end has cam with slots parallel to frame and raised portion facing gear lock. Recheck position of crank arms (must be in same relative position to within one gear tooth). Assemble lockwasher and nut, then tighten.

7) Fill gear housing ½ full with MoPar Speedometer Cable Lubricant (Part No. 1243632) or Auto-Lite Gear Grease (Part No. ST-294A), place gaskets on heads, reassemble covers. Be sure pin in parking switch is in position.



8) Run motor, check crank arm parking position. Arms should park so that they are approximately parallel with frame. Parking position can be adjusted by moving arm extending from under parking switch cover.

9) Install motor in car, tighten mounting nuts securely. ***CAUTION—Do not over-tighten to crush eyelets in mounting grommets.***

10) Install new pivots with new gaskets. Sponge rubber gasket is installed inside car and rubber coated paper gasket on outside. Tighten mounting screws temporarily.

11) Install new links, add drop of oil to felt washers, then run motor momentarily to be sure pivot crank arm swings centrally between rubber bumpers. If necessary to center crank arm swing, file off index on top of pivot and move pivot sideways to provide proper adjustment, tighten pivots securely, install arms and blades.

12) Check installation to be sure blades park properly. Parking position can be adjusted by moving the parking switch adjustment lever on wiper motor or by moving wiper arms on serrations on wiper pivot.

AUTO-LITE "DOUBLE END" MOTOR WINDSHIELD WIPER

REDMOND ELECTRIC TYPES

Dodge Six (1951-54)
Plymouth (1951-54)
Studebaker Commander (1952-55)
Studebaker Champion (1952-55). Optl.

►*DODGE & PLYMOUTH NOTE—See "Auto-Lite Windshield Wiper (Single End Motors) and (Double End Motors)" for other applications.*

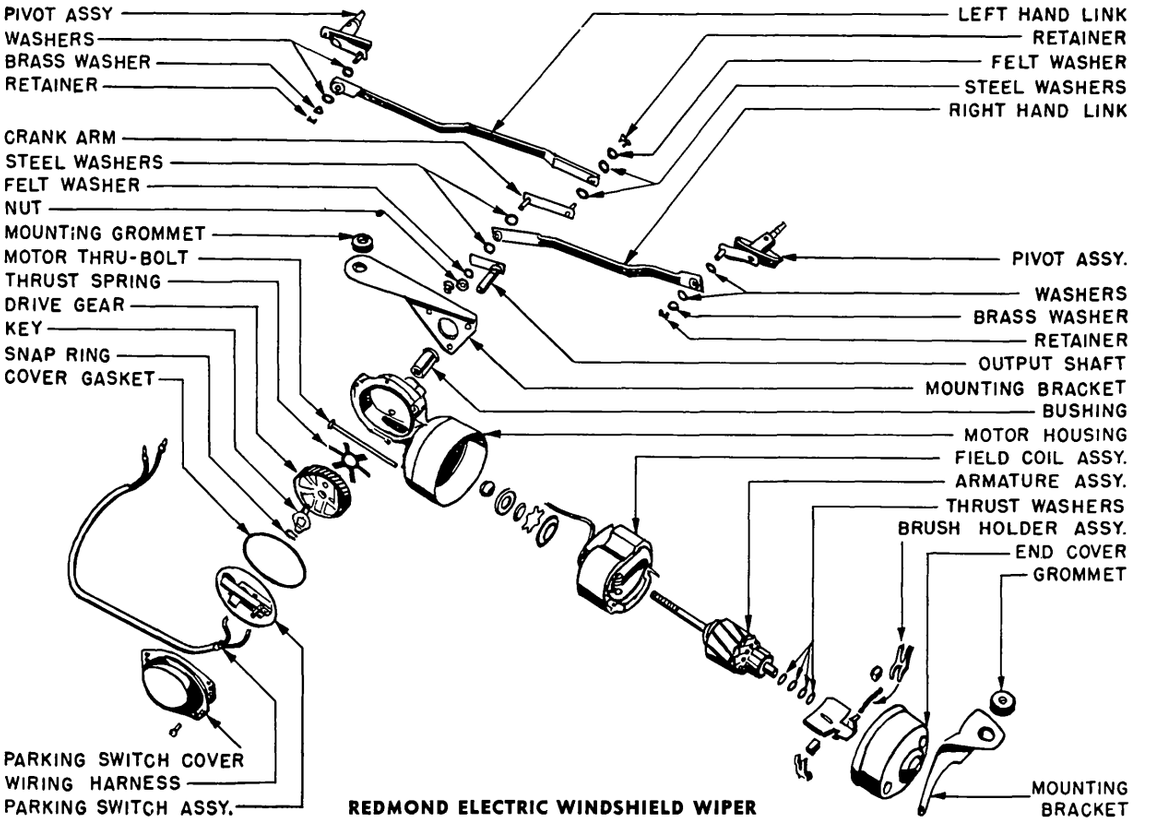
►CHANGES, CAUTIONS, CORRECTIONS

1952 DODGE & PLYMOUTH IMPROVED LINKAGE ASSEMBLIES: Stronger linkage assemblies (Longer channel section on links, hardened links, and new design crank arms) furnished for service in special kit, Mopar Part No. 1479947. Install parts as follows: Remove drive gear housing cover for access to output shaft retaining snap ring, remove snap ring, remove crank arm assembly. ***(CAUTION—do not disturb position of drive gear in housing—if gear disturbed reset Parking Position as directed below).*** Install new longer crank arm and new crank lever. Connect links (NOTE—use felt washer on each side of link, install lockwasher under nut at crank arm, and plain washer under clip on crank lever stud). DO NOT use oil on felt washers (use graphite only). Make certain that nuts are tight and that snap ring and clip properly installed.

►***1953 STUDEBAKER WINDSHIELD WIPER RUNNING IN "OFF" POSITION (First Cars):*** On cars with windshield wiper motors made before Jan. 23, 1953 (code dated earlier than 23-X-1), if wiper motor continues to run after switch is turned off, replace motor with one of later manufacture (Code dated 23-X-1 or later). These later motors have been changed to eliminate possibility of this condition.

►***1953 STUDEBAKER WIPER BLADES LIFTING OFF GLASS AT HIGHER CAR SPEEDS:*** This condition can be helped by installing wiper arms having higher tension (as used in later production). These later type arms have 7¾-8¾ ozs. tension (increased from 6½-7½ ozs. tension on first type).

Higher Tension Wiper Arms



Model	Assy. Part No. (R&L)
All (exc. Coupe & Hard-Top)	290288-9x2
All (Coupe & Hard-Top)	290288-9x3

DESCRIPTION: Wiper consists of motor mounted on a single gear assembly which drives both wiper arms through a double crank. Parking switch is mounted on gear assembly housing. System is protected by circuit breaker in control switch.

PARKING ADJUSTMENT: ***Required when drive gear position in housing disturbed.*** Place shaft in housing so that crank arm points to left and downward at an angle of about 30° with crank lever horizontal or approximately parallel to center line of motor. With arm and lever in this position, high side of parking index cam must be toward left (viewing face of gear with housing cover removed). ***See Blade Adjustment also.***

BLADE ADJUSTMENT: Blades can be placed in proper operating position by loosening attaching nuts and moving arm on serrated mounting. A further MINOR adjustment can be made by moving the parking switch lever of the motor assembly DOWNWARD (this will park blades closer to the lower windshield moulding).

REMOVAL: Remove radio, disconnect wires from switch. Disconnect wiper linkage, using care not to damage it, then remove screws holding brackets to body and remove wiper assembly.

REDMOND ELECTRIC WINDSHIELD WIPER

►***CAUTION—Keep hands and fingers away from windshield wiper operating linkage when wiper motor is running. Power of wiper motor is sufficient to cause serious personal injury.***

TESTING WIPER MOTOR: With motor removed, ground case and connect one lead wire to a 6-volt battery. When one of wires is connected to battery, motor should run continuously; connecting other wire should cause it to complete one cycle and park.

RECONDITIONING WIPER MOTOR: Disassemble wiper motor, remove gear box cover. Inspect for wear, corrosion or damage. Clean armature commutator with 00 or 000 sandpaper or, if necessary, turn down commutator. Replace worn or oil soaked brushes. Check armature and crankshaft in their respective bushings, replace worn parts if any looseness detected. End play in armature shaft is controlled by a thin thrust washer in end plate. Inspect gears for worn or broken teeth and replace those showing damage or excessive wear. Be sure parking switch contact is clean and dry.

Refacing Commutator: If commutator rough, out-of-round, burned or bakelite is even with or extends above surface of commutator, commutator should be turned down. **Remove only enough metal to give smooth, clean surface.** Be sure commutator is clean and free from oil or grease. A dirty, greasy commutator will cause high resistance and greatly impair efficiency of wiper. Assemble frame, armature and head, being careful to raise brushes to allow entrance of commutator. Rap motor frame several times with rubber hammer to align brushes.

INSTALLATION: When installing motor be sure not to tighten attaching studs too tightly. Rubber mounting will be distorted and cause metal-to-metal contact resulting in wiper motor noise. Place drop or two of machine oil on each of felt washers in linkage assembly. Check to see that ground strap on housing and mounting bracket is in place. Be sure linkage is properly positioned when replacing motor. Each arm is identified as being either right or left (stamped "R" or "L").

TROUBLE SHOOTING: Check as follows:

Wiper Motor Will Not Run: Test for defective switch, inspect for binding linkage, defective motor, loose or defective wiring.

Wiper Operates Slowly: Check for high resistance in brush to commutator contact, or carbon deposits in slots, high resistance in ground connection, pivot shaft binding, defective control switch, worn or damaged motor.

Wiper Motor Runs and Stops: Inspect for faulty or defective wiring, check for linkage binding. Operating arm should be parallel with crank arm.

1954 (P25 Late)	EMU-4001

►*DODGE & PLYMOUTH NOTE—See "Auto-Lite Windshield Wipers (Double End Motors)" and "Redmond Windshield Wipers" for other applications.*

►CHANGES & CORRECTIONS

►*"EMU" TYPE WIPER PARKING ADJUSTMENT NOTE: Parking Switch is different than used on other type wipers. See "1955 Single End Windshield Wiper Motors."*

►*1952 DODGE & PLYMOUTH IMPROVED LINKAGE ASSEMBLIES:* Stronger linkage assemblies (Longer channel section on links, hardened links, and new design crank arms) furnished for service in special kit, Mopar No. 1479946 (exc. Convt. & Belvedere), No. 1479948 (Convt. & Belvedere). Install parts as follows: Remove drive gear housing cover (for access to output shaft), remove nut on end of shaft, remove crank arm assembly *(CAUTION*—do not disturb position of drive gear in housing—if gear disturbed, reset Parking Position as directed below). Install new longer crank arm and new crank lever. Connect links *(NOTE*—use felt washer on each side of link, install lockwasher under nut at crank arm, and plain washer under clip on crank lever stud). DO NOT use oil on felt washers (graphite only). Make certain that nuts are tight and that clip properly installed.

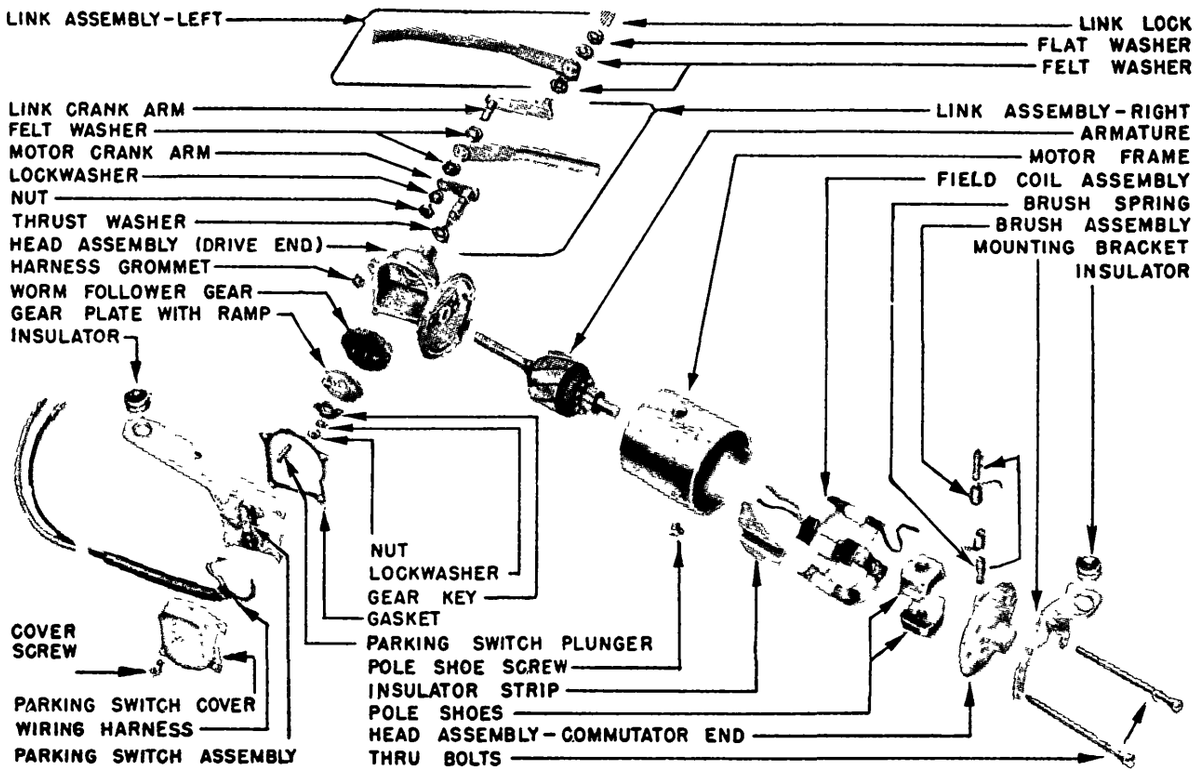
►*1953 DODGE & PLYMOUTH IMPROVED WINDSHIELD WIPER MOTOR DRIVE PARTS (For smooth operation of Two-Speed Motors):* Modify motors on first cars by installing all parts furnished in kits listed below (Crank Arms, Gears, Pivots).
CAUTION—DIFFERENT kit required for motors with ⅛" or 3/16" thick gears. Determine kit required by inspection of gears or note thickness of mounting grommet which will indicate gear thickness as follows: 5/16" grommet—⅛" gear, 7/16" grommet—3/16" gear.

Motor Type	Modification Kit Part No.
⅛" Thick Gears	1540496
3/16" Thick Gears	1540503

►*WINDSHIELD WIPER NOISE & VIBRATION:* If installation of improved drive parts (above) does not correct this condition, remove and discard rubber grommets, metal ferrules, and attaching nuts and washers from mounting brackets *(CAUTION*—ferrules must be removed from motor mounting studs). Install three new rubber grommets **without** ferrules (Part No. 1540181) in bracket mounting holes, install motor and bracket assembly on mounting studs, assemble new sleeve nuts (Part No. 1527832) and plain washers (Part No. 632258) on studs, tighten nuts securely *(CAUTION*—Do not overtighten these nuts).

DESCRIPTION: Wiper assembly consists of single speed motor mounted on a single gear assembly which drives both wiper arms through a double crank. Parking switch is mounted on gear assembly housing and is operated by plunger and gear plate with ramp.

REMOVAL: Disconnect wires from switch and disconnect wiper link assembly by removing nut from motor crank arm (see illustration) and pulling out link crank arm. Remove screws holding mounting brackets to body and remove wiper assembly.



►***CAUTION—Damage to wiper assembly will result if wiper blades and arms are moved manually.***

DISASSEMBLY: Remove parking switch cover and take out parking switch assembly (part of mounting bracket) and lift out parking switch plunger. Remove nut from gear shaft and then take out lockwasher, gear plate (with ramp) and worm follower gear (see illustration). Carefully press motor crank arm and gear shaft out through front of gear housing. ***(CAUTION—Use care when handling the worm follower gears, these are easily damaged).*** Remove the long bolts through motor and take off both head assemblies (after unsoldering field coil leads).

INSPECTION: Inspect motor parts for wear or damage. Clean commutators with double or triple "O" sandpaper, or if necessary, turn down and undercut commutator. Undercut should not be deeper than 1/16". Use a very fine hack saw blade. Worn or oil soaked brushes must be replaced. Check play of armature and crank arm shafts in their bushings and replace worn parts. Replace any worn or damaged gears.

REASSEMBLY: Assemble motor frame, armature and heads, making sure field coil leads have been resoldered properly. Check armature endplay, if not .005-.032" (EWR), .015-.030" (EWY), .005-.015" (EMD with spring washer—installed between two bakelite washers—not compressed), adjust by installing correct thickness washer .023", 1/64", 1/32" thick, on armature shaft just inside drive end bearing. Rap the motor frame sharply with a rubber hammer to align bushings, then check to see that armature turns freely. Slide washer over crank arm shaft then apply a thin

CONTINUED ON NEXT PAGE

1951-54 AUTO-LITE "SINGLE END" MOTOR WINDSHIELD WIPER

1951-54 AUTO-LITE "SINGLE END" (C nt.)

coating of grease to shaft and install through head. Place spring washer and thrust washer over shaft and install gears in position. The holes in the gear must be lined up with flats on shaft (NOTE—Have prick punch mark up, when gears are so marked). Fill gear housing ½ full with a light high temperature non-fibre grease. Install plate (with ramp), then turn armature shaft until motor crank arm is pointing AWAY FROM MOTOR (ramp on gear plate should be directly under plunger position). Install gear key, lockwasher and nut. Install gasket, then insert plunger in switch assembly and install assembly on housing (make sure plunger is directly over ramp on plate). Install switch cover.

INSTALLATION: Reverse the Removal instructions given above. *See "Windshield Wiper Noise & Vibration" correction under Changes, Cautions, Corrections above.*

BLADE ADJUSTMENT: Wiper blades can be adjusted for position by removing the nut on the pivot shaft and moving the blade arm on the serrated pivot. Minor adjustment can be made by moving the parking switch lever on the motor assembly up which will cause the blades to park closer to the lower windshield moulding. *See Parking Adjustment.*

PARKING ADJUSTMENT: *Required whenever position of drive gear and contact switch contact plate disturbed.* Parking switch contact mounting plate can be turned to make adjustments *(CAUTION*—plate mounting rivet should be tight enough so that plate will not slip and will still allow movement of the lever at the side of the gear chamber). Make certain that all parts correctly installed (see Reassembly above), adjust switch so that crank angle and parking angle are correct as follows:

Model	Crank Angle①	②Parking Angle
EWR-5001A, B, D, E③	15° ± 0.5°	14.5°
EWY-4003④		9.5°
EWY-4003A④		4.5°
EWY-5001A, B, D④	15° ± 0.5°	14.5°
EMD-4001, B③		9.5°
EMD-4001A③		4.5°
EMD-4002, B③		10.0°
EMD-4002A③		5.0°
EMD-4003, 4003B		10° ± 7.5°
EMD-4003A		5° ± 7.5°
EMU-4001		5° ± 5°

①—Angle between crank arms and pivot.

②—Angle between crank arm and centerline of motor. Variation is plus or minus 7.5°.

③—Crank arm pointing out away from motor.

④—Crank arm pointing in toward motor.

LUBRICATION: Lubricate when overhauling and assembling unit. Put 10 drops medium engine oil on felts at armature bearings, drain off excess. Grease crank arm shaft and fill gear chamber ¾ full with light high-temperature non-fibrous grease (ST-294A). Lubricate pivots yearly with this ST-294A grease.

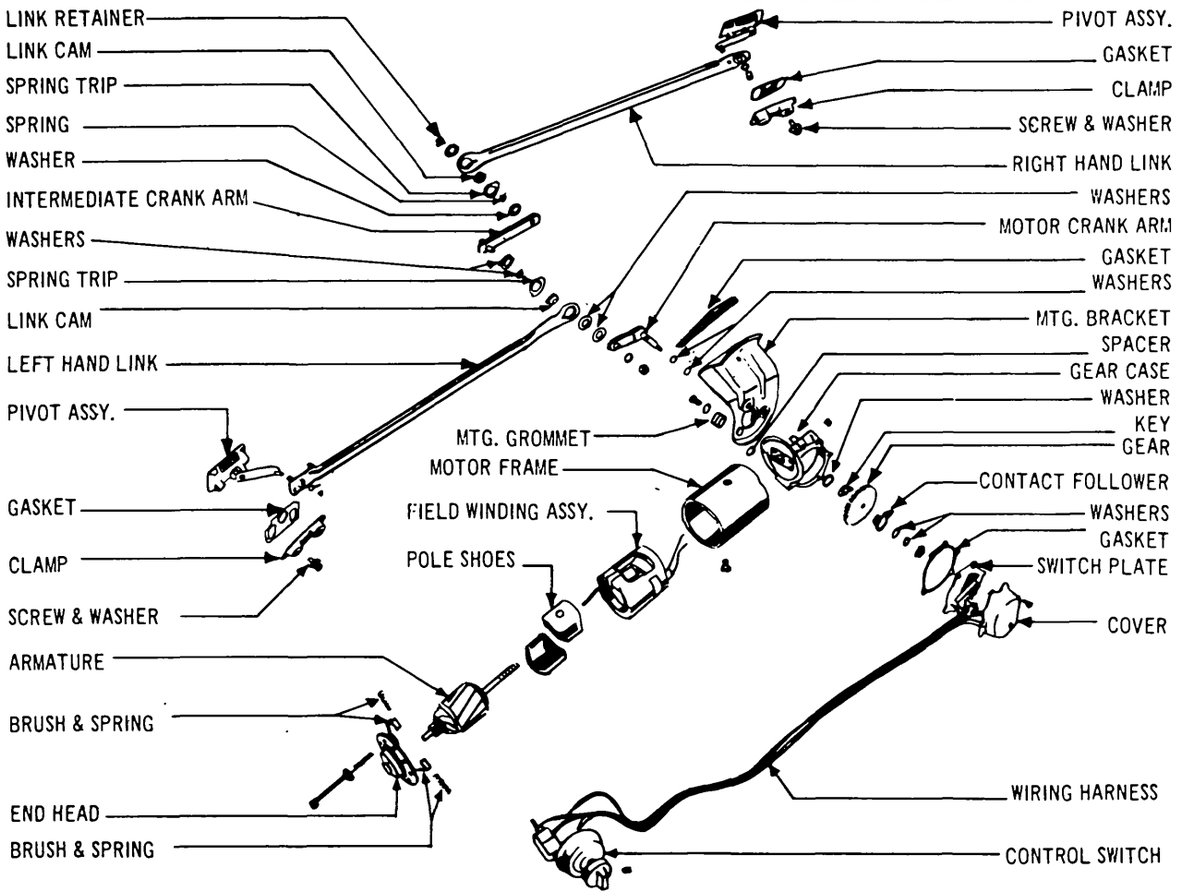
SPECIFICATIONS: **Wiper Motor**

No-Load Current Draw—(EWR) 3.5-5.0 amperes at 7.0 volts, (EWY) 4.0-5.5 amperes at 7.0 volts, (EMD) 5.7-6.1 amperes, (EMU) 5.8-6.3 at 6.0 volts (Cold—70°F).

Field Coil Draw—(EWR) 2.2-2.4 amperes, (EWY) 1.6-1.8 amperes, (EMD) 2.2-2.5 amperes (EMU) 3.2-3.5 amperes. All at 6.0 volts (Cold—70°F).

Parking Switch

Contact Pressure(EWR, EWY) 2-4 ozs.,(EMD) 3-5 ozs.



Contact Pressure—(EMU) 16-24 ozs. when pressed to ½" from switch plate.

Plunger Clearance—(EMD) .010-.020", (EWY-EWR) .020-.030" between contact spring arm and end of plunger with plunger in "down" position. Adjust by bending contact mounting bracket.

1955 AUT -LITE ELECTRIC WINDSHIELD WIPER

1955 AUTO-LITE "SINGLE END" (C nt.)

DESCRIPTION: Wiper assembly consists of motor mounted on single gear assembly which drives both wiper arms through double crank arms. Parking switch is mounted on gear assembly housing and can be adjusted for properly parking the wiper blades. Constant and variable speed motors use same wiper blades, arm assemblies, and pivots. On Convertibles and Sport Coupes, arms (All Models) and pivots (Plymouth only) differ from other models. Reversible variable speed motor has "Off Glass Parking". When switch is turned "OFF", motor reverses direction and parking cams, at pivot pins of intermediate crank arm, rotate 180°, lengthening linkage slightly to park blades against moulding. Linkage shortens when motor runs in wiping direction.

►*CAUTION: To avoid damage to wiper motor gears, DO NOT move wiper blades to clean windshield glass. Lift wiper blade arm outward and away from glass against pivot spring mechanism.*

REMOVAL: Plymouth—Remove radio if so equipped. Disconnect wiper links at pivots, remove motor bracket nuts, lower motor, and remove right side. Use care so as not to bend links.

►*WIPER MOTOR REMOVAL CAUTION: (EMZ-4001)*—Wiper should be operated and shut off by disconnecting it at the circuit breaker, or by turning off ignition key. Damage to motor switch and spring parking cam, upon removal of switch cover will result if cranks are in parked position.

Chrysler, DeSoto, Dodge—Disconnect the wiper leads, remove radio if so equipped, remove right hand fresh air door. Remove clips from pivot cranks, (by lifting top tab and sliding sideways). Remove brass spacing washer, slip end of link containing nylon ball bushing off pivot crankpin, and remove three windshield wiper bracket retaining nuts. Remove motor and bracket with links as an assembly. Remove thick rubber gasket.

DISASSEMBLY (Chrysler, DeSoto, Dodge, Plymouth): Wiper Links (Constant Speed)—Remove clip that holds left link to crank pin, bevel washers and link. Right hand link removed in same manner. **(Variable Speed)**—Remove clip that holds left hand link to crank pin, remove bevel washers, link, cam and spring release. Note stop on pivot end of link. Spread ends of coil spring and remove from around pin, remove spring washer. Right hand link removed in same manner.

Variable Speed Wiper Switch—Remove switch cover plate. Note position of cam spring and remove it. Never attempt to disassemble switch while wiper is in parked position. *See "Wiper Motor Removal Caution (EMZ-4001)" above.*

Motor—Disassembly of the motor is accomplished in the same manner as other wipers of the single gear box type. *See "1951-54 Auto-Lite Windshield Wiper Single End Motor".*

REASSEMBLY (Chrysler, DeSoto, Dodge, Plymouth): Motor - *See "1951-54 Auto-Lite Windshield Wiper Single End Motor".*

Variable Speed Wiper Switch—Be sure gear box contains lubricant. Install parking switch cam spring so that it will engage with the nylon drive gear and the top end of spring points in same direction as the crank arm. Install switch plate and cover.

Wiper Links—(Constant Speed). Reverse removal procedure. **(Variable Speed).** Install spring washer, concave surface towards the crank arm. Compress ends of crank pivot coil spring to expand it, then install pivot and spring release. *NOTE*—Springs and spring releases are both interchangeable. Install parking cam so that it will index with spring release and engage ends of spring between the spring release and parking cam in openings at the point of index. *(See Parking Cam Installation Caution below).* Install spring washer, convex surface towards cam assembly, link arm with stop projection on link arms towards the cam assembly. Install retaining bolt and nut. Reassemble the left link and cam assembly in the same manner, locking in place with a clip in place of bolt and nut.

►*PARKING CAM INSTALLATION CAUTION:* Parking cam is interchangeable, but face of cam marked "L" must be away from the link when installed on left link, or face marked "R" must be away from link when installed on right link. When assembling to the left link, both the "L" on the left crank and on the parking cam should be seen. The same is true of the right link and the letter "R".

REINSTALLATION: Work the links up behind the dash panel and attach to pivot crank pins. Install brass spacing washer. Install lock clips on pivot crank pins and make sure wiper bracket to dash panel rubber gasket is in place, then install wiper motor and bracket assembly. *NOTE*—Do not over-tighten retaining nuts excessively compressing rubber gasket as it will permit transmission of wiper noise. Reinstall fresh air door and adjust. Adjust parking position (see below), reconnect wiper motor wires to wiper control switch.

PARKING ADJUSTMENT: Adjust parking cam at the motor switch plate so that blades park as low as possible. Then loosen the blade arms at the pivots. Position the blades against the windshield moulding on variable speed motors and tighten attaching nuts. Position blades on constant speed motors one inch from windshield moulding.

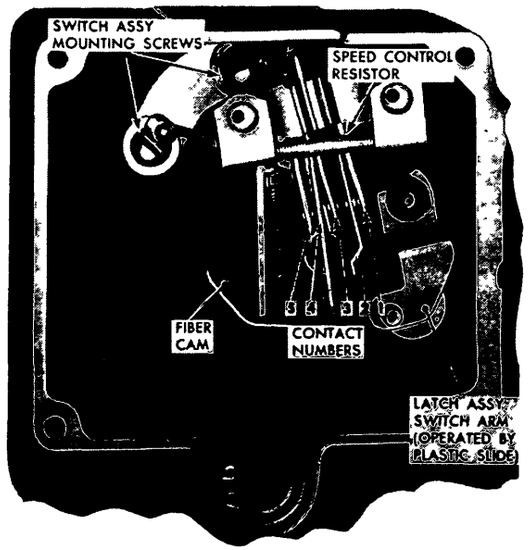
1955 CHEVROLET ELECTRIC WINDSHIELD WIPER

DESCRIPTION & OPERATION: Wiper assembly consists of a single electric motor, auxiliary drive and two transmissions (Electric motor interchangeable with Vacuum type). Transmission incorporates spring loaded pulleys for wiper adjustment. Motor auxiliary drive incorporates two drums to which cables are attached. Wiper motor and auxiliary drive assembly are mounted on engine side of dash and can be removed individually or as a single assembly. Motor controlled by knob on dash panel. Turn knob clockwise for "Low" or "High" speed positions, and counter-clockwise to park wipers.

►*CAUTION: Do not move wiper blades by hand through normal path of operation as damage to mechanism will result.*

►*INSTALLATION CAUTION:* Shims between motor unit and dash panel hold drive unit in proper alignment. Incorrect number of shims, or no shims at all, cause bind in drive resulting in sluggish operation or complete stoppage. *Note number of shims before removing motor.*

MOTOR REMOVAL & INSTALLATION: Loosen screw securing Bowden wire to motor and remove cable. Disconnect feed wire from under dash panel. Remove mounting screws. *NOTE*—Ground wire is attached under one mounting screw. To install, reverse above procedure, using exact number of shims removed.



AUXILIARY DRIVE & TRANSMISSION REMOVAL: *See "Cable Operated Vacuum Windshield Wiper".*

TROUBLE SHOOTING: On the Car—Make the following inspections or adjustments before replacing motor unit.

Motor Unit Inoperative: Can result from any of the following:

1) ("IGN" Switch On). No voltage at motor terminal.

CONTINUED ON NEXT PAGE

CHEVROLET WINDSHIELD WIPER CONTROL

1955 CHEVROLET ELECTRIC WINDSHIELD WIPER (C nt.)

Check wiring.

2) Unit improperly grounded. Clean and tighten ground at auxiliary mounting screw.

►*Disconnect Bowd n wire and remove motor switch cov r b fore proc ding with 3, 4, 5, & 6.*

3) ("IGN" Switch On). Check voltage between contact No. 4 and ground. Contacts number from right to left. No reading indicates open internal motor circuit. Replace motor.

4) Check for loose connections in field leads to switch assembly. Correct defective soldering

5) Switch fiber cam not tripping contact No. 4 against contact No. 3. (Manually operate switch arm to turn unit on and observe action of fiber cam). Fiber cam must be in correct position, contact No. 4 toggle must bottom in fiber cam slot, toggle spring must be in position and coil spring connected.

6) Dirty contacts (No. 3 or No. 4). Clean contacts with crocus cloth.

Hard To Turn On: Can be caused by either of the following:

1) Bowden wire kinked or bent. Remove kink or replace wire.

2) Switch fiber cam not sliding up over oscillating shut-off arm when unit is turned on. Remove switch cover and operative unit to move oscillating arm away from switch fiber cam and polish end of switch fiber cam with crocus cloth.

Unit Will Not Shut Off: Caused by failure of oscillating shut-off arm not tripping contact No. 4 away from contact No. 3, or poor switch adjustment. Oscillating arm should come up and push against lower half of the end of the switch fiber cam. Adjust switch as follows: Loosen switch assembly mounting screws, move switch toward oscillating arm and tighten mounting screws. Test for slow, fast, and park positions.

No Fast Spe d: 1) Caused by No. 1 and No. 2 contacts not opening in fast speed switch position. Remove switch cover, manually switch arm that is normally moved by the plastic slide to the high speed position. Ear on switch fiber cam should move contact No. 2 away from contact No. 1, or adjust switch as follows: Loosen switch mounting screws, move switch assembly toward motor section of wiper unit and tighten mounting screws. Test for slow, fast, and park positions

2) Switch fiber cam slot not seated properly in contact No. 4 toggle blade. Position fiber cam slot in toggle blade.

3) Switch cover shorting on resistor terminal nearest motor. Bend down resistor terminal so that it will clear cover.

No Slow Speed: Contacts No. 1 and No. 2 not making contact at "Low" speed position. Check for dirty contacts and clean as necessary. If contact No. 1 and No. 2 seem to be separated in the "Low" speed switch position, it may be possible to bend contact No. 1 slightly so that it will make contact with No. 2.

Wip r Blad s N t Parking Against L wer Edg f Windshi ld, (jumps away from dg 30-45°): No slow speed. *S r m dy for "No Slow Speed" abov .*

High Speed Excessive (Contacts No. 1 and No. 2 Open): Excessive speed (above normal 160-180 wipes per minute) caused by switch assembly resistor mounting rivets loose or resistor open. Tighten rivets to make solid contact, replace motor unit if resistor open.

Excessive Speed Both "Low" & "High" Positions: Caused by defective soldering of the black shunt field lead to the switch assembly, Resolder lead to switch.

DESCRIPTION: Wiper consists of a single motor unit connected to left and right hand wiper arm shafts by flat or round metal links. Motor control valve is built-in or separate.

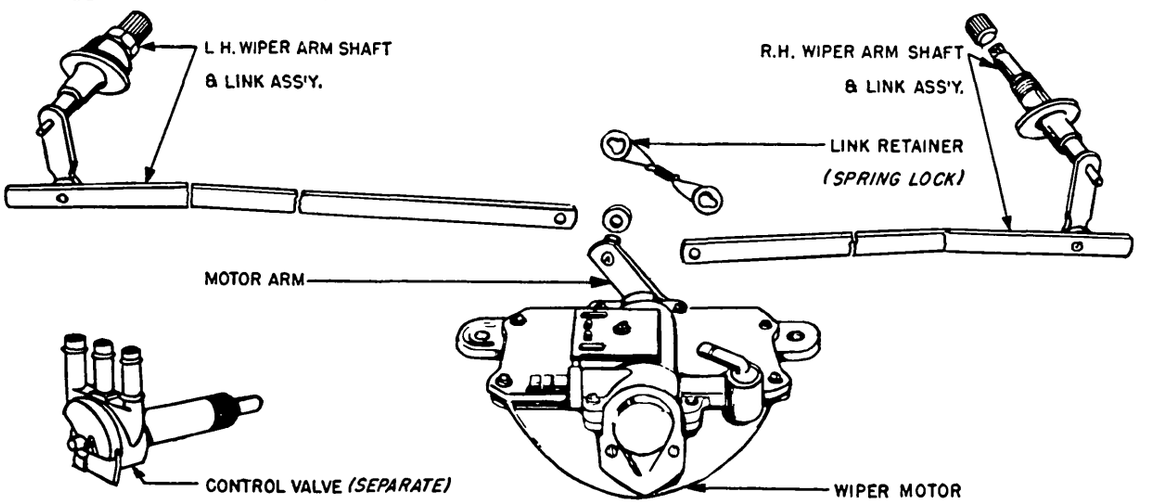
Windshield Washer Connection—Vacuum line connection provided on some motors for washer operation (capped if washer not used).

Wiper Arm Shaft & Link Assembly—Left and right (non-interchangeable) assemblies consisting of arm shaft and crank connected to the motor arm by a flat metal link. Assembly is not adjustable.

Separate Control Valve—Mounted separately behind instrument panel and connected to motor by two vacuum lines (in addition to manifold vacuum line) as follows: 1) Running or operating vacuum line (large hose), 2) Parking vacuum line (small hose).

REMOVAL & INSTALLATION: Wiper units can be serviced separately as follows:

►**Ford & Mercury Design Change**—Mount arm, which formerly held wiper motor and two arm and pivot shaft assemblies, has been eliminated in later models.



Wiper Arm: Various types of retainers used. Remove each type as follows:

Retainer Nut—Remove nut on arm at outer end of wiper shaft, pull arm off shaft.

Lock Wire—Disengage lock wire from recess in shaft at back of arm, pull arm off serrated end of shaft.

Flat Spring Lock—Pull blade end of arm out or away from windshield to disengage spring from recess in shaft, pull hub end of arm straight off serrated end of shaft.

CONTINUED ON NEXT PAGE

LINK-AND-CRANK ARM WINDSHIELD WIPER (WITH SEPARATE CONTR L VALVE)

VACUUM WINDSHIELD WIPER LINK & CRANK ARM (C nt.)

Wiper Arm Shaft & Link Assembly: *CAUTION—See special removal instructions required for cars listed below.*

Removal—See special car data below. Remove wiper arm (above), disconnect link at motor shaft arm (free spring lock or remove clip, pull link off motor arm pin). Unscrew retainer nut (remove driver or "burr" from end of shaft if nut will not clear), remove cover and gasket. Pull shaft and link assembly out to rear and remove from beneath instrument panel.

Buick, Series 40—Remove the defroster hose, glove box and defroster housing as required to reach the windshield wiper motor and the transmission to be removed. Disconnect transmission link at wiper motor. Remove screws holding motor to body.

Ford & Mercury (1948-51)—Do not disconnect motor links. After removing shaft retaining nuts and covers, **remove shafts and links as an assembly with the motor** (see Motor Removal below).

Lincoln (1949-51)—Same as Ford & Mercury (above).

Motor: *CAUTION—See special removal instructions required on cars listed below.*

Ford & Mercury (1946-47)—Do not remove motor mounting screws—take out bracket mounting screws and **remove motor and bracket as an assembly.**

Ford & Mercury (1948-51)—After removing wiper arm shaft retaining nuts (above), disconnect wiper motor vacuum hose, disconnect control valve cable (1949 models only), pull entire wiper assembly to rear (motor, links, shaft & arms, and mounting arm) until shafts clear cowl, then remove assembly from beneath instrument panel.

Lincoln (1948-51)—Same as Ford & Mercury (above).

Oldsmobile Super 88, 98 (1951-53)—Disconnect left defroster outlet from heater and the defroster duct from left defroster nozzle and from center clip on dash panel, then remove duct from body. Disconnect transmission arms from motor, then remove screws attaching motor to support, and then lower motor sufficiently to disconnect vacuum line and control cable; then remove motor from body.

Separate Control Valve: Removal—Disconnect all vacuum line hoses, remove control knob, use spanner wrench to remove nut and washer on valve stem, remove valve from behind instrument panel.

Installation—Make certain that vacuum line hoses are correctly connected at control valve.

►*CAUTION—Hose connections must not be interchanged.*

ADJUSTMENT: Wiper blades can be adjusted for correct "park" position and for desired sweep or travel of the blades on the windshield. Motor can be adjusted to correct uneven blade travel.

Park Position of Blades: Operate wiper with arms and blades removed (see Wiper Arm Removal), turn wiper off to establish the "off" or park position of arm shafts, install arm so that blade just clears molding at lower edge of windshield glass.

Sweep or Travel of Blades: If arm stroke not uniform (one blade has longer travel than other), loosen wiper motor mounting screws, shift motor in direction of arm which has shorter travel. If necessary, change arm position on shaft (see Park Adjustment above).

VACUUM WINDSHIELD WIPER LINK & CHAIN TRANSMISSION

Buick, All Series (1939-42), 40 (1946-48)
Cadillac, All Series (1938-47), 75 & 76 (1948)
Chevrolet, All Models (1939-48)
Hudson 6 & 8, All (1939-47)
①Lincoln (Zephyr), All Models (1939-48)
②Oldsmobile 6 & 8, All (1939-48)
Pontiac, 6 & 8, All Models (1939-48)
Plymouth Convt. & Sta. Wgn. (1941-50)

①—Except Stewart-Warner Electric on Zephyr (1941-42) and Custom (1941).

②—Except Cable Operated on Futuramic 98 (1948).

DESCRIPTION: Wiper consists of a single motor unit connected to left and right hand wiper arm shafts (Transmission Assemblies) by flat metal links. Motor control valve is built-in or separate (see illustrations).

Wiper Motor—Half-round type. Motors with built-in valve have single manifold hose connection, motors used with separate control valve have two hose connections (see illustrations).

►**Windshield Washer Connection**—Vacuum line connection provided on some motors for washer operation (capped if washer not used).

Transmission Assembly (Wiper Arm Shaft)—Left and right (non-interchangeable) assemblies with upper (wiper arm) and lower (link connector arm) sprockets connected by a chain which transmits power to the wiper arm. Adjustment provided to take up slack in chain (see ADJUSTMENT).

Separate Control Valve—Mounted separately behind instrument panel and connected to motor by two vacuum lines (in addition to manifold vacuum line) as follows: 1) Running or operating vacuum line (large hose), 2) Parking vacuum line (small hose).

►*CAUTION—These hose connections must not be interchanged.*

REMOVAL & INSTALLATION: Wiper units can be serviced separately as follows:

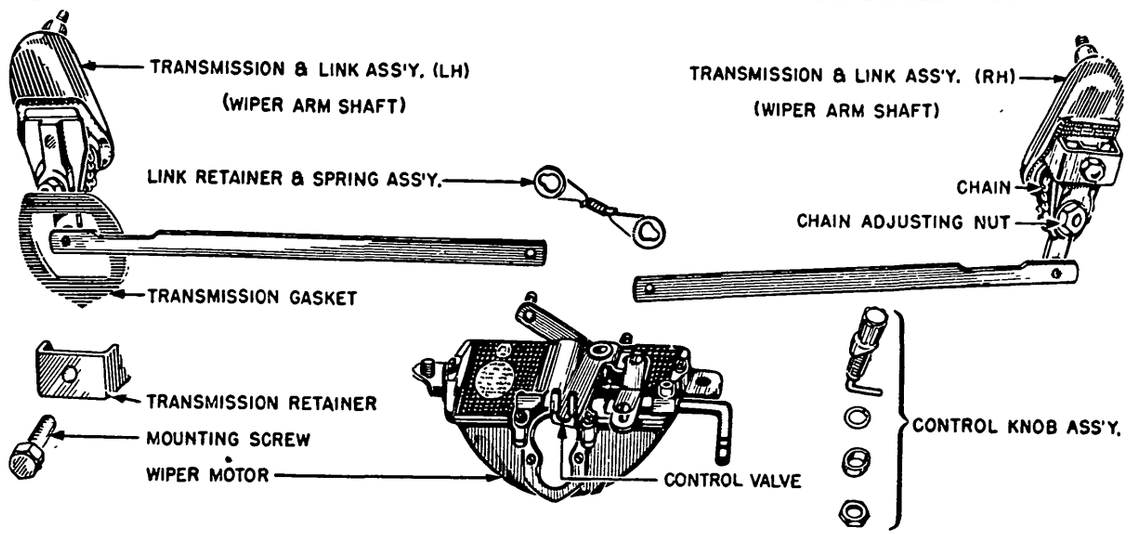
Transmission Assembly (Wiper Arm Shaft & Link):

►*CAUTION—See special removal instructions required on cars listed below.*

Removal—See special car data below. Remove wiper arm (above). Disconnect link at motor shaft arm (free spring lock, pull link off arm pin). Disconnect washer hose (if used) at transmission. Remove capscrew, lockwasher, and retainer from back of transmission assembly under cowl. Lift transmission and link assembly up and out of cowl from outside. Remove old gasket, thoroughly clean old gasket cement from cowl and transmission mounting flange.

Buick (1946-48)—For access to transmission mounting screw and retainer, remove screws in bottom section of garnish molding, pull molding away from glass, remove screw from defroster funnel, unhook opposite side and remove funnel.

Cadillac & Pontiac (1942-48), Oldsmobile (1946-48)—Same as Buick (above).



Installation—Coat mounting surfaces of cowl, new rubber gasket, and transmission assembly with rubber cement, install gasket on cowl, and use extreme care that gasket does not slip out of position while installing transmission.

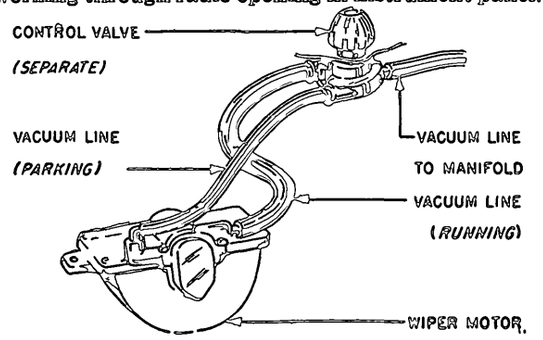
►*CAUTION—Correct positioning and cementing of gasket important to prevent water leaks.*

Motor: *CAUTION—See special removal instructions required on cars listed below.*

Removal—See special car data below. Disconnect vacuum line hoses at motor, disconnect links at motor shaft arm (free spring lock, pull links off arm pin), take out motor mounting screws, lift motor out and disengage control valve link (types with built-in control valve).

CONTINUED ON NEXT PAGE

LINK-AND-CHAIN TRANSMISSI N WINDSHIELD WIPER (WITH BUILT-IN CONTR L VALVE)



VACUUM WINDSHIELD WIPER LINK & CHAIN TRANS. (Cont.)

Installation—Install motor but do not fully tighten mounting screws, connect vacuum lines and links. With motor control "off", operate engine to supply vacuum which will cause wiper motor to centralize itself, then tighten motor mounting screws securely. Install the arms and blades, check operation (see Adjustment data below), adjust arms if required.

Separate Control Valve: *CAUTION—See special removal instructions required on cars listed below.*

Removal—See special car data below. Disconnect all vacuum line hoses, remove control knob, use spanner wrench to remove nut and washer on valve stem, remove valve from behind instrument panel.

Pontiac (1942-48) With Radio—Radio must be dropped for access to control valve as follows: Remove radio knobs, locknuts, and face plate. Loosen mounting bolts and tilt radio set back at the top, then remove windshield wiper control valve by working through radio opening in instrument panel.

WIPER MOTOR
SEPARATE CONTROL VALVE

Installation—Make certain that vacuum line hoses are correctly connected at control valve.

▷*CAUTION—Hose connections must not be interchanged.*

ADJUSTMENT: Wiper arms can be adjusted for correct "park" position and for desired sweep or travel of the blades on the windshield. Motor and transmission can be adjusted to correct uneven blade travel or short choppy strokes or noise caused by excessive play.

Park Position of Blades: Operate wiper with arms and blades removed (see Wiper Arm Removal), turn wiper off to establish "off" or park position of arm shaft, install arm so that blade just clears molding at lower edge of windshield glass.

Sweep or Travel of Blades: Check and adjust transmission chain (below). If arm stroke not uniform (one blade has longer travel than other), loosen wiper motor mounting screws, shift motor in direction of arm which has shorter travel. If necessary, change arm position on shaft (see Park adjustment above).

Transmission Chain: Loosen hexagonal nut on lower end of transmission assembly (accessible from under instrument panel—nut on back of transmission), move bolt and nut downward to take up play or slack in the transmission chain, tighten nut securely.

▷*CAUTION—Do not overtighten chain (nut can be moved upward to loosen chain).*

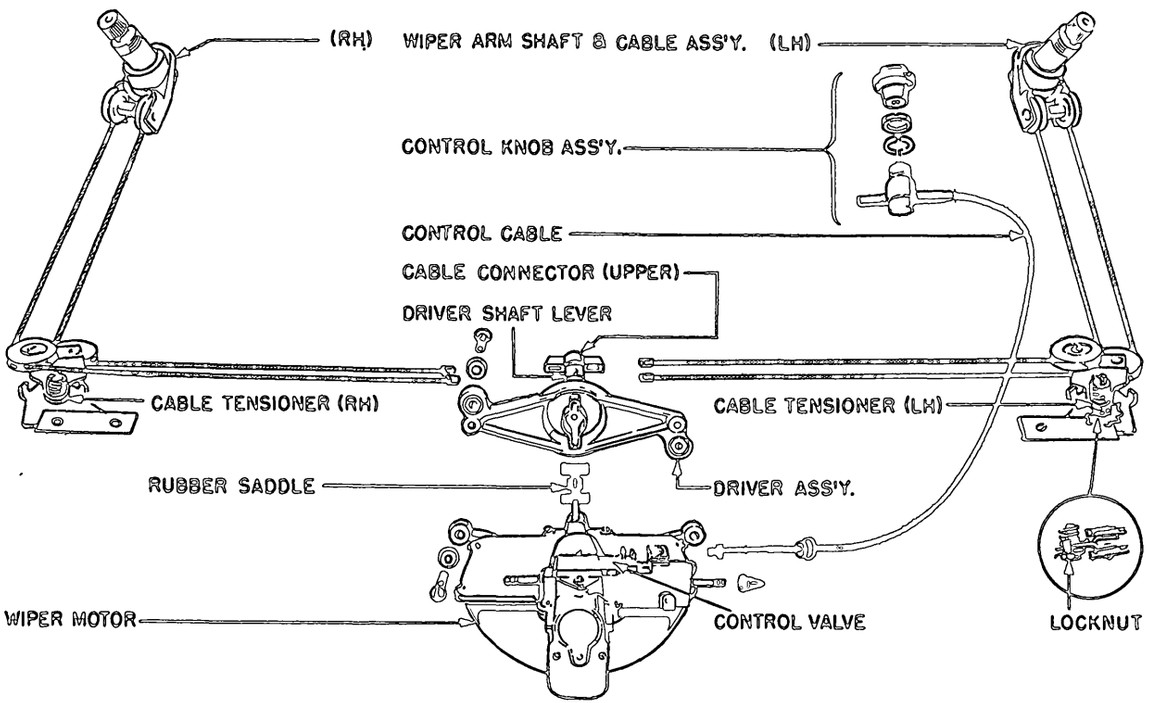
Rambler, Nash & Hudson (1950-52)

▷CHANGES, CAUTIONS, CORRECTIONS

▷*1953 CHEVROLET & PONTIAC DRIVE PRODUCTION CHANGE:* New auxiliary drive consisting of two drums (spiral drive) replaces auxiliary drive lever used on early cars.



▷*1954 BUICK SLOW OPERATING WIPER MOTOR CORRECTION:* If wiper operates slowly with wiper control knob in full "on" position, and with glass wet, the condition may be caused by insufficient travel of control valve on wiper motor. Correct by loosening screw on housing which clamps outer control cable to motor housing, and with control knob in fully "on" position, adjust outer cable toward motor until plastic motor control valve seats against motor casting. Hold valve in this position and tighten clamp screw on housing.

▷*1954 BUICK SERIES 40, 60, 100 WIPER BLADE CHANGE: (To Reduce Racking at Outer End of Blades):* The condition can be corrected by installing new wiper blades, Part No. 566213.

▷*1954 CADILLAC WIPER BLADE TENSION ADJUSTMENT NOTE (To Prevent Damage to Glass):* Adjust cable tension as outlined below, then check for twisted wiper arm as follows: Wet windshield and operate wiper, stopping it when blades are in the straight up and down position. Remove wiper blade, allowing arm to rest against windshield glass. The end of the wiper arm must rest flat against the glass. If it does not, hold wiper arm close to inner end with pliers and twist outer end as necessary to make it lay flat. Install wiper blades and operate wiper, with the windshield wet, to be sure that metal portion of blade does not touch glass in any position.

▷*1954 BUICK WINDSHIELD WIPER OVERTRAVEL CORRECTION (To Prevent Damage to Glass):* Check wiper blade at "park" position and make sure it is resting against windshield rubber channel. With windshield wet, measure the distance of maximum travel of outer tip of blade. This distance should not be greater than 27¼" measured in a horizontal line from center-

CONTINUED ON NEXT PAGE

TYPICAL CABLE OPERATED WINDSHIELD WIPER

CABLE OPERATED VACUUM WINDSHIELD WIPER (Cont.)

of rear view mirror to tip of blade (do not follow curvature of windshield glass). If distance is greater, remove and reinstall wiper transmission in correct position.

▷*CHEVROLET TRANSMISSION TOOL CHANGE (For Use on 1955 Model Cars):* To use Tool J-5449 on 1955 models, it will be necessary to drill a 5/8" hole, 1-5/8" deep, from large end of tool, and relocate the 3/16" hole in handle to 1-7/8" from larger end of tool and at right angles to old hole. New Tool No. J-5449-A will remove wiper transmission spacer nut from outside transmission escutcheon on this model.

DESCRIPTION: Drive is through auxiliary pulleys and cable to windshield wiper transmission at each side of windshield (Except Chevrolet & Pontiac which have a drum or spiral drive to wiper transmission). Cable tensioners are located in pulley brackets on all models except 1953 and later Chevrolet & Pontiac, and 1954 and later Buick, Cadillac, Oldsmobile. Windshield washer connections and vacuum line connections are provided on some motors, and piping on some housings for windshield washer operation.

CABLE TENSION ADJUSTMENT: *NOTE - Three types of tensioners have been used and are adjusted as follows:*

Adjustable Type Tensioner: (1946-50 Models): Located in pulley brackets and identified by absence of spring and ratchet on tensioner. To adjust, loosen locknut under cable and tap bolt to loosen lockwasher which will permit spring to move pulleys away from center of car to take up cable slack *(CAUTION - Do not pry pulley mounting, which will cause over-tension).* Hold pulley mounting bracket in this position while tightening locknut. Repeat operation at other cable tensioner for other side of car. Cables must run in center of pulley groove and not contact any part of cowl.

Automatic Adjusting Type Tensioner (1950-55 Models Except 1953 & Later Chevrolet & Pontiac, and 1954 & Later Buick, Cadillac & Oldsmobile): Located in pulley brackets and identified by spring and ratchet on bracket assembly. Cable tension is automatically maintained and adjustment is not required.

Semi-Automatic Type Tensioner (1954-55 Buick, Cadillac & Oldsmobile, 1955 Chevrolet & Pontiac): On early 1954 models, remove windshield wiper blade and arm assemblies. Hold serrated transmission shaft and loosen screw in end of shaft 3/4 turn. Tap screw lightly. On later models (without screw in end of transmission shaft) push base of wiper arm inward, where it fits over end of transmission shaft. *(NOTE* - On cars with Cam-O-Matic Control, remove cam from beneath wiper arm so transmission shaft can be moved inward). Internal springs in transmission pulleys will automatically adjust cable tension.

1953-54 Chevrolet & Pontiac - On Early 1953 Models with arm type drive (later models have drum type drive) move the wiper arms by hand, midway in their travel arc. With the arms in this position, the motor auxiliary drive lever should be in vertical position *(NOTE* - it is not necessary to position blade and arm assemblies on later models with drum type drive). Remove arms and blades and loosen screw in end of transmission shaft 3/4 turn. Tap screw lightly to insure full tension. From under cowl, take cables between thumb and finger and increase finger pressure until one notch movement can be felt or heard. While holding cables in this position retighten the tension screw. *(NOTE* - Two men are required for this operation). Repeat the above operation on opposite wiper transmission.

CAM-O-MATIC CONTROL ASSEMBLY: Consists of a cam located on transmission shaft and cam follower on wiper arm, plus new control switch which operates both the wiping range and speed.

Wiper Arm Removal & Installation: Raise upper section of wiper arm and blade assembly to disengage cam follower from cam, carefully pry or pull arm from transmission shaft. Remove spanner nut, wiper arm cam, and transmission escutcheon from transmission shaft. To install, reverse removal procedure, making sure that key on bottom of wiper arm cam is located in keyway in bottom of transmission escutcheon.

Wiper Control Assembly Removal & Installation (1955 Buick & Cadillac): Detach wiper control cable from wiper motor at front of dash. Remove control knob by pulling it out from instrument panel, then remove "super-speed" control knob. Remove spanner nut from wiper control shaft, push wiper control forward through instrument panel. Tag hoses for proper replacement before removing them from the assembly. To install wiper control assembly, reverse above procedure. "Super-Speed" hose from vacuum line attaches to "steel" colored connector. Hose from motor attaches to "Copper" colored connector. Handles of both control knobs should be in vertical position when wiper is in "off" position and in normal speed range. *NOTE* - When removing wiper motor, the "Super-Speed" vacuum hose must be disconnected from front of motor, and reattached after installation of motor.

WIPER MOTOR REMOVAL & INSTALLATION: Disconnect vacuum tube (and washer tube if used) and control cable. Remove attaching screws and withdraw motor from auxiliary drive assembly. To install, reverse removal procedure.

WIPER TRANSMISSION & CABLE ASSEMBLY REMOVAL: On models with "Adjustable Type" tensioner, loosen locknut on bracket and move pulley mounting toward center of car. Hold in this position and tighten locknut. On models with "Automatic Type" tensioner, apply a slight pressure to ratchet spring and rotate upper section holding pulleys, until locking pin hole is in line with similar hole in lower section. Insert a pin punch in holes to hold tension in the slack position. On models with "Semi-Automatic Type" tensioner, loosen screw in end of transmission shaft (first type), or push in on transmission shaft (later type), have helper carefully pull on transmission cables to obtain slack, and while holding cables, tighten screw in transmission shaft or release pressure on shaft to lock tensioner in the slack position. Remove transmission. Before disconnecting cables from auxiliary drive, mark location of cables for correct reassembly. Note following for special procedures required on different models.

1948-53 Buick: Use Tool J-2682 to remove burr on end of transmission shaft. On early models, the transmission assembly is attached by two screws under the cowl. On later models, a single escutcheon nut is located near outer end of transmission housing. To remove the right hand transmission, remove the glove box for access.

1953-55 Chevrolet: Remove transmission shaft escutcheon nut using Tool J-5449 (1953-54), J-5449-A (1955). See Tool Modification Note above. Remove glove box and heater defroster duct.

1948-53 Cadillac: Use Tool J-2682 to remove burr on end of transmission shaft. On 1948 Models to remove right hand transmission, the lower right panel must be removed from instrument panel assembly, and the Ventilating DeFroster Heater must be removed. To remove left transmission, remove instrument panel cluster and also the small lower left panel. On 1949 Models, remove heater assembly for access to left hand transmission. Remove clock for access to right hand transmission. On 1950-53 Models remove hand brake handle bracket and instrument panel cluster for access to left transmission. Remove glove box for access to right transmission.

1954-55 Cadillac: Remove upper section of instrument panel for access to transmission. Remove transmission spanner nut using Tool J-5659.

1948-54 Hudson: Remove glove box for access to right hand transmission.

1949-51 Lincoln: Radio and heater chamber must be removed for access to transmissions and cables.

1952-55 Lincoln: For removal of right hand transmission, remove the defroster outlet.

1949-51 Nash (Exc. Rambler): For access to cable and transmission assemblies, remove the Weather-Eye heat deflector.

1948-51 Oldsmobile: Remove glove box for access to right hand transmission. Use Tool J-2682 to remove burr from end of transmission shaft.

1954-55 Oldsmobile: Remove glove box for access to right hand transmission. Use Tool J-5610 to remove escutcheon spanner nut and escutcheon.

1950-52 Rambler: Wiper motor must first be removed before removing either transmission.

WIPER TRANSMISSION & CABLE ASSEMBLY INSTALLATION: Reverse the removal procedure and note the following:

1953 Chevrolet & Pontiac (Early): On models without drum type auxiliary drive, the cables running to the left transmission are parallel, the cables to the right transmission are crossed.

1953 & Later Chevrolet & Pontiac: On models with a drum type auxiliary drive, rotate the drive counter-clockwise and attach right transmission cables, copper end to copper drum and steel colored to steel drum. Rotate drum auxiliary drive clockwise and attach left transmission cables to their respective drums. Adjust cable tension.

LUBRICATION: Use light oil on pulley bearings at tensioners and wiper housings. Coat cables with light grease only on portions travelling over pulleys or drums.
